In the United States alone, approximately 6.2 million children have asthma [2]. Each year, acute asthma events result in 600,000 visits to the ED [2]. In the ED, emergency medicine physicians (occasionally with pediatric specialty) and nurses are the primary health care providers for children presenting with acute asthma exacerbations. There are two major tasks in the treatment of these patients: 1) assess and diagnose the acute asthma event and; 2) determine and monitor asthma severity.

In today's emergency room environment, the data needed to support these tasks are dispersed throughout many areas within the electronic medical record. Information regarding diagnostic imaging results are included in the imaging section, results on arterial blood gas levels would be found in laboratory notes, and additional testing such as spirometry results may be entered in a flow sheet. These multiple sources result in the need for extensive internal data representation and increased cognitive burden to identify trends in the patient's respiratory status and asthma history. For some patients, the declining trend may be represented slowly over days to critical levels if left improperly treated, while others may experience a rapid decline to complete respiratory failure within hours [2].

To further complicate this scenario, it is less common for providers in these departments to have proficiency in managing these severe conditions. In a study conducted by Bratton et al. [3] on the care provided to 13,552 pediatric critical care cases, the results showed a drastic variety in not only the prescribed medications and use of mechanical support, but also the inconsistency in testing and assessment. Sigsbee and Bernat [9] have reviewed potential outcomes ranging from fatigue and job unsatisfaction to increased rates of suicide and depression. Among the four factors in clinician burnout studied were the complexity and time consumption of maneuvering in the electronic health system [9]. For these reasons, the creation of a consolidated acute pediatric asthma display will aid in the care provided to these patients with the goal of improving the efficiency and consistency by which they are treated - ultimately reducing the length of stay, complications, and morbidity in these patients.

Theoretical Frameworks and Methods

Prior to the development of the new Asthma Visualization, current literature on pediatric asthma care in the ED was reviewed. Opportunities for improvement were identified and extracted for evaluation. Our findings suggest that inadequate assessment of patient visit information, history, results, and inaccurate evaluation of asthma severity were the overarching gaps in the current state of pediatric asthma care.

To arrive at an impactful solution to improve and support care delivery to pediatric patients presenting with asthma in the ED, we performed a twofold evaluation specific to the identified gaps in asthma care: 1) the tasks associated with clinical care delivery for pediatric asthma patients in the ED and; 2) the tasks associated with the use of current clinical tools utilized in pediatric asthma care assessment (PACA) in the ED to determine severity. The evaluation process involved a review of the literature, user interviews, and an ethnographic analysis within the users work context.

Care delivery tasks for pediatric asthma patients in the ED

To adequately assess a pediatric patient presenting with asthma symptoms in the ED, the current literature suggests that four clinical tasks should be completed:

Task 1 - A Chest X-Ray must be ordered to help rule out other respiratory problems like pneumothorax and pneumonia.
Task 2 - An arterial blood gas (ABG) test is ordered to evaluate

the level of oxygen in the bloodstream

Task 3 - Pulmonary function tests such as the spirometry and peak flow ratio are performed at regular intervals to monitor the patient's airflow.

Task 4 - Current allergies and medications and reviewed and reconciled.

Tasks for the assessment of pediatric asthma in the ED

Our research findings indicated that current tools used to review patient visit information, screening and diagnostic test results and other pertinent history information were not consolidated, but rather, were in multiple locations within the EHR, in different EHRs, with some even still on paper. We identified the tasks and sub-tasks to be completed for adequate review of the ED visit information and accurate assessment of asthma severity (Table 1).

Table 1 Five Tasks without PACA

5 Tasks without PACA
Task 1 - Review chest X-ray impression
• Subtask 1 – Login to EHR (or source where located)
• Subtask 2 – Find the desired patient
• Subtask 3 – Find X-Ray results for the desired date
• Subtask 4 – Open X-Ray results
○ Subtask 1 – (If image desired) Login to PACs system
○ Subtask 2 – Find Patient
○ Subtask 3 – Find X-Ray image for the desired date
○ Subtask 4 – Click on image to view
○ Subtask 5 – Retain X-Ray results (cognitive task)
Task 2 - Review arterial blood gas results
• Subtask 1 – Login to EHR (or source where located)
• Subtask 2 – Find the desired patient
• Subtask 3 – Find ABG results for the desired date
• Subtask 4 – Open ABG results
• Subtask 5 – Retain ABG results (cognitive task)
Task 3 - Review pulmonary function test results
• Subtask 1 – Login to EHR (or source where located)
• Subtask 2 – Find the desired patient
• Subtask 3 – Find pulmonary function test results for the desired date
• Subtask 4 – Open pulmonary function test results
• Subtask 5 – Retain pulmonary function test results (cognitive task)
Task 4 - Review current medications, allergies, and other pertinent historical information
• Subtask 1 – Login to EHR (or source where located)
• Subtask 2 – Find the desired patient
• Subtask 3 – Find allergies and medications section
• Subtask 4 – Retain allergies and current medications (cognitive task)
Task 5 - Indicate Asthma severity
• Subtask 1 – Login to EHR
• Subtask 2 – Find the desired patient
• Subtask 3 – Find the section in EHR to indicate asthma severity
• Subtask 4 – Recall information about task 1 – 4 from multiple sources (cognitive task)
• Subtask 5 – Indicate asthma severity

We hypothesized that a single display with pertinent recent information on the asthma patient, and a design process incorporating the theories of information display would enable adequate assessment and directly impact the accuracy of asthma severity (Figure 1).

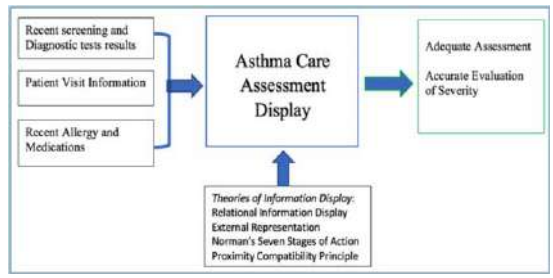

Figure 1 Asthma Care Assessment Display Methodology

To eliminate the inefficiencies associated with current EHRs, we focused on developing an information visualization that would eliminate the need for users to forage through the EHR to find relevant results. Instead, we sought to reduce the above list of tasks to just one (Table 2).

Table 2 One Task with PACA

1 Task with PACA
Task 1 - Review Asthma Assessment Display
• Subtask 1 – Login
• Subtask 2 – Find the desired patient
• Subtask 3 – Review X-Ray results for the desired date
○ Subtask 1 – (If image desired) click or hover over chest X-Ray section
• Subtask 4 – Review Arterial Blood Gas (ABG) test results
• Subtask 5 – Review pulmonary function tests results
• Subtask 6 – Review current medications, allergies, and other pertinent historical information
• Subtask 7 – Select from drop-down asthma severity

The design would incorporate a combination of four theories of information display including, the theory of Relational Information Display, the theory of External Representation, Norman's Seven Stages of Action, as well as elements from the Proximity Compatibility Principle.

Relational Information Displays

According to Zhang [12], Relational Information Displays (RID) represent relations between dimensions. The dimensions are the values to be represented in a display. There are two types of dimensions in a RID, the value to be represented, and how the value is represented. For instance, given a patient weight of 150 pounds, the value to be represented is 150. How we choose to represent it could either be as a name or in relation to other values in order of magnitude. "In order for a RID to be accurate and efficient, its physical dimensions must represent the dimensions of the original domain accurately and efficiently" [12]. Additionally, the potential tasks to be completed using the RID should be at the forefront of the design.

External Representation

The classical view of cognition was that all information processing occurred within the mind and that the external environment (i.e., sight or sound) acted as mere inputs [13]. It wasn't until recently that the cognitive science community began to recognize the interplay of both internal (in the mind) and external (in the world) representations of a task [7]. A common example used to describe this interactivity is the use of multiplication aids. Mental multiplication by itself is not a difficult concept, however, as the numbers grow larger, the partial results of the calculation must be stored in the mind, which tends to exceed the limits of a person's memory. An external structure, writing the partial results on paper, is used to allow a

Figure 2 Asthma Care Assessment Display

person to store this information externally, thus extending their working memory [4]. Other forms of external representations include images, sounds, or even the physical constraints of an object (i.e., being unable to move an object in some desired fashion).

Norman's Seven Stages of Action

This feeling of direct interaction can be broken down into two phases and seven stages according to Norman's model of the Seven Stages of Action [8]. The first phase is composed of stages that comprise the *execution* of a task, and the second phase addressing the stages that enable *evaluation* of the task [8]. The complexity of turning a goal into a path of execution is referred to as the "gulf of execution", where the ability to evaluate the effectiveness of the result is considered the "gulf of evaluation" [6]. Well-designed direct interaction interfaces will attempt to reduce the 'distance' of each gulf by aligning the interface to the way the user would describe a task (semantic distance), and ensuring the forms or images used are accurate to represent the task (articulatory distance) [6]. Reducing these gulfs will support rapid user adoption and efficiency, but rigidness of design may limit users' ability to imagine new ways to evaluate the data [6].

Proximity Compatibility Principle (PCP)

Wickens and Carswell [11] describe PCP as a guideline to use in determining where a display should be located, given its relatedness to other displays. As task complexity increased, it was shown that for integrative tasks, the dimension of the representation should also increase. These results suggest that by applying PCP to data displays, designers can optimize the integration or correlation of displayed information and maximize parallel processing, while also allowing specific elements to be extracted through focused attention. Previous research has concluded that there exists a link between task proximity (i.e., how closely related are individual tasks) and display proximity (i.e., how closely related are the object representations) [11], and displays that adhere to this theory are associated with more efficient and effective information retrieval.

Results

Our Pediatric Asthma Care Assessment visualization contains access to all pertinent information needed to allow the clinician to assess the asthma severity level of a child presenting in the ED with respiratory distress. Our screen design format emphasizes overview-first followed by a click and expand capability when more detail is desired. We employed the use of spatial proximity, enclosure, and colors to separate and group items of similarity. The two main tasks to achieve the clinician's goal were identified, and our screen design aimed to provide the user's ease in executing and evaluating these tasks. We maximized external display to limit cognitive burden and ensure the categories are appropriately represented in a relational information display to avoid over or under-representation of data. There are four sections to the PACA display (Figure 2).

Section 1 The area along the top quarter of the screen contains the patient and care team detail. This section is where one would find patient detail such as gender, age, and name. The right portion notes all of the participating care team members. In the middle of section 1 is an initial asthma severity drop down to allow the ED clinician to review the initial severity level assigned (Figure 4).

Section 2 This area is outlined in yellow to draw attention to the dimensions required to assess and diagnose the acute asthma event. The dimensions accessed in this section are reported triggers, allergies, and medications. Also visible are lab results such as chest X-rays, lung function graphs, and ABG findings. Hovering over the chest x-ray description brings up the actual patient images for review (Figure 3). Color is used to represent the lung function test results. Color is also used to differentiate between normal, caution, and medical alert to speed up information processing.

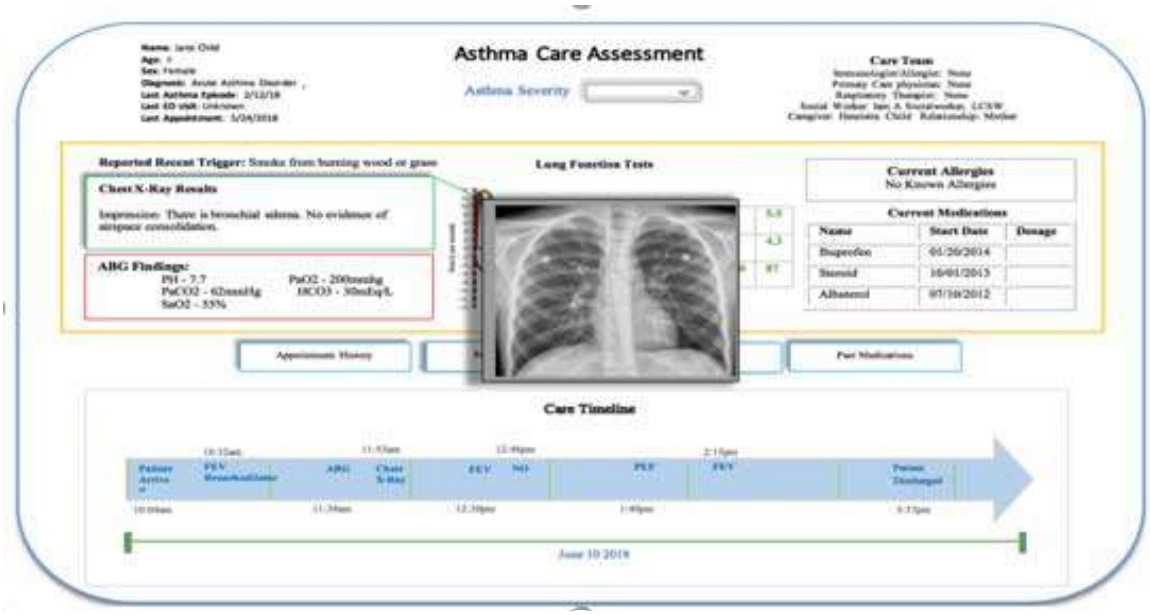

Figure 3 Asthma Care Assessment Display with Imaging View

Section 3 This area will show buttons to expand on further patient information if required by the clinician. Patient information like past surgical history, appointment history, other test results, and past medication is accessible from this section. Our design chooses to represent non-essential data as a button for selecting when desired, rather than cluttering up the screen with extraneous data. The screen is not busy and allows the clinician memory and attention to be uncluttered and focused.

Section 4 This area is outlined in blue to draw attention to the dimensions required to determine and monitor asthma severity. The care timeline shows events such as admit/discharge times, lung function readings, timestamps for each test and when each drug is administered. The section allows the clinician to easily review the care given to the child from ED admission to discharge. All pertinent events for a pediatric ED visit are visible in the line graph.

Discussion

The PACA visualization was developed to reduce the cognitive load on clinicians caring for pediatric patients in the ED. Relevant data that is often located on a number of separate screens in the EHR was represented on a single. Additionally, each data dimension was matched with an appropriate representing dimension to maximize the external representation within the display. For example, the lung function test, which was represented only in tabular format is now also represented graphically. To accomplish this, multiple information visualization principles and theories were referenced. Zhang and Walji [14] provided the TURF framework that informed the initial analysis of the user's work domain. The theory of relational information displays and the theory of external representation provided guidance on mapping the represented and representing dimensions for our given distributed task. The proximity compatibility principle focused our efforts on grouping related objects of interest to reduce the cognitive cost of clinicians integrating information internally.

Our work aligns with other literature on the use of efficient data displays to reduce cognitive load. Teets, Tegarden, and Russell [10] demonstrated that when the PCP was combined with the theory of cognitive fit, there was increased efficiency in information integration during simulated tests within a set of manufacturing facilities. Marino and Mahan (2005) showed that configural displays could increase the speed at which consumers were able to process the relationship between nutrients on a food label. Alonso, Rose, and Plaisant [1] found much faster response times related to a graphical information display in comparison to tabular format for personal history information. Unfortunately, only a few studies have attempted to analyze the impact of data display within healthcare. Even fewer have deployed the displays within a live clinical setting such as the ED. Furthermore, while EHRs have been around for some decades, common data display methods have been habitually ignored. As far back as 30 years ago, a physician named Larry Weed introduced the problem-oriented medical record, but clinicians are still forced to search across multiple screens to find all of the information they require.

Data display continues to be an essential component within healthcare to realize the full potential of information technology. Healthcare is an incredibly complex sociotechnical environment, which creates the opportunity for workarounds or mistakes that can lead to serious adverse events. The tragic story of Genesis Burkett is one example of such an event, where the patient died after a pharmacy technician entered incorrect information onto a screen [5]. As a result, an automated system prepared an IV solution that was more than 60 times the amount ordered by the physician [5]. This story highlights the profound impact health data displays can have on patient safety. While the PACA visualization adheres to proven theories and methods in the design of data displays and usability, further research is needed to ensure the application is used as intended when implemented within a live production EHR.

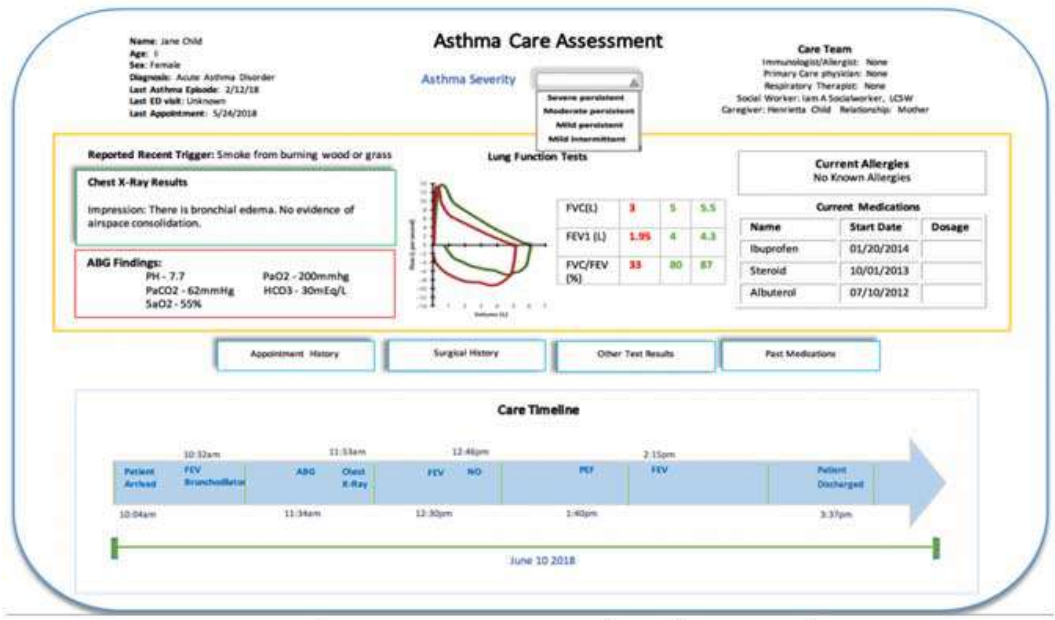

Figure 4 Asthma Care Assessment Display with Severity Selection

Limitations and future work

Although our design is based upon proven framework and theories, we would prefer there be a more formalized expert domain review of tasks to ensure a solid understanding by the developers. This screen would need to be utilized as part of a clinical workflow of an actual ED to prove the efficiency of the tasks to complete the goal.

Conclusion

The increased demand on clinician has produced a critical problem with clinician burnout. Through the application of the visualization frameworks and design principles, the PACA visualization is expected to reduce the cognitive load and burden on the clinician. While the user may benefit and reduce the effects of clinician burnout, the resulting display most importantly allows for the informed, efficient, and consistent treatment of pediatric patients experiencing an acute asthma event.

Abstract

Immunization information systems and registries are essential for vaccine programs to succeed. Personal Health Record should improve decision making of healthcare providers and consumer outcomes. This article aims to describe the software development of an immunization module using a user-centered design, starting from the analysis of potential users' needs. The design was made through cycles of iterations, adjustments were made validating real scenarios and taking into account the user needs. The main features identified through interviews were: vaccination schedule, further information on vaccines' usefulness, notification, downloadable patient vaccination status and other vaccines outside the official calendar. The final scope is to create a simple, efficient and safe platform for patient immunization management.

Keywords:
Personal Health Record, Vaccines, Software Design

Introduction

Personal Health Records (PHR) can be defined as "*an electronic application through which individuals can access, manage and share their health information, and that of others for whom they are authorized, in a private, secure, and confidential environment*" [1]. In this way, patients and their families can interact with health care systems, becoming involved in the medical decision-making process and thus achieve empowerment [2,3].

PHRs should improve the decision making of caregivers and patient outcomes. However, despite the promise of better health care through patient-centered information empowerment, little progress has been made in terms of immunization information systems.

On the other hand, smartphones have demonstrated the ability to improve immunization practices, and the use of reminder text messages increases vaccination coverage in both, pediatric and adult populations [4–6]. Furthermore, a group of experts in Canada has developed a free smartphone app that currently functions as a digital tool for people to monitor their own and their families' vaccines. This app allows to access vaccination information and see outbreaks of preventable diseases with vaccines close to the user area [7].

Immunization information systems and their registries are critical to the success of immunization programs [8]. The PHR establishes a digital connection between patients and health information systems. This is an opportunity to develop new services and collect new information by patients themselves or their relatives connected into their own clinical records.

Access to vaccination records through health information technology presents an opportunity to empower patients easily with their own health information. Accurate immunization status has a greater value for patients, vaccine providers, public health officials and industry [9].

It is essential to record all vaccines administered to children. For some providers have an "unregistered vaccine is equivalent to non administered vaccine" and, overall, there are safe and centralized computer systems that could allows knowing the immunization status at any time and everywhere. [10].

Currently, caregivers continue to use paper vaccination notes to provide families with essential information about the immunization status of their children. There are many emerging challenges for the adoption of new systems, which include: the frequently release of new vaccines to the market, and the consequent changes in the official vaccination calendar, new recommendations, multiple brand products, the use of multiple immunization providers, under registration, and / or administrations in several locations (included in the intrahospital network, or not) [11].

We propose, through the use of a new information technology development, to overcome these challenges, to explore the needs and barriers of the users, with the scope of designing a user-centered interface for the management of immunizations and evaluating the effectiveness and user satisfaction.

Methods

Setting

The Hospital Italiano de Buenos Aires (HIBA) is a non-profit organization with 165 years of history in Argentina. Its healthcare network includes a university hospital of high complexity that covers health care from outpatient, inpatients, emergencies, critical care, home care, chronic care and medical and surgical specialties. It has its own medical insurance service (Health Insurance Plan), with more than 160,000 patients enrolled, and provides health services to 1,500,000 people with other health insurances. Annually, more than 45,000 patients are admitted to their hospitals, and 45,000 surgical procedures and 3,000,000 outpatient visits are made.

Since 1998, the HIBA has his own health information system (in-house) that includes the management of clinical and administrative information. Its Electronic Health Record (EHR) is an integrated, modular, problem-oriented and patient-centered system, used in the different clinical scenarios (ambulatory, hospitalization, emergency center and home care) [12,13].

As part of the information system, an integrated PHR called POPES is available to all outpatients since 2007. The PHR allows patients receiving medical care in the hospital network to access, verify clinical and administrative information and interact with the health system. Among the main functions, the PHR allows users to update their personal information, share

information, manage schedule appointments, view orders results, have a messaging service with the general practitioner, check, order and buy medication prescribed, and the possibility to consult with the health team by Telemedicine tools, among others. At present, POPES has approximately 400 thousand registered users, of which 15.000 are under the age of 18 years old [14].

The project was carried out in the Health Informatic Department of our center, a university hospital of high complexity in Argentina.

Design

This article uses a mixed methodology that assesses and describes the user centered development of a module to manage the immunization of the patient. The development was divided into 2 stages, the *situational diagnosis* and the *prototype development.*

Stage 1: Situational diagnosis

The first stage consisted of a qualitative analysis through individual interviews with adult patients with at least one child in charge, in order to explore the user needs. For the selection of the sample, a list of the patients who fulfilled the following inclusion criteria was requested:

- Argentine nationality,
- current users of the institutional PHR,
- adult over 18 years, with at least one child (under 18 years old) in charge,
- the patient should have an ambulatory appointment programmed in the hospital during the month that the interviews were planned.

A convenience sampling was conducted, establishing contact via email and to offer an interview before or after the assigned appointment.

Oral informed consent was given before the interviews, which lasted between 30 and 45 minutes, were audio recorded for further analysis, and the data was kept anonymous. The analysis process was carried out simultaneously with the information recollection process, through the codification and categorization of the information, based on a comparison process. The categories were built taking into account both, the central questions of the research team and the findings emerged from the interviews [8].

Stage 2: Prototype development

This stage was divided into two phases, the *prototype design* and 5 rounds of *usability testing*, in order to achieve an efficient design, with a lower error rate and greater value for the user.

Phase 1, prototype design: A new vaccine module was built for the PHR. This module was determined by a list of vaccines segmented by periods of vaccination (newborn, 2 months, 3 months, etc.) similar to the vaccination calendars on paper. Each segment contained the type of vaccine for that age, administration status, number of doses required, previous vaccine received and date of administration, information related to the vaccine and administration data.

The user possible actions were located in the top of the screen (registration, request, reminders settings and download immunization status). The prototype was completed with a link to the current official vaccination calendar and a series of filters for viewing the vaccine status. For the registration interface (new vaccination), the following fields were included: the corresponding age of vaccination, date of administration, institution, vaccine or brand name, batch and voucher. In the "prescribe vaccines form", it was enough to select the ages on the calendar (for example, those corresponding to 2 months of age) to be prescribed electronically by the health professional. For the functionality "download vaccination status", we chose to create a PDF with patient identification data and a description of the vaccines administered and validated by the attending physician. Finally, for the "notification settings" interface, it was decided to replicate what already exists in the PHR, where the patient selects by which way they are used to be notified (SMS, email or through the PHR).

All the prototypes were designed in Illustrator (Ai) and Balsamic, 5 iterations were needed to achieve the final version.

Phase 2, usability test: Consists in the interviews with the patient, showing the developed prototype to 5 users of the PHR (who meet previously mentioned inclusion criteria), to detect usability problems.

The test is an exercise of practice of use. The participant must read aloud the tasks and try to solve them. At the same time, they are requested, as the test goes forward, to express what happens, their interpretation and thoughts. The interviews include 3 participants: the user, the facilitator (who moderates) and the observer (who observe and records on paper). Finally, at the end of the test, a System Usability Scale (SUS) questionnaire was conducted to evaluate satisfaction of use. This entire exercise is recorded with MORAE, with prior informed consent.

Five iterative testing cycles were made, modifying the usability problems detected until reaching a final proposal. Each round of testing was carried out with five different users. In the validation of the prototypes, for each of them, the metrics related to the measurement of effectiveness (percentage of tasks performed correctly), and satisfaction of use (SUS) were established.

Results

About the user perceptions of vaccine registry, we detected through the interviews the following main user needs:

- digitization of vaccination calendar,
- notification system,
- downloading updated vaccination status,
- complementary information about the usefulness of vaccines (mandatory vaccines and extra official calendar).

The Italian Hospital, where the dispensation of vaccines is determined by the medical prescriptions, make as decided to include a functionality to "Request Vaccine Prescription". This functionality already exists for other prescriptions, (e.g. medications) and allows the users to order a delivery at home of vaccine prescribed.

First iteration:

Although 100% complete correctly the registration form (Fig. 2), the users had difficulties to find the main actions due to the amount of elements on the screen. The difficulty was bigger at

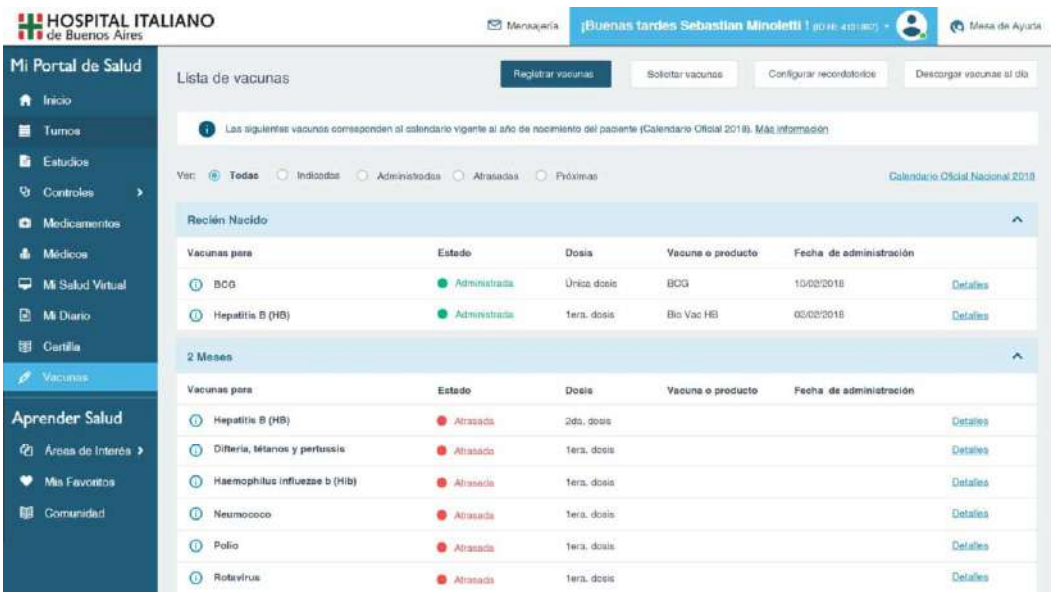

Fig. 1 - Personal Health Record, vaccine module view

displaying the results, then they try to look for a vaccine, they could not recognize which was the correct option because, according to them, the vaccines were similar. (Fig. 1) Another limitation was the expected feedback from the system, this was not accurate or clear in its content. Regarding the Request Vaccine Prescription (fig 3) 60% of users completed the task, although they did not understand why they should request vaccines that are free and obligatory. To obtain the vaccination status, 20% of users find it hard to find the option since the chosen term was not clear. As for satisfaction, the SUS value was 85.

Fig. 2 - Registration form view. To add an administered vaccine.

Fig. 3 - Request vaccine prescription view.

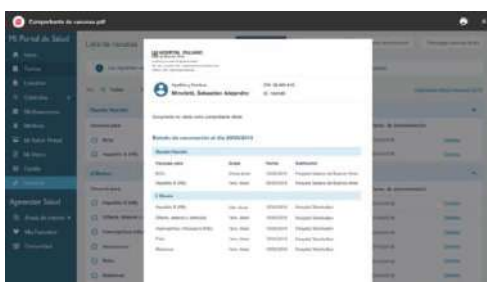

Fig 4 - Vaccination status view.

Second iteration:
The states of the vaccines are clear, but excessively overloaded, making it difficult to recognize the main actions. The lack of understanding of search field results, the status after a new registration and request a vaccine prescription persisted despite the update.

Despite the problems described, 100% of people completed the registration and it was easy after the first record. Only 60% request vaccine prescriptions for the next month. As for the vaccination status, only 20% managed to complete the task, since the name of the button (print state of vaccines) was not clear. Regarding the satisfaction of use, it dropped 1 point in relation to the first iteration, 84.

Third iteration:
A status and age filter was incorporated, to display the vaccines according to the patient calendar, which was accepted by users.

The lack of clarity in the search field results is maintained with the new update. The new changes brought a reduction in the registration form, 80% completed the task. The request task is maintained at 60% and the vaccine status improves to 60% with the new name (voucher download).

The satisfaction of use had a value of 83, one point less than iteration two.

Fourth iteration:

In this stage, we locate the actions "register" and "request" in each row of the list. Although 100% of the users managed to complete the registration, the time to understand the screen and perform the task was higher.
In the registration form, a new visualization of results was proposed, where a brief definition is attached to each vaccine, either generic or brand name, in order to improve understanding.
The rate of request a vaccine was 60%, maintained as well as the voucher download. The SUS scored 87 points.

Fifth iteration:

After 4 iterations, we decided to analyze the functionalities that were understandable and easy to use, and those that were not (Fig 5-7).

Registration: the minimum fields should be the name of the vaccine, the number of doses, date of administration and the voucher.

Request: it was decided not to continue with this functionality since it was not a user need, understood as an action of the health personnel.

List of vaccines: the biggest problem founded was the overloaded information, the user spends a lot of time identifying each element. We decided to simplify the interface, where we eliminated the list of mandatory vaccines to replace it with a button for the registration form. On the right side, a timeline of the current calendar is available as a reminder.

The actions were limited to two: register and download voucher. The 100% of users completed the task of registration and download the voucher, in both cases there were no problems. The SUS value was 84 points.

Table 1 - Effectiveness of each iteration.

Task	Test 1 Correct %	Test 2 Correct %	Test 3 Correct %	Test 4 Correct %	Test 5 Correct %
Find who indicated BCG	Not tested	100	80	100	100
Find the 1st. dose of rotavirus	Not tested	60	80	100	60
Register pentavalent	100	100	80	80	100
Register Hepatitis B	100	100	100	100	100
Register Pneumoc.	100	100	100	100	100
Register Rotavirus	100	100	100	100	100
Register yellow fever	Not tested	Not tested	0	20%	Task not understand able
Request 3rd. month vaccines	80	60	60	60%	Task removed
Vaccination status / voucher	80	20	60	80%	100

Discussion

The main strength of this work is that the potential user needs were analyzed at the beginning, and the user was incorporated in all the process of design, which allowed to generate a tool based on user-centered design. Through the iterations, adjustments were made, validating the real scenarios of patients and taking into account their needs. The ultimate goal was to generate a simple and secure platform, being effective and efficient. The SUS value always remained bigger than 80.2, meaning that users love the application, and even recommend the use of it to a partner.

Electronic vaccines management represents an optimal tool to monitor the quality and safety of patient care, through the ability to allow real-time management by patients. In the pediatric population, this challenge becomes even more complex, taking into account the number of vaccines included in the official calendar, the responsibility centralized in the adult in charge and the preventive relevance of immunization in this particular population.

The final version represents an efficient design with great value for the user, adjusted to their needs. Have the potential

to improve communication between health professionals and patients.

Among other features, more information on vaccines was incorporated, which will improve registry and accessibility of patient information.

In the case of yellow fever vaccine, rather than been an error, usability test could not be performed, since being an optional vaccine (not in the official vaccination calendar), it is recorded in a section of the paper vaccination registry where users do not usually read. Also, because it was a test, we could not interfere and induce the user to register that specific vaccine.

We believe that the use of this new technological development will be able to overcome challenges, the complexity of registries and administration of immunizations. It is currently in development. It is planned to carry out a test with a beta version in order to obtain a baseline (starting point), for future measurements and also, based on this experience, we plan to incorporate the adult population.

Conclusions

A tool based on user-centered design was generated, starting from the analysis of potential users needs. Through the iterations, adjustments were made to validate the actual conditions of the vaccination process, the real scenarios of the users, was taken into account. A simple and safe, efficient and satisfactory platform was designed.

Acknowledgements

This study was carried out under the Residency Program in Health Informatics and the Area of Information Technology Oriented to the Community of the HIBA. We want to thank the entire interdisciplinary team (doctors, nurses, designers, developers) for the work you have done.

Abstract

In 2018, the Saudi Commission for Health Specialties (SCFHS) created a national working group composed of key health informatics (HI) professionals, researchers and educators tasked with the development of a draft competency framework for Saudi HI professionals. Over an eight-month period, the research group collected data obtained from literature sources (both academic and grey), international competency standards, participant surveys, focus groups, and expert panel reviews. Through multiple rounds of discussions and graphic visualisation of the information collected using Microsoft PowerPoint and flip charts, the data were summarised and a visual representation of the proposed SHICF was developed. The result of this effort was the development of the first Saudi Health Informatics Competency Framework (SHICF). This paper provides a comparative assessment between the Saudi HI competency framework development and that of other internationally recognised HI competency development frameworks. Challenges related to the development of the SHICF are also discussed.

Keywords:

Health Informatics, Professional Competency, Saudi Certification.

Introduction

Obtaining formal recognition for Health Informatics (HI) as a licensed and credentialed profession was the aim of many leading HI professional organisations such as Canada's Health Informatics Association and HISA (Health Informatics Society of Australia). Projects were carried out to identify the core HI domains and competencies that would describe the performance and set pathways of a health informatics professional. Due to the evolving and multidisciplinary nature of health informatics, it has been a challenge for HI professional organisations to define the competencies and core domains of HI in a manner that would satisfy the variety of stakeholders practicing the HI profession. Nonetheless, this has not stopped HI professional organisations from trying to develop core domains and competencies to define the HI field.

In March 2018, the Saudi Commission for Health Specialties (SCFHS) invited key health informatics educators and researchers to participate in a national working group which, over an eight-month period produced the first competency framework for Health Informatics professionals in Saudi Arabia. The purpose of this paper is to compare the competency development project that was carried out in Saudi Arabia with similar projects in five internationally recognised HI professional organisations and identify the challenges that the Saudi national competency working group faced in the development of SHICF. We anticipate that our work will provide insights for future countries and/or regions when conducting similar work.

Methods

As part of the Saudi HI competency framework development project, the working group searched the literature and identified five primary organisations that previously created HI competency frameworks from Europe, North America and Australia: Digital Health Canada, formerly known as COACH [1], The International Medical Informatics Association (IMIA) [2], EU-US eHealth Collaboration Initiative [3], the Certified Health Informatician Australasia (CHIA) [4], American Medical Informatics Association (AMIA) and CAHIIM [5]. The HI competency frameworks for each country were reviewed and studied through a comparative analysis between the work the different organisations conducted in the creation of their own HI competency framework. An online discussion also took place between the key research members involved in this study between October 1 and November 15, 2018 to identify the challenges and issues relating to the development of the Saudi HI competency and domain-based framework. Comparisons relating to project's objectives, approaches of competency development, key outputs (framework), and framework applications were conducted between the different HI competency and domain-based HI professional frameworks. Figure 1 summarises the methodology followed.

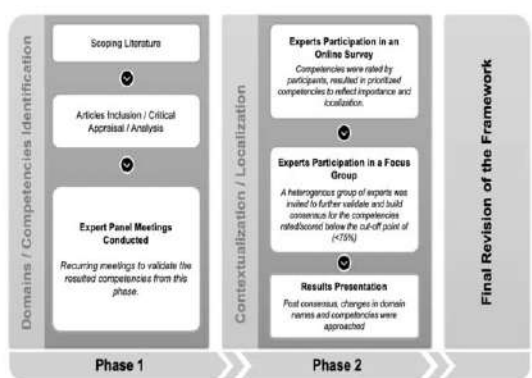

Figure 1– Methodology Followed in Developing the Saudi Health Informatics Competency Framework (SHICF).

Table 1 – Summary of the Comparative Analysis of Competencies Development Projects of Five Leading Organisations in HI with the Saudi Project

Country	Canada	Switzerland	Europe	Australia	USA	Saudi Arabia
Body/ organisation/ initiative description	**Digital Health Canada, formerly known as COACH:** Canada's Health Informatics Association is the organisation focused on advancing health informatics (HI) practices and professionalism in Canada.	**The International Medical Informatics Association (IMIA)** is an independent organisation established under Swiss law in 1989. IMIA plays a major global role in the application of information science and technology in the fields of healthcare and research in medical, and health informatics.	**EU-US eHealth Collaboration Initiative (Workforce Development Group):** Memorandum of Understanding (MoU) was signed between the European Union and the United States (The Office of the National Coordinator for Health Information Technology (ONC). Two work groups were launched: 1. Interoperability. 2. Workforce Development.	**CHIA (Certified Health Informatician Australasia):** It was launched by the Health Informatics Society of Australia (HISA), the Australasian College of Health Informatics (ACHI), and the Health Information Management Association of Australia (HIMAA).	**Health Informatics Accreditation Council (HIAC):** AMIA joined the CAHIIM and established HIAC. It was charged with revising the existing CAHIIM Curriculum Requirements document and the "Accreditation Standards for Masters' Degree Programs in Health Informatics".	**Saudi Commission for Health Specialties (SCFHS)**: National Health Informatics Competency Working Group was established as part of the Saudi National Health Informatics Advisory Committee.
Project's foundation year	2007	2010	2010	2013	2015	2018
Project's main objective/s	To set out a common core or shared set of skills, knowledge, attitudes, and capabilities necessary to effectively perform as a Health Informatics Professional.	To provide a framework for individual curriculum development in the field of biomedical and health informatics (BMHI).	To define standards, develop competencies and produce useful tools that support this work.	To develop a new competency framework based on the existing frameworks but with a focus on the Australian healthcare system.	To build CAHIIM Accreditation Standards to reflect the emergent knowledge, skills, and attitudes reflecting the foundational domains set forth in the AMIA White Paper of 2012.	To develop a new competency framework but with a focus on the Saudi healthcare system.
Approach for competency development	- LR (Journal articles, textbooks and the Internet were reviewed). - Existing provincial, territorial, national and international competency frameworks pertaining to HI were reviewed. - Workshops were carried out to revise list of competencies obtained from LR. Participants were leaders in the field,	- Establishing a Working Group on Health and Medical Informatics Education - Reviewing the publications by organisations on the development of competencies - Revising the existing international recommendations in health informatics /medical informatics education.	Members met every week for 20 months: 1. Narrowing down the focus to one setting where roles could be mapped to and evaluated against Health IT competencies 2. Collating and mapping over 250 job roles and careers in the Acute Care setting in the EU and US 3. LR (Gathering competencies from 15+ organisations from both the EU and US)	Three organisations (AMIA, IMIA, COACH) were reviewed. Any repetitions, overlaps, and redundancies were removed, and the new competencies were restructured, ultimately producing the final competency framework.	Through an iterative process of review and revision by the AMIA Accreditation Committee (AAC) of organisations, papers, and recommendatio ns pertaining HI.	- LR (published and grey literature were reviewed). - Existing international competency frameworks pertaining to HI were reviewed. - Seventeen expert panel meetings - Online survey followed by a focus group (workshop) were carried out to revise

	representative of the HI profession from across Canada.		4. Organising, levelling and categorising the competencies. 5. Reviewing and reworking the competencies.			list of competencies obtained from LR. Participants were leaders in the field, representative of the HI profession from across Saudi.
Key Output	Health Informatics Professional Core Competencies Framework (version 3.0), released 2012. It includes - 3 domains, - 7 areas of competencies, and - 51 competencies.	A three-dimensional framework: - 1) professionals in healthcare, - 2) type of specialisation in BMHI, and - 3) stage of career progression.	HitComp tool (http://hitcomp.org), released 2015. It includes - 5 domains, - 33 areas of skills, and - 1000 competencies.	CHIA Health Informatics Competencies Framework (edition 1), released 2013. It includes 6 domains and 52 competencies	Health Informatics Competencies Framework, released 2016. it includes 10 domains and 22 competencies.	Saudi Health Informatics Competencies Framework (version 1.0), released 2018. It includes 6 domains, 22 subdomains or areas of competencies, and 92 competencies.
Visual illustration of competencies?	Yes	No	No	Yes	Yes	Yes
Framework Applications	- Establishing Professional certification based on the core HI competencies required in the Canadian health system. - Establishing a Career Matrix and the Role Profiles. - Setting the minimum requirements in terms of skills, knowledge, understanding and capabilities that will enable a candidate to perform in a professional environment. - Defining more clearly the body of knowledge underpinning this discipline.	Accreditation of BMHI educational programs. Curricula guidelines for academic institutions that define minimum-level competencies required for each level and knowledge/skill domain. Recommendations for Bachelor, Master and Doctoral Programs in Biomedical and Health Informatics In future, IMIA will also develop teaching credentialing criteria to serve as a guide for teachers wishing to participate in BMHI education.	- Hiring Manager – needs all candidates to have eHealth skills - Technology College – developing new eHealth certificate program in management, quality and improved outcomes - ICT/IT Specialist – wants to transition to eHealth	- Providing the context in which the questions for the exam have been developed. - Setting guidelines for recruiting purposes, definitions of career pathways, or the design of educational and training activities. - Setting the minimum requirements in terms of skills, knowledge, understandings and capabilities that will enable a candidate to perform in a professional environment. - Defining more clearly the body of knowledge underpinning this discipline.	- Curriculum development - Accreditation quality assessment for graduate (Master's level) education in applied health informatics. - Setting the minimum requirements in terms of skills, knowledge, understandings and capabilities that will enable a candidate to perform in a professional environment. - Defining more clearly the body of knowledge underpinning this discipline.	- Establishing a professional credential certification based on the core HI competencies required in the Saudi healthcare system. - Setting the minimum requirements in terms of skills, knowledge, understanding and capabilities that will enable a candidate to perform in a professional environment. - Defining more clearly the body of knowledge underpinning this discipline.

Results

Table 1 presents a high-level summary of the competency development projects in Europe, Canada, Australia, United States and Saudi Arabia. The following sub-sections provide a summary of the body/organisation initiative, foundation year of the project, the project's main objectives, approach for competency development, key outputs, and visual illustrations of the competency framework. It also illustrates challenges and issues relating to the development of the Saudi HI competency framework.

Foundation Year of the Projects

When compared to other countries, Saudi Arabia is the latest country to join in developing a HI competency framework for HI professionals. Canada was the first to begin this task in 2007, followed by Europe in 2010, Australia in 2013, and the United States in 2015. Saudi Arabia's delay in the development of a HI competency framework can be attributed to the novelty of HI education within the country, undefined roles of HI professionals working within the Kingdom, and recognition of HI as a health profession vs a computing science profession.

Project's Main Objectives

Digital Health Canada and CHIA aimed to develop new competency frameworks that set out a core list of knowledge and capabilities necessary to effectively perform as a HI professional. IMIA and HIAC however built accreditation standards and guidelines for curriculum development that reflect the key knowledge and skills in HI as a discipline. On the other hand, EU-US eHealth Collaboration Initiative established Workforce Development that aimed at defining a variety of healthcare roles and careers, levels and areas of knowledge.

In Saudi Arabia, at the beginning of the project, there was a debate among the panel's members on whether we should adapt an existing competency framework or build a new one. Decision was made to build our own framework for the following reasons:

- EU-US eHealth Collaboration Initiative project was not designed to establish a professional credential certification which was an essential aim for our work in Saudi. A total number of 1000 of competencies were identified which means that they did not set the minimum requirements in terms of skills and knowledge to perform in a professional environment.
- HI is a rapidly evolving field. Some competencies were outdated; e.g., IMIA's framework was developed from 2010.
- The Australasian framework was built with a focus on the Australian healthcare system.
- AMIA and CAHIIM competencies were designed for curriculum development, not for providing professional credential certification.

Approaches for Competency Development

The comparative analysis of competencies development projects showed that most of the identified leading HI professional organisations (e.g., COACH, IMIA, etc.) had different project objectives but similar approaches for competency development. For example, review of published and grey literature, review of existing national and international competency frameworks pertaining to HI, and workshops and/or panel meetings were carried out by all HI professional organisations around the globe.

The Saudi approach was different in a number of ways than other approaches (see Table 1) primarily due to the complexity, diversity, and novelty of health informatics education and professional practice within the country. Our approach focused on building consensus among the diverse academic and professional perspectives by generating a list of key professional and educational stakeholders and inviting them to participate in both an online survey and a focus group session to garner their feedback on the proposed Saudi HI competency framework.

The online survey asked the participants to rank the competencies in order of importance. Once the survey and analysis were complete, the stakeholders were invited to a focus group session to discuss the findings and garner consensus for selecting the key elements of the Saudi HI competency framework. The findings were presented to the group via a PowerPoint presentation and each element of the proposed Saudi HI framework was discussed until a consensus was reached either to include, exclude or postpone discussion at a later date for the relevant competency discussed.

Key Outputs

EU-US eHealth Collaboration Initiative developed HitCopm tool (http://hitcomp.org). HitComp is a searchable database designed for interested parties in healthcare information technology and eHealth such as educators, workforce developers, students, eHealth managers, etc. It defines 5 domains (Administration, Direct Patient Care, Engineering/Information Systems/ICT, Informatics, and Research/Biomedicine), 33 areas of skills, and 1000 competencies.

Digital Health Canada built the Health Informatics Professional Core Competencies Framework (version 3.0). It includes 3 domains (Management Science, Health Science, and Information Science), 7 areas of competencies, and 51 competencies. Similarly, HISA developed CHIA Health Informatics Competencies Framework (edition 1). It has 6 domains (Management Science, Health Science, Information Science, Information and Communication Technology ICT, Scientific skills of Health Informatics, Human and Social Context) and 52 competencies.

AMIA and CAHIIM established the Health Informatics Competencies Framework for curriculum development that includes 10 domains and 22 competencies. This framework has six major domains: Health, Information Science and Technology, and Social and Behavioural Science, Professionalism, Interprofessional Collaborative Practice, and Leadership. The first three domains intermingle and provide four co-mingled domains: Health Information Science and Technology, Human Factors and Sociotechnical Systems, and Social and Behavioural Aspects of Health. On the other hand, IMIA built a three-dimensional framework. These dimensions are: professionals in healthcare (e.g. physicians, nurses, BMHI professionals), type of specialisation in BMHI (IT users, BMHI specialists), and stage of career progression (bachelor, master, doctorate).

The Saudi Health Informatics Competency Working Group developed the Saudi Health Informatics Competencies Framework (version 1.0). It has 6 domains (Core Principles in HI, ICT, Health Sciences, Data Science, Education and Research, and Leadership and Management), 22 sub-domains or areas of competencies, and 92 competencies.

All of the above projects were established by independent organisations/bodies that aim to foster the HI profession. However, in Saudi Arabia, SCFHS provided support for the Saudi project although it is not devoted for the HI profession. SCFHS is a professional body that regulates health care-related practices and accreditation at all levels in Saudi Arabia. Lack of independent body for taking charge of the HI profession may obstacle the process of keeping the framework updated. To achieve this state of sustainable professional presence, HI workforce development play a significant role, which can be accomplished by an independent professional body to fulfil this

purpose, or SCFHS via establishing a specialised unit to foster the HI profession. A collaborative initiative by SCFHS and the National Health Information Centre may be needed to set together the future career needs to ultimately improve overall HI profession scope and definition in Saudi Arabia.

Visual Illustrations and Framework Applications

The projects of competencies development that were conducted by HI organisations had led to building a variety of frameworks that visually define a set of fundamental competencies for describing the HI profession. Few organisations did not provide a visual illustration of their competencies. For example, EU-US eHealth Collaboration Initiative developed HITComp tool instead, and IMIA presented their framework in the form of guidelines and recommendations to guide the development of biomedical and health informatics bachelor, master, and doctorate programs.

The applications of the developed competencies-based frameworks varied from one organisation to another. For example, Digital Health Canada and CHIA established professional certification based on their frameworks that define the core HI competencies required in the Canadian and Australian health systems respectively. IMIA and HIAC, on the other hand, applied their framework for curriculum development and quality assessment for undergraduate and graduate education in HI.

In Saudi Arabia, SCFHS will use SHICF to guide the development of a professional credential examination. The SCFHS currently interviews candidates without providing the interviewer or interviewee with specific areas of study, leading to a very subjective interview process. Using the Saudi competency framework would provide valuable guidance and needed consistency to the SCFHS evaluation team when interviewing and credentialing HI professionals. In future phases, a written examination is needed to be developed based on the framework. A team of HI experts from academia and industry should work on developing exam questions using the competency framework produced from this project.

SHICF will also be utilised to refine the Health Informatics academic programs of local educational institutions. Since this initial framework has been developed, the framework itself may not be reflective of what is being taught today in HI programs across the country. Therefore, a collaborative initiative by SCFHS and the Ministry of Education may be needed to build guidelines for current university programs to be refined based on the competency framework, and specifically, the competencies for each sub-domain. Meanwhile, the need for building guidelines based on the framework to design and/or update academic programs/degrees in HI is essential to maintain consistency between the proposed framework and the current educational programs and practises.

Discussion

A number of attempts have been made in the last ten years to define the HI profession through the development of an HI competency framework to guide both HI professional practice and curriculum development. Our results show consistency between our work and the work developed by the selected five organisations. Also, our initial work will provide valuable benefits to the SCFHS in supporting planning activities for health informatics professional credentialing within the Kingdom of Saudi Arabia.

The project that was carried out over the past eight months illustrates the difficulties involved in developing a local framework given the discord between current programs being delivered and international standards for HI professionals. The lack of independent body for taking charge of the HI profession in Saudi could be a big challenge that may obstacle the process of keeping the framework updated.

Conclusions

The Saudi Health Informatics Competency Framework (SHICF) can be utilised to define the field of health informatics within the country. SCFHS can use the framework to define the boundaries of the field of health informatics and distinguish it from areas such as Bioinformatics based on the competencies outlined in the framework. As a result, SHICF will provide a clearer definition and formal recognition of the health informatics filed as it is practiced within the country. In addition, the work conducted in our project could be a first step towards providing a fair, objective, and reliable assessment and guidance for HI professionals, employers, and academic institutions within the country.

The health informatics field will continue to evolve and the SCFHS should continually review the proposed competency framework in order to develop in future a context-based HI competency framework that would make HI professionals competitive, competent, and reliable in helping improve overall healthcare quality within the Kingdom of Saudi Arabia.

Abstract

Patient portals are offered by health care organizations to facilitate health information sharing and patient empowerment and support patient-centered care. The aim of this systematic review is to assess the effect of patient portals on patient empowerment and health-related outcomes. After a systematic literature search, ten randomized controlled trials (RCTs) were included in this review. Of these, seven RCTs were conducted in the United States., two in Canada, and one in Japan. Study characteristics, risk of bias, and outcomes were extracted. varied in terms of intervention, included patients, and outcome.. Most studies found no or only a small, clinically non-relevant effect of patient portals. The review showed that future research should develop a taxonomy to describe patient portal functionalities to facilitate the aggregation of evidence.

Keywords:

Electronic Health Records, Review, Patient Participation

Introduction

Patient-centered care has gained importance in both medical research and clinical practice. The concept of patient-centeredness is based on patient empowerment, patient participation, and shared decision-making [1–3]. Health information sharing and patient engagement in health care decisions are seen as preconditions for patient-centered care [1].

To facilitate health information sharing and patient involvement in the care process, healthcare organizations are increasingly offering their patients' access to their health data in the institution-based electronic health record (EHR). Patients can access these data and integrate it into any (electronic or paper-based) type of personal health record [4].

The interface that provides EHR access is called patient portal [5]. These portals are typically web-based, allowing patients independent access to their data from anywhere as a primary feature. A patient portal may also offer additional features such as medication refill requests, appointment scheduling, secure messaging, personal health-related reminders, individual therapeutic recommendations, personal diaries, and social networking with other patients.

In addition to being offered by healthcare organizations, EHR access may also be offered to patients on a national level. Some countries, including Austria, Denmark, and Sweden, have already started eHealth projects to make selected health-related data from various healthcare organizations available to their citizens [6].

A uniform theory or clear evidence of how EHR access via patient portals might contribute to patient-centered care and related concepts such as patient empowerment or patient participation or even improved health outcomes, does not exist. Nevertheless, qualitative reviews have shown that patient portals may improve patient empowerment, patient adherence, and clinical outcomes [7,8]. However, systematic reviews on patient portals have found inconclusive results to date [8–12]. As all of these reviews were published before 2015, it is possible that more evidence is now available. In this systematic Cochrane review, we assess the effects of providing access to EHR for adult patients on patient empowerment and health-related outcomes. We summarize characteristics of the identified Randomized Controlled Trials (RCTs) and present preliminary results on the effect of providing access to EHRs for adult patients on patient empowerment and health-related outcomes.

Methods

We used a Cochrane protocol for conducting this review [13]. We systematically reviewed RCTs investigating the effects of providing EHR access to adult patients. First, we developed a patient portal taxonomy describing seven functionalities:

- *Access*: Access to health-related data (e.g., visit notes, test results, medical history).
- *Remind*: Personalized health care reminders (e.g., for mammography or immunization).
- *Request*: Transactional services (e.g., scheduling appointments, prescription request).
- *Communicate*: Bilateral communication (e.g., secure messaging).
- *Share*: Patient self-documentation and sharing (e.g., patient uploads of blood pressure measurements).

- *Manage*: Disease management (e.g., individualized recommendations from guidelines).
- *Educate*: General health-related education (e.g., disease information leaflets).

Primary outcomes for this Cochrane review are the effect of EHR access on patient knowledge and understanding, patient empowerment, patient adherence, patient satisfaction, and adverse events.

Secondary outcomes for this review are health-related outcomes including quality of life, psychosocial health outcomes, health resource consumption, and patient-provider communication.

In our review, all studies offering EHR access to adult patients were included, independent of the medical condition of the patients. Only studies where EHR access was provided via a web-based application were included, thus excluding office-based systems. Only RCTs were included.

We systematically searched electronic libraries including Central, Medline, Embase, PsycInfo, Scopus, and CINAHL; in proceedings of Medinfo, AMIA, and MIE; and in major health informatics journals. We also searched for studies cited in earlier systematic reviews on patient portals and in identified RCTs. Two authors independently screened all titles and abstracts to determine whether they meet the inclusion criteria.

The following information were extracted by two authors using the software Covidence (Version v1062 115d548c):

- Study identification (e.g., country, clinical setting).
- Study methods (e.g., aim of study, intervention and control group, number of arms, study design, funding source).
- Population (e.g., target group, inclusion and exclusion criteria, age, gender).
- Intervention (e.g., name, functionality, usage patterns).
- Risk of bias (e.g., random sequence, allocation, blinding, selective outcome reporting) [14].
- Outcomes (e.g., methods and timing of assessing outcomes, instruments used, methods for follow-up, effect size, mean change in intervention and control group, adverse events, measure of uncertainty).

Primary and secondary outcome results were extracted in systematic evidence tables. More details of data extraction are published in a Cochrane protocol [13].

Results

We identified ten studies that represent distinct RCTs on EHR access for adult patients (seven RCTs and three cluster RCTs). Figure 1 shows the flow chart of this systematic review. The studies included between 78 and 4,500 patients.

Identified studies were very heterogeneous in terms of included patients' diseases (hypertension, diabetes, asthma, glaucoma, congestive heart failure or unspecific) and outcome measures (e.g., frequently patient adherence and health-related outcomes, less often patient satisfaction and patient empowerment), making meta-analysis challenging.

Seven RCTs were conducted in the United States, two in Canada, and one in Japan (Table 1). The majority of studies were published in 2012 or earlier, indicating a scarcity of newer studies.

Table 2 shows functionality supported by patient portals, based on our taxonomy. All included studies offer "access to data", as this was an inclusion criteria. No portal offered the functionality "request".

There was substantial heterogeneity across studies regarding instruments used and study outcomes. For example, the three studies measuring patient empowerment used four different questionnaires. For two of these instruments, there was no statistically significant difference in patient empowerment. For the other two instruments, the effect was statistically significant, but the effect size was too small to be clinically relevant.

Eight studies measured changes in health-related outcomes. These include a outcomes such as asthma control and mortality, but mostly risk factors such as hemoglobin A1c (HbA1c), blood pressure, low-density lipoprotein and body mass index. Of the six studies measuring the effect on HbA1c, two found a statistically significant, yet small improvement. Of the four studies measuring the effect on blood pressure, only one found a statistically significant, small improvement.

When looking at usage patterns, the functionality offered by the patient portal was often not used consistently. For example, in one study, the number of logins declined over time [21]. In another study, less than 25% of patients used the portal consistently [20]. In one RCT, 16% of patients never logged in over the three-month study period [15]. Users of the patient portal were more often male, white, commercially insured, and college-educated [16,19].

Sub-group analysis of the intervention group revealed that, in this group, portal users show better outcome than portal non-users in three studies [19,20,22].

Discussion

We identified ten randomized controlled studies that evaluated the effect of patient portals on a range of outcomes. In summary, most studies found no evidence for an effect or only a small, clinically non-relevant effect.

Two studies reported no differences on mortality [22,24], and none of the included RCTs reported other adverse effects of patient portals. In general, EHR access may increase feelings of confusion and anxiety when patients read clinical information that is unclear to them [8], but this effect was not reported in the included studies.

EHR access, like many other digital health solutions, is sometimes said to be created for "people like me", meaning that these digital solutions may only address the needs of "[…] well-educated and well-to-do users rather than the needs of the most disadvantaged in society (the disempowered, disengaged, and disconnected" [25]. Two studies [16,19] found indeed that active portal users were more often white, male, and college-educated.

Among other factors, health literacy may help to reliably interpret content provided in the EHR. The level of health literacy may influence the frequency of use and the potential benefits from accessing EHR. data Besides disease-specific knowledge in one study [22], health literacy was, however, not analyzed in any study.

Three studies found that active users showed better outcomes compared to non-users in the intervention group. The concept of "implementation fidelity" [26] refers to the degree in which an implementation is delivered and used as intended. Low frequency and duration of portal usage may show low fidelity and may explain lack of visible effect. Another likely explanation for the better effects in users may be patient characteristics (e.g., education status) that may be associated with both higher portal use and better health outcome; therefore, the identified difference may be an overestimation of the true effect.

Nine of the ten reviewed RCTs included patients with various chronic diseases (Table 1). While earlier research assumed that chronic patients may benefit from patient portals [27], we did not find clinically relevant effects for this group. We thus do not expect to see effects from portals in other user groups.

Due to the small number of studies, further sub-group analysis such as patient group, portal functionality, or fidelity of implementation are not possible.

We were not certain that we have identified all RCTs on patient portals, due to various terms describing the intervention or the observed effects. So, we also searched in major health informatics proceedings, references of other portal reviews, and references of the identified RCTs.

Conclusions

Preliminary results of this systematic review of RCTs of patient portals did not reveal clear evidence of substantial and consistent positive effects of patient portals on patient empowerment and health-related outcomes.

The number of identified studies, however, is small, quite diverse, and many were published in 2012 or before . Also, in several studies, a part of the intervention group did not use the patient portal consistently.

Future research should develop a taxonomy to describe patient portal functionalities to facilitate the aggregation of evidence in future systematic reviews.

Abstract

[Background] Recent reports of some studies have described that the cognitive function of cancer patients often declines by a phenomenon designated as cancer related cognitive impairment (CRCI). For patients' decision-making, detecting CRCI is important. To do so, this study uses language-based CRCI screening to examine participants' language ability. [Objective] This study was conducted to ascertain whether a Natural Language Processing (NLP) based system can detect CRCI, or not. [Materials and Methods] We obtained materials of two types from cancer patients (n=116): (1) speech samples on three topics, and (2) cognitive function level test scores from Hasegawa's Dementia Scale – Revised (HDS-R), a test used in Japan for dementia patients. The test is similar to the Mini-Mental State Examination. [Results and Discussion] Cancer patients with lower HDS-R scores showed a significantly lower Type Token Ratio (TTR). [Conclusion] This result demonstrates the feasibility of the proposed speech–language-based CRCI screening method.

Keywords:
Cancer, Cognitive Dysfunction, Natural Language Processing

Introduction

Rapidly advancing medical technology brings huge numbers of treatment options for patients. Consequently, it is important to choose among various available options to find a suitable treatment. This decision-making process requires careful and thoughtful consideration. Cognitive impairment of patients is an important difficulty that disturbs patient decision making. Recent reports of some studies have described that the cognitive function of cancer patients often declines by a phenomenon designated as cancer related cognitive impairment (CRCI). Although as many as 75% of cancer patients have CRCI, little is known about its mechanisms [1]. Consequently, a large and precise CRCI study must be done.

To date, CRCI studies have adopted various approaches: biomedical studies have investigated genetic factors; neuropsychological examinations have used MRI images; and self-report questionnaire-based surveys have also been used. Although various approaches have presented some results, most have been preliminary studies of small numbers of patients. A difficulty of CRCI studies is obtaining a large number of patients, which in fact motivates the development of a method of rapidly investigating CI. Dementia is diagnosed when cognitive impairment has become sufficiently severe to reduce social functioning. Mild CI (MCI) is intermediate between normal cognition and dementia.

From the perspective of CI (or MCI) measurement, Alzheimer's disease has spurred development of an MCI measurement system. A rapid MCI measurement system is speech-based. A salient benefit of speech-based approaches is that they require only a patient speech sample [2–5] with no intervention. From speech samples, the system estimates the patient vocabulary, which is closely related with cognitive functions.

This study's method was designed to infer CRCI quickly from a speech sample. This study was conducted to evaluate CRCI from a cancer patient's speech narrative. To do so, we recruited cancer patients, and obtained both narrative and the cognitive test results.

The research questions (RQ) of this study are summarized as presented below:

- RQ1: to investigate the ratio of Japanese cancer patients with CRCI.
- RQ2: to investigate whether a system detect the CRCI only from patient speech.

Materials

Participants: Cancer patients have been recruited from the Osaka International Cancer Institute since July 11, 2018. Patient recruiting continues to the present day. In this recruiting, 171 patients in all used the system. Among them, 116 patients finished all tasks (55 (=171-116) were dropout). Participants included 53 men and 61 women, with 2 of unknown gender. Their average age was 64 years old (SD =15.2); the median was 67 years old (min=19, max=90). All participants were Japanese and fluent Japanese language speakers. All were present cancer patients or had a past history of cancer.

Methods

The research design: **Prospective cohort study**.

For this study, we developed a system for cancer patients (Fig. 1). We designate this system "KOTOBAKARI", which means language (/kotoba/) measurement (/bakari/) in Japanese.

System configuration: "KOTOBAKARI" consists of a touch panel computer (Windows 10) and a microphone for speech sampling.

Procedure: The measurement procedure comprises three steps. The measurement time is about 10 min in our preliminary experiments conducted with healthy users.

1. **Login:** a patient enters the booth and touches the screen. The patient then swipes the hospital ID cards to log-in.
2. **HDS-R** [6]. The HDS-R is a short cognitive test that is popular in Japan and which is similar to the Mini Mental State Examination (MMSE).
3. **Narrative Sampling**: The three questions below are given.

> *(1) What is your most joyful event that you experienced in recent days?*
> *(2) How do you come to the hospital?*
> *(3) How did you play during your childhood?*

A patient responds to each question. The system also displays "your talk should be about 3–4 min."

If a patient talks longer than 5 min, then the system displays "the amount of data is sufficient."

For 50% of participants, step 2 and the step 3 were inversed (Step 1 – Step 3 – Step 2) to mitigate order bias.

Inclusion and Exclusion Criteria

Inclusion criteria: cancer patient (any kind of cancer, any stage, any treatment is included).

Measurement Method

The measurement metrics, four NLP metrics, are presented in Table 1.

Table 1– Speech Indicators

Metrics	Description
Type token ratio (TTR)	Vocabulary size
Educational level (EL)	Vocabulary level
Word Commonness index (WCI)	Word commonness
Length (LEN)	Speech length

- **Type Token Ratio (TTR)**: TTR represents the vocabulary size, as derived from the ratio of word type to token (i.e., type/token, where type refers to the number of the use of different words in a text and token refers to the number of words in a text). We have disambiguated orthographic variants using a Japanese morphological analysis system. For example, "*itta* (went; past tense)" was normalized into "*iku* (go; present tense)" using the Japanese morphological analysis system, or JUMAN [7]. This study assessed both the word function and content.
- **Educational Lexicon Level (EL)**: EL represents the average difficulty in lexical choice. This metric was created originally for non-native speakers of Japanese. We used the word scores provided in the Japanese Learner's Dictionary [8]. In this dictionary, the most common 17,928 words are classified into the following three levels: beginner, intermediate, and advanced. To derive the score, we extracted and summed the number of nouns belonging to the intermediate or advanced levels. Then we divided this figure by the sum of intermediate and beginner level nouns. Details are presented in an earlier report [9].

Word Commonness Index (WCI): WCI represents the average use of common words. FPU represents the degree of commonness of words. The manner of calculating the commonness of words is proposed in [10]. We use a dictionary constructed in the work. This measure differed from the frequency of the occurrence of the word because such frequency deals with the number of the usage of the word no matter who the user might be, whereas WCI deals with the number of people who use the word.

- **LEN**: Number of characters of speech.
- **TIME**: Time of speech.

These metrics are calculated automatically from transcripts.

Measuring Cognitive Function Levels: The HDS-R, a screening test used in Japan for dementia patients, is similar to the Mini-Mental State Examination: the tests show a high degree of mutual correlation [6]. HDS-R scores that are 20 or lower (from a possible maximum score of 30) are regarded as indicative of dementia (sensitivity 0.90, specificity 0.82). Normal cognitive function is indicated by an HDS-R score of 27 or higher.

We implemented this HDS-R test into the system. Although most sub scores were judged automatically, several sub-scored items required human judgment, such as "list up as many vegetable names as possible." A clinical psychologist judged such questions.

Ethics Statement: This study protocol was approved by the Medicine Ethics Committee of the Osaka International Institute, 2018.

Figure 1 – "KOTOBAKARI" system. A speech booth in a cancer center (top left and top right) consists of a PC and mouse. Patients can freely enter the booth and use the system (bottom left and bottom right).

Results and Discussion

Results are two-fold, corresponding to two research questions.

RQ1: Does the cancer patient exhibit cognitive impairment, or not?

To answer this question, we investigated the cognitive scores as shown in Figure 3. As described, the cutoff score between healthy and mild cognitive impairment (MCI) is 20 (20 and more indicates healthy; less indicates MCI). The result indicates that not a few patients (n=30) show the MCI level score.

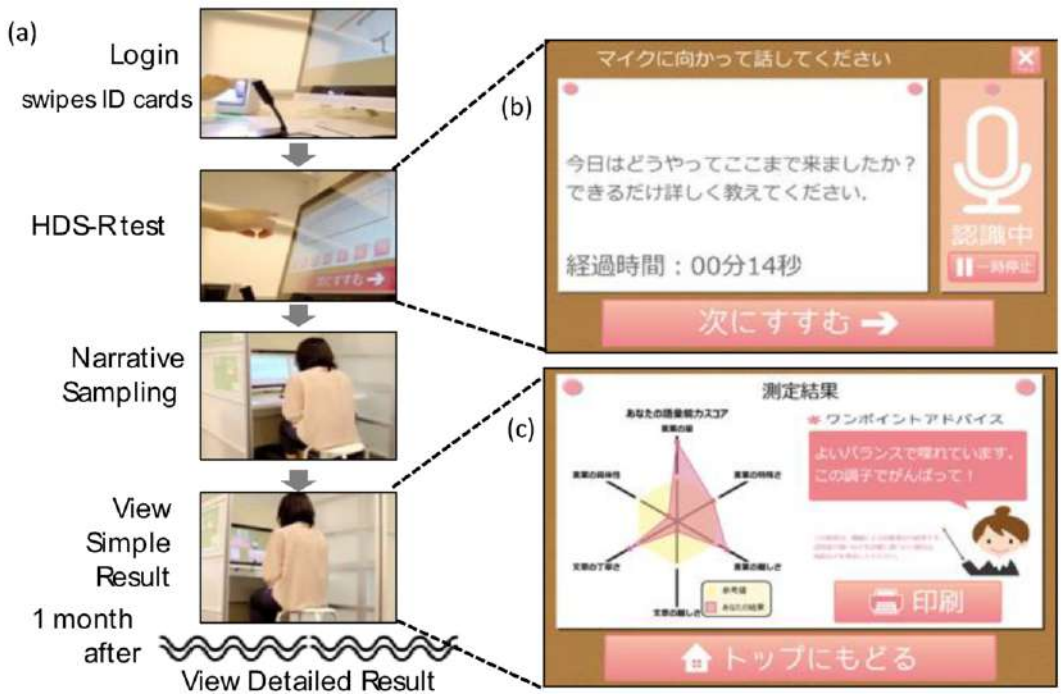

Figure 2 – "KOTOBAKARI" system screenshots. A patient can take tests of two types: (1) cognitive tests (HDS-R) and (2) Speech Tests (proposed method). Speech tests consist of three questions such as "(1) what is the most joyful event that you experienced in recent days?" A patient answers the questions by speaking. After the test, the speech is recognized and the result summary is displayed. This result is a rapid version based on automatic speech recognition. The final result is presented after judgment by a clinical psychologist.

Many factors might bias the results, such as the recruiting method and participant effects. The largest bias might be the patient age. Figure 4 depicts the distribution of HDS-R scores and ages of participants. Results show that age is highly correlated with HDS-R scores. Future studies should pursue more precise analyses that remove these biases. Although various biases exist, cancer patients tend to have cognitive impairment for some reason.

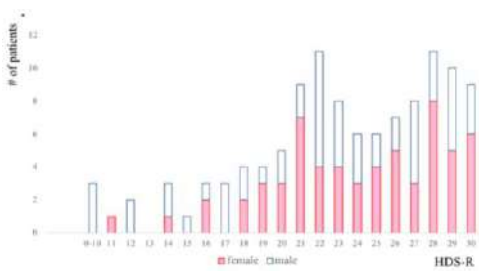

Figure 3 – HDS-R score distribution.

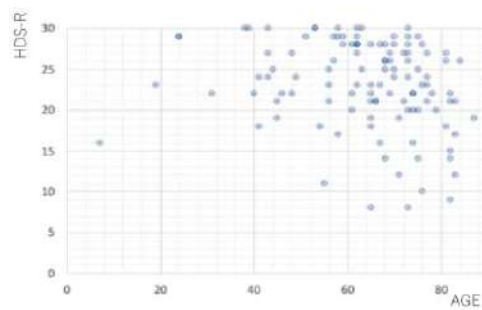

Figure 4 – Age and HDS-R score.

RQ2: Do cancer patient narratives suggest cognitive impairment, or not?

To answer this question, the relation between language abilities and HDS-R scores is shown (Fig. 5). To compare different scale language scores for (1) TTR, (2) EL, (3) WCI, and (4) LEN, scores are shown in order (higher to lower). The X-axis shows the order rank (TTR 10% means the top 10% rank in TTR). The Y-axis shows the HDS-R score.

The correlation ratio between language abilities and HDS-R is TTR (r=-0.34), EL (r=0.15), WCI(r=-0.05), and LEN (r=0.27). Among the four language abilities, TTR shows the highest correlation to the HDS-R score.

Next, we investigated the TTR screening performance. We divided the patients into two groups (higher and lower cognitive

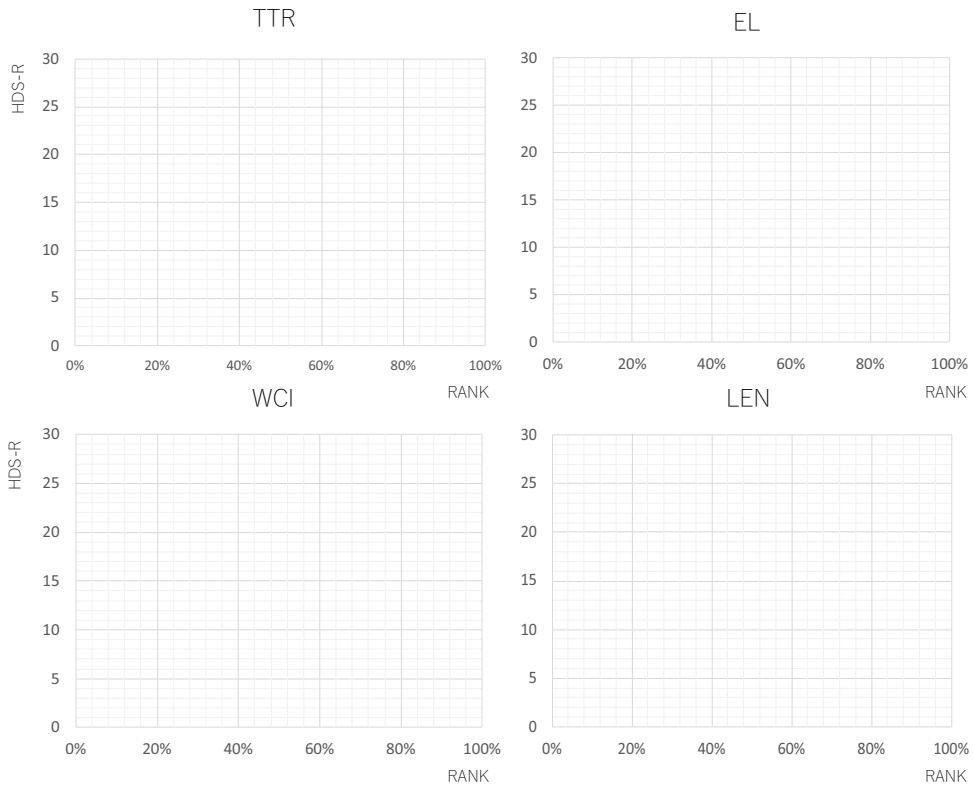

Figure 5 – Language abilities and HDS-R score. X-axis shows the language abilities (ordered by the rank). Y-axis shows the HDS-R score.

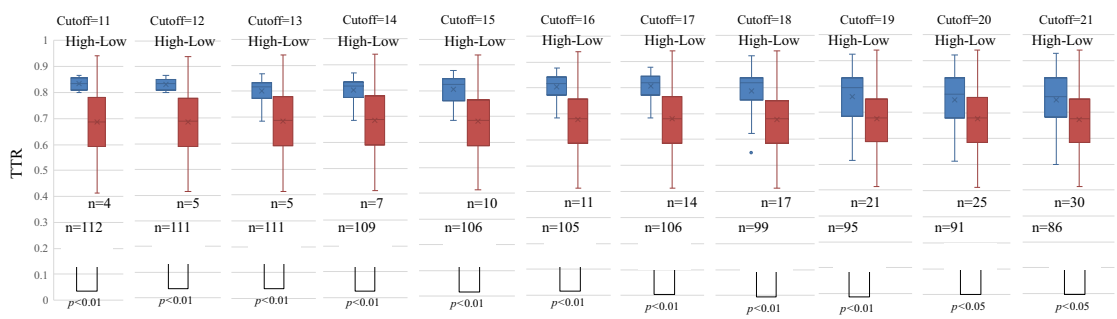

Figure 6 –HDS-R score and Type Taken Ratio (TTR; TTR of higher HDS-R group and lower group). We divided patients into two groups (higher HDS-R group and lower HDS-R group) using various HDS-R cutoff scores. At all cutoff points (from HDS-R 11–21), both groups showed significantly different TTR scores. Especially, HDS-R lower than 19 is significantly different ($p<0.01$), suggesting that serious CRCI is readily distinguished by TTR.

groups) using various HDS-R cutoff scores. The TTR performance is presented in Figure 6. In cutoff scores (HDS-R of 20–21), two groups showed significant TTR difference. Furthermore, in cutoff scores of HDS-R from 11 to 19, many differences were observed.

Results indicate two findings. (1) TTR-based screening of cognitive impairment is feasible. (2) Patients with a low HDS-R score are especially easy to detect.

Discussion

This study assessed the basic feasibility of speech-based cancer related cognitive impairment (CRCI) screening. To date, many studies examining Alzheimer disease patients have shows lower language ability, especially in the Type Token Ratio (TTR) [9, 11–13]. This study first demonstrated that not only Alzheimer's disease, but also CRCI shows lower language abilities. Results also reveal that TTR is the highest performance language indicator. Considering TTR is based on simple metrics (number of type and number of token), TTR-based screening has high potential for practical use.

Nevertheless, the relation between the TTR and diseases affecting cognition such as CRCI and Alzheimer disease remain unknown. Alzheimer disease examinations are classifiable into three types: (1) examinations evaluating cognitive function mainly based on memory, (2) examinations evaluating behavior disorders and mental symptoms, and (3) examinations assessing daily living behavior. Actually, TTR is related with the three functions above. Future studies must investigate the mechanisms of CRCI and language ability.

Limitations

This study has limitations. An important limitation is that the speech recognition accuracy is insufficient. This experiment relied on human transcription: a time-consuming and expensive task. Future clinical trial phases must resolve this problem and either find or produce a fully automated system.

Another limitation is that of screening performance. Results show that group-based differences in TTR (higher cognitive function group and lower cognitive function group showed the significant difference in TTR). However, the individual differences are smaller than group differences: patients sometimes show high TTR but lower HDS-R, or *vice versa*. The speech is highly dependent on the topic and personality, causing the instability. To address this shortcoming, one approach is to control the topic and personality. Moreover, a long time series analysis is highly desired.

Conclusions

Recent reports of some studies have described that the cognitive function of cancer patients is often declining. This study investigated this phenomenon, designated as Cancer Related Cognitive Impairment (CRCI). Using our proposed system, KOTOBAKARI, we collected cancer patients' cognitive function scores and speech samples. Among cancer patients (n=116), 30 showed mild cognitive impairment. Additionally, experiment results revealed that CRCI patients have a significantly lower type token ratio (TTR). This result demonstrated the feasibility of speech-based CRCI screening.

Development of Pictograms for an Interactive Web Application to Help Hispanic Caregivers Learn About the Functional Stages of Dementia

Adriana Arcia[a], Niurka Suero-Tejeda[a], Suzanne Bakken[b]

[a] School of Nursing, Columbia University, New York, NY, USA,
[b] School of Nursing and Department of Biomedical Informatics, Columbia University, New York, NY, USA

Abstract

Caregivers of persons with dementia need anticipatory guidance about the stages of dementia in order to prepare for the caregiving situations they will face. The study objective was to develop a set of pictograms representing the functional stages of dementia for eventual inclusion in a tailored, educational web application. We used a hybrid iterative participatory design process. A graphic designer prepared prototypes in a flat, minimalistic style. These were then culled and refined based on feedback from 16 Hispanic caregivers in six design sessions in English and Spanish. The resulting 19 pictograms representing the functional stages and substages of dementia were acceptable to and easily comprehended by participants. Short, plain-language captions support comprehension and aid discrimination between similar scenarios. Our participants preferred candid depictions of all aspects of dementia, including bodily functions, but acceptability may vary by population so further testing is warranted prior to deployment with a new population.

Keywords:

Consumer Health Information, Health Literacy, Patient Participation

Introduction

Caregivers require timely anticipatory guidance to prepare them for the complex and changing care needs of persons with dementia. Caregivers may need to acquire new skills or equipment, connect with community resources, or recruit additional caregiving assistance as the care recipient's condition progresses. An important way to prepare for the demands of caregiving is to understand the abilities or deficits associated with each of the 16 functional stages and substages of dementia [14; 15]. Numerous digital information resources about dementia exist, such as websites and mobile applications, but barriers like Low Health Literacy (LHL) and Limited English Proficiency (LEP) may limit the comprehensibility of these text-heavy resources for some caregivers in the United States [3].

Hispanics suffer disproportionately from dementia, including Alzheimer's dementia, and the associated caregiving burden, compared to non-Hispanic Whites [13]. Hispanics are also over-represented among individuals with LHL and LEP [16]. As a result, there is a need for culturally-competent resources that are designed specifically to meet the information needs of Hispanic caregivers.

One promising approach to supporting comprehension of health information among people with LHL and/or LEP is the use of visual enhancements, such as infographics [1] or photos. A photographic guide to caregiving for dementia is commercially available, but it is targeted to professional caregivers rather than family members and is only available in English [10]. Several studies report on the use of *fotonovelas*—soap opera-type stories in a photographic comic book format—to help Hispanic caregivers gain a general understanding of dementia [18] or learn strategies to reduce depression and stress [7]. However, our search did not uncover any research on visually-enhanced resources intended to make information about the functional stages of dementia easy for Hispanic caregivers to understand and use.

To meet this need, our objective is to develop an interactive web application, entitled **I**nteractive **F**unctional **A**ssessment **St**aging **N**avigator (I-FASTN), to inform caregivers about the functional stages of dementia. The application will be tailored to the user in that it will highlight the specific functional stage of the care recipient while also allowing the user to review the other stages. Screens for each functional stage will offer links to additional caregiving tips and strategies relevant to that stage. A long-term objective is to make I-FASTN available within patient portals through the Fast Health Interoperability Resource (FHIR) Health Level Seven standard and the Substitutable Medical Applications and Reusable Technologies (SMART) platform that enables systems to behave as 'iPhone-like platforms' through an application programming interface (API) and a set of core services that support easy addition and deletion of third party apps, i.e., the core system is stable and the apps are substitutable [12].

The first step in the creation of I-FASTN was content development. Therefore, the objective of this study was to develop a set of pictograms to represent the functional stages of dementia. For specific examples of functional deficits, we drew from both Functional Assessment Staging (FAST) [15] and the Global Deterioration Scale (GDS) [14]. We accomplished our objective through a hybrid iterative participatory design process in which experts create a starting set of prototype images which are then culled and refined based on participant feedback.

Methods

The Institutional Review Board of Columbia University Irving Medical Center approved this study. Written informed consent was obtained from all participants.

Participants

We recruited participants from the **N**ew York City **His**panic dementia caregiver **R**esearch **P**rogram (NHiRP), a study of family caregivers of persons with dementia. Participants were eligible for the present study if they met the NHiRP inclusion criteria: self-identified as Hispanic, 18-90 years old, related to the care recipient, physically able to provide care, not have a diagnosis of a major psychiatric disorder apart from depression, not have depression with psychotic features or suicidal ideation within the preceding 5 years, and expected to live in New York City for at least 12 months.

Procedures

Prior to starting design sessions, we prepared multiple prototypes to illustrate each functional stage and substage of dementia. In order to maximize our options for I-FASTN content, we aimed to identify as many prototypes as possible that participants indicated were clear representations of the intended meaning. We planned to undertake revisions until reaching design saturation, which is the point at which participant feedback yields no further substantive changes.

Iterative participatory design sessions were held in November and December of 2016 in New York City in English and Spanish. We collected basic demographic information from participants. Two investigators experienced in participatory design (AA, NST) led the sessions which were also attended by the experienced graphic designer (NSG) who had created the initial prototypes. In the sessions, we informed participants of the intended meaning (e.g., "Here we are trying to show difficulty managing complex tasks") and showed the captioned prototypes printed on 8.5" x 11" (22 cm x 28 cm) card stock. We solicited preferences among the prototypes by voice or hand vote and used open-ended questions to elicit suggestions for improvement. Sessions were audio-recorded and study staff took notes.

Analysis was concurrent with data collection: at the end of each session, study staff met to 1) synthesize the findings from the session, 2) identify poorly-performing prototypes to be removed from further consideration, and 3) come to consensus about revisions to the favored prototypes based on participant feedback. We then carried out any needed revisions between sessions. In later sessions after the set of prototypes had been narrowed down, we showed the pictograms in the context of preliminary layouts for the I-FASTN interface. After all the sessions were completed the study staff reviewed the notes, audio recordings, and resultant transcripts to audit the results and ensure important insights had not been missed.

Results

Thirteen women and three men (N = 16) participated in three English (n = 6) and three Spanish (n = 10) sessions. They ranged in age from 49 to 86 (M = 61.8) and had been caregiving for an average of almost 9 years. With respect to educational attainment, 12% (n = 2) had some high school, 44% (n = 7) were high school graduates, 25% (n = 4) had an associate's degree, and 19% (n = 3) had a bachelor's degree. Participants were predominantly born in or had family roots in Caribbean countries, rather than Spain or Central or South America.

We tested a total of 54 prototypes, which we subsequently reduced to a final set of 19 pictograms for the 16 stages and substages of dementia, as shown in Table 1. Stages 1, 4, and 5 each yielded two viable pictograms, so these were retained. Just over half of the pictograms (n = 10) underwent one revision, one went through two revisions and the remainder (n = 8) were unchanged from the original prototypes.

Participants' judgments about the extent to which the prototypes accurately represented a stage or substage were often unanimous and unequivocal, with clear favorites emerging early on. Participants narrowed down to the 19 final pictograms so quickly that by the fourth session we began to combine the pictograms into preliminary layouts for the I-FASTN interface to gather preliminary data for developing the interface. Participants in sessions four through six had no additional suggestions for improvement of the individual pictograms and thus we achieved design saturation. Participants displayed ease of comprehension with the final set of pictograms. For example, in sessions four and five participants were asked to review a preliminary I-FASTN layout for Stage 5 that had thumbnail images—less than 0.5" (1.27 cm) high—without captions of Stages 6a-6e printed in one corner of the page. In each of the two sessions, a participant spontaneously and correctly interpreted the meaning of the thumbnails. One man in session 5 explained: "Either they can't dress themselves, they are not bathing themselves, they need help going to the bathroom. Let me see this… they're having accidents."

Despite the ease with which participants interpreted uncaptioned pictograms, we concluded that they functioned best when accompanied by the captions included in Table 1, particularly to help differentiate between stages. For example, without captions, the distinction between Stage 5, "difficulty selecting appropriate clothing," and Stage 6a, "difficulty dressing without help," is an important one that might be lost on casual observation.

We noticed a general preference among participants for pictograms that featured people rather than objects. For example, the pictogram for Stage 3 originally had just the street signs; the person shown in the final version was added at participants' request. Participants also preferred imagery that was candid and unflinching. For instance, the initial prototype for 6e, fecal incontinence, showed the figure from the front with only the wavy lines to indicate the meaning. The more explicit depiction of sagging, soiled briefs was made per participants' specific request. In general, we noted that prototypes showing the presence of something were far more readily understood than those that attempted to show the same idea from the perspective of absence. For example, the pictogram for 7e showing a face with a drooping mouth was more readily understood as representing "cannot smile" than a smiling face marked with an X. Similarly, the final pictogram for Stage 4 in which a person appears confused as they think about money was preferred over a prototype showing a stack of cash with a slash through it.

Discussion

In this study, we worked with Hispanic caregivers to develop a set of pictograms that effectively represents the functional stages of dementia in a culturally acceptable manner. The pictograms are an important contribution to consumer health informatics and health communication because they facilitate access to necessary health information for a population at risk for health disparities. It is important to note that this work is distinct from research aimed at developing visualizations for non-literate populations [2] because we find that our population has little-to-no difficulty reading short passages of plain-language text. Rather, we have observed that comprehension deficits are related to uncertainty about having arrived at correct conclusions and limitations in understanding the basic

Table 1– Pictograms of the Functional Stages and Substages of Dementia.

Functional stages and sub-stages ***Captions***	**Related Pictogram(s)**	**Functional stages and sub-stages** ***Captions***	**Related Pictogram**
1. No objective or subjective functional decrement *Able to work; normal functioning*		6d. Urinary incontinence *Urinary incontinence*	
2. Subjective deficit only *Forgets where they placed familiar objects*		6e. Fecal incontinence *Fecal incontinence*	
3. Deficits noted in demanding occupational and social settings *Gets lost when traveling to new locations*		7a. Speech limited to about six words in the course of an average day *Speech limited to a few words*	
4. Deficits in performance of complex tasks of daily life *Difficulty managing complex tasks; unable to manage finances*		7b. Intelligible vocabulary limited to generally a single word in the course of an average day *Speech limited to one word*	
5. Deficient performance in choosing proper attire *Difficulty choosing appropriate clothing; can't remember the names of close family members*		7c. Ambulatory ability lost *Needs help to walk*	
6a. Requires actual physical assistance in putting on clothing properly *Difficulty dressing without help*		7d. Ability to sit up lost *Cannot sit up without support*	
6b. Requires assistance bathing properly *Unable to bathe properly*		7e. Ability to smile lost *Cannot smile*	
6c. Requires assistance with mechanics of toileting *Unable to manage the details of using the bathroom*		7f. Ability to hold head up lost *Cannot lift head by themselves*	

implications of a text. As such, pictograms support comprehension by using familiar imagery to reinforce the meaning of a text. For example, if a reader is uncertain about precisely what is meant in Stage 5 by "appropriate clothing," the pictogram gives a visual example of the incongruous combination of jacket and flip-flops.

The validity of these pictograms as representations of the stages of dementia is underscored by participants' quick, definitive judgments and strong interpersonal consensus when selecting from among prototypes. Participants' spontaneous interpretations of uncaptioned images, even when reproduced in thumbnail size, is robust preliminary evidence of the pictograms' comprehensibility. Group dynamics limit the ability to conclusively establish every participant's level of comprehension, but further testing may be undertaken by adapting methods outlined by the International Organization for Standardization in ISO 9186-1 for testing the comprehensibility of graphical symbols [5; 9].

For this project, we chose to use pictograms in a flat, minimalistic style rather than more detailed illustrations for two reasons. One, prior research has shown that viewers, particularly those with LHL, are at risk of misconstruing the intended meaning of complex illustrations because of a tendency to focus on irrelevant details [8]. Two, we wanted to minimize details within the images that might prevent a diverse population of users from identifying with the figures in the pictograms. Implementation of the chosen style was facilitated by the inexpensive commercial availability of royalty-free stock images which we adapted as needed. This style is consistent with other studies that have successfully used what have been described as "restroom icons" to convey health-related risks [20] and "stick figures" to develop easily comprehensible symbols for wayfinding in health care settings [4; 11].

In addition to style, other aspects of the final set of pictograms are consistent with prior research. When Weiner and colleagues [19] set out to design an illustrated patient satisfaction questionnaire for low-literacy populations, they found that "a few words go a long way" which is in keeping with our conclusions about the value of short, plain-language captions. As in our study, their illustrations successfully used question marks to depict confusion but their attempts to use slashes to indicate the negation of an idea (e.g., illustration of the response option "not applicable") were as unsuccessful as ours. Foster and Afzalnia tested the comprehensibility of various symbols to represent a cash machine and found that images that depicted human interaction with an object (i.e., a hand holding a stack of bills) were more easily comprehended than images of the object alone [6]. In a similar vein, we found that participants generally preferred the images that contained people.

Although these pictograms were developed to suit the needs of Hispanic caregivers in the United States, we believe the images will be easily comprehensible to a broader range of users. However, not all groups may consider all of the pictograms to be culturally acceptable, particularly those that depict bodily functions [17]. Given that our sample predominantly has roots in Caribbean countries, our findings may or may not extend to Hispanics from other regions. Explicitly testing for cultural acceptability and comprehensibility is warranted before pictograms are deployed with a new population.

The next step for our project is to design and test the I-FASTN interface (i.e., heuristic evaluation with experts followed by usability testing with end users) using the pictograms presented in this report. Spanish-language captions and vector files of the pictograms are freely available for non-commercial use upon request from the corresponding author.

Conclusions

Application of hybrid participatory design methods resulted in pictograms that were acceptable and comprehensible to Hispanic caregivers as an essential first step in developing tools to meet their needs. Well-designed pictograms are a useful adjunct to text for meeting information needs in consumer health informatics tools.

Abstract

Increasing attention is paid to the Handoff Process and EHR-integrated tools to enhance the Handoff Process and aid in creating Handoff Notes are becoming more prevalent. In this study, we attempted to determine the ideal content of the Handoff Note based on the preferences of the resident physicians for whom the tool was being constructed. This commenced with an initial semi-structured interview and culminated in a large-scale survey. Overall, 315 resident physicians completed the survey. Plan of Care, Illness Severity, and Patient Summary were the most important content elements to resident physicians. The importance and trustworthiness of other content elements, as well as their preferred display and level of granularity within the Handoff Note, varied considerably. Subjective assessment by a colleague of a patient's hospital course and plan of care, rather than any single piece of objective data, are preferred as ideal content for Handoff Note composition by resident physicians.

Keywords:

Patient Handoff, Electronic Health Records

Introduction

The transfer of patient care between physicians in the acute care setting commonly referred to as the "Handoff Process", has become more frequent with the advent of American Council for Graduate Medical Education (ACGME) restrictions on resident physician work hours. Numerous studies have identified inpatient Handoff as a source of preventable medical errors [1; 2]. The ACGME, Joint Commission, and Agency for Healthcare Research and Quality have all identified inpatient Handoff as a priority for improving patient care [3; 4]. Beginning in 2003, numerous reports have been published on the benefits of Electronic Health Record (EHR)-integrated Handoff Notes [5; 6]. No true standard exists for what content elements should be contained within EHR-integrated Handoff Notes [7; 8].

Methods

In order to investigate the preferred content of Handoff Notes, we first conducted a series of semi-structured interviews with resident physicians engaged in active clinical service on inpatient units within our hospitals. We then utilized the major themes discovered within the semi-structured interviews to develop an online survey containing discrete, multiple choice questions that could provide quantifiable data regarding the preferred content of Handoff Notes by the resident physicians for whom this electronic tool was being designed.

Semi-structured Interview

In order to gain an initial sense of resident physicians' views of current Handoff Note-generation techniques, content, and satisfaction, we conducted semi-structured interviews with resident physicians on inpatient clinical service teams at either our tertiary, acute care adult hospital or our tertiary, acute care pediatric hospital. Resident physicians functioning as junior level residents, who were actively involved in the process of Handoff Note creation as part of their daily work or who functioned as inpatient cross-cover residents who were actively involved in the process of Handoff and receiving Handoff Notes to guide their care of patients, were interviewed. Resident physicians came from Pediatrics, Internal Medicine, and Surgery teams. Pediatrics and Internal Medicine teams were from general pediatrics and general medicine teams. Surgery teams were either General Surgery or a surgical subspecialty, including Colorectal, Thoracic, Vascular, and Surgical Oncology.

Resident physicians were first presented with a sample Handoff Note typical for that specialty. At this time in our institution, different specialties were utilizing different techniques and styles for generating Handoff Notes. Pediatrics and Internal Medicine teams were utilizing quasi-EHR integrated Handoff Note generating techniques while Surgery teams utilized Microsoft Word-based Handoff Notes stored on local computers at specific workstations throughout the hospital. Therefore, when initially asked to comment on the quality and utility of Handoff Notes, resident physicians were presented with examples as similar to their specialty's current practice as possible. During the semi-structured interview, resident physicians were presented with a common clinical scenario encountered during cross-cover periods (a patient with hypotension) and then were asked what data in the Handoff Note was useful for clinical decision making. They were then asked to comment on the trustworthiness of the data elements found within the Handoff Note. Finally, resident physicians were asked to comment on their beliefs for what would be required of an EHR-integrated Handoff Note that would contain optimal clinical information and be easily constructed and shared with colleagues. Interviews were conducted by one of two study investigators (EGA and RKO) and voice recordings were performed for each of the interviews. Narrative content of the interviews was then analyzed for major themes and headings.

Institution-Wide Online Survey

We then utilized the major themes and headings discovered within the narrative content of the semi-structured interviews, as well as previous review of the literature on content of EHR-integrated Handoff Notes (Arsoniadis et al, unpublished), to develop an online survey for distribution among resident physicians enrolled in American Council for Graduate Medical Education (ACGME) – accredited residency and fellowship programs at our institution. The goals of the survey were to assess the importance of different data elements within the Handoff Note, assess the trustworthiness of certain data elements within the Handoff Note, and determine the preferred format and level of granularity at which certain Handoff Data is displayed within an EHR-integrated Handoff Note functionality

The survey was developed by two physicians (EGA and RKO) with experience in health informatics and an expert in human factors and usability (JM). Resident physicians were asked to identify their specialty and level of training, as well as experience using the EHR. Resident-physicians were asked to rate the importance of different content elements within the Handoff Note according to a Likert-style scale, with 1 being "Not Important" and 5 being "Very Important" for accomplishing clinical care. An additional option for free text response was included at the end of the survey. Content elements included in the survey were extracted from either previous review of the literature on standard or suggested content for electronic Handoffs [7; 8], from the prior semi-structured interviews with resident-physicians, or both.

A Likert-style scale was also utilized to determine the level of trustworthiness of certain content elements to resident physicians, including Code Status, Patient Summary, Post-Operative Day, To-Do List, and Anticipatory Guidance. The trustworthiness of these data elements was of special interest, given the varied opinions voiced during the semi-structured interviews performed previously. Options ranged from 1, "I do not trust at all" to 5 "I trust completely".

The preferred format and granularity at which certain Handoff Note data is displayed was also queried through a series of multiple-choice questions in our survey. These questions included content elements such as patient problem list, past medical/surgical history, clinical data (vital signs, imaging and laboratory studies, fluid balance), and medications, among others. Again, these multiple choice questions were formulated based on themes generated from our initial semi-structured interview.

The final content of the survey was reviewed by five resident physicians currently involved in active duty on inpatient clinical service teams and minor revisions made based on their input. It was released to all physicians in ACGME-accredited residency and fellowship programs involved in inpatient acute care (anesthesiology, radiology, ophthalmology, pathology, and dermatology excluded). The survey was approved by the Dean for Graduate Medical Education as well as the Institutional Review Board of the University of Minnesota. Participating resident physicians gave informed consent, and were entered into a lottery for one of two iPad Airs for their participation.

Results

Semi-structured Interviews

Sixteen resident physicians (first through third years of training) from three specialties (Internal Medicine, Pediatrics, and Surgery) were interviewed. They were asked to comment on the clinical utility and trustworthiness of various content elements on an example Handoff Note currently in use by that specialty.

Table 1 – Survey Participants by Training Level and Program

Training Level	Surgery	Pediatrics	Internal Medicine	Total

Clinical Utility and Trustworthiness

The utility of content elements in Handoff Notes for clinical decision making during cross-cover periods varied between resident physicians. Summary statements about the patients were nearly universally utilized in clinical decision making. Two-thirds of resident physicians interviewed felt the Medications to also be useful. Some content was specialty specific. For instance, Procedure Name and Date were regarded as useful content by four of five Surgery resident physicians. However, these content elements were not even present in the versions of the Handoff Note being utilized by Internal Medicine and Pediatrics resident physicians. Similarly, the trustworthiness of different content elements varied, with some resident physicians implicitly trusting all or most of the content elements and others trusting almost none of them. The trustworthiness of content elements did not seem to be affected by the source of the data, whether manually entered or automatically generated from the EHR. Interestingly, mistrust of data in the Handoff Note was most prevalent in the comments of Internal Medicine resident physicians, who contributed 18/21 comments (86%) that called the trustworthiness of various content elements into question.

Table 2 – Most Important Handoff Content Elements

Content Element	% Ranking Important (4 or 5)
Plan of Care	95%
Name & Age	89%
MRN & Room Number	83%
Illness Severity	78%
Code Status	77%
Patient Summary	77%

Table 3 – Least Important Handoff Content Elements

Content Element	% Ranking Not Important (1 or 2)
Primary Care Physician	84%
Fluid Balance	50%

Suggestions for Improvement

Transcripts for interviews were coded by two authors (EGA and RKO) and major themes emerged regarding improvements resident physicians felt could be made to EHR-integrated Handoff Notes. Sixty three percent of comments related to improvements focused on the importance of including information from the primary service team regarding their subjective assessment of the patient, including a brief summary of the patient and their hospital course, assessing patients' illness severity, providing anticipatory guidance for addressing possible issues that may arise during the cross-cover period, and providing a To-Do list for tasks that needed to be accomplished in the cross-cover period. The structure and format of the Handoff Note were addressed by several resident physicians. Some favored a more standardized approach with decreased content and "white noise". Others favored a Handoff Note that was more customizable, with resident physicians being able to

control the content elements included in the Handoff Note. Another theme included the level of granularity with which certain data were displayed. Some suggestions included specifying the infusion rate of intravenous fluids and a patient's diet. The display and organization of Medications was a very frequent topic of commentary, with many resident physicians voicing the desire for a more concise medication list, organized in a systems-based format (e.g. pain medications, antibiotics, anticoagulants), while others wanted only scheduled medications reported and PRN (as needed) medications removed.

*Table 4 – Somewhat Important Handoff Content Elements**

Content Element	4-5	3	1-2

Psychosocial Concerns	21%	35%	44%
Consulting Services	21%	32%	47%

**Percentage of Likert-style scores per Content Element; 4-5(Important), 3(Somewhat Important), 1-2(Not Important)*

Survey

Given the diverse (and at times competing) ideas for ideal EHR-integrated Handoff Note content and structure, we utilized an online survey sent to all resident physicians in our institution practicing in the acute, inpatient setting. The intent was to utilize the themes that emerged from our convenience sample of interviewed resident physicians and create a survey through which more generalizable preferences for ideal EHR-integrated Handoff Note content and functionality could be ascertained. Three hundred thirteen of 715 eligible resident physicians completed the survey (44%). Forty-two percent were in their first or second year of training (Table 1). Thirty-six percent were in their third or fourth year of training, and 20% were in their fifth year or greater of training. Thirty-six percent were enrolled in a surgical specialty, while 25% were from Pediatrics or a pediatric subspecialty and 40% were from Internal Medicine or a medical subspecialty (e.g. Cardiology, Gastroenterology). The vast majority (91%) of resident physicians reported at least three years (including medical school) of experience working with electronic health records and 75% reported at least three years of working with the Epic EHR specifically. Seventy-five percent reported that at least half of their clinical time was spent caring for patients in acute care, inpatient setting (as opposed to outpatient clinics). Seventy-eight percent reported serving as a cross-cover physician an average of at least three times per month or more during their training.

Clinical Utility

When ranking the importance of various content elements using a Likert-style rating scale there were several content elements that resident physicians found most important, with an overwhelming majority (>50%) ranking as Important or Very Important (ranking 4 or 5) (Table 2). These included content elements such as Plan of Care (95%), Name and Age (89%), Medical Record Number and Room Number (83%), Illness Severity (78%), Code Status (77%) and Patient Summary (77%). There were also content elements that the majority (>50%) of resident physicians ranked as not important (1 or 2) (Table 3). These were Primary Care Physician and Fluid Balance. The remaining content elements were more variable in the importance placed in them by resident physicians (Table 4). Some of them, such as Medications and Procedures Performed, had nearly 50% of resident physicians ranking them as important, while others, like Psychosocial Concerns or Consulting Services, were ranked as not important by nearly one-half of resident physicians. Other content elements, such as Vital Signs, and Labs and Imaging, had nearly even distributions, with one third ranking them as important, one third ranking them as somewhat important, and the remaining third ranking them as not important.

*Table 5 – Trustworthiness of Various Handoff Content Elements**

Content Element	4-5	3	1-2
Code Status –			
EHR Generated	41%	43%	16%
Manually Entered	82%	16%	2%
Postoperative Day			
EHR Generated	64%	26%	10%
Manually Entered	46%	36%	18%
Illness Severity**	86%	12%	2%
Patient Summary**	82%	16%	2%
"To Do" List**	91%	9%	0%
Anticipatory Guidance**	91%	8%	1%

**Percentage of Likert-style scores per Content Element; 4-5(Trustworthy), 3(Somewhat Trustworthy), 1-2(Not Trustworthy)*

***Only manually-entered versions of these content elements are available*

Trustworthiness

Resident physicians also ranked various content elements using a Likert-style scale as trustworthy (5) or not trustworthy (1) (Table 5). Some of these content elements could be either manually entered into Handoff Notes or automatically derived from the EHR. The source of the content affected the trustworthiness of the data. For instance, 82% of resident physicians ranked Code Status manually entered into the Handoff Note as trustworthy (4 or 5) while only 41% ranked EHR generated Code Status as trustworthy. This is in contrast to Postoperative Day (the number of days that have passed since a patient's surgery occurred), where the majority (64%) of resident physicians ranked EHR-generated Post Operative Day as trustworthy while only 46% ranked manually entered Postoperative Day as trustworthy.

Other content elements, such as To-Do List and Anticipatory Guidance, could only be manually entered into the Handoff Note. These content elements were ranked as trustworthy by the majority of resident physicians (91% ranking both as trustworthy) (Table 5).

Data Display and Content Source Preferences

Resident physicians also showed some clear preferences for the level of granularity with which certain content elements were displayed in Handoff Notes and the source of such content elements (Table 6). For instance, 65% of resident physicians preferred an Admission Diagnosis and Problem List that was manually entered by a colleague as opposed to automatically entered by the EHR, or Admission Diagnosis alone. Seventy-seven percent of resident physicians preferred Past Medical and Surgical History to be entered manually. Sixty-eight percent of resident physicians preferred both Scheduled and PRN (as needed) medications to be displayed, but not patients' home medications. Sixty-six percent preferred the attending physician's contact information to be displayed. There was a trend toward favoring display of objective data from the past 24

hours, with 78% and 52% favoring displaying the fluid balance and vital signs over the past 24 hours, respectively, as opposed to over the previous nursing shift (8 or 12 hours), or from the entire hospital stay.

Table 6 – Data Display Preferences

Data	%
Prefer Attending Physician Contact Displayed	
Yes	66%
No	34%
Admission Diagnosis & Problem List	
Only Admission Diagnosis from EHR	3%
Only Admission Diagnosis Manual	21%
Admission Diagnosis & Problems List EHR	12%
Admission Diagnosis & Problem List Manual	65%
Past Medical & Surgical History	
EHR generated automatically	23%
Manually generated	77%
Medications	
Scheduled medications	14%
Scheduled and PRN medications	68%
Scheduled, PRN, and Home medications	16%
Scheduled and Home Medications	3%
Vital Signs	
Most recent	32%
Past shift	15%
Past 24 hours	52%
Entire hospital stay	1%
Diagnostics	
Laboratory data only	37%
Imaging data only	6%
Laboratory and Imaging data	57%
Laboratory Values	
Most recent	52%
Past 24 hours	45%
Entire hospital stay	3%
Fluid Balance	
Past shift	16%
Past 24 hours	78%
Entire hospital stay	6%
Fluid Type	
Total Intake/Output	21%
Total Intake/Output & Urine Output	31%
Total Intake/Output, Urine Output, & All Other Drain* Ouptut	26%
Total Intake/Output, Urine Output, Other Drain Output, and Oral Intake	23%
Consulting Service	
Physician Services	54%
Physician and Ancillary** Services	12%
No Consulting Services	34%

**e.g. Nasogastric tube, Surgical drains, Ventriculostomy, etc.*

***e.g. Physical Therapy, Nutrition, Social Work*

Preferences were less clear for the display of other content elements. Fifty-two percent of resident physicians favored the most recent set of Laboratory Values to be displayed while 45% wanted Laboratory Values from the past 24 hours to be displayed. Fifty-seven percent wanted to display both Laboratory and Imaging Data, while 37% wanted to display Laboratory Data alone. The display of Fluid Balance was most variable, with a near-even distribution of resident physicians favoring the display of only Total Intake and Output as opposed to intake and output being parsed out into Urine Output, Drain Output and Oral Intake (Table 6).

Free Text Commentary

Resident physicians were allowed optional free text commentary for other thoughts on Handoff Note content. The free text commentary was reviewed. Several themes emerged from the free text. Many comments focused on the optimal content of the Handoff Note. Generally, the importance of a patient summary statement and anticipatory guidance on potential issues in the ensuing cross-cover period were highlighted in many comments. Many comments also noted that certain content elements were only important for certain patients and in certain situations. Similarly, there were other comments that discussed the importance of certain content elements varying based on the type of medical team and physician specialty. Many comments alluded to the fact that the Handoff Note need not contain every piece of important data on each patient, and that in most instances the resident physicians would look up patients in the Electronic Health Record for more granular data. Other comments noted a preference for brevity in the Handoff Note. Finally, some comments focused on problems with current functionality for EHR-generated Handoff Notes.

Discussion

The importance of the Handoff Process has been increasingly recognized, and current restrictions on resident physician work hours make the occurrence of Handoff a cultural norm at hospitals that employ physicians in training [1]. Despite this, there is still no standard for the Handoff process, although certain formats, such as the I-PASS mnemonic, have been gaining in popularity [9]. Similarly, there is no standard for content that should be included in the Handoff Note that accompanies the Handoff Process. Prior work highlights the diverse content included in various published reports of EHR-integrated Handoff Note content [7; 8]. Here we report our experience with attempting to determine the ideal content of an EHR-integrated Handoff Note to serve as a standard template for resident physicians at a single, tertiary care, University-based adult and pediatric hospital. We did this utilizing both one-on-one semi-structured interviews with a convenience sample of resident physicians, as well as a large scale survey. From our interviews, we learned that views on ideal Handoff Note content and format are extremely variable and that there were great distrust and dissatisfaction with current modalities (both EHR-based and Microsoft Word-based). In order to gain a more generalizable knowledge of resident physicians' preferences that could be translated into actionable items when designing the Handoff Note template, we created an online survey with both discrete data and free text elements.

Engaging resident physicians in user-centered design of electronic Handoff tools is not a new concept [5], with many utilizing committees that included several resident physician members [10; 11]. One other study has described using a survey to derive optimal content for EHR-integrated Handoff Note functionality [12]. Our institution-wide survey encompassing trainees in multiple disciplines and every year of training is the largest reported in the literature to our knowledge.

The most important content elements to resident physicians at our institution included Plan of Care, Illness Severity, and Patient Summary (along with Name, Location, and Code Status). It is interesting to note that the most important content to resident physicians was not a single piece of objective data, such as laboratory values or vital signs, but rather a free text narrative that contained their colleagues' subjective interpretation of the patient and the plan formulated based on that interpretation. Earlier work by Flanagan and Patterson looking at an EHR-integrated Handoff tool that included only objective data noted that a large portion of resident physicians cited the absence of the patient's Assessment and Plan written by a colleague as a major design flaw of that system [13]. Our similar findings regarding the importance of the Assessment and Plan mirror prior work, and perhaps speak to the fact that

the ultimate purpose of the Handoff Note is to provide the physician with a succinct summary of the patient and plan of care. Should clinical decision-making be required during the cross-cover shift because of a newly arising patient issue, this initial understanding of the patient can be further enriched as needed by objective data found within the EHR. In fact, a large portion of the free text commentary in our survey focused on the fact that should further details be necessary, resident physicians would access the EHR for data to guide decision making. They did not have any expectation that the Handoff Note would (or should) contain the level of detail appropriate for such decisions.

The remaining content varied in its importance to resident physicians. Interestingly, even the content elements that ranked least important still had at least 20% of resident physicians ranking it as Important (score of 4 or 5 – see Table 4). Another major theme discovered in the free text commentary was the dependence of certain content elements on the specific situation. Many resident physicians recognized that while certain content elements were not usually important for a cross-cover shift, in certain situations those data points were actually quite useful. This again argues for the importance of a place for free text data to be included so that resident physicians can enter these data based on their judgement in the appropriate clinical context. While automated entry of certain data directly from the EHR into the Handoff Note might prove helpful, high-quality Handoff Notes still require the skill and sound judgement of the author. Indeed, the ability to recognize important data points and succinctly surmise a complex hospitalization into only a few sentences requires sound clinical judgement and practice. In the words of one of our respondents "this is how learning happens and this is how doctors are trained". EHR-based tools to streamline and standardize the Handoff Process must take these details into account; one cannot automate wise judgement and clinical reasoning.

We recommend to system developers that EHR-integrated Handoff Notes contain, in addition to basic patient identifiers, a free text field for Patient Summary, which should include an assessment of illness severity and a free text field for Plan/To-Do List, which should include appropriate anticipatory guidance. Code Status, automatically derived from the EHR, is a useful addition to the Handoff Note. Further content elements in the Handoff Note, such as Vital Signs, Laboratory Values, or other data, should be customized according to the local needs and culture of the physician specialties and levels of training for which its use is intended. The principles of User-Centered Design should be followed, and active resident-physician participation in EHR-integrated Handoff Note development should be sought early in the design process.

Conclusions

The importance of the Handoff Process and the accompanying Handoff Note are becoming increasingly and deservedly recognized. The ideal content is rarely a specific, objective data point. Rather, succinct summaries of patients' hospital course, current trajectory, and plans of care composed in a thoughtful manner by those caring for them are the most important and useful content elements. Those attempting to construct EHR-integrated tools to guide the Handoff Note composition process must take into account that this process can never be completely automated and that sound clinical judgement and attention to detail are at the very heart of excellent Handoff Notes.

Acknowledgements

The authors wish to thank Fairview Health Services and the Office of the Dean for Graduate Medical Education at the University of Minnesota Medical Center for their support of this work.

Abstract

"Journalen" is a patient accessible electronic health record (PAEHR) and the national eHealth service for Sweden's citizens to gain access to their EHR. The Swedish national eHealth organization Inera, responsible for Journalen, created an inbox to receive voluntary user feedback about Journalen in order to improve the service from the user perspective. Based on voluntary user feedback via email. This study explored patients' experiences of using the national eHealth service and identified pros and cons. A mixed method content analysis was performed. In total, 1084 emails from 2016-2017 have been analyzed. 9 categories were identified, the most frequent ones related to questions about why some information was not accessible (due to regional differencies), feedback (including only positive or negative comments as well as constructive improvement suggestions), and emails about errors that user found in their record. These data can be successfully used to continuously improve an already implemented eHealth service.

Keywords:

Patient Portals; Health Record, Personal; Consumer Health Informatics; Electronic Health Records; Evaluation

Introduction

eHealth is an increasing part of healthcare worldwide. It involves a service or a tool, which purpose is to improve prevention, contribute to diagnoses and treatment, as well as monitoring and management, and is built up of information and communication technologies (ICT) [1]. An example of an eHealth solution are patient portals, which give patients access to their own health data online and can give the patient access to a patient-accessible electronic health record (PAEHR) [2]. The US initiative OpenNotes is an example of a movement striving to increase and improve patients' access to clinical notes [3], through e.g. patient portals.

Journalen is the national Swedish PAEHR service used by Sweden's citizens to read their health records online. The purpose of Journalen is to contribute to increased quality of care and cost-effectiveness, but primarily to increase patients' empowerment and engagement in their own care [4]. The service aims to give all residents from 16 years access to all information about themselves documented in tax-funded health and dental care [5]. The national eHealth organization Inera AB is responsible for the maintenance and development of the service [6]. To access Journalen, the user must log on to the national patient portal 1177 Vårdguiden through authentication using a nationally approved BankID/eIdentification [7]. Potential users of Journalen are the 10 million Swedish citizens. Currently over 2.6 million citizens use the service, with close to two million logins to the service every month [8]. Sweden has a decentralized healthcare system, i.e. regional responsibility, resulting in that patients have access to different features in the service depending on in which county council or healthcare region they have received care [5].

As Sweden is a world-leading nation in ICT solutions [9-11], it is important also for the healthcare sector that users of different eHealth services find the solutions useful. Since Sweden offers the citizens the right to access their own health documentation online, such a service should also be as easy to use and easily navigated as possible for all kinds of users. In line with the Swedish Vision for eHealth and eHealth Strategy, that all Swedish citizens should have access to all their health information online by 2020 [12, 13], Inera AB created an email inbox in order to get voluntary user feedback about the service to guide their improvement work [5]. From 2015 to spring 2018 users could provide feedback directly to the service provider after logging into Journalen by using the inbox. However, Inera could not provide emails from 2015, as they had only saved emails from 2016.

Despite a lot of interest and debate around the implementation of PAEHR, both in Sweden and internationally, there is still a lack of research and evidence around the benefits and drawbacks of these types of solutions. [14]. In Sweden, the PAEHR Journalen has been studied for various purposes, e.g. to capture patients and healthcare professionals' opinions [15], to analyse the national regulatory framework for citizens access to their health records [16, 17], to describe challenges during the implementation [7, 18] – all relevant to this study. However, there are few studies that focus on how end-users (patients) themselves experience the use of the service. This study will explore patients' experiences of using Journalen as expressed in voluntary feedback to the service provider. Focus is on the problems and benefits, and how Journalen, according to the real users, can be improved by illustrating the problems they have experienced when using the service.

Methods

A mixed method analysis was conducted, including a qualitative content analysis of the emails, and a quantitative analysis of frequency. An inductive approach has been used throughout the research, which followed an iterative process for the categorizations and analysis of the experience's patients/users expressed in the feedback emails. The data consisted of a large amount of emails, all highlighting the views from a user perspective of Journalen. Therefore, the quantitative perspective of

the study was deemed important, as it was of interest to show the number of emails belonging to each category, hence, a mixed method content analysis [19].

In the PAEHR service, the users were invited to share their experiences of the service, and how they used the information in Journalen [5]. The voluntary user feedback was analysed manually, a main-analysis made by the first author and a sub-analysis made by the second and third author. About 1084 emails were examined. The emails were obtained from the national eHealth organization Inera AB. Emails received between the years of 2016-2017 were anonymized and only the content of the emails were analysed further. Each email was read several times, and categorized into a type of email. Nine categories were created during the reading of the emails (Table 1). All emails containing positive and negative feedback, or descriptions of experiences of using the e-service were grouped into a general feedback category that was further divided into sub-categories (Figure 1). No other categories contained sub-categories.

The study was conducted in accordance with the Helsinki Convention and its ethical principles for medical research involving human subjects [20]. The voluntary user feedback contained patient opinions about the eHealth service, and are presented here as anonymous data.

Results

By analysing the emails, commonly used topics have been sorted into categories, which are presented in Table 1. We will here highlight some of the more interesting categories.

Region dependent comments

Each of the 20 regions in Sweden who provide the majority of healthcare, were given their own choice in deciding what information to make accessible to patients and when [16]. This has resulted in major differences in what information can actually be accessed depending on which region you have received care in [7].

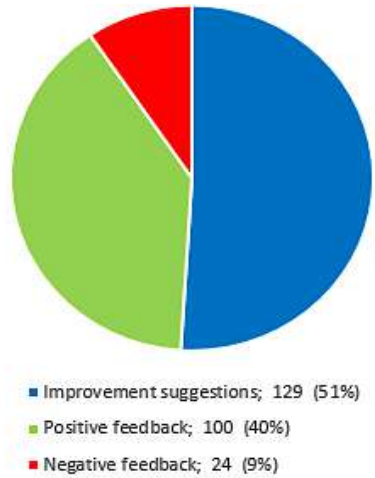

Figure 1. Presents how the feedback category is categorized, and the quantity of the three categories.

40% of the emails analysed in this study were related to users requesting access to information or features that their healthcare provider had decided to not make accessible. The majority of these emails were received during 2016 (308 emails compared to 125 in 2017), which may indicate that the situation was improved over time.

Wrong medical content

A total of 8% (N = 89) of the analysed emails concerned errors that the user had found in their record. We have not made an assessment of the severity of the identified errors, but the emails show that patients may act a quality control for the record content, but also that easier ways of reporting errors to the correct organizations are needed.

Table 1. Identified categories.

Category	Description	2016	2017	Total	
1. Region-dependent comments	The user is missing info or requesting features that do not exist due to decisions of the county council or healthcare region he/she belongs to.	308	125	433	40%
2. Feedback	Improvement suggestions are identified based on a problem the user has with the service, as well as positive and negative feedback comments.	108	145	253	23%
3. Wrong medical content	The user has detected wrong medical content, mostly in the record entries or in the medication list	36	53	89	8%
4. Seeking health care	The user wants to get in touch with his/her medical care provider/healthcare organization	16	25	41	4%
5. Requesting their health record	The user requests his/her health record in paper copies.	18	15	33	3%
6. Block or seal	The user wants to block or seal his/her health record, i.e. the entire service.	7	3	10	1%
7. Access their child	The user cannot see or access his/her child's record.	5	4	9	1%
8. Errors	Emails that are illegible and have appeared in error codes	35	22	57	5%
9. Other	Emails that are difficult to categorize because of its rare occurrence, and cannot be put into an own category	83	76	159	15%
	Total	***616***	***468***	***1084***	***100***

Feedback

This is the category, or topic, that emphasizes users' views about Journalen. The feedback category can in turn be broken down into improvement suggestions, only positive comments and only negative comments about the service, as presented in Figure 1. The feedback category is region independent unlike the first category in Table 1. Out of all feedback, 129 contains improvement suggestions, 100 only positive comments about the service, and 24 only negative comments. What is meant by 'only' positive and negative comments is when the researchers interpret that the sender has intended to only write something positive or only something negative about the service.

The users who expressed positive feedback (N = 100) (Table 2) believe that the service is a generally good service, which they embrace, and the majority of positive comments simply express that Journalen is a good service in general. About a quarter of the positive comments are praise for specific features, such as being able to access lab results, vaccinations, diagnosis, referrals, and so on. Many users want to share how good the service is, as it serves as a memory support after the appointments. Another recurring positive feedback describes how users appreciate being able to read Journalen in peace and quiet at home since it can be reached online. Journalen is also described as positive when it comes to clarifications, and 10% of the positive feedback emails describes how users check to see if any misunderstandings have occurred after an appointment. Without the e-service, they would never know this, if they would not request paper copies, which itself is a time-consuming process. Some users also expressed how good it is when all information is collected in one place.

Table 2. Categorized positive feedback about the service.

Category	Example of comments	Quantity	
A good service	*" I just want to say that the service of reading my online journal is amazingly good and useful"*	41	41%
Access to specific info	*"It is great and useful to be able to read the lab results"*	23	23%
Memory support	*"It is good to be able to read the health record, as many details are often forgotten after a doctor's appointment"*	12	12%
Peace and quiet	*"I find it calm to visit Journalen at home in peace and quiet, which is helpful because of my hearing impairment"*	10	10%
Clarifying	*"It is good to be able to read my health record online if there were any misunderstandings during the appointment"*	10	10%
One place	*"It is good that all information is collected in one place and easily accessible. Now I do not have to save and look for paper copies"*	4	4%

Emails containing only negative feedback was much rarer (N = 24). The majority of the negative comments concern Journalen as an eHealth service in general, the users express that the service is simply bad and difficult to navigate. Some comment that Journalen is not patient-safe, and that sensitive information should not be available on the internet. A few users believe that it should be up to each individual to be able to decide on their own medical information and be able to make changes in the information. Since this is not possible it is a bad system according to these users (Table 3).

Table 3. Categorized cons about the service.

Category	Example of comments	Quantity	
A bad service	*" I have been logged into it, and it is totally worthless. It is difficult to interpret and understand. It is a big joke!"*	17	71%
Not patient-safe	*"Such information as someone's medical information shout not be available online. It is not patient-safe"*	4	16%
Decide about the info	*"This is a really bad system. I want to be able to make changes in the content because it is about my identity! I want to be able to decide about the written info about me and how it is formulated"*	3	13%

The majority of the feedback category consisted of *improvement suggestions* (N = 129). Most users asked for older health records, and this can be explained by the fact that many regions decided to only give access to notes from the date Journalen was introduced (or shortly before this) which meant that much of what the users expected to see when the logged in was not actually there. This was followed by suggestions on how the interface could be improved to facilitate the navigation, such as making certain buttons more visible. Several users provided improvement suggestions for lab results, such as clarifying information of each lab result. Text reminders for new events in Journalen was also requested, and some wanted to see X-ray/MR results, which are currently not available at all in the service. Improved support for communication with the healthcare providers was also requested, for example having a direct phone number or other contact information visible. There were also some suggestions for clarifications of other specific information in Journalen, such as unclear instructions on how one's health record can be ordered in paper copies. Some of the users had opinions that they needed to see their children's information, and that some sections of Journalen required excessive number of mouse clicks to reach it. Some users considered that Journalen should be individualized and that users themselves should be able to determine what information should be accessible through the service.

A few had opinions about how the search feature in Journalen could be improved, and that only signed and validated information should be displayed to the patient, and that visible unsigned information can be considered a patient risk. Some healthcare providers choose to give immediate access to all notes, whether they are signed or not, whereas others keep unsigned notes hidden from the patient until they have either been signed or two weeks have passed, at which point the note is automatically locked for updates [21]. A few of the users considered that logs should be available to the patients, i.e. who have visited the patient's heath record. This feature is currently only activated by a few healthcare providers [22]. Another proposed improvement was to make a glossary of medical terms available in Journalen to all patients.

Discussion

The results presents users voluntarily given feedback about the service with identified pros and cons and experienced issues. There were few complaints and many positive comments. The improvement suggestions pointed to several issues and problems that the user experience, yet overall they mostly expressed positive feelings towards the service and wanted it to continue and be further developed to be even better. This is well in line with a recently published survey study among users of Journalen, in which 96% of the respondents believed that this was a good intervention. [22]. Compared to this figure, the emails analyzed in our study had a much higher expression of negative feedback, however this is likely related to the data source; when asked to voluntarily submit feedback a user who is very negative to an e-service may be more inclined to answer than someone who is positive.

The users' comments about their experienced benefits and problems can also be supported by an earlier interview study which aimed to provide in-depth understanding of cancer patients' attitudes and experiences of online health records [15], and other international studies within this field, for example the OpenNotes initiative in US which focus on patients ability to view clinical notes [3]. The study found that users of PAEHR services uses the service to see that they understood the information they received from the physician correctly. Another study [23] also found that one of the biggest reasons why patients read their health record entries are to be sure that they understood what the care provider said. This is also expressed by some of the users of Journalen in this study who believe that it is very good to be able to read their health records in retrospect to prevent misunderstandings (Table 2).

The study [15] emphasizes that most of the participants find that PAEHR services serve as a memory support, since it is easy to forget information from a physician's appointment. Similarly, several of the users of Journalen who emailed feedback expressed that it was a very good memory support to be able to read on their own what has been said and done during the appointments, as there is often a lot of information provided that is easy to forget about afterwards. Below is a quote from one of the users of Journalen (Table 2):

"It is good to be able to read the health record, as many details are often forgotten after a doctor's appointment"

In a study from the US [24], the purpose was to gain more knowledge about patient experiences where patients/users of a PAEHR service could provide feedback on their visit notes through a specific feedback tool within the service. The conclusion showed that patients can relate to personal, relational and safety benefits. Demand for similar features is also found in the results of this study. Below is a quote from one of the users of Journalen (Table 3):

"I want to be able to make changes in the content because it is about my identity! I want to be able to decide about the written info about me and how it is formulated"

Having other studies [3, 15, 23-24] with similar feedback reinforces the feedback given by the users of Journalen on how a PAEHR service can be improved and made as easy and clear as possible.

Methodological concerns

The data source needs to be considered when discussing the results of this study. We have analysed voluntary feedback that has been sent by the users of Journalen over two years. How representative this information is of the opinions of all users of Journalen is impossible to say, and therefore the numbers presented in Table 1 cannot be interpreted as valid for all users. As an example, the 8% of emails concerning errors in record does not mean that 8% of all records have errors in them nor that 8% of all users find errors. Yet, that so many individuals have made the effort to send an email about this issue could be considered an important indicator that this is an area to be further explored.

We also consider the fact that this information is voluntarily provided by users without being asked specific questions makes the data source especially interesting. This is feedback given without influence of how questions are formulated, fatigue from filling out a long survey or a willingness to please the researchers asking the questions.

Another limitation that could impact the outcome are the manually counting of the emails. However, the format of the email feedback required an aspect of human interpretation, sometimes the latent content of an email, the tone and sentiment of the message, was crucial for the result of the study. Using an automatic quantification by a software tool would have risked missing some of these subtleties of the material.

Voluntary feedback as formative evaluation

The feedback received through the email inbox have been continuously used by the developers of the e-service to improve it. One example is that since such a high rate of emails concerned missing information, it became clear that the users had trouble understanding *why* parts of their record where not shown. In order to make this more clear to the users, an interactive map of Sweden was implemented in the e-service showing which regions made what information accessible. When choosing a specific part of the record (e.g. diagnosis or lab results), the map will also automatically show which regions make this information available (figure 2). This easily accessible visualization of information access may be the reason for the decline in emails in this category during 2017 compared to 2016.

Figure 2 – map over which healthcare providers show lab results

This may be one way of using rapid, unstructured user feedback as part of formative evaluations to facilitate continuous improvement of an eHealth service.

Future research

The content of the voluntary feedback would be interesting to compare in more detail to results of a recently published survey among all users of Journalen [22]. How does the voluntary feedback correspond to the results obtained when users are asked direct questions about specific features? Repeated surveys should also be performed, as the eHealth service is continuously improved and a steady increase of users can be seen. We need more long-term follow-up of the users experiences, e.g. through re-occuring surveys among the users. As the improvement suggestions are handled in the continued

development of the service, we ought to be able to track and see improvements also in the users feedback. Exploring the usefulness of the voluntary feedback compare to other forms of feedback or evaluations for the developers of Journalen would be of great interest from a methodological perspective.

Conclusions

This research is the first study in Sweden that evaluates and analyses the users' voluntary submitted opinions about Journalen and uses these to emphasize improvement suggestions about the service. These data can be successfully used to continuously improve an already implemented eHealth service. The results shows that having healthcare providers that makes different information accessible through the same eHealth service, will cause confusion and questions from users, but most feedback received was positive, which is in line with other research into patients access to their EHR. The results also shows that the users are channeling their questions to Inera instead of to their healthcare provider, which means other communication paths are needed between patient and healthcare provider.

Representation of the Transgender Population in Electronic Health Records: Implementation Strategy in the Public Health Care System of Buenos Aires City

Denise Levi[a], María Victoria Vazquez[a], María Victoria Giussi[a], S. Esteban[a], Analía Baum[a]

[a] *Health Information Systems Office, Ministry of Health, Buenos Aires City, Argentina*

Abstract

Electronic Health Records (EHR) face the challenge of collecting data about patient's gender identity in order to provide standardized and quality data to manage public policies in order to improve health disparities of the Trans population. Innovation in Health Information Technologies (HIT) develops in the midst of a cultural change process related to social representations of gender in favor of a diversity perspective. Understanding the health field as a complex adaptive system, the changes in the systems must consider multiple factors in every stage of the process. It is relevant to consider the people involved in it and the culture in which they are embedded. This article describes the implementation strategies of functionality that represents the transgender population in the EHR of the Public Health Care System of the Buenos Aires City.

Keywords:

Electronic Health Records; Transgender Persons; Cultural Evolution

Introduction

Transgender people are individuals whose gender identity differs from their sex assigned at birth, and may involve the modification of their appearance or body function through pharmacological, surgical or other means. In recent years, the Electronic Health Record (EHR) faced the challenge of representing the transgender population. Correctly identifying this population allows longitudinal health records that facilitate continuity of health care. On the other hand, it is indispensable to have standardized data in order to obtain quality metrics and create research opportunities that contribute to the management of public health policies for this vulnerable population.

On the legal level, in different countries transgender people can change their name and gender in their identity documents. However, the laws vary in different countries and localities. Since the process of opening a patient's chart in the EHR depends on the patient's identification, changing the name or gender of any individual represents a challenge when it comes to ensuring the longitudinality of the clinical record.

Articles from different countries mention how the systematic legal, economic, and social exclusion of trans people negatively affects every area of their lives: family, health, education, work, housing, and security. Their living conditions often face poverty, precarious housing or homelessness, and inequality in education, work and health.

Experiences of stigma and discrimination have been described in various areas, highlighting health in particular, protagonized by both administrative staff and health care professionals. The most feared situation that trans people describe is to be called by the name that appears in the person's legal documentation instead of the chosen one. This produces discomfort and ridicule that can lead to absenteeism of future healthcare appointments [1-3]. These experiences have a negative impact on patient satisfaction, the patient-professional relationship, and can also lead to a risk of verbal and physical assault by other patients in the waiting rooms.

In Argentina in 2012, National Law 26.743 "Gender Identity" was passed. This law granted people the right to be identified according to their self-perceived gender in the instruments that accredit their identity, among other rights [4].

In the United States in 2016, The Centers for Medicare & Medicaid Services (CMS) and The Office of the National Coordinator for Health Information Technology (ONC) announced that every entity certified under the Meaningful Use incentive program, will be requested to create structured fields allowing users to register, change, and access data on their gender identity [5]. Since then, several recommendations and guidelines have been developed in order to ensure efficient documentation of these data. It has been detailed how to request, store and display the data in the user's interface [6-8]. Furthermore, the incorporation of structured fields for the recollection of the chosen name, gender identity, sex assigned at birth and pronoun preference as demographic variables have been described [9-11]. Other research inquired about the perspectives of Trans people and healthcare professionals in relation to providing or having gender identity data [12-15]. Even controlled vocabularies for statistical and epidemiological analyzes such as the International Classification of Diseases 11th Edition (ICD-11) of the World Health Organization (WHO), proposed a new chapter related to sexual health conditions. The proposal was to include "Gender Inconsistency" as diagnostic category, instead of as a mental disorder as described in ICD-10 [16, 17]. The same happened with the Diagnostic and Statistical Manual of Mental Disorders (DSM) on its 5th edition [18]. Since 2009, people and organizations from different countries have set up an International Network for the Depathologization of Trans Identities. The goal has been to raise awareness and expose the psychiatrization of gender diversity and request the withdrawal of the aforementioned diagnostic categories from the ICD and DSM, previously classified as mental disorders [19].

A process of cultural change is currently gestating in favor of the recognition of the diversity of gender. It implies a modification of structures and social representations. It is important to take into consideration the cultural aspect, since it constitutes a system of shared meanings from which people interpret reality, define their way of acting and how to proceed. Otherwise, the mere IT tool that allows the recording of data in question would be insufficient. The goal of this paper is to describe the strategy that was used in the Public Health System of the Autonomous City of Buenos Aires for the implementation of functionality that represents the transgender population in the EHR.

Methods

Setting

The City of Buenos Aires has an area of 204 km² inhabited by 3,059,122 people. The health care system has 3 main sectors: The public sector, social security, and the private sector. These 3 can often coexist. The public health care system strives to offer medical access to all its inhabitants.

According to 2016 statistical data, 20% of Buenos Aires' population can only access healthcare through the public system. This percentage rises to 50% within the most unprivileged who live in the south of the city [20]. And it scales up to 78% among the transgender population [1].

Software

Since June 2016 an EHR has been gradually implemented within the outpatient setting [21]. In 2017, the "Self-perceived Name" functionality was incorporated, which allowed the user to to register a patient's preferred name in relation to their gender identity, when this names differs from their identity document.

Subsequently, in all the places where the person's name displayed in the EHR, the self-perceived name is displayed, with the initial letter of the identity document in parentheses next to the self-perceived name. All data related to the patient can be found within the personal data sheet. From this sheet, the name registered in the person's documentation can be extracted in order to be used in billing processes, prescription of medication or other legal operations.

Study Design

This is a descriptive study about the implementation strategies of a functionality that represents the transgender population in the EHR of the Public Health System of Buenos Aires City.

Results

The implementation strategy of this functionality included the following aspects:

1. Intersectoral approach

We convened the General Directorate of Coexistence in Diversity of the Undersecretariat of Human Rights and Cultural Pluralism, with dependence on the Vice-Government Office. Its responsibilities are to work on public policies and spaces for promotion, prevention and protection to reduce acts of discrimination and violence towards the people of the various groups that cohabit in the Autonomous City of Buenos Aires.

2. Profile stratification

The diversity of actors was stratified in different profiles to personalize the content. The stratification was decided according to the fulfilled function;

- Implementers: train end-users of the healthcare information system.
- Help Desk Operators: provide technical and functional support to the system users' queries.
- Administrative Staff: the patient's first point of contact when interacting with the healthcare system and are in charge of collecting the identification data.
- Healthcare professionals: professionals from different disciplines that provide healthcare.

3. Preparation of materials

Specific materials were developed for each profile, including: instructions explaining how to operate the new functionality, specific conceptual content of this topic (Table 1) and its legal framework. This was also made available on the Primary Health Care Web Portal, an intranet service that provides a communication space among healthcare workers.

4. Institutional stratification

The institutions that had the largest Trans population were identified in order to intensify the training.

5. Training

Two types of training were planned for all profiles:

- Face-to-face group training: a 3-hour workshop format was implemented. The aim was to raise awareness about gender issues. To accomplish this, different triggers were used to get in touch with the actors' perceptions which allowed to explain the concepts of gender binarism and heteronormativity. Then the concept of gender identity was introduced and it was differentiated from the concept of sexual orientation. Living conditions and health indicators for the Trans population were shared and the legal framework was deepened.
- Individual virtual training: several courses taken by administrative personnel and healthcare professionals were modified. The courses that were modified related to the use of applications for identifying people, granting and managing shifts, and the EHR application.

6. Communication

The communication strategy had 2 main recipients:

- Users of the information system: a pop-up was introduced in the login interface to the system notifying about the new functionality with a link to materials and instructions. In addition, a message to all users was posted on the Web Portal, emphasizing not only the opertation part, but also conceptual issues and regulatory framework.
- Users of the healthcare system: the Trans population was informed that they can register with their self-perceived name in the public healthcare system.

As of November 2018, there are a total of 170 Self-perceived Name records (Table 2).

Table 1 - Illustrative content about gender issues

Concept	Definition
Gender identity	The internal and individual experience and feeling of each person's gender which may or may not correspond to the sex assigned at the time of birth.
Biological Sex	The set of chromosomal, anatomical and physiological information that differentiates men and women. It is used to assign gender at birth.
Intersex	People whose anatomy does not fit the standards of female or male biological sex. It makes reference to the corporal diversity.
Gender expression	It involves everything that is communicated from our gender to others: clothing, hairstyles, body language, our interactions and social roles.
Gender binarism	It is a social construct that classifies people, limiting themselves to fulfilling feminine or masculine roles based on their anatomy.
Cisgender	People whose gender identity matches the sex assigned at birth.

Transgender	People whose gender identity differs from the sex assigned at birth.
Sexual Orientation	The ability of a person to feel emotionally, sexually and affectively attracted by a person of the same gender (homosexual), of the opposite gender (heterosexual), of more than one gender (bisexual).
Queer	Sociocultural movement that considers gender and sexual orientations as a social construct and seeks the disappearance of this categorization.
Heteronorm-ativity	The social rule that assumes the alignment of biological sex, gender identity and heterosexuality as desirable and normal.

Discussion

As seen from the diagnostic categories of ICD-10 and DSM-5, historically the transgender population has been considered in terms of abnormality, anomaly or disorder [19]. In recent years, questioning of gender binarism and heteronormativity have given rise to a broader perspective of diversity, thus beginning a process of cultural change. Even so, these changes are incipient. The lack of legal frameworks in many countries and the persistence of stigma and discrimination affect the quality of life of this population in various areas of their lives.

This paper describes the implementation strategies for functionality that allows the identification of transgender people according to their self-perceived gender identity. Multiple strategies were contemplated with an emphasis on raising awareness on this matter, going beyond the use of the system. The intersectoral approach made it possible to have the resources and means necessary for communication and training. It was also key to have specialists involved in the subject matter for the preparation of contents and materials in order to provide training that encouraged active participation. This helped to address people's concerns, questions, and understand their emotions given the complexity of the subject.

Initially, when face-to-face group trainings were conducted, the perceptions and previous knowledge about being a woman or a man were explored. The goal was to visualize the representations of social models of the binary gender system and understand them as a social construct were people are classified into two unique categories – feminine and masculine – based on biological differences, and also linked to social roles, behavioral expectations, sexual orientation, etc, which helps to maintain control and establish social order. After this collaborative work, the gender diversity perspective was introduced. This way of presenting the content was planned as a strategy to minimize resistance, using a deconstructive current. This current established that only by revealing the apparently hidden, and previous pragmatic elucidation of the success of an ideological system, there is a chance to actually glimpse the questioning or disarticulation of a socio-cultural structure and dynamics in view of its transformation or construction of a new meaning [22].

On the other hand, the strategy of stratifying profiles had its foundation in understanding health organizations as complex adaptive systems, shaped by dynamic networks of actors interconnected with different roles, functions, conflicts and interests [23]. Therefore, the contents were customized with a focus on the fact that implementers' and help desk operators' profiles should have tools to train all user profiles. The administrative profile is the patient's first contact with the healthcare system and they are in charge of collecting identification data. It was also taken into consideration that within the medical profile, the biologicist conception usually predominates. At the same time, these institutions are characterized by the concentration of power at their bases and not only in the hierarchical areas that are laid out on the formal organization chart. The governance in relation to both administrative and professional workers has a particular complexity. A great deal of emphasis was placed on the legal framework – the National Gender Identity Law No. 26,743 and the National Law No. 23592 Antidiscrimination – and how the system allows respecting the provisions of the law [9].

The stratification of institutions with the greatest Trans population was carried out with the aim of reinforcing training. Surprisingly, we found that they were the users with the highest awareness and had the best manners when it came to Trans patients. However, since they were familiar with the patients, many users indicated that they did not register Trans patients' data in the system since they were well known by every worker in the healthcare institution. In these cases, the training was directed to the importance of the registry of data, explaining that other institutions of the public healthcare system network can also access to this information.

Conclusions

Incorporating structured fields to the EHR to represent Trans people with standardized data that allow a correct identification of this population is essential to ensure the continuity of care. However, even though systems accompany the cultural changes, the computer tool alone do not transform people's practices. Therefore, it is important to consider the human factor and the culture in which people are embedded as a part of the strategy to implement functionality that meets the neds of the Trans population.

Limitations and Future Direction

Future research is needed to evaluate the implementation and perceptions of patients in relation to the quality of care in healthcare institutions, as well as the development of indicators to monitor the quality of the registry. In addition, other lines of work should aim to relieve specific information needs that are required at the EHR level for this population's healthcare.

Acknowledgments

We are grateful to the General Directorate of Coexistence in Diversity of the Undersecretariat of Human Rights and Cultural Pluralism, under the Deputy Chief of Government of the City of Buenos Aires, Argentina. How Does GDPR Support Healthcare Transformation to 5P Medicine?

Abstract

Health systems advance towards personalized, preventive, predictive, participative precision (5P) medicine, considering the individual's health status, contexts and conditions. This results in fully distributed, highly dynamic, highly complex business systems and processes with multiple, comprehensively cooperating actors from different specialty and policy domains, using their specific methodologies, terminologies, ontologies, knowledge and skills. Rules and regulations governing the business process as well as the organizational, legal and individual conditions, thereby controlling the behavior of the system, are called policies. Trust and confidence needed for running such system are strongly impacted by security and privacy concerns controlled by corresponding policies. The most comprehensive policy dealing with security and privacy requirements and principles in any business collecting, processing and sharing personal identifiable information (PII) is the recently implemented European General Data Protection Regulation (GDPR). This paper investigates how GDPR supports healthcare transformation and how this can be implemented based on international standards and specifications.

Keywords:
European data protection, governing, privacy

Introduction

In the course of methodological paradigm changes, healthcare systems advanced from empirically describing health problems with one solution fits all to dedicated care, stratifying population for specific, clinically relevant conditions resulting in evidence-based medicine. Stratifying population by risk profiles, the current phase of healthcare transformation towards personalized, preventive, predictive and participative precision (5P) medicine considers the individual's health state, conditions and contexts, thereby integrating research and practice. Conditions and contexts include legal, social, environmental, occupational, or any other context. Disciplines or domains engaged in 5P medicine cover medicine, natural sciences, social sciences, engineering, etc., considering the individual from elementary particle to society. The required knowledge sharing and cooperation of multiple stakeholders from different domains using their methodologies, terminologies and ontologies establishes a legal, cultural and language challenge. As individual health state, conditions and contexts are highly dynamic, it is impossible to predefine the business systems, its processes and policies for meeting the business system objectives comprehensively, uniform and legally binding in a static way. Thus, 5P medicine requires the automated management of multiple dynamic domains including multiple dynamic policy domains. [1]

The paper investigates a) how the European General Data Protection Regulation (GDPR) [2] reflects architecture and policies of transformational healthcare systems and b) how GDPR must be implemented to support healthcare transformation. For that purpose, GDPR is structurally and functionally analyzed. For meeting principles and services required by GDPR, standards, specifications and products are recommended and explained in some details.

Methods

For analyzing such complex settings like 5P medicine under dynamically changing perspectives and contexts, a system-theoretical approach is used. According to IEEE 1471-2000, a system is a collection of components organized to accomplish a specific function or a set of functions to realize the business objectives of that business system intended by the involved stakeholders [3]. Systems interact with their environment and can be decomposed to subsystems or composed to super-systems in a recursive way. A system is defined by the system's architecture, i.e., its components, their functions and relations on the one hand, and the system's behavior represented by the system's policy on the other hand. The term policy implies any set of rules for selecting components and functions as well as constraints of the relations according to a business case, thereby controlling the behavior of that system. It represents the perspectives of all domains involved, i.e., process policies, legal constraints, individual preferences, resource management, etc. This behavioral description applies to any of the aforementioned subsystem or super-system.

A security and privacy policy according to ISO 22600 Health informatics – Privilege management and access control [4] is a complex of legal, organizational, functional, social, ethical and technical aspects to be considered in the context of privacy and security. It defines a framework, privileges and obligations, but also consequences and penalties when the regulations are ignored.

Ecosystems are structured systems and communities of living and non-living components, which follow specific rules (policies) and interact as unit among themselves or with their physical environment.

The approach is based on the Generic Component Model (GCM) introduced by the first author in the mid-nineties [5, 6].

How Does GDPR Reflect 5P Medicine?

While the EU Data Protection Directive (Directive 95/46/EC) [7] defined just direct or indirect identifiers as personal data, GDPR extends in Art. 4(1) that definition including "one or more factors specific to the physical, physiological, genetic, mental, economic, cultural or social identity" of a natural person [2]. That way, GDPR defines data characterizing an individual's health status, context and conditions in the sense of 5P medicine as personal data. The extended definition of processing in GDPR Art. 4(2) meets contrary to the one in Directive 95/46/EC, the process of 5P medicine as well. GDPR Art. 6(3) requires explicit policies, which have to be represented formally and machine-processable and bound to the information objects or process steps (Art. 4(20) and Art. 26(1)). Those policies must represent the current context, and – because that context is changing – must be managed dynamically (Art. 26(1)). For guaranteeing comprehensive interoperability, policies must be represented using terminologies and ontologies of the addressed audience (Art. 7(2) and Art. 12(1)), that way meeting the requirements of 5P medicine ecosystems. Design and management of that highly complex and highly dynamic ecosystem have to address the security and privacy perspectives according to the ISO 23903 Interoperability Reference Architecture [8], ISO 22600 [4] mentioned before, or ISO 21298 Health informatics – Structural and functional roles [9]. Properly managing the dynamic system in that respect proactively, a permanent risk analysis must be performed, turning the Data Protection Officer from a checkbox marker to a risk manager, directly intervening in the business system and processes throughout the complete system lifecycle presented in the next section.

How to Define a GDPR-Compliant 5P Medicine Ecosystem?

A GDPR-compliant 5P medicine ecosystem must be designed and implemented in an automated process as an architecture-centric, ontology-based, policy-driven multi-domain business system. This has to be done in a formalized and standardized way. Starting point of an appropriate solution is the ISO Interoperability Reference Architecture model and framework developed by the first author. For representing a systems model and framework manageable by engineers, the formal representation of an n-dimensional concept space deploying universal type theory, thereafter refined to a parametrized Barendregt Cube [10, 11], has been transformed in a 3-dimensional system engineering model (Figure 1a). One dimension covers the generic granularity levels or composition/decomposition of any system. The second dimension addresses the system development process following standardized approaches such as ISO 10746 Information technology – Open distributed processing – Reference model [12], SOA (Service-Oriented Architecture) methodology, or the Unified Process (formerly Rational Unified Process). The third dimension concerns the different perspectives on the multi-disciplinary business system in question represented by the variety of domain experts involved in the business process. The concepts have to be represented for each component using the related domain ontologies. The different domains can be properly refined into subsystems with different (sub)ontologies. In the context of GDPR-compliant ecosystems, the policy domain combines different perspectives on ruling the system such as the medical process policy domain, the contextual policy domain, and the administrative/ organizational policy domain managing resources, etc (Figure 1b). The contextual policy domain can be furthermore refined into the legal and regulatory domain, the personal policy domain, and the conditional/contextual domain representing environmental, social, occupational or other contexts.

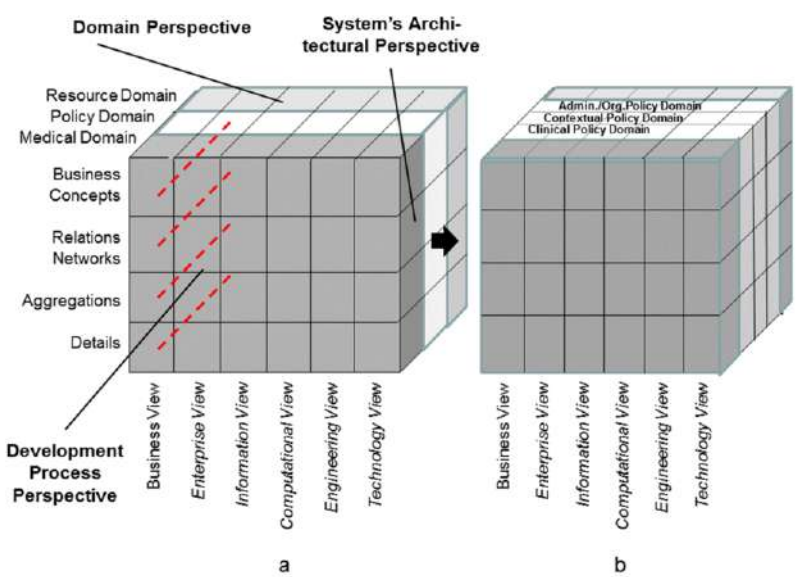

Figure 1. ISO Interoperability Reference Architecture [9]

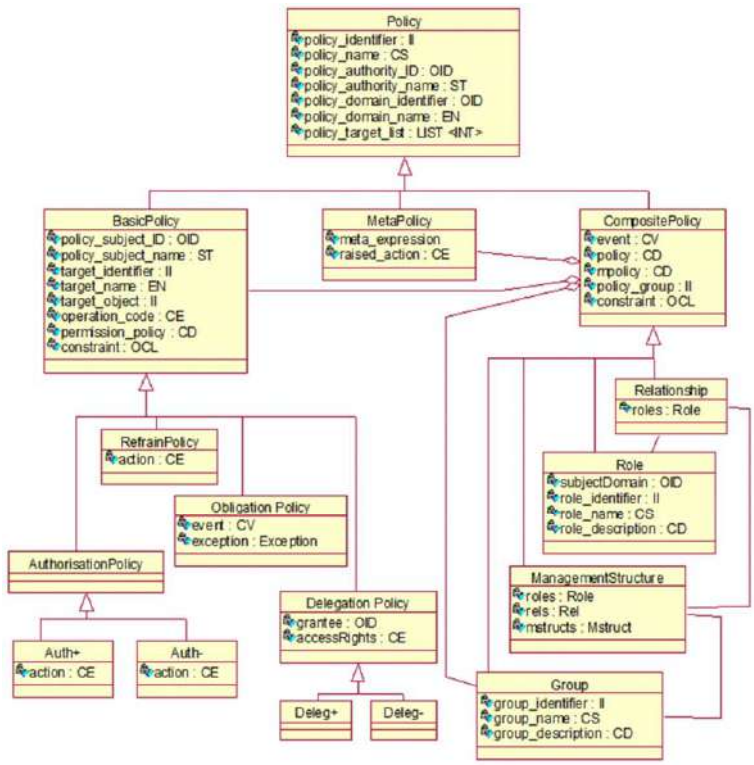

Figure 2. Policy Ontology according to ISO 22600 [4]

For representing policies, the first author has developed a policy ontology based on Damianou's Ponder Policy Specification Language [13]. That policy ontology has been standardized in ISO 22600 Health informatics – Privilege management and access control [4] (Figure 2). The policy ontology defines the entities to be instantiated (left hand side) and the policy management processes (right hand side). Using the presented approach, legally correct policies can be created using specific tooling, e.g., to support the subject of care – usually being a layman in the healthcare domain – to express her will and to understand the policies of other actors using the domain-specific jargon.

The other requirement of GDPR is the binding of policies to information objects and/or activities in the business process to dedicatedly managing them. This mechanism allows for definition and enforcement of data governance, i.e., of constraints on the WHO, HOW, WHEN, WHERE, WHAT FOR and WHY – or in other words, on the actor (which is not necessarily a person) and the context – for accessing and using PII. Such services also address, e.g., the data subject's right of being informed about the processing of personal data as well as rectifying those data if needed. That way, the limitations of that data subject's right offered ín GDPR could be minimized or fully overcome if it proves to be impossible or would involve a disproportionate effort. Alternative to policy binding, binding of labels referring to policies stored in policy repositories can be used. Both ways of binding policies or labels have been standardized in HL7's Healthcare Privacy and Security Classification System (HCS) [14]. As security and privacy labels have been defined: Confidentiality, Sensitivity, Integrity, Compartment and Handling Caveats. The first four are bound to information objects, and the last is bound to activities. The logical architecture to implement the described solution is shown in Figure 3. For enabling an assessment of trustworthiness of the offered service by the service user, a monitoring as well as a trust calculation service have been added to the architecture. Policy binding makes only sense when information is properly structured to enable the assignment of different policies to single, or groups of, information objects on the one hand, or different policies to single actions or related groups of actions on the other hand. Such data segmentation for privacy has been standardized at HL7 [15]. The entire system was demonstrated at HIMSS 2012 [16] and – with further extensions and improvements – also in the following years.

Discussion

Contrary to the Directive 95/46/EC, offering a limited scope and static controls for protection of personal health information, GDPR sets requirements, principles and methodologies to be applied to protect personal identifiable information of EU citizens and to document and demonstrate the compliance with the GDPR independent of the location and the technologies data collection, processing, communication and deployment of that information happen.

Acknowledging the nowadays organizational, methodological and especially also technological paradigm changes leading to highly distributed, complex, highly dynamic settings, turning the data subject to a consumer and changing her role and responsibility, GDPR excellently accommodates healthcare transformation. For that purpose, it has to establish the same

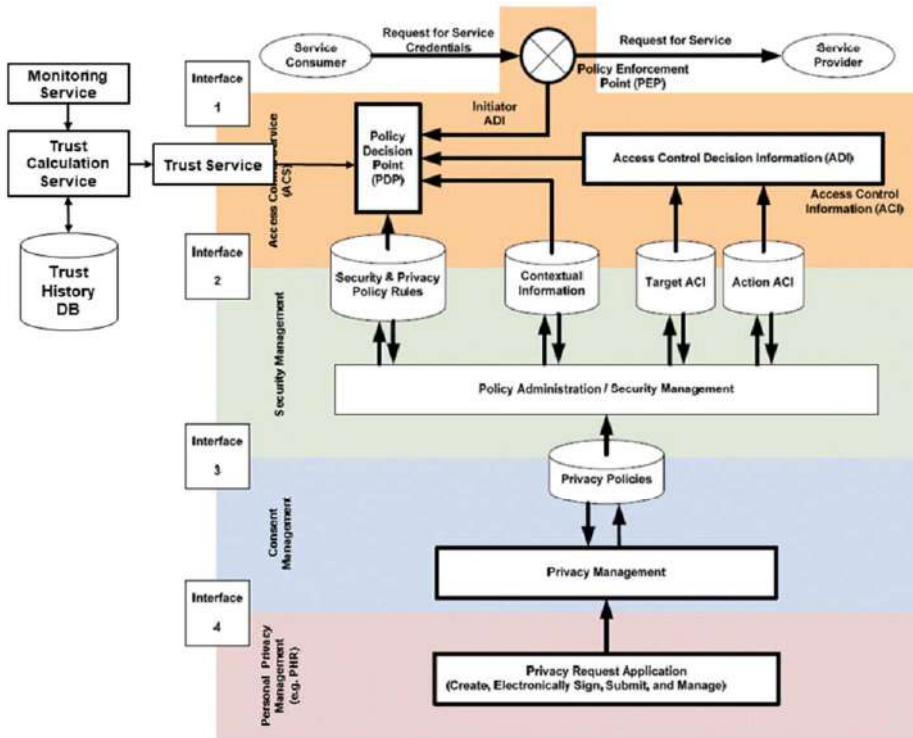

Figure 3. Authorization Reference Model [14]

principles of flexibility, dynamics, complexity, transparency, adaptation, intelligence, automation, etc. Defining principles and methodologies of data governance, GDPR and ISO/IEC 27001 Information technology – Security techniques – Information security management systems – Requirements [17] as well as ISO/IEC 27002 Information technology -- Security techniques -- Code of practice for information security controls [18] are closely interrelated. While GDPR focuses on the rights of affected persons, ISO addresses the related compliance issues.

Meanwhile, a bunch of standards, specifications and applications for adequately managing GDPR are available, like HL7 Artifacts to support managing GDPR. Here, the HL7 Security Labeling Service has to be mentioned, which contains a Policy Adjudication Engine for policy harmonization, an Ontology Reasoner to check the applicability of security and privacy policies against clinical policies, and the finally the Policy Inference Logic. Furthermore, specific trust services are provided. Most of those services are specified as implementable FHIR resources [19]. Examples are: FHIR consent resource [20]; FHIR AuditEvent or Provenance for storing information about data sources; FHIR AuditEvent enables tracking data communication including the deletion of data; FHIR Security Labels allow tagging data when the purpose of use has changed. For coding the purpose of use, specific vocabulary can be deployed.

Conclusions

Paradigm changes in health and social care lead to highly distributed and dynamic ecosystems, integrating multiple jurisdictional and policy domains, technologies, methodologies, knowledge and concept representation style, languages, cultural background and expectations, education and skills, etc., requiring advanced interoperability solutions. The interoperability challenge is not limited to ICT environment, but includes the entire ecosystem. Appropriate security and privacy solutions provide trust and therefore acceptance of health solutions and their IT support, as shown in Table 1.

Table 1. Relations of GDPR and 5P Medicine

GDPR	Details	Impacts to system architecture	Impacts to 5P medicine
New definitio n to PII	PHI characterizes health status and individual context/ conditions	Multi-domain business system architecture incl. development process	Individually tailored diagnosis and therapy including prediction and prevention
Explicit policies	Machine-processable, dynamically managed, ontology-based know-ledge-driven interopera-bility	Representation and transformation of a real-world business system to implementable artefacts, managing all concept levels from knowledge space to data models	Systems medicine incl. all perspectives from elementary particle to society with active participation of data subject
Business system and business process aware privacy	Permanent risk analysis, business system and process mngt, data governance management	Enterprise model and RM-ODP views for managing the system and selecting and correctly interrelating/ constraining existing resources	Democratizing health and social care, respecting personal wishes and expectations, combined with legal, ethical and fair principles

Thereby, security and privacy are not disabling but enabling new technologies. Security and privacy management will be increasingly model-driven, ontology-based and automated, using system intelligence such as AI and machine learning. Definition, harmonization and enforcement of policies must be automated as well. For that reason, policies must be represented comprehensively and formally. The presented system-theoretical, architecture centered modeling approach does not re-write problematic legislation [21], but supports use case specific analysis, management and design of needed comoonents and relations for 5P systems. That way, it enables intelligent, adaptive systems for advanced 5P medicine.

Acknowledgements

The authors are indebted to thank their colleagues from EFMI WGs "EHR" and "Security, Safety and Ethics" as well as from the IMIA WG "Security in Health Information Systems" for their valuable input. The work would not have been possible without the cooperation with ISO/TC215, CEN/TC251, HL7 International, Inc., but also without the support of the German Data Protection and Data Security Association (GDD).

An Extensible De-Identification Framework for Privacy Protection of Unstructured Health Information: Creating Sustainable Privacy Infrastructures

Stefano Braghin[a], Joao H Bettencourt-Silva[b], Killian Levacher[a], Spiros Antonatos[a]

[a] Data Privacy Group, IBM Research, Dublin, Ireland

Abstract

The volume of unstructured health records has increased exponentially across healthcare settings. Similarly, the number of healthcare providers that wish to exchange records has also increased and, as a result, de-identification and the preservation of privacy features have become increasingly important and necessary. Governance guidelines now require sensitive information to be masked or removed yet this remains a difficult and often ad-hoc task, particularly when dealing with unstructured text. Annotators are typically used to identify such sensitive information but they may only be effective in certain text fragments. There is at present no hybrid, sustainable framework that aggregates different annotators together. This paper proposes a novel framework that leverages a combination of state-of-the-art annotators in order to maximize the effectiveness of the de-identification of health information.

Keywords:

Privacy, De-Identification, Natural Language Processing

Introduction

Information exchange is a routine activity among practitioners in healthcare organizations. Much of the information that physicians require to deliver care is recorded and exchanged internally in patient records and, externally, via formal communication letters between referring and consulting physicians across organizations. Other forms of exchange include, for example, legal reasons or claims between providers and payers. As electronic medical records evolved and larger amounts of data were recorded, the value of the secondary uses of healthcare data became apparent [1; 2]. Both the new uses as well as improvements in exchange systems mean that information can more easily be misplaced or accessed by third parties without justifiable reasons.

Early efforts took place in the UK in the 1990s [4]. In the early 2000s, the Health Insurance Portability and Accountability Act (HIPAA) Privacy Rule was introduced in the US in order to regulate and safeguard the use and disclosure of protected health information (PHI), which is sensitive and identifiable [5]. The same rule sets out clear definitions of the types of information that are considered to be PHI, such as a patient's name or social security number, as well as guidelines on how to remove such information, such as the Safe Harbor method [5]. De-identification is the process in which PHI in a given patient record is either removed or masked such that it is not possible to link that particular record back to the identity of the original patient. Approaches for estimating the likelihood that de-identified information can be re-identified have been proposed [6] and blanket protection policies and methods such as the Safe Harbor, although effective, may still leave organizations susceptible to re-identification.

De-identification approaches may focus on structured data, for example, estimating the population size cut-offs for geographical areas so that no data suppression or further aggregation is necessary [8]. Other approaches, such as the anonymisation of clinical profiles in the form of International Classification of Diseases (ICD) codes, have also shown that it is possible to share information while safeguarding the privacy of the underlying individuals [11]. However, the rising need for sharing free-text records has boosted the need for Natural Language Processing (NLP) methods and techniques [9]. A systematic review of de-identification techniques revealed that the majority of systems focused on structured data and only a few addressed automatic text de-identification [10]. Furthermore, most systems performing annotation relied on pattern matching, rules, or dictionaries and the latter has shown better performance overall but lacks generalisation [10].

Free-text de-identification tools such as MIST [15] and the various systems in [10] have been more recently evaluated in [14]. The results of this evaluation showed the most successful system (MIST) had a precision of 97.8% and a recall of 95.1%. These evaluation metrics are defined in Figure 1. A different study [13] compared the performances of human annotators against a system using pattern matching based on a dictionary, regular expressions and heuristics. The results showed low precision (75%) but high recall (96%), meaning that the output is mostly de-identified, but also that there is a large amount of over de-identification. Similarly, in [12], the authors tested the performance of human annotators against MIST and an in-house identifier based on MALLET [18] that replicates MIST's design. The results were reassuring, reaching 95% precision in some entity types after adding pre and post processing to the workflow, in addition to model training. Similarly, [16] proposes a system called Medical De-identification System, designed to process HL7 messages in order to remove HIPAA and non-HIPAA specified identifiers. This system relies on scrubbing instead of providing a configurable masking system, yet the authors report results in line with the state-of-the-art systems.

$$P = \frac{detected\ relevant\ entities}{detected\ entities},\quad R = \frac{detected\ relevant\ entities}{relevant\ entities},\quad F_1 = 2\frac{P*R}{P+R}$$

Figure 1 Evaluation metrics: Precision (P), Recall (R) and the harmonic mean of P and R (F_1).

De-identification remains a task that cannot be perfectly handled by automated systems [14] yet, in practical scenarios, such systems have the potential to assist humans in performing de-identification if all the limitations are known and

acknowledged by the users. Contrary to previous work, the approach presented in this paper leverages an ensemble of annotators, taking advantage of the strength of each specific annotator. Moreover, this approach exposes a more flexible configuration to the user, thus allowing easier transition between domains (such as between clinical and financial/billing).

This paper presents the first hybrid framework for automatic text de-identification that combines different annotators together in order to maximise de-identification performance and increase generalisation. The methods section describes the framework in detail, how it was built and their individual components. The results section reveals the performance of each of the annotators, both individually and in combination, based on a representative corpus of clinical notes.

Methods

We have designed and implemented a de-identification pipeline that consists of five main steps, shown in Figure 2. The first step includes input handling and content extraction. The second step performs the pre-processing of the extracted text followed by an annotation step, where the individual annotators perform entity detection. The fourth step includes the post-processing of the results, false positives (i.e. incorrectly detected entity types) elimination and prioritisation. Finally, the de-identification step ensures the protection of the identified entities.

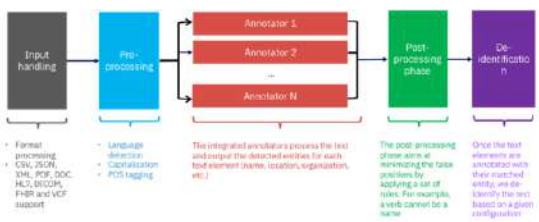

Figure 2 The high-level architecture of our de-identification pipeline

Input Handling

As we need to deal with a diverse set of input formats, our pipeline supports the following formats: CSV, JSON, XML, XLS/XLSX, PDF, DOC/DOCX, HL7, DICOM, VCF as well as plain text documents with no specific format. The user can specify which input elements contain free text information, for example, specific DICOM tags or HL7 segments. The input handling step is responsible for content extraction from the various input formats and preservation of the semantics that are necessary during the reconstruction phase.

Pre-Processing

The pre-processing phase includes three key steps: language detection, correct input capitalization and part-of-speech tagging.

Step 1 – Language Detection: the first step of the pipeline is to perform language detection. Based on the detected language, the system decides to proceed with the remaining steps depending on which annotators are available. For the vast majority of our use cases, we have to deal with input based on the English language but since we are integrating with international platforms, this step is essential. We rely on Apache OpenNLP[1] language detection components,[2] that support 103 languages.

Step 2 – Capitalization for Caseless Input: The input to the pipeline may be caseless; it can be either all lowercase or all uppercase. This has a significant impact on most of the annotators, hence this step is necessary for normalizing the input. We rely on Stanford CoreNLP's truecase annotator to handle such cases.[3]

Step 3 – Part-Of-Speech Tagging: Part-of-speech (POS) tagging is the last part of the pre-processing phase. Each token of the input is tagged with its part-of-speech information. This information is later used in the post-processing phase to alleviate false positives. Several annotators come with POS tagging functionality, such as Apache OpenNLP or Stanford CoreNLP. The POS tags used in this phase must be part of the Penn Treebank POS tagset.[4] For the POS taggers that do not follow this tagset, we manually created the mapping. POS tagging functionality can be extended in our pipeline.

Annotation Phase

During this phase, each annotator is called separately for the same input and then the individual results are gathered and merged. There is no inter-dependency among the annotators so this phase can be fully parallelized for performance.

Post-processing Phase

The post-processing phase includes several steps intended to increase the accuracy and quality of the end results.

Eliminating False Positives Based on POS Information

Since the entities to be de-identified are comprising of either nouns or adjectives, we can eliminate false positives based on the part-of-speech information. For example, if our input is "Will increase Lisinopril to 40 mg daily." and one of the annotators detected that "Will" is a name (this can happen due to blind dictionary matching) then this result can be filtered out since "Will" is neither a noun nor an adjective in the context of this sentence.

POS information need to be ignored for certain entities otherwise true positives would also be removed. Numeric entities, like phone numbers or credit card numbers, e-mail addresses, IP addresses, URLs and datetime entities can be classified as neither nouns nor adjectives, but they must not be discarded. Therefore, we provide configuration options to make sure that the pipeline handles these special cases accordingly.

Priority System

Since we invoke multiple annotators, there may be conflicting results for the same input token(s). In order to handle the potential conflicts, we introduced a priority system per annotator and per entity type. For each annotator, we assign a weight (a value in range [0, 100], with 1 as default) to each of the entity types supported. The initial weight assignment was performed based on the evaluation results of each individual annotator. The priority system also allows us to disable entities for a specific annotator. A weight value of 0 for an entity will force the pipeline to ignore the results for that entity for that annotator. The priority system allows us to disambiguate entries like “Alzheimer” which can be identified both as a name and a medical term, given that medical term classifier has higher priority over the name classifier for the conflicting terms.

[3] https://stanfordnlp.github.io/CoreNLP/truecase.html

[4] https://www.ling.upenn.edu/courses/Fall_2003/ling001/penn_treebank_pos.html

Merging of Connected Entities

There are cases where an entity is split into separate results by an annotator. For example, let us consider that the input is "Health Center of Washington". An annotator can detect two entities: "Health Center" as an organisation and "Washington" as a location. However, we want to detect only one entity and that is the entire sequence as an organization. The pipeline enables the merging of these two results into a single entity. Users can specify, through a configuration, the left and right-hand side types of the connected entities along with the connecting particles and/or pronouns, such as “of”, or “on”.

Blacklisting

The final step of the post-processing phase requires checking the results, per entity type, against a configurable blacklist. These contain tokens that are not to be considered matches. For example, for date and time entity type, we assigned that the token “currently” is a blacklist term. It is also possible to blacklist entity types from the final report. As an example, UMLS[5] dictionary entries if they are not going to be de-identified. This feature is enabled in our system in order to reduce over-classification, hence reducing the loss in utility.

Identifying Missing Repetitions of Identified Entities

There are cases where an instance of an entity is recognized once but then subsequent instances are not recognized. The pipeline includes a mechanism to detect unrecognized occurrences for entities previously identified by the annotators. The mechanism assigns types to the missed entities based on previous occurrences. Newly annotated entity types will be processed using the previously described steps (earlier in Post-processing) in order to remove false positives.

De-identification Core

The final step of the pipeline is the de-identification of the detected entities. This step ensures that any PI/PHI is sufficiently protected and that the usability of the end result is at an acceptable level. This can be performed, for example, by an expert accessor as defined in the HIPAA Expert Determination Method.

Data masking is applied on the detected entities and it replaces the original values with fictionalized ones. Our pipeline offers masking capabilities for all supported data types, as listed in Table 1, as well as some generic masking providers, such as redaction, nullification, hashing, randomization, truncation and numeric value shifting. Replacing values with their entity types (for example, e-mail address "test@domain.com" can be masked to "EMAIL-0") is also an option. Two key properties are supported**. Extensive format and semantic preserving masking**: format and semantic preservation is a key aspect of masking, since in many cases the data recipient needs to operate on the masked data. Approaches such as hashing, encryption or redaction, would limit (or even eliminate) the value of the masked data and allow users only to perform basic operations (e.g. counting). Our approach provides utility-preserving masking for each identified type, such as replacing Social Security Numbers with fictional numbers following the same standard, or replacing gender-specific names with other names of the same gender. **Consistent masking**: this feature ensures that the original values are always masked to the same fictionalized value. Consistency is an important requirement for data analytic purposes in healthcare, since it is the only accurate way to measure uniqueness and to do identity matching.

Annotators

Our de-identification pipeline includes a list of existing annotators. This section describes the available annotators. However, as mentioned before, the real power of the toolkit is in its configurability and extensibility. The annotators listed below were selected based on availability and quality criteria.

PRIMA Annotator - The PRIMA annotator is a set of 38 classifiers that cover basic PI/PHI entities based on our work for structured data [17]. PRIMA embeds three types of classifiers: regular expression-based, dictionary-based and custom-logic-based. Entity types like e-mails, addresses and URLs can be detected via regular expressions. Other entity types, like names, cities, countries and ICD codes, are detected using dictionaries. For the rest of the entity types, we use custom code for type detection. For example, credit cards are firstly detected by a specified prefix but the correctness of the check digit is also verified. A list of the currently supported entity types is shown at Table 1. PRIMA exposes the necessary interfaces to easily extend and localize the available functionality, as described in [17]. PRIMA is able to parse HL7 and FHIR messages as it has been designed to be compatible with healthcare systems.

Table 1: Supported entity types for PRIMA annotator.

Demographics	Location	Healthcare	Technology	Banking	Telco
Date and time	City	ICD v9	E-mail	SWIFT	IMSI
Name	Country	ICD v10	URL	IBAN	IMEI
surname	Continent	NDC	MAC address	CC number	Phone number
Religion	Address	ATC	IP Address	CC type	
Marital status	Latitude/Longitude	CPT			
Ethnicity	US states	Hospital name			
National ID	US counties	DICOM metadata			
SSN US	US/UK ZIP Codes	Patient ID			
NINO		MR number			
Occupation					

The application of regex-based or dictionary-based classifiers over free-text can miss entities spanning across multiple tokens. For example, consider the input “Health Center of NY is currently expanding its ICU”, along with the objective to de-identify the organization term “Health Center of NY”. Applying classifiers only for every distinct token will not return any results, even if our dictionaries include terms like “Health Center of NY”. To tackle this issue, we implemented a shingle filter mechanism. For each token, we examine the token itself and the next 1 to N tokens. For example, with N=4 the filter will produce the shingles “Health”, “Health Center”, “Health Center of”, “Health Center of NY”, ..., "currently expanding its ICU". For each shingle, all available PRIMA classifiers are invoked. This mechanism enables detecting entities that span across multiple tokens. Shingles, however, may still return overlapping results yet the subsequent steps in this pipeline are used to merge them with results from the other annotators.

Apache OpenNLP - Apache OpenNLP supports the most common NLP tasks, such as tokenization, sentence segmentation, part-of-speech tagging, named entity recognition, chunking, parsing, language detection and coreference resolution. Apache OpenNLP comes as an offline Java library. Trained models are also available for several languages in addition to English.

Stanford CoreNLP - Stanford CoreNLP [19] provides a set of human language technology tools. It can give the base forms of

[5] https://www.nlm.nih.gov/research/umls/

words, parts-of-speech tagging, named entity recognition, normalize dates, times, and numeric quantities, mark up the structure of sentences in terms of phrases and syntactic dependencies, indicate which noun phrases refer to the same entities, sentiment analysis, extract particular or open-class relations between entity mentions, and more. Stanford CoreNLP comes with models for the most commonly spoken languages.

SystemT - SystemT [20] is a declarative information extraction system that has been designed and developed to perform the task of extracting structured information from unstructured or semi-structured data. It is based on the basic principle underlying relational database technology: complete separation of specification from execution. SystemT uses a declarative rule-based language and an optimizer that generates high-performance algebraic execution plans.

Advanced Care Insights - The Advanced Care Insights[6] (ACI) Service uses healthcare annotators that accelerate natural language processing capabilities to identify medical and social information in physician notes, discharge summaries, and pathology reports. ACI identifies, normalizes, and codes medical and social facts, including symptom, disease, procedures, allergies, medications, smoking status, lab results, ejection fraction, and various daily living assistance terms. Note that, like the other annotators, the ACI service can be used in a HIPAA compliant manner.

Extensibility and Integration -There are cases where we need to detect entities based on either dictionaries, regular expressions or custom logic. In order to address such cases, the pipeline supports the loading of dictionary-based and regex-based identifiers via configuration and external files. There is also provisioning for the user to load their own annotators and POS taggers as well as localize the resources used for the detection and de-identification components. This can be done by implementing a Java interface and instructing the pipeline on how to use and configure the annotators via a configuration file.

The pipeline also includes NLP Tools from the Cognitive Computation Group of the University of Illinois[7], Watson Natural Language Understanding[8] and out-of-vocabulary classifier. For brevity, we will not elaborate on each of these annotators.

Results

Entities and Coverage

The pipeline supports the identification and masking of 38 entities. However, this number can be increased by plugging in custom functionality. The out-of-the-box supported entity list is based on the HIPAA Safe Harbor compliance standard but was augmented based on use cases we encountered during development and deployment.

We have classified each entity either as “direct”, which means that it directly identifies an individual, or “indirect”. Some indirect identifiers can be treated as direct in specific contexts, for example, if occupation is “chief of medicine” then it is a direct identifier. However, we do not cover such cases as disambiguating these cases requires additional, contextual, information that might not be available.

Figure 3 describes the supported entities along with their classification and supported annotators. With respect to Stanford, SystemT and Apache OpenNLP annotators, the non-supported entities can be covered after creating custom models to the respective annotation core. The same applies for PRIMA, with the difference that PRIMA also accepts simpler regex-based and dictionary-based identifiers.

As shown in Figure 3, no single annotator covers all entities effectively, at least not without considerable customisation and custom model training. However, our pipeline allows the concurrent execution of all available annotators, so all entity types can be covered. Note that certain entities are marked as "*" in Figure 3. The reason behind this is that such entity types do not have a universally accepted format, contrary to other entity types such as IP or e-mail addresses. These entity types, e.g. medical device identifiers and health beneficiary numbers, can vary between manufacturers and countries and it is therefore non-trivial to provide general models.

Entity	Classification	Stanford	ACI	SystemT	OpenNLP	PRIMA	Overall
Name	Direct	S	S	S	S	S	S
Location	Direct	S	NS	S	S	S	S
Dates	Indirect	S	NS	S	S	S	S
Phone numbers	Direct	NS	S	S	NS	S	S
Email	Direct	NS	S	S	NS	S	S
Social Security Numbers	Direct	NS	NS	NS	NS	S	S
Medical Record Numbers	Direct	NS	NS	C*	NS	C*	C*
Health Beneficiary Numbers	Direct	NS	NS	C*	NS	C*	C*
Organizations	Indirect	S	NS	S	S	S	S
Account numbers	Direct	NS	NS	C*	NS	C*	C*
Certificate / License numbers	Direct	NS	NS	C*	NS	C*	C*
Medical Device Identifiers	Direct	NS	NS	C*	NS	C*	C*
URLs	Indirect	NS	NS	S	NS	S	S
IP Addresses	Direct	NS	NS	C	NS	S	S
Occupation	Indirect	NS	NS	C	NS	S	S
Symptoms (optional)	Indirect	NS	S	C	NS	NS	S
Procedures (optional)	Indirect	NS	S	C	NS	NS	S

Figure 3. List entities supported by each of the annotators. S – Supported; NS – Not Supported; C – Customisable, not prebuilt.

Evaluation and Outcomes

We evaluated the performance of our pipeline in terms of precision and recall based on a random sample of 400 manually annotated medical notes, each referring to an individual patient. The sample was drawn from a large dataset from a US-based healthcare provider and ethical approval was obtained. The full dataset includes medical notes for more than 100,000 patients each of which has at least a medical note. The sampling processes removed machine generated notes and notes not containing any PHI. The notes contained entities for age, date, location, medical record numbers (MRN), names, phones and URLs. We compared our pipeline against NLM Scrubber.[9]

NLM Scrubber is a freely available, HIPAA compliant, clinical text de-identification tool designed and developed by the National Library of Medicine. It is the de-facto standard for de-identification of clinical notes in practical use cases and this allowed us to directly compare similar entity types. For the purpose of evaluation.

The results are summarized in Table 2. Using our pipeline, precision, recall and F_1 are consistently better across all entities. NLM Scrubber does not include models for ages and URLs. The recall is lower than NLM Scrubber only in the case of location and name entities but it is important to note that NLM Scrubber has very low precision on these entities, which means that NLM Scrubber will incorrectly identify as names or location “words” that are not actual names or location, respectively.

Phone	100	93.88	96.84	100	97.50	98.73
URL	0	0	0	100	100	100

Discussion

A multitude of highly specialized annotators are available and significant research has been undertaken to improve the accuracy of specific entities, such as names or medical terms. However, there is at present no existing framework to combine annotators so as to construct a robust pipeline that is able to satisfy multiple governance, regulatory and business purposes. This approach aims to create a flexible system that adapts to a plethora of scenarios. Similarly, a system able to support real-world heterogeneous data poses several challenges not captured by standard benchmarks. Clinical notes typically include typos, mixed cases (different across notes), and partially structured machine generated data (e.g., lab notes with alerts).

The approach proposed in this paper focuses on the identification of entity types, since regulatory requirements are not global or constant and on the premise that ensemble approaches outperform individual annotators. The pipeline proposed in this paper outperformed NLM Scrubber (see Table 2) and provided similar or better results than other approaches [12]. The latter proposes a framework and model that can be refined and where identifiers are customised. The generated models in [12] are trained and updated, however, this would typically mean a loss in precision when new entities are added to the classification model. The main difference between our approach and the one presented in [12] is that our models can return multiple types with weights in addition to the combination of information during post-processing with any other information available (e.g. using POS information to reduce false positives).

Combining positive with negative models helped increasing accuracy, for example, disambiguating between names (sensitive) and medical conditions (not sensitive according to HIPAA). Future development would include automating the priority system, for example, using semi-supervised learning techniques.

Conclusions

Automatic text de-identification is becoming increasingly important as larger volumes of narrative data containing PHI are being used. This paper presents a new hybrid system that combines different annotators and demonstrates how this new approach has a substantial effect on performance and generalisability. This is a useful tool for any data privacy expert following the HIPAA Expert Determination Method. To the best of our knowledge, this is the first framework that combines annotators together to provide precision and recall values better than any of the single annotators alone. Our results are also in line with, when not better than, other free text de-identification systems described in the literature. Further work is underway to evaluate this approach on larger corpora and to cover new data types.

A Glimpse at the Australian Health Information Workforce: Findings from the First Australian Census

Kerryn Butler-Henderson [a] and Kathleen Gray [b]

[a] University of Tasmania, Launceston, Tasmania, Australia,
[b] Health and Biomedical Informatics Centre, The University of Melbourne, Melbourne, Victoria, Australia

Abstract

The Australian Health Information Workforce is a critical discipline in the health sector as the investment in digital technologies increases. Yet historically there was no standardized reporting about the workforce and its six professional areas: clinical coding, costing analysts, data analysts, health informaticians, health information managers and health librarians. This paper presents the findings from the inaugural Australian Health Information Workforce Census. Analysis of 1,596 responses indicates this is an aging (56.1% ≥45 years) workforce with a large (78.1%) female population. Working in permanent (82%), public hospital (72%) roles, in professional or managerial roles (84%). The majority (93.2%) of respondents hold a tertiary qualification in health information, one-quarter of these at masters or doctoral level. Fewer than 30% of respondents hold a health information credential from a professional or industry association. The data from the ongoing national census will inform workforce planning and enable forecasting of the future workforce needs.

Keywords:

Censuses, Informatics, Health Manpower.

Introduction

The health information workforce is a specialized discipline responsible for the development, maintenance and governance of the systems for the management of health data, health information, and health knowledge [1]. A 2013 examination of the workforce established it is poorly defined with a lack of accurate data about the professions that constitute the workforce [2]. The Health Workforce Australia report [2] made six recommendations: 1). delineate the workforce, 2). improve data collection, 3). support strategic partnerships between stakeholders, 4). consider the future configuration of workforce, 5). address known health information workforce shortfalls, and 6). promote health information training and careers. Subsequently the 2016 National Health Information Workforce Summit [3] agreed to the following alliance strategy "Strategy A: We need a census of the health information workforce and regular collection of data". The Health Information Workforce Census Project ("Census Project") was developed to address these recommendations and strategy, with the project aim to provide timely evidence about the nature and scope of the Australian health information workforce through a national census.

The Australia Health Information Workforce Alliance [4] states the workforce consists of the following professional areas: (1) Clinical coding; (2) Clinical costing analysts; (3) Health data analysts; (4) Health informaticians; (5) Health information managers; and (6) Health librarians. Yet, there is no empirical research to support this delineation. Existing empirical research has only focused on part of the workforce. Half of the workforce do not have an Australian and New Zealand Standard Classification of Occupations (ANZSCO) classification, so they are not captured by the national household census [5]. And where information is captured, past research suggests it may not be an accurate representation [4]. There have been a small number of Australian profession specific surveys [4, 6-8] that only survey professional members of peak bodies and/or one or two professional areas of the workforce. Never before has the entire workforce been examined with a scientifically developed and validated instrument.

There is also a lack of workforce data internationally. The most scientifically rigorous health information workforce research to date was undertaken in Canada [9], which included the health informatics, health information management, and clinical coding professional areas. This study estimated the hiring requirements for these professionals in 2008 and 2013 and identified roles for which there is a risk of skills shortages in Canada. Yet, the study used data from existing data collections systems and not from the individual, and did not examine the educational background of the population, the day to day operations of the role, the professional development requirements of individuals, peak body membership, credentials, or the future intentions of the workforce.

The increase in both digitization and adoption of technological approaches has created a growing demand for workforce specialists.[10], and the converging interests of the global health information workforce is now being recognized [11]. But without a clear picture of who the workforce is, the health system is unable to forecast future workforce needs.

A 2015 focus group suggested that Health Workforce Australia recommendation 1 and 2 could only be addressed by an integrated, scientific data collection system, such as a routine census [12]. Such a system would enable the collection of data to inform the other Health Workforce Australia recommendations. This paper describes the partnership between the authors and Australian peak bodies, the Australasian College of Health Informatics (ACHI), Australian Library and Information Association (ALIA) Health Libraries Australia (HLA), Health Informatics Society of Australia (HISA), Health information Management Association of Australia (HIMAA), and key government organizations, the Australian Digital Health Agency (ADHA) and the Victorian Department of Health and Human Services Workforce Branch, to develop a national census. The aim of the census itself is to quantify and qualify the Australian Health Information Workforce, specifically to delineate and count the workforce,

consider the future configuration of the workforce, identify health information workforce shortfalls, and identify current health information training and career pathways to meet future workforce demands. The results from the first Australian census shall be presented below.

Methods

The census instrument was developed through a large national study involving Australian and New Zealand stakeholders [13]. A Delphi approach was adopted to enable the staged development of the instrument through seven rounds: data elements (rounds 1-3), question and response format (rounds 4-6), and lastly the pilot testing of the instrument (round 7). Representatives from the six partner organizations, and the Clinical Coding Society of Australia and Health Informatics New Zealand were invited to join an Expert Panel, who were closely consulted through both face to face focus groups and online surveys at each stage during the project. A larger Consultation Group was formed with more representatives from these organizations, and other identified stakeholder organizations in Australia. This group was engaged through online surveys at all stages throughout the project once the Expert Panel had finalized their input. The sixth round of the project included a consultation with the Executive from each of the partner organizations to obtain their feedback on the instrument, and the seventh round was the overall pilot testing of the instrument by anyone who had been involved in the previous rounds. This testing included both testing of the questions within the instrument and the user experience of the online census.

The census is housed within the REDCap (Research Electronic Data Capture) system hosted at the University of Tasmania. This is a secure online research data capture system, that includes a survey capability. This system was selected as it will allow the ongoing capture of repeated census data collection. REDCap configures surveys to be displayed on any type of device and is compatible with all browser types. The census was also available in paper format on request.

Throughout the development of the census instrument, and in the lead up to the census month, there was extensive communication with stakeholders and individuals who registered through the census website. Recipients were encouraged to distribute the information throughout their networks in an attempt to reach as much of the workforce as possible. Figure 1 outlines the eligibility criteria for participation.

> To complete the Australian Health Information Workforce Census, a participant must:
>
> 1. Work (including volunteer or actively seeking) in a role where the primary function is related to developing, maintaining, or governing the systems for the management of health data, health information, or health knowledge. AND
>
> 2. Work (including volunteer or actively seeking) for/with an organisation that operates in Australia, where the role relates to the Australian operations, and relates to the health sector.

Figure 1– Participation eligibility statement

The census was deployed in May 2018, with ongoing communication throughout the month to the stakeholder list. There was large national engagement and international interest, with the census website receiving nearly 5,000 visits during May. Once the census closed on the 31 May 2018, the data was cleaned and analyzed.

Results

There were 1,597 participant responses included in the analysis. This response rate is estimated to be approximately 20% of the actual workforce, based on comparisons to previous reports about subsections of this workforce [4, 6-8].

There was representation across the six professional areas identified by the Health information Workforce Alliance [4]. A summary of the distribution is provided in Figure 2.

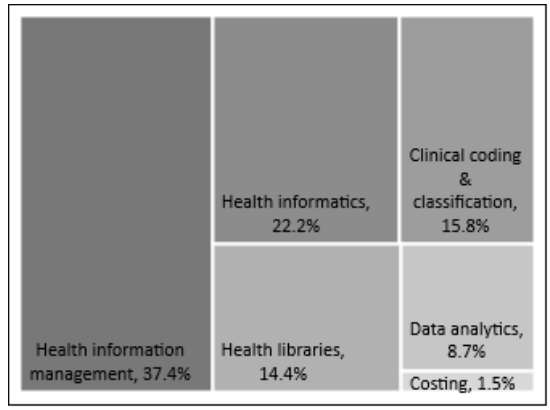

Figure 2–Distribution of professional areas

The census results indicate three quarters of the Australian workforce were born in Australia, with 98.3% either an Australian citizen or permanent resident. The majority of respondents live in Victoria (38.1) and New South Wales (24.1%). 0.8% of respondents indicated they reside outside of Australia.

The gender distribution amongst respondents was strongly skewed towards one gender, with 78.1% of respondents identifying as female, 21.6% as male and 0.3% as other. 56.1% of respondents are aged 45 years or older (Figure 3). Only 1.9% of respondents identified they are an Aboriginal Australian and/or Torres Strait Islander person. 3.4% of respondents specified they had a disability of health condition that limits their participation in activities.

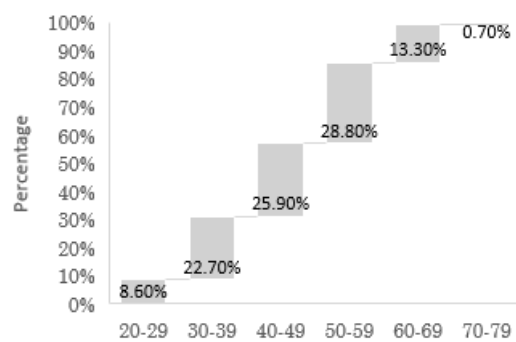

Figure 3 – Age distribution of participants

The majority of respondents work in permanent roles (82%) in the public hospital sector (72%). 15.1% of respondents are actively seeking employment in a health information role, half of which already work in a heath information role. Only 1.4% of respondents identified as self-employed. Respondents indicated they have been in their current role for 7.2 years, with nearly half (47.9%) of respondents reporting they have held their current position for more than 5 years. The majority (84.8%) of respondents indicated they are working in a managerial or professional role, with 13.5% identifying they work in a clerical role. The average weekly remuneration (before taxation) was in the $1,500-$1,999 bracket, with 51.1% of respondents reporting earning between $1,000-$1,999 per week (before taxation). The average number of hours worked per week was 32.6 hours. Respondents indicated they plan to remain working in the Australian health information workforce for an average 14.6 years.

The majority (93.2%) of respondents hold a tertiary qualification in health information. Table 1 summarizes the distribution of highest health information qualifications. Over a quarter (26.0%) of the workforce hold a Masters or Doctoral qualification in health information.

Table 1 – Distribution of educational level

Educational level	Percentage
Certificate I-IV	8.3
Diploma	5.5
Associate degree	1.4
Bachelor degree	40.3
Bachelor honours	3.2
Graduate certificate or diploma	15.3
Master degree	21.7
Doctorate	4.3

11.5% of respondents did not undertake any professional development in the last 12 months. Work base learning (40.3%) and professional activities (24.1%) were the most popular professional development activities (Figure 4). Nearly three quarters (71.8%) of respondents do not hold a health information credential (Figure 5), but 12.3% maintain their health practitioner registration under the National Registration and Accreditation Scheme. Over half (55.5%) of respondent maintain a professional or industry association membership (Figure 6).

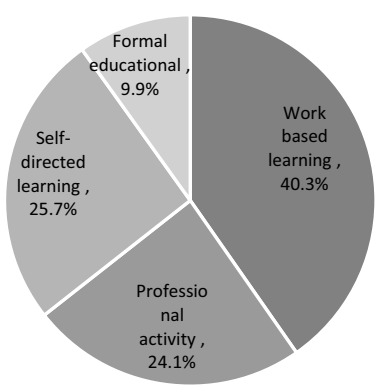

Figure 4 –Distribution of professional development

Discussion

It must first be acknowledged that the sample size for this first census cannot be determined because we simple do not know the size of the workforce in Australia. As the census shall be repeated in 2020 and every three years thereafter, it is anticipated participation will increase. However, an estimate indicates the 2018 result represent approximately 20% of the workforce and the results did provide many insights into the Australian workforce.

This is the first study to establish there is an international health information workforce servicing Australia's health sector needs, Whilst only 1% of the workforce is located outside of Australia, this number is likely to be significantly larger. It will be difficult to reach that workforce to complete the census, but it is important they are included to measure their impact on the Australian workforce.

The results indicate this is an aging workforce. The Australian Intergenerational Report [14] suggests by 2055 there will be a decline in the traditional workforce population (15-65 years old), with an increase in average life expectancy for those aged over 65 years. With an already aging workforce (≥45 years [15]), the Australia health information workforce is at risk of not meeting the productivity demands of the health sector. Investment in a younger workforce is required now to meet these future needs. This is compounded by a largely permanent workforce who remain in a position for several years. Without constant movement across the workforce, opportunities for advancement is reduced, resulting in further loss from the workforce as younger professionals seek opportunities elsewhere.

Diversity is lacking in this workforce across several areas. The census reported a very large female population. Further analysis of the gender data is required to identify if there is a gender pay disparity, and the percentage of women in senior health information positions in health. Further investment is also required to increase participation in this workforce by Aboriginal Australians and Torres Strait Islander people. The results from this census indicate this population is currently under-represented in the workforce compared to their representation in the Australian population.

In terms of how the workforce views itself as a professional workforce, the results showed there is still a critical technical and clerical element. Yet, the majority of respondents have a tertiary qualification. The ongoing census will be necessary to monitor if the discipline evolves from operational roles to information strategist professional roles as digital transformations and automation changes the landscape [16]. Further research is required to examine the level of education and career opportunities.

Opportunities exist for peak bodies and educational providers to provide professional development opportunities. This may increase individual's enthusiasm to obtain professional credentials and join their professional or industry membership organizations.

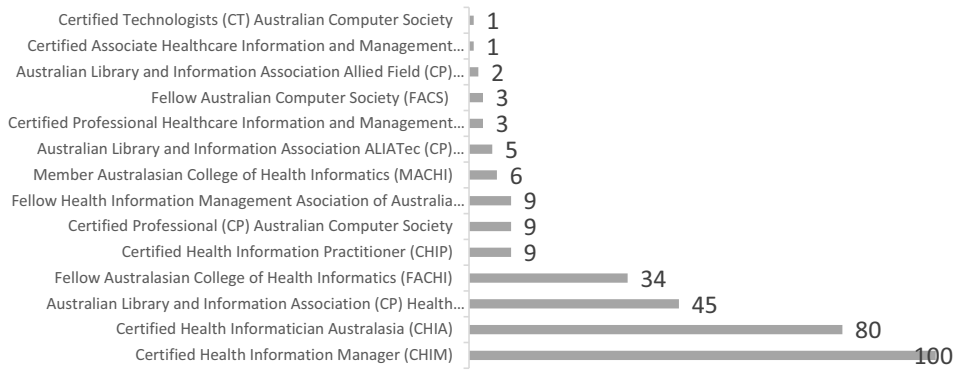

Figure 5 –Distribution of professional credentials

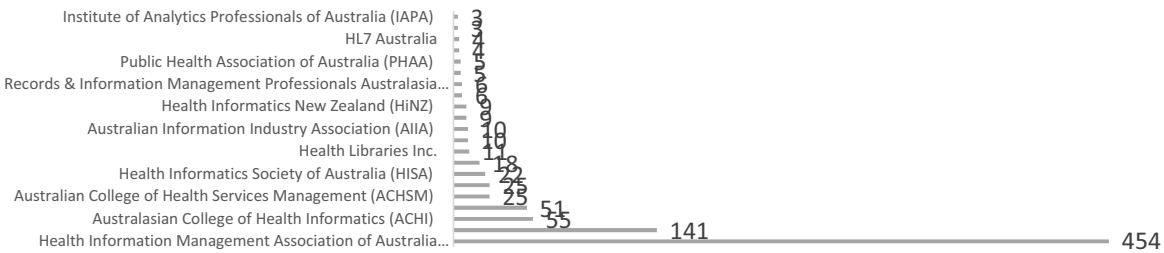

Figure 6 –Distribution of professional and industry membership

Conclusions

In a data driven, technological world, the health information workforce has emerged to be a critical area in the health sector. Prior to the Australian Health information Workforce Census there was no standardized and valid means of measuring the workforce. This results from the Australian Health information Workforce Census will enable workforce planning and enable forecasting of the future workforce needs.

Abstract

The negative effects of long-term stress on health outcomes are well-documented. Emerging technologies that harness mobile technologies have been linked to positive effects on stress management. However, the ways in which existing inter- and intrapersonal theories of behavior change are integrated into development processes of these mHealth technologies for stress coping are limited. In this paper, we present a novel theory-driven approach to develop and implement a sustainable mobile application for stress education and management. Specifically, we integrate the taxonomy of Behavior Change Techniques and user engagement framework to model and adapt theory-driven techniques in the context of mobile technologies. A total of 12 behavior change techniques were incorporated into our mobile application. Initial user evaluation and usability testing was conducted. Results indicate heuristic modifications could improve overall delivery of content, and potential user satisfaction is likely. We conclude that this novel approach may have implications well beyond stress management.

Keywords:
Psychological stress, behavior therapy, telemedicine.

Introduction

Psychological stress (in lay terms, stress) occurs when the demands on an individual exceed the ability to cope [1]. The negative effects of long-term stress on human health has been well-documented [2]. Stress includes mental health symptoms such as anxiety and depression [3]. The global cost of mental illness is estimated at one trillion dollars and affects 300 million people [4]. Americans' average stress levels are 4.8 out of 10, 45% experience sleeplessness due to stress, and 75 % experienced 1 or more symptoms of stress in the previous month, including nervousness or anxiousness [5]. Stress costs the U.S. enterprise economy up to 2.6% of the GDP annually and in Europe the cost can be as much as 3.3% [6]. Stress can be managed using self-care behaviors, such as avoiding alcohol, finding social support, eating and sleeping well, and staying active [7]. Literature shows that evidence-based practice can reduce perceived stress [8]. Recently, mHealth applications promoting behavioral change were found to have positive effects on workers' perceived stress [9].

Emerging trends in mobile smartphone apps can provide new frontiers to management of chronic conditions such as stress [10]. 77% of Americans own mobile smartphones, and 90% own a mobile phone of some kind [11]. With mobile network capabilities and affordable smartphones reaching well beyond other infrastructure in countries with low- and mid-range economies, mHealth and health promotion efforts in these areas are able to be offered in new ways via mobile phone technology, such as personalized care or public health [12]. Literature suggests that cost effectiveness of mHealth solutions is likely [13]. Platforms for mHealth or eHealth with designs that allow for innovation in aspects such as use, utility, financial impact, sustainability, scalability, and impact will be needed for advancement [14,15]. Mobile health technology can improve user adherence in a variety of health behaviors [16,17]. It is known that mHealth also can deliver education and patient self-care, among other health benefits [18]. Evidence-based smartphone apps for mental health have been shown to be effective and to have the potential to reach beyond current treatment limitations [19]. Large-scale clinical trials establishing effectiveness and efficacy of using app based modalities are sparse and often indecisive. Despite the overall lack of evidence-based smartphone apps in existence, there is potential for successful delivery of evidence-based stress management strategies [20]. Efforts have been made to understand the utility and manifestation of behavior change techniques, however, specific software development approaches to generate synergistic collaborations between technology developers and health research are limited [21]. In this paper, we present an integrative approach to infuse theory-driven techniques and engagement features to develop novel, evidence-based, and engaging mHealth applications. Specifically, we utilized the taxonomy of Behavior Change Techniques (BCT taxonomy) [22] and the Patient engagement framework [23] to consolidate uniquely identified behavior change concepts and user engagement features in a mobile format. In the next sections of the paper, we describe in detail our approach for the development of a mobile application, NewCope, and initial results of the system evaluation through user testing and usability analysis.

Related Works

Existing work focusses on reviews of smartphone apps that deliver stress management behavior therapy. For example, the "Tension Tamer" app, which uses systolic blood pressure as a measure of stress, focused on breathing awareness meditation [24]. Similarly, heartrate has been used as a measure of stress in the "It's Time to Relax" app, which focuses on mindfulness [25]. Similarly, the "Virtual Hope Box" app was designed based on Cognitive Behavioral Therapy (CBT) [26]. "Headspace," which utilizes mindfulness and meditation, has been used for stress management delivery in multiple mHealth stress management studies [27, 28].

Additionally, other mHealth solutions have been developed to address the needs facing delivery of stress management therapy. Method of Levels transdiagnostic cognitive therapy

was used in the development of the "MindSurf" app, which showed positive results in preliminary function and usability testing [29]. And importantly, the Virgin Pulse Global Initiative (VPGI) was an mHealth solution that overcame existing paradigms to show a positive outcome for workers completing the mHealth behavioral program [9].

Methods

Theoretical Rationale

Taxonomy of Behavior Change Techniques

Michie et al. [22] defined a set of theory-linked techniques that can be used to integrate, implement, and harness multiple theoretical constructs to unify inter- and intra-personal processes of human behavior into technology features that can assist and support sustainable positive health behaviors. Their taxonomy of 93 theory-linked techniques is the first step towards creating a model that provides a snapshot of intervention content in the context of theory-driven behavior change constructs [22]. The taxonomy provides a common vocabulary to understand the ways that sociobehavioral and cognitive constructs of the existing behavior change theories can be operationalized in a specific intervention. The complete list of techniques of the taxonomy with definitions and detailed examples can be found here [22].

Patient Engagement Framework (PEF)

The PEF has been developed by the Healthcare Information and Management Systems Society (HIMSS) through a cumulative layering of five phases: "inform me," "engage me," "empower me," "partner with me," and "support my e-community." A total of nine features have been specified at the highest engagement level, including 'information and way-finding', 'e-tools', 'forms', 'patient-specific education', 'patient access and use', 'patient generated data', 'interoperable records', 'collaborative care and community support'[23]. This framework was used in our study to sketch the functionality of the mHealth infrastructure which potentially facilitates the adoption of the tool, self-management, goal setting and reinforcement, peer support, and patient-provider communication.

Technology-Theory-Engagement Mapping

A mapping process was conducted to identify BCT techniques in conjunction with user engagement features that could be used to operationalize the delivery of stress management-related content to users. The BCT techniques allowed us to understand the characteristics of the information that should be delivered to the user. We also specified the level of intended user engagement to characterize the granularity and complexity of the system features. Tables 1 and 2 provide a summary of the BCTs and engagement functions that were selected for implementation at feature level and content level.

Development

NewCope was built on the opensource Ionic Framework (ICL version 4.1.1) [30]. Native Ionic features such as modals, cards, slides and buttons were used in the app design, in addition to custom coded features such as the progress bar and imbedded "fun fact" questions. The NewCope design does not necessitate the collection of any Personal Health Information (PHI) including email address or other personally identifying user information, so Google's Firebase database was used for the sake of simplicity and ease of set-up. User authentication was handled via a user-generated username and password.

NewCope has five main component pages, including a homepage with primarily informational resources, a dashboard page that provides feedback to the user, a self assessment page, a journal page, and a page that offers information about the app, help to the user, and a place to contact the researchers.

Table 1– Theory Mapping for App Content and Functions

BCT name	Definition	Example
Instruction on how to perform the behavior	Advise or agree on how to perform the behavior	Education
Social comparison	Draw attention to others' performance to allow comparison with the person's own performance	Education
Self-talk	Prompt positive self- talk before and during the behavior	Daily task
Valued self-identity	Advise the person to write or complete rating scales about cherished value or personal strength as a means of affirming the person's identity as part of behavior change strategy	Journal
Information about health consequences	Provide information about health consequences of performing the behavior	Education
Incentive	Inform that a reward will be delivered if and only if there has been effort and/or progress in achieving the behavioral outcome	Daily task
Self-monitoring of behavior	Establish a method for the person to monitor and record their behavior(s) as part of a behavior change strategy	Progress
Behavior practice/rehearsal	Prompt practice or rehearsal of the performance of the behavior one or more times in a context or at a time when the performance may not be necessary, in order to increase habit and skill	Daily task
Focus on past success	Advise to think about or list previous successes in performing the behavior	Daily task
Social support (emotional)	Advise on, arrange, or provide emotional social support for performance of the behavior	Daily task
Credible source	Present verbal or visual communication from a credible source in favor of or against the behavior	Education
Restructuring the social environment	Change, or advise to change the social environment in order to facilitate performance of the wanted behavior	Daily task

Table 2- Engagement Features and Ontology Relations

Engagement phase	Description	Technology feature
Engage (Level 2)	e-Tools	Perceived stress scale integration
Self-monitoring		Daily task
Goal setting		Stress feedback
Create synergy and extend reach (Level V)	Education	Journal
Self-management	User-specific feedback	Daily task
Daily reminders (e.g. Lifestyle tip)		Progress summary

The health education materials provided in the application relate to stress prevalence [31, 32], guides meditation, stress management techniques associated with relatable people as

#hashtag signs. The dashboard includes a checklist of three daily tasks designed to help the user adopt and sustain positive health changes that can aid them in stress coping with user-specific feedback, thus promoting self-monitoring habits. As can be seen in Figure 1, examples of tasks on the daily checklist are "listen to music," "go through old photo albums," "call a loved one", and "write your personality strengths." These tasks are related to the specific BCT techniques, "Restructuring the social environment", "Valued self-identity", and "Social support (emotional)" respectively.

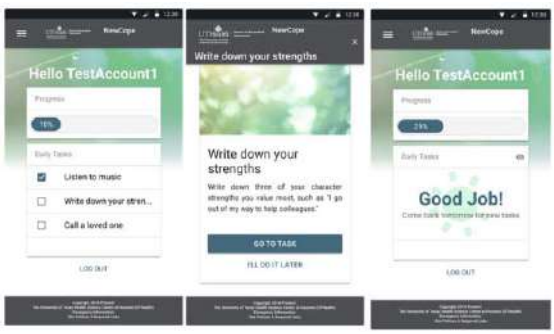

Figure 1– "NewCope" Dashboard

The self-assessment page utilizes the Perceived Stress Scale to evaluate the user's perceived stress level as low, medium or high [33]. The monitoring instrument addresses specific BCT techniques, "Feedback and monitoring" and "Goals and planning." The journal page is designed for use both in daily tasks that the user is asked to complete, such as "write down your strengths," which embodies "Self-belief", and for general use by the user, which further supports "Identity." Journal entries are designed to appear on "sticky note" graphic elements that can be edited, deleted, and rearranged by the user.

Evaluation

The prototyped app was reviewed for usability and accessibility and for use by human participants. One usability expert evaluated the user interface and generated a list of heuristic violations according to the Nielsen–Shneiderman Heuristics [34]. For each violation a severity rating (scale 1 – 4 where 1-Minor, 2-Moderate, 3-Major, 4-Catstrophic) was assigned. The design was refined to meet shortfalls that were most relevant to user testing. A secondary usability evaluation was conducted with five participants, selected based on recruitment by the researchers. The participants were recruited to test the app via a protocol of six timed tasks and the System Usability Scale (SUS) [35]. The UTHealth Internal Review Board approved the study for human participants.

Results

Initial Evaluation

The results from the heuristic evaluation revealed a total of 47 violations, eight of which were minor, 14 moderate, 19 major, and six catastrophic. Most violations represented issues with consistency (see Table 3).

Table 3– Heuristic Evaluation Summary

Violations	Minor	Moderate	Major	Catastrophic	Total
Consistency	5	3	7	1	16
Control		1	1	1	3
Flexibility		1	1		2
Help		2	1	1	4
Language	2	1	4	1	8
Match		4	1	1	6
Memory			1		1
Minimalism	1				1
Visibility		2	3	1	6
Total	8	14	19	6	47

The results from the user evaluation were as follows: All users were successful in completing all tasks, though some required assistance. The percentage of independent user completion was between 40 and 80% for all tasks, with user satisfaction maintaining a score between 1.2 and 1.8 for all tasks. The average completion time for tasks was between 8.0 and 126.8 seconds (see Table 4).

Table 4– Task Completion Summary

	Task Area					
	Create Ac-count	Self Assess-ment	Checklist	Video	Journal Entry	Article
User completed independently	80%	40%	60%	80%	80%	80%
Average completion time (sec)	50.4	126.8	8.0	88.4	38.4	59.0
Average user satisfaction 1-high 5-low	1.6	1.8	1.8	1.5	1.2	1.2

As seen in Table 5, the SUS scale results for positively correlated items showed an average of 4.04 out of 5, while negatively correlated items showed an average of 1.28 out of 5. Average item scores for positively correlated items were between 3.6 and 5.0, while average negatively correlated item scores were between 1.0 and 1.4.

Table 5– SUS Summary

Positive Items	**Frequency**	**Easy**	**Integration**	**Learnable**	**Confident**
Mean	3.6	3.8	3.8	5.0	4.0
Range	1-5	2-5	2-5	5	2-5
Negative Items	**Complex**	**Technical**	**Inconsistent**	**Cumbersome**	**Acquisition**
Mean	1.4	1.2	1.4	1.4	1.0
Range	1-2	1-2	1-3	1-2	1-1

Discussion

While the sample size limits the statistical validity of the quantitative data, we do observe the clustering of responses on the SUS items, particularly the negatively correlated items. This potentially indicates that participants in the trial were more consistently not put off by the system than that there was a consistent desire among the participants to use the system. As participants were not screened for stress level or desire for stress management, this result may not be unexpected. In fact, our findings from the evaluation determined that the average user stress level was 21.2 out of 40, which is classified as "moderate stress." Qualitative user data has indicated that users were often uncertain if task completion for the purposes of the trial included clicking buttons, with 5 of 11 trial administrator interventions based on helping the user to decide on button pressing behavior. This was primarily seen in the Self-assessment task (n = 3). Additionally, qualitative data shows that users had trouble locating the task checklist on the

dashboard screen when described as a "checklist." This accounted for the 40% administrator assistance rate on the View Checklist task, and 20% of the administrator assistance rate on the Self-Assessment task. User suggestions included using larger font sizes for the buttons, moving the "quit assessment" button further away from the "next question" button, and having Google prompt the user to automatically remember the password. User results do not, however, indicate a barrier to delivering BCTs via a smartphone app. All heuristic and user-identified barriers to the usage of the app were based on the user experience and user interface critiques. Design features can be further refined to create a smoother user experience while maintaining the necessary BCT components.

Methodical integration of known behavior change techniques has resulted in the convergence of constructs from multiple theories of behavior change including the Transtheoretical Model of Change [36], Social Cognitive Theory [37], and Health Belief Model [38], thereby ensuring our application harnesses inter- and intra-personal processes of behavior change [39]. Further, predetermined engagement levels allowed rapid prototyping with a generalized understanding of software features and malleable modes of theory-driven content delivery. This, while leaving room for clinical partner and wellness service integration, which is vital for large-scale dissemination of health promotion technologies.

Limitations

There are several limitations to our study. We have used a specific theoretical taxonomy to guide the development process. While the taxonomy is integrative, participatory and crowdsourced design activities that employ social listening can result in a holistic development approach. Additional features ,including online communities and smart technology synching, are important to improve the user experience and sustained use of NewCope. Our evaluation results are limited by the size of the participant pool and did not account for long term user engagement measures. Future studies should consider large-scale evaluations for better understanding of the acceptance of technologies such as NewCope.

Conclusions

Mental well-being, chronic disease management, and general health are affected by an individual's ability to manage stress, playing a role in one's happiness and productivity. Our paper describes a novel approach for the integration of evidence-based, theory-driven techniques in the digital era. The proposed approach is generalizable to other health conditions and can have implications well beyond stress management. Integration of theoretical models of human behavior into emerging technological domains such as mobile applications is important to facilitate effective dissemination of evidence-based strategies at scalable and sustainable levels. Attrition with the use of technology-based health promotion can be addressed with the proper implementation of user engagement principles.

Abstract

Changing physician behaviors is difficult. Electronic health record (EHR) clinical decision support (CDS) offers an opportunity to promote guideline adherence. Behavioral economics (BE) has shown success as an approach to supporting evidence-based decision-making with little additional cognitive burden. We applied a user-centered approach to incorporate BE "nudges" into a CDS module in two "vanguard" sites utilizing: (1) semi-structured interviews with key informants (n=8); (2) a design thinking workshop; and (3) semi-structured group interviews with clinicians. In the 133 day development phase at two clinics, the navigator section fired 299 times for 27 unique clinicians. The inbasket refill alert fired 124 times for 22 clinicians. Fifteen prescriptions for metformin were written by 11 clinicians. Our user-centered approach yielded a BE- driven CDS module with relatively high utilization by clinicians. Next steps include the addition of two modules and continued tracking of utilization, and assessment of clinical impact of the module.

Keywords:

user computer interface, clinical decision support, electronic health record, behavioral economics

Introduction

Changing ingrained physician behaviors is difficult [1]. Integrating behavioral economic (BE) strategies into electronic health records (EHR) using various clinical decision support (CDS) tools is a novel approach to improving guideline adherence that also seeks to minimize negative impacts on clinical workflow and cognitive load. This study's hypothesis is that employing a user-centered approach to design a CDS module that incorporates BE strategies will result in a low burden tool to support provider adherence to guideline-based recommendations.

Maximizing the potential of CDS through behavioral economics and user-centered-design

Large, systematic reviews of EHR-based CDS have demonstrated a moderate ability to reduce morbidity, utilization, and costs [2, 3]. These modest improvements, however, are undermined by the well-documented problems of alert fatigue and poor workflow integration, which together blunt the potential of the EHR and CDS to improve healthcare outcomes [4]. New approaches are needed to complement the traditional alerts, reminders, and other CDS tools that disrupt clinical workflow, increase cognitive load, and stress the limited capacity of clinicians to rationally process and evaluate the diverse and competing demands on clinician attention. Behavioral economics has shown success as an approach to support evidence-based decision-making with little additional cognitive burden to clinicians; however BE strategies are rarely leveraged in current CDS tools.

A user-centered design approach employing design thinking strategies is common in digital development projects outside of healthcare. Prior research, including that of the research team, show the value of taking a user-centered approach to development of CDS [5-8]. A user-centered approach employs design thinking exercises designed to identify opportunities to incorporate BE in CDS related to the target user – in this case physicians – to stimulate idea generation. Design thinking strategies are well-suited to exploring physician motivations and workflow opportunities which require understanding for successfully incorporating BE to create feasible, usable decision support solutions likely to achieve adoption.

Choosing Wisely guideline for older adults with diabetes is an opportunity to explore this potential

The objective of this study was to develop a scalable, EHR module that incorporates BE strategies to promote appropriate diabetes care in older adults based on the American Geriatric Society's Choosing Wisely (CW) guideline, which aims to reduce over-treatment to benefit older adults with diabetes.

The CW guideline for older adults with diabetes recommends clinicians "avoid using medications other than metformin to achieve hemoglobin HbA1c<7.5% in most older adults; moderate control is generally better" [9]. This offers an opportunity to explore the potential of BE in the EHR to support guideline adherence for providers. In spite of this guideline, which recommends less aggressive target A1c levels based on older age and lower life expectancy, a substantial number of older adults with diabetes continue to be prescribed more aggressive therapies that may not only be unnecessary but also harmful [10-12].

This paper 1) outlines a user-centered approach to the development of a BE inspired EHR-CDS module for promoting guideline-based treatment of older adults with diabetes, and 2) reports on module activity metrics from the 4.5 month development phase of the project (June-October 2018).

Methods

Overview

This study employed a pragmatic (emphasis on real-world clinical workflows), user-centered approach to develop a new BE inspired CDS module (BE-EHR) to improve provider adherence to the CW guideline targeting over-treatment among older adults with diabetes.

To accomplish this, we conducted:

1. semi-structured interviews with key informants (n=8);
2. a two-hour design thinking workshop with a multidisciplinary group of clinicians, informaticists, EHR analysts, product designers and others to derive and refine initial module ideas; and
3. semi-structured group interviews with clinic leaders and clinicians at each of two "vanguard" sites to elicit feedback on three draft module components (inbasket refill, medication preference list, navigator tab).

Setting and population

The intervention was developed by a multi-disciplinary research team at a large academic medical center and deployed in two "vangaurd" ambulatory primary care practices serving patients with a diverse range of socio-demographic characteristics. The BE-EHR module was deployed for internal medicine and endocrinology physicians and nurse practioners.

Two "vanguard" practices were selected purposefully based on key characteristics: a primary care focus, a relevant patient population (i.e. adults over age 76 with diabetes), and a willingness of practice leadership to serve as a test site for implementation of module prototypes and provide periodic feedback.

Life expectancy algorithm

In order to build a user-centered CDS tool that triggers appropriately for the target patient population, algorithms were built into the BE-EHR module to drive the timing and content of module alerts that incorporate both patient life expectancy (high, medium, low) and target glycemic index per the CW guideline. These categories were defined in the algorithm as follows:

1. healthy older adults with an HbA1c target range of 7-7.5% and long life expectancy (defined here as 10+ years);
2. those with moderate comorbidity and a life expectancy of 3+ to 10 years, with a target range of 7.5-8%; and
3. those with multiple comorbidities and life expectancy of less than or equal to 3 years, with a target range of 8-9%. [13]

Analysis

Key informant, group interview data, and insights generated at the design thinking workshop were recorded by research staff in the form of field notes and summarized by usability theme and, when appropriate, by module component for rapid iteration of the prototype. Once findings were incorporated into the module prototype, the module was deployed in the two vanguard sites. EHR-based reports were built to track frequencies of module component firings and action taken (navigator tab component only). These metrics were calculated per number of unique patients and number of unique providers at the vanguard sites throughout the development phase (first 133 days of implementation). EHR reports also served to confirm the module and related outcomes reporting tools were firing as expected.

Results

Module development

Key informant and vanguard clinic group interviews identified the refill protocol and medication preference list as promising candidate CDS tools for the BE-EHR module based on their compatibility with provider workflows. These components were refined based group interview findings combined with current best practices in CDS development (e.g. avoid interruptive alerts) [14].

For example, the medication preference list component leveraged the behavioral economics principle of availability bias (tendency to rely on easy-to-access examples) by placing the CW recommended medication (metformin) at the top of the medication preference list (Figure 1).

Findings from the design thinking workshop included refinements to both the refill protocol and the medication preference list components. Two new ideas were generated that incorporated a combination of behavioral economic principles: one new EHR CDS component (a navigator tab for older adults with diabetes illustrated in Figure 2), and a non-EHR based supportive "campaign," as an adjunct to the BE EHR-CDS module to raise awareness of the CW guideline. The campaign, requiring significant additional design work, was not deployed in the development phase.

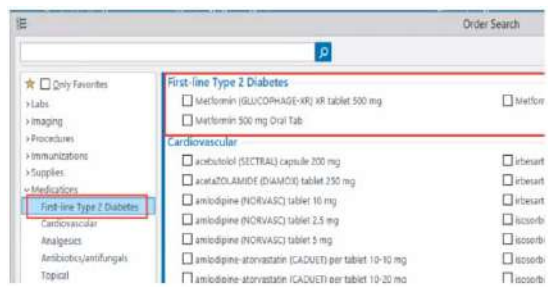

Figure 1- Medication preference list module component

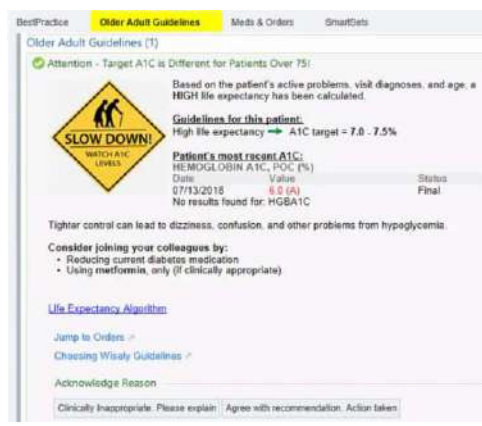

Figure 2- Navigator tab module component

Once prototyped, user feedback from site visits confirmed the compatibility of the navigator tab with clinical workflows and contributed to refinement of design and content.

Module activity

Table 1 shows the components of the nudges implemented during the development phase along with frequency of module firings. In the first 133 days at the two vanguard clinics, the navigator tab fired 299 times for 193 unique patients and 27 unique clinicians across sites. The inbasket refill alert fired 124 times for 84 unique patients and 22 unique clinicians (Table 1). Fifteen prescriptions for Metformin (guideline recommended medication if appropriate) were written to 14 unique patients by 11 unique clinicians – 31% of all clinicians (n=35) – who

prescribed metformin to the target population from the preference list at the two vanguard sites during this time period.

Table 1- BE-EHR module components activity

Module component	# fire	# patients	# clinicians
Inbasket refill	124	84	22
Navigator tab	299	193	27
	# Rx	**# patients**	**# clinicians**
Preference list Rx	15	14	11(31%)
Metformin Rx total	123	98	35

Discussion

Design thinking, employed as an approach to facilitate successful implementation and sustainability of the BE-EHR-CDS intervention, is a useful tool in building an intervention with institutional and clinician buy-in. Our user-centered approach to design yielded a behavioral economics driven CDS module with relatively high engagement by clinicians. The incorporation of behavioral economic principles into EHR CDS tools shows promise as a strategy to improve guideline adherence by addressing stubborn barriers, such as alert fatigue and poor compatibility with workflow, that can prevent CDS from having the desired impact on clinician behavior.

A pilot study incorporating finalized versions of the three module components developed and implemented in this vanguard phase as described here, along with additional components, is recently underway in 4 additional clinics. New module components include, for example, an email message to be sent to clinicians by clinic medical directors with content leveraging the behavioral economic principle of social comparisons (comparing their proportion of patients within CW A1c target range with that of peers at their clinic and institution wide) has been developed and will be sent out monthly throughout the 6 month pilot period.

The proposed BE-EHR module serves as a highly scalable platform for embedding a BE-based CDS into any EHR system. Importantly, this module can be easily applied to many other conditions in older adults and other populations where combining BE with EHR-based clinical decision support will be useful for improving guideline adherence such as CW recommendations related to preventative screening procedures (e.g. colonoscopies), or increasing compliance to tobacco cessation.

Limitations

While the design of the BE-EHR module reflects input from a large number and wide variety of key informants and end users, utilization numbers reflect only the two vanguard practices. This is appropriate, however, for a development phase of such a project and in line with the user-centered design approach which values early, iterative feedback prior to widespread tool deployment. Additionally, key informant and group interviews were recorded with field notes taken by research staff rather than audio-recorded and transcribed. This was a conscious decision by the research team to serve the quick CDS development timeline and to allow for rapid iteration of module components. Finally, measurement of user engagment with or adoption of the module components is difficult given they are built, by design, not to be interruptive (requiring user interaction to resolve); process metrics collected therefore focus on opportunities for users to view module components.

Conclusions

The resulting BE-EHR module establishes a platform for exploring the ability of BE concepts embedded within the EHR to affect guideline adherence for other CW target areas. Moreover, it represents an exciting new channel for influencing provider behavior through less cognitively burdensome methods. Evidence and lessons learned from this study can potentially inform the design, testing, and implementation of similar interventions for other CW target conditions and beyond.

Abstract

Patient safety is a critical component of health care services; however, it has beent mostly conceptualized for the hospital sector. As home health care expands, it is important to examine the concept of patient safety in the home and identify opportunity for personal health information management (PHIM) tools to support and maximize patient safety. The goal of this study is to explore how PHIM can be a facilitator for patient safety in the home. We explore a comprehensive framework of patient safety in the home and identify the role of PHIM in this context. We analyzed the coded transcripts of in-depth interviews with 88 older adults (60 year and older), 56 family members or informal caregivers and 27 clinicians. Findings demonstrate the physical, emotional, social and functional dimensions of patient safety in the home and concrete ways for informatics tools to maximize safety aspects.

Keywords:

Patient Safety; Home Care Services; Health Records, Personal

Introduction

Home health care is the fastest growing segment of the US health care system with a rapidly increasing number of patients receiving care services in their home and a well-documented shift from acute to home care for patient populations across the lifespan. As patients with complex needs and their families are faced with challenges of care coordination in the residential setting, patient safety in the home needs to be examined to identify barriers and facilitators in this unique context. A significant body of literature has examined patient safety in clinical settings, mostly in the hospital setting, and various frameworks and instruments have been developed to define, measure and track patient safety in in-patient settings. Less emphasis has been placed on a formal examination of patient safety in the home setting, although recently more efforts are underway to address this area.

As Lang et. al. [1] point out, applying the notion of patient safety as conceptualized for the hospital sector (with a sole focus on error detection and adverse events) is too narrow and therefore, insufficient for home care. Safety in the home setting requires a broader definition to acknowledge the complexity of health conditions, residential settings and family dynamics and the unregulated and at times unpredictable process of health care delivery within the home. There are structural and procedural differences between the hospital and home setting that affect patient safety considerations. One example is the fact that home health staff often work alone in the field during a home visit with support resources available remotely (in contrast to clinical teams within the hospital that operate as teams of care physically co-located). Often, physicians rely to home care nurses to make assessments and communicate findings while they may have little or no direct contact with patients. Home health care nurses spend more time on documentation and addressing reimbursement issues than hospital nurses [2]. Additionally, patient autonomy is respected in both settings but overseeing the implementation of a behavioral or pharmaceutical or other intervention varies based on the opportunities for observation and reinforcement. Medication adherence is one such area where hospital-based care may be more effective in eliminating barriers. Patient variables such as reading skill, cognitive ability and financial resources have been found to affect patients' ability to safely manage medication regimens in the home [3] whereas these parameters are less instrumental in effective medication administration in the hospital setting. Finally, family members often play an essential role in the health care of a patient in the home and need to play an essential role in the discourse on patient safety [4]. As significant elements of the health care services delivered to patients become responsibilities of family or informal caregivers, challenges arise related to training, supervision, competencies and information flow during transitions of care that require coordination across multiple stakeholders and settings of care.

Efforts to address patient safety in the home include initiatives that target specific aspects of home care such as fall prevention [5], medication management [6], unplanned hospital admissions [7], functional outcomes [8], wound [9] and pressure ulcer management [10]. However, a more comprehensive conceptualization of patient safety in home care is needed in order to identify opportunities for tailored interventions. Lang has developed a model to outline four dimensions of safety in the home [11]: The physical dimension involves the physical attributes of the home care setting, including environmental hazards such as home layout and infrastructure, clutter, and unsanitary conditions. Key processes of care that affect home safety — medication management, infection control, nutrition, fall prevention, complex clinical care, and care coordination — are also included in this category. The emotional dimension of home care safety involves stress, trauma, and discomfort related to receiving and providing care. Finally, the social and functional dimensions of home care safety involve the community and the network of support, and the effects of health conditions on activities of daily living [12].

As with any health care process, delivery of care in the home setting involves information gathering and exchange among various stakeholders and between different systems of care. Home care patients and their families are called to manage personal health information generated from multiple sources and often between systems and across sites of care facing challenges of interoperability and threats to continuity of care. Personal health information management is critical to ensuring care coordination and high quality of care and affects all four dimensions of patient safety.

Personal health information management (PHIM), defined as the entire set of activities that "support consumers' access, integration, organization, and use of their personal health information" [13] is at the core of patient safety considerations in home care where care transitions, personal relationships, unsupervised caregiving work, and environmental attributes introduce unique challenges. The goal of this paper is to explore how PHIM can be a facilitator for patient safety in the home. We aim to discuss a comprehensive framework of patient safety in the home and identify the role of PHIM in facilitating patient safety based on a secondary data analysis of interview data with community dwelling older adults to highlight these considerations.

Methods

We conducted a qualitative analysis of interview data using the theoretical framework by Lang et. al. [11] to highlight the underlying elements of patient safety in the home. The qualitative data were generated as part of the SOARING study (soaringstudy.org), a five-year investigation of the personal health information needs and practices of adults 60 years and older living in a metropolitan area in the Pacific Northwest in the United States. The SOARING project focuses on information needs and personal health information management of older adults; patient safety in the home is not examined in that parent project but its large data set is used for a secondary analysis for the patient safety focus of the study presented here. Secondary data included interviews conducted over a three-year period with older adults and their friends and family members that were involved in their health and health information management [14]. Interviews focused on health, health information seeking, technology use and health information management. Purposive sampling ensured a diverse representation of gender, living situation, race, and income. Living situations included independent living, retirement communities, assisted living and homelessness. Inclusion criteria for participation included age 60 or over, ability to communicate in English, and lack of cognitive impairment. Additionally, interviews were conducted with health care providers who provide care to older adults. The interview protocol covered a broad range of topics including needs and preferences pertaining to personal health information management, and the personal stories of aiming to maintain independent aging. We analyzed the coded transcripts which were collected from in-depth in person interviews with 88 older adults (60 year and older) and phone interviews with 56 identified by older adults as friends and family who were involved in their health and health information management, and 27 clinicians (physicians, nurses, social workers). Older adult participants had an average age of 76 years, were predominantly female (69%), and white (72%). In terms of living arrangements, they lived in various settings: in independent private residences (25%), independent-shared dwellings (27%), retirement communities (27%), assisted living facilities (19%), and homeless (2%). The content analysis was informed by the theoretical framework by Lang et. al. [11] in order to highlight the underlying elements of patient safety in the home. We reviewed transcripts for their pertinence to patient safety issues in particular along the dimensions of care (physical, emotional and social and functional). For each of these themes we described the role of information technology as a patient safety facilitator.

Results

Table 1 provides a summary of the dimensions of patient safety in the home with example quotes from our corpus of qualitative data generated by interviews with older adults and their families and providers demonstrating instances where a specific dimension may become a challenge for patient safety.

The use of the framework by Lang et. al. [11] enabled us to confirm its validity by identifying the underlying dimensions in our own data and also inform how PHIM may become a facilitator in that context. The physical dimension of patient safety in the home context includes multiple sub-themes. There are numerous key processes of care that may include safety risks when information flow or oversight are deficient. These processes include medication management, infection control, fall prevention, nutrition, complex clinical care coordination and transitions of care. Challenges associated with medication management and adherence have been well documented and are expected to intensify with aging as patients may experience cognitive or functional limitations [15]. The physical dimension also includes environmental hazards that pertain to aspects such as the home infrastructure and physical layout of the residential space as well as potential clutter.

The emotional dimension of patient safety includes concepts such as burden, stigma, self-view, confidence and resilience, all psychological constructs that affect self-efficacy, communication and coping, ultimately impact patient autonomy and safety.

The social dimension includes elements such as family and community support and social isolation and loneliness. As Lang notes, patients may face increased risk to their safety simply because of the desire to remain at home "at any cost." Illnesses bring about inherent limitations in daily functioning, which may multiply as an illness progresses. However, the extent to which safety risks increase, and for whom, is a function of the patient's social matrix.

Finally, the functional dimension of patient safety includes numerous potential limitations such as visual, hearing, mobility, and cognitive limitations that may affect one's ability to safely manage their health condition in the home and the degree to which assistance or additional tools may be necessary to safely execute health related procedures and tasks.

Discussion

Our findings validate the dimenions of patient safety in the home setting as outlined by Lang's framework [11] and demonstrate how information management may act as mediator for these patient safety attributes. Informatics can play a role in facilitating information flow and exchage among

stakeholders to address and maximize patient safety. Various informatics tools such as passive monitoring sensors, personal health records, wearables, symptom management tracking and reporting apps can support the physical, emotional, social and functional dimensions of patient safety. Patient and family characteristics, available resources and the participating entities in transitions of care and coordination of services have to be considered when designing strategies to safeguard patient safety in home health care. Additionally, our findings demonstrate that home care patients may often struggle with information management challenges while trying to cope with complex care needs. Educational initiatives to increase awareness of patient safety among clinicians, family members and patients themselves can be tailored to address the unique challenges and opportunities as outlined in this framework. System designers can integrate informatics elements into the system overall functionalities to promote safety and well-being of home care patients. Personal health records and other PHIM tools may benefit from incorporating a patient safety perspective in their design in order to improve processes of health care and meaningfully engage or even empower home care patients and their families.

Conclusions

The findings of this qualitative analysis demonstrate patient safety concerns and challenges as experienced by older adults, family members and health care providers. Patient safety in the home needs to be examined beyond previous work that has defined and measured safety solely in the hospital setting. This is to our knowledge the first comprehensive inquiry of patient safety as a broad concept in the home setting engaging multiple stakeholder groups and examining the potential of informatics tools to serve as safety facilitators. Personal health information management and informatics tools can be implemented to promote patient safety in an inclusive approach that covers the physical, functional, social, emotional and social dimensions of patient safety. Our findings can inform the design of tailored patient safety interventions in home health care.

Table 1– Dimensions of Patient Safety in the Home in the Context of Personal Health Information

Safety Dimension		**Definition** *Selected Participant Quotes* *OA-Older Adult Participant* *P-Provider* *FC-Family Member)*	**Informatics tools as facilitators**
Physical	Medication Management and Adherence	Challenges include risks for wrong dosage, missed dosage, wrong medication, side effects, administration of medication *So knowing what their* [patients'] *medicines are, is actually a huge barrier. I literally have to track down their mental health provider. Page, call, recall, receive faxes, take phone calls, just so that I can get a med list.* (P)	IT tools to provide: • Reminders • Automatic dispensing • Tracking of medication administration • Communication of adherence challenges • Notifications • Reporting of Side Effects
	Infection Control	Challenges to infection surveillance, prevention and control in the home setting can jeopardize patient safety and well-being. Tools are needed to measure and study the risks for home-care acquired infections (including valid definitions, measures and tools for surveillance). *Another thing I'm starting to do is infection control. I need to start tracking who has infections that mostly is communicable, like flu or pneumonia, or something like that.* (P)	IT tools that track: • Physiological variables associated with infection (e.g. temperature) • Photographic or video-assessment of wounds or other infection sites • Access to information • Symptom tracking and reporting
	Fall Prevention	Falls are a major risk for home care patients, especially frail elderly patients and those with rehabilitation needs after a major health event. *a fear of falling because I know that – I've – it's been several years since I fell, but I've fallen twice and the older I get, the less inclined I – I mean the more inclined I am to not want to fall anymore because – yeah. I mean your bones get more brittle and I don't want to break anything, let alone a hip. So yeah.* (OA)	IT tools to facilitate • Fall Prevention (e.g., motion sensors to detect mobility patterns, gait monitors to assess gait characteristics over time) • Fall Detection (e.g. sensors that detect weight and pressure, acoustic sensors that register fall, wearables that track falls)
	Nutrition	Nutritional needs may have a great level of complexity. Considerations include nutritional guidelines informed by the diagnosis or symptom management needs of the patient as well as potential challenges in accessing and preparing meals that adhere to specific dietary restrictions (including potential practical barriers to grocery shopping, transporting and storing food items, meal preparation and feeding). *If we plan to do something, we need to know when he needs to eat. Or we're always arranging any activities around the schedule of his insulin and his dietary needs also. We're aware of that, so if we're cooking or – we're all watching him because we know the signs now of when something's not right.* (FC)	IT tools that facilitate • Tracking of dietary choices • Access to information about nutritional values • Reminders

Table 1 (cont.)

	Care Coordination and Transition	Patients with complex care needs experience transitions from various care settings (e.g., discharge from hospital to a rehabilitation site to home health care) and challenges include barriers to information flow across settings. Missing or incomplete information and lack of coordination may introduce significant patient safety risks. *But it has happened several times that I'd come home and find him unconscious on the porch, … he's had an incident with his insulin. And so, I've asked them to please give me the information or tell me what they want me to do or what we're supposed to do.* (FC)	IT tools that provide a platform for access, sharing and transferring of data sets across stakeholder groups and systems of care
	Environmental Hazards	Environmental hazards include elements of the home infrastructure and physical layout, challenges of clutter in the home and unsanitary conditions. The actual residential infrastructure may introduce risks to patient safety. Infrastructure elements may include attributes such as temperature, light and level of accessibility that may hinder or pose a risk as residents carry out activities of daily living. *I wish I had a bath tub instead of a shower so it's a sit-down shower and that's just hard for me.* (OA) *I mean, her apartment is such a mess. So, that's another thing that can interfere with people's ability to keep track. They absolutely don't know where anything is.* (P)	IT tools that facilitate environmental scanning and assessment to identify accessibility issues as well as ongoing monitoring of hazards or triggers for adverse events.
Emotional	Emotional Challenges	Emotional challenges such as lack of confidence and resilience, issues of self-view and perceived stigma of frailty or vulnerability may affect the ability of a patient to engage in effective disease management to maximize patient safety. *But I had this terrible night where I really wanted to die –my daughter is still kind of out there somewhere. She texts me, but I don't see her anymore and I really wanted to die.* (OA)	IT tools to promote assessment of mental health issues and psycho-social aspects of mental health and well-being
Social	Social Support	Social support includes family and friends and other community members who interact with a home care patient and can provide practical or emotional support. Lack of social support may lead to isolation and loneliness, both linked to disease trajectory and clinical outcomes and as such may affect overall patient safety. *It occurs to me that that's probably something if you can help the patient to understand how necessary it is that the people around them have a list of what to watch out for and what to do about it.* (FC)	IT tools that facilitate: • virtual connections and social interactions with friends and family • sharing of information, messaging, communication • assessment of ongoing social interactions, visits, calls and detection of trends of social isolation • tools to promote social inclusion in virtual and physical communities
Functional	Functional Limitations	Functional limitations (including visual, hearing, mobility and cognitive limitations) may affect patient safety as they can interfere with the ability to independently carry out activities of daily living and also engage in disease management and symptom control activities. *The fire alarm going off and me not being able to go up and down the stairs that well because you can't use the elevator.* (OA) *And I have come in here and the stove has been left on. That's very scary to me.* (FC)	Informatics solutions that provide audio-assistance such as voice-interfaces to process visual information, that facilitate hearing aids or provide alternative (such as visual) displays of information, and cognitive orthotics (reminders, voice-interfaces to provide contextual information for activities)

Towards Emotion-Sensitive Conversational User Interfaces in Healthcare Applications

Kerstin Denecke[a], Richard May[a], Yihan Deng[a]

[a] Bern University of Applied Sciences, Institute for Medical Informatics, Bern, Switzerland

Abstract

Perception of emotions and adequate responses are key factors of a successful conversational agent. However, determining emotions in a healthcare setting depends on multiple factors such as context and medical condition. Given the increase of interest in conversational agents integrated in mobile health applications, our objective in this work is to introduce a concept for analyzing emotions and sentiments expressed by a person in a mobile health application with a conversational user interface. The approach bases upon bot technology (Synthetic intelligence markup language) and deep learning for emotion analysis. More specifically, expressions referring to sentiments or emotions are classified along seven categories and three stages of strengths using treebank annotation and recursive neural networks. The classification result is used by the chatbot for selecting an appropriate response. In this way, the concerns of a user can be better addressed. We describe three use cases where the approach could be integrated to make the chatbot emotion-sensitive.

Keywords:

Conversational user interface, sentiment analysis, deep learning, natural language processing

Introduction

A fundamental shift in healthcare takes place, driven by an aging population and the increasing incidence of chronic conditions that are induced by behavior. Changing individual behavior is increasingly at the center of healthcare. The reactive system where a patient's acute illnesses are treated is evolving to a treatment more centered on patients, prevention, and the ongoing management of chronic conditions. Beyond, mobile health applications are increasingly used by patients offering the opportunity to collect health data, to continuously monitor the personal health and to be accompanied by a personal health coach all over the day.

To realize such applications, conversational user interfaces (CUI) gained in interest for mobile health applications in the last years [1]. Different terms have been used for a conversational user interface or agent such as: chatbot, machine conversation system, virtual agent, dialogue system, and chatterbot. A CUI-based system is a computer program that interacts with users using natural language (written or spoken). The purpose of such system is to simulate a human conversation. There are two types of chatbots: Unintelligent chatbots interact using a predefined conversation flow. Intelligent chatbots use machine learning to automatically generate responses on the fly. The chatbot architecture integrates a language model and computational algorithms to generate an informal chat communication between human and computer using natural language. Interacting with intelligent agents is not a new topic, but reliable linguistic functionality, availability as services and inclusion of intelligence through machine learning and deep learning has increased its popularity.

CUI have been used in health related applications for example to achieve a health behavior change [2] or to support disease self-management. Lokman and Zain [3] introduced a chatbot that serves as a virtual dietitian for diabetic patients. The chatbot asks questions and gives at the end a diet advice suitable for the current diabetic situation. The conversation is going along a path that is remembered by the system to consider all answers in the decision making.

Similar to this virtual dietitian, the majority of existing medical chatbots only allows for constrained user input (e.g. multiple choice of several options instead of natural language input) to avoid misunderstandings that can occur within natural language interpretation. However, a more realistic, natural interaction requires a natural language user interface without predefined answers, but with integrated information extraction and natural language processing capabilities to recognize and interpret the content correctly. In this work, we are focusing on such chatbots with unconstrained natural language input capabilities. In these applications, users communicate with the system in their own words. In this way, it is possible to express personal emotions and sentiments in certain situations, for example when a person is not feeling well. However, this requires CUI-based applications that can analyze and interpret emotions from user input which are so far rarely available.

The objective of this work is to introduce a concept for analyzing emotions and sentiments resulting from interactions with a CUI. More specifically, our ultimate goal is to equip a health chatbot with capabilities to determine emotions and sentiments expressed in a chat with a CUI-based application in order to better focus suggestions and to increase the impact of recommendations of the application on the behavior of a user (e.g. increase compliance, react on negative emotions).

The main questions addressed in this paper are:

- How emotion and sentiment analysis could be integrated in mobile health applications with CUI?
- Which use cases exist for emotion-sensitive CUI in healthcare?

Conversational agents and sentiment analysis

There are several mobile health applications using CUI available. Some of them have been studied with respect to efficacy in clinical trials; most of them not [1]. Amoto et al. [4] introduced a chatbot-based recommender systems HOLMeS (Health On-Line Medical Suggestions). The system is designed to autonomously interact with a user by understanding natural language in a chat and acting as a human physician. It provides general information on itself or the affiliated medical center, collects patient information and enables a patient to book an

appointment in the affiliated medical center. It is implemented using the IBM Watson Conversation Service and trained via the Bluemix platform. VPBot, a SQL-based chatbot that simulates a patient that medical students can interview. VPBot was successfully exploited in Harvard Medical School's virtual patient program [5]. In such use cases for education or information provision, emotions and sentiment are not extremely relevant or do not even occur. Emotion and sentiment in this context comprises subjective, emotional statements e.g. description of the health status ("I am feeling well"), outcome of a treatment or experiences with it ("The therapy session was helpful"), emotions ("I feel enirely loss").

However, there are use cases where it becomes essential to identify and analyse expressions bearing emotions. Woebot [6] is a chatbot designed for supporting cognitive behavioral therapy. The chatbot allows to enter emotions by selecting terms from a list of suggestions. This limits the user to comprehensively express his or her actual emotions and feelings. In that case, natural language processing and sentiment analysis could be very useful to assess and address the user's mood and situation carefully. When it comes to mobile applications that aim at encouraging behavior changes, behavior models and motivation strategies have to be considered.

Aberg [7] analyzes different motivation strategies realized as chatbots as a mean to motivate people to live more sustainable lives. The effect of motivational factors from behavioral psychology were tested, and as well as the impact on people's food consumption habits. The findings of this paper were based on three chatbot prototypes; one that is built on the motivational factor of information; a second one that is implemented on the motivational factor of goal-setting, and a third one that follows the motivational factor of comparison. The result from the user interviews indicates that chatbots can affect and motivate people to consume food in a more sustainable way.

Analyzing emotions and sentiments resulting from interactions with CUI has so far only rarely been addressed. There are multiple ways to enable a chatbot to choose an emotion category for a response. On the one hand, the chatbot can be equipped with a personality and background knowledge. On the other hand, training data can be used to find the most frequent response emotion category for an emotion in a given response and use this as the response emotion.

Previous research by Skowron proposed affect listeners, i.e. conversational systems that can respond to user's utterances on a content-, but also on an affect-level [8]. Zhou et al. [9] describe an emotional chatting machine that can generate appropriate responses fitting in content and emotion to a user's response. The architecture consists of a recurrent neural network enabled with GRU cells with attention mechanism. It contains three different mechanisms for generating responses with a specific emotion: External knowledge serves to model emotions explicitly using an external emotion vocabulary. Internal memory captures emotion dynamics and finally, different emotion categories are represented as embedded vector. Socher et al. introduced a sentiment treebank that includes fine grained sentiment labels for parsing trees of sentences. On this treebank, they applied recursive deep models to predict sentence level sentiment. With a relatively complicated treebank annotation, the proposed method has better recognized the negated sentiment and achieved more than 80% overall accuracy [10].

Sentiment and emotion analysis in a medical context has been mainly addressed for web content. Denecke and Deng reviewed the state of the art and studied the challenges of sentiment analysis in medical settings [11]. They found out that given the varying usage and meanings of terms, sentiment analysis from medical documents requires a domain-specific sentiment source and complementary context-dependent features to be able to correctly interpret the implicit sentiment. The challenges of sentiment and emotion analysis in health chatbots have not yet been considered so far. Further, health applications equipped with emotion and sentiment analysis are still missing. In contrast to existing work, our aim is not to create a chatbot that formulates its responses with certain emotion terms, but to develop a method to analyse a user statement to select an appropriate, motivating or encouraging response given a specific user emotion.

Material and methods

Synthetic intelligence markup language (SIML)

SIML, pronounced "si mal", is used to build the chatbot's brain in our application (https://simlbot.com). It is a derivative of Extensible Markup Language (XML) and is able to react to user input, collect and manage data, learn from it and generate new content for conversations. The official parser was developed for C# and can be used on all Windows platforms supporting .NET Framework 4.5 or higher as well as under Linux and Mac (Mono). SIML contains two specifications: SIML Classic and SIML Modern/OSCOVA. All specifications are interpreted differently and are aimed at different target groups. SIML Classic is used in our application because we resist on using internal natural language processing as SIML Modern offers.

In SIML, all data is arranged in the form of a large decision tree and can be addressed by pattern matching. SIML files consist of a large number of tags. The basic structure is created by concepts and models, which are enclosed by the SIML tag. Concepts are the basic unit of knowledge storage in SIML. Each concept is a rule for matching an input and converting to an output, and consists of a pattern, which matches against the user input, and a response, which is used in generating the chatbot answer. In SIML, it is possible to use regular expressions and loops within a model, to interpret JavaScript and to create own tags to call specific methods of the program code. Another function of SIML is the usage of mappings which we will use to select an appropriate response for a user statement containing emotions and sentiments.

Sentiment and emotion analysis

Traditional sentiment analysis approaches classify texts or sentences according to their overall sentiment which can be positive, negative, neutral or even have more fine-grained sentiment categories. They often base upon a bag of word representation. Additionally, the polarity shifting and syntactic structures are transformed into rules to regularize the composition of sentiment at sentence level. However, the performance of bag of words based methods has not reached an accuracy of 80%.

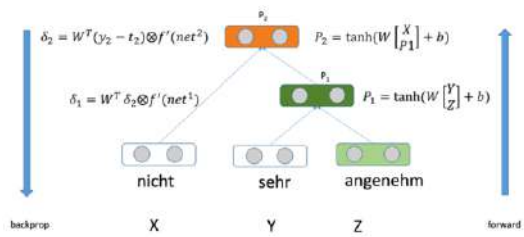

Figure 1. Compositional function of recursive neural networks and backpropagation of errors. Light green color indicates the positive polarity of joy, dark green represents intensified polarity and joy while orange shows negated polarity of joy.

A tree-based composition of a sentiment treebank has been proposed by Socher et al. [10] in order to improve the accuracy. The recursive neural network that is used in their approach requires a well-formed tree annotation corpus as training data. A recursive neural network is a type of deep neural network created by applying the same set of weights recursively over a structured input, in this case a linguistic parse tree of a sentence. The annotation of a sentiment treebank is quite laborious and sophisticated, since the polarity of the sentence (polarity at root) must be determined by a composition of all subtrees. The annotator needs to judge the polarities at different levels and provides also an overall value to the tree root. Our approach for an emotion analyzer is inspired by the work of Socher et al. [10], see Figure 1 and 3.

The classification of user statements in the context of a chatbot is an important step for automatic, appropriate answering of user statements by a chatbot. The concrete task is to categorize a user statement into predefined emotional categories. We currently employ seven axes of emotions (disgust, joy, surprise, anger, fear, sadness, contempt), see Figure 2. The polarity is transformed to a respective emotional tree. For each emotion class, a treebank classifier is trained. The emotion of one sentence is represented as the following polarity vector:

$P_i = (x_{anger}, x_{disgust}, x_{joy}, x_{surprise}, x_{fear}, x_{contempt}, x_{sadness})$

where P_i represents the i-th user statement of the chatbot conversation. The value x represents the normalized strength of the emotion where we distinguish 3 classes (low, medium, high). To obtain a vector of polarity for a user statement, seven instances of the classifier based on recursive neural networks pass through the seven polarity treebanks for initial pre-training.

Before the classification starts, the user statement is linguistically parsed into a syntactic tree. Each node of the tree is represented by word vectors learned from a corpus of German Wikipedia and medical forum entries. During training, one feedforward step is conducted to learn the structure (bottom-up) whereas a back-propagation step is performed to adjust the errors (top-down).

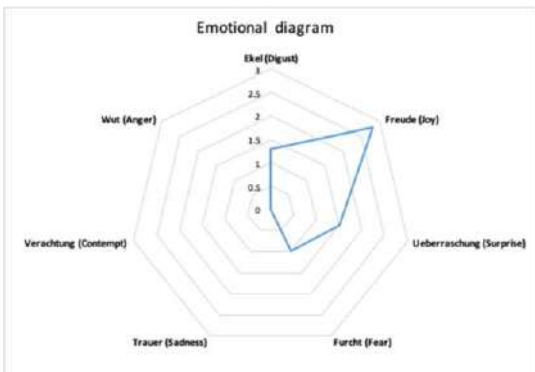

Figure 2: Emotional diagram with seven axes: disgust, joy, surprise, fear, sadness, contempt, anger

In Figure 2, we can see one example of recursive neural networks that we will apply for the emotion detection. The leaf nodes represent the emotion-related terms in the parsed sentence. In this example, the polarity of "angenehm" (pleasant) has been intensified by "sehr" (very) and finally negated by "nicht" (not). Apparently, the syntactic tree has better represented the semantic scope with negation. For the negation parsing, we have chosen FastContext[1] [12] with German negation corpus.

The objective of the optimization is maximizing the probabilities of the correct prediction while minimizing the cross-entropy error between the predicted distribution y_i and target distribution t_i. For the classification into one of the three polarity strength classes, the posterior probability over labels given the word vector via $Y^x = \text{softmax}(W \cdot X)$

where $W \in \mathbb{R}^{3Xd}$ is the emotion classification matrix.

Results

Concept for an emotion-sensitive chatbot

Our concept for integrating emotion analysis into a SIML-based chatbot is shown in Figure 4. A user input resulting from an interaction with the chatbot application is analyzed by the above mentioned emotion analysis algorithm. The resulting polarity vector with strength per emotion class is used to select the corresponding answers based on predefined selecting metrics. SIML mappings assign an emotion label after receiving the emotion vector. Depending on the emotion, we use loops within the models to find matching answers to the user input in the chatbot's knowledge base. These answers can be randomly selected from a pool of matching answers to make the conversation more natural. The answer is displayed on the user interface of the application. In this way, the conversation can be continued coherently considering the emotional fluctuation of users. At the current step, we focus on recognizing the primary emotional polarity of a user input. For treebank construction, we will select 100 sentences for each of the seven classes of emotions (see Figure 3) and parse them into a tree structure. These tree structures will afterwards be annotated with polarity values ranging from 1 to 3 by human annotators.

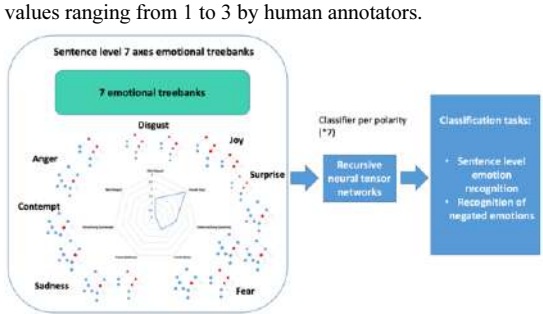

Figure 3. Training of the emotion analyzer based on annotated treebanks

Use case scenarios

Traditional models of care delivery basically base upon face-to-face interactions between clinicians and patients. However, new technologies are augmenting this interaction model and fundamentally transforming the ways in which clinicians deliver care to individuals. Mobile apps, for example, can facilitate tracking and monitoring. These remote and self-care-oriented technologies may help creating a truly interactive healthcare ecosystem for patients. The following use cases base on mainly two paradigms: Engaging individuals by interacting with a CUI and utilizing remote and self-care-oriented technologies to support and empower individuals. Emotion and sentiment analysis will help to realize these two paradigms.

[1] https://github.com/jianlins/FastContext

Addressing concerns during medication management

eMMA, the electronic medication management assistant [14], is a mobile application to support in the medication management. In its current version, it is designed to collect compliance information from a patient, to provide information on interactions between food and medications and to answer his or her questions on the medication [14]. Equipping eMMA with capabilities for automatically recognizing and classifying concerns of a user mentioned in the application could help to address appropriately the concerns of the user. In this way, the compliance could be improved. The chatbot will not convince the user, but recognizes concerns which are stored for discussion with the physician and provides information for engaging the user to take the medication as recommended by the physician. In case the system detects serious concerns and symptoms, it could suggest to contact the physician.

Addressing problems and concerns during self-anamnesis

Ana is a system for collecting the medical history within the context of music therapy using a CUI [15]. Equipping Ana with emotion and sentiment analysis capabilities would enable the system to identify situations when the user runs into problems and concerns because of the questions he or she has to answer. In a usability study with that system [15], the users confirmed, that they liked the possibility of entering free text to communicate with the chatbot. However, they asked for better interactions with the chatbot, in particular when she states that she is not feeling well. Such expressions could be detected and analyzed by our method for providing an appropriate reaction.

Determine cognitions and suggest behavior changes

Another use case is to recognize the tone of a client's response to suggestions made by a chatbot. The suggestions might be for example therapeutic suggestions within a mobile cognitive behavior therapy (CBT) or motivational suggestions within a mobile application targeting at achieving a personal health goal. Within the HABIT project, a mobile application for CBT has been developed that uses a chatbot interface for delivery of CBT [16]. CBT shares the idea that behavior change may be affected via cognitive change [17]. A chatbot system for CBT requires facilities to assess a client's mood overall, or the tone of the response to a particular suggestion in the therapeutic chat. For example a negative answer, high emotional, neglecting a suggestion of the therapist might be interpreted as low acceptance of the immediately prior recommendation. Our emotion analyzer could support in automatically analyze the responses of a user, supporting the therapist in analyzing the chatlog afterwards or enabling chatbot responses that address these moods and tones of user statements.

Discussion

In the general domain, the objective of enriching a chabot with emotions is to achieve a more human-like interaction style. In contrast, in our scenarios the objective is to determine the emotion of a patient for future interpretation by the treating physician or by addressing concerns directly by the chatbot.

Sentiment analysis in the medical domain differs from sentiment analysis in other domains [11]. We address this fact, by training the treebank classifier on a data set of health-related content. Additionally, health-related lexicons could be integrated in the parsing process. Asgar et al. [18] suggest a bootstrapping model and a dataset of health reviews to learn a health-related sentiment lexicon. Rane et al. introduce their concept for using sentiment analysis to improve emotional health of a user [19]. More specifically, they analyze the sentiment or emotion of a user and display specific media to counter the emotion. They used a Naïve Bayes classifier based on supervised learning that was trained on a twitter data set. Besides the different technology, our approach aims at considering the peculiarities of sentiment in the health care domain, which is lost when training is realized with a non-domain-specific data set.

The use of ontologies to support interpretation of several types of data (audio, video, and text) from a chatbot's environment has been analyzed in previous work. Formal concept-based rules are suggested to express affective behavior aiming at improving the empathy of bots [12]. The proposed technique relies on semantic technologies such as OWL and SWRL languages. Affective states are exploited to improve the bot's empathy in the interaction based on an emotion ontology. In a chatbot conversation, user statements might be short. This makes it even more challenging to find appropriate methods. It is still unknown to what extent the previous statements in a conversation and the user context can contribute to the interpretation of expressed emotions.

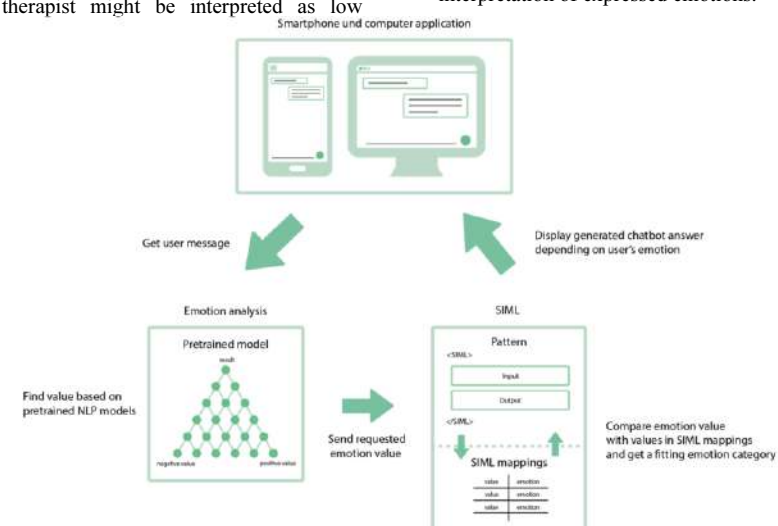

Figure 4: System architecture

Conclusions

In this paper, we introduced a concept for an emotion analyzer for natural language statements as they result from a chatbot conversation. This approach is currently implemented. In future work, we will evaluate the above mentioned method. For this purpose, we will compare the recursive neural networks with the traditional kernel based method in terms of sentence level polarity recognition and the detection of negation. We will run the sentiment analysis using SVM or convolutional neural network on the sentence level annotation to serve as benchmark [20]. Further, we will extend one of the introduced mobile applications with the emotion analyzer.

Abstract

A learning management system (LMS) used for the initial training of health professionals has been rejected by students. Our study aimed to explain the reason of this rejection. We performed this evaluation on a sample of health students in 2012 and 2017 (n=144). We used scales from the literature (Technology Acceptance Model, General Self-Efficacy Scale, LMS-Self-Efficacy Scale), and studied the social representation of the LMS. The system seemed accessible and useful, but unfortunately with similarities to the system used in a traumatic student environment. Health students using the system did not have a lower self-efficacy. Although the LMS seemed relevant to students, its initial rejection might have been due to a confounding context that created confusion in the acceptability of the tool. To conclude, there is a need to create new dematerialized course formats but with strong tutorship to improve the usage of the technologies by students.

Keywords:

computer-assisted instruction, educational models, medical education.

Introduction

Context

In France, the first year of health studies contest (PACES in French) is stressful and typically is aimed to be a highly selective filter, which is not the optimal means to encourage learning [1]. This first year ends with a ranking examination that is used to select around 10% of students to continue their studies in the health disciplines of either medicine, midwifery, pharmacy, or dentistry. In 2006, the members of the advisory board of Grenoble Medical School decided to change the pedagogical paradigm to assure more fairness and improved learning for health students during PACES.

Since 2006, the paradigm is a blended-learning system that includes flipped classrooms [2]. This is a stepwise program on a 4-week cycle (Fig. 1). For example, on week 4 of the university calendar, students learn the knowledge capsule of the 4th course on their Learning Management System (LMS), they ask online questions to the lecturer of the 3rd course of the year, they participate in face-to-face explanations with the lecturer of the 2nd course of the year, and they manipulate the concepts of the first course of the year that have been learned during the first three weeks.

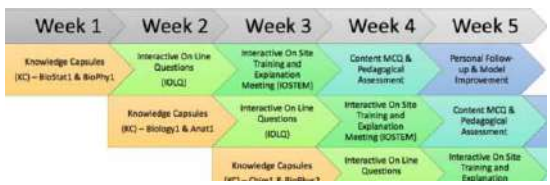

Figure 1– Stepwise learning method in sequences of 5 activities

Between 2011 and 2017, all the curricula of health studies in Grenoble were reformed in the same way (medicine, pharmacy, midwifery, and paramedical studies). However, the initial reactions of staff differed to those of the students. For example, students found this LMS was not appropriate; particularly the students of year 2 who stated that using this LMS created social isolation [3]. Students also declared that they felt themselves inefficient while learning Knowledge Capsules. But the teaching staff found the Knowledge Capsules relevant during face-to-face sessions. These two different feedbacks prompted us to consider the link between the acceptance of the LMS and students' self-efficacy. Our main objectives were to understand the initial rejection of the LMS and to improve this pedagogical method used by more than 5,000 health students.

Concept: Acceptance

The "Technology Acceptance Model" (TAM) described by Davis [4] proposed a model of the way that users accepted and used an information system in order to diagnose design issues. This model has been validated in distance learning contexts [5]. Davis defined the perceived usefulness as the degree to which a person believes that using a particular system will enhance job performance. He defined the perceived ease of use as the degree to which a person believes that using a particular system will be free from effort. These two concepts impact on the user's intention to use the system.

According to Venkatesh and Davis [6], the use of information and communication systems by professionals depends on a subjective standard, which is the perception by the user that the group to which he belongs considers that he should, or not, use the system. They suggested TAM2, a model derived from TAM, as adapted to mandatory use contexts. It is therefore particularly suitable for health students in Grenoble, since it is mandatory for them to use their LMS as part of their studies.

Concept: Self-Efficacy

General Self-Efficacy covers all the tasks that a health student is required to do during his/her training and is defined by Luszczynska [7] as "the belief in one's competence to tackle novel tasks and to cope with adversity in a broad range of stressful or challenging encounters as opposed to specific self-efficacy, which is limited to the particular task at hand". There is a benefit in correlating the general self-efficacy to the self-efficacy focused on technological tasks [8]. According to Martin et al. [9], Learning Management System Self-Efficacy is defined as self-assessment of one's skill in using the LMS. It is based on a model developed by Compeau and Higgins [10] for studying the relationship between specific self-efficacy and students' performance during distance or blended learning. Different dimensions were analyzed, including the skills in accessing courses, the skills in performing tests, the skills in synchronous and asynchronous communication and the skills in using advanced tools (blogs, collaborative work, etc.).

Hypotheses

We decided to analyze the link between the acceptability of the LMS and students' self-efficacy, its alteration between 2012 and 2017, and students' social representation of the LMS. Our assumption was that if students do not perceive the LMS as useful, usable, and acceptable, they will not perceive it as a helping and motivating tool, which could reduce their self-efficacy. We hypothesized that:

- General Self-Efficacy is poorer in students with poorer technology acceptance.
- If 2017 students have a better acceptance of the LMS than 2012 students, their General Self-Efficacy will be better.
- The social representation of the LMS is generally negative, although some aspects such as practicality may be positive.

Methods

Overview

During the PACES, students can choose to pursue studies in one to four of the health curricula proposed (medicine, pharmacy, midwifery, or dentistry). To access each chosen curriculum, the second semester of the PACES includes some specific courses and a specific ranking examination. Classically, students choose 2 or 3 curricula. When they fail to access the curriculum they prefer, their perception of the LMS could be linked to the exam failure and to variations of self-beliefs such as self-efficacy.

Participants

We decided to analyze the population with the longest experience using the LMS and a high rate of multiple choices of curricula. Students who met these criteria were year 2 midwifery students of the 2011-2012 class (those that are the closest to PACES), and all the 2016-2017 midwifery students (to study the alteration of the acceptance). Students of the years 3, 4, and 5 of the 2011-2012 class were excluded because of they did not use the LMS.

Materials

Many scales to evaluate the Technology Acceptance Models are described in the literature. Most of them were created for the evaluation of Information and Communication Technologies (ICT) tools used in business contexts. However, some [11][12] have been validated in learning contexts. These scales analyze Perceived Ease Of Use (PEOU), Perceived Usefulness (PU), and Perceived Acceptability (PA).

We also used the validated General Self-Efficacy Scale (GSES) [13] to assess general self-efficacy. We partially used the LMS-self-efficacy scale (LMSSES)[9], by retaining 12 items (of the original 24) and removing those items that corresponded to functions not offered by the studied LMS.

Finally, we used prototypical analysis to study social representations of the LMS. According to the extended TAM and the concepts that could influence acceptability of a technology, we decided to evaluate the way students think about the "job relevance" of the LMS (i.e. the way they think the LMS is useful in their student activities), and also the "results demonstrability" (i.e. the way the LMS shows them "learning results").

We used the prototypical analysis [14] to identify the semantic field linked to these concepts. From these semantic fields, students gave a value to each induced word according to the significance it had for them. They had to prioritize words in order to create a structure of the social representation with a core area, surrounding items and contrasted elements. Prototypical analysis was performed by calculating the citation frequencies and the rank assigned to each word or expression by each respondent. This analysis was represented graphically by rank and frequency.

Procedure

This study was a user-centered evaluation of the LMS, based on a self-administered questionnaire by students performed after a complete semester of blended learning. Thus, the questionnaire was presented in the week after the last exams of the first semester. This was a paper-based questionnaire for the 2012 population, and an online questionnaire for the 2017 population. Three reminders to complete the questionnaire were sent weekly and the study ended just after the beginning of the second semester.

Analysis

To validate our assumption, we had to study the population characteristics that could influence the analyzed concepts. We used the Spearman correlation coefficient, to demonstrate:

1. that perceived usefulness and perceived ease of use are correlated to the perceived acceptability, so as to validate the TAM2 model in this population;
2. that the TAM2 score is correlated to the general self-efficacy;
3. that the TAM2 score is correlated to the LMS self-efficacy; and
4. that the upper-TAM2-score students and the lower-TAM2-score students (subdivided by the mean TAM2-score of the population) present a different correlation between TAM2 and self-efficacy.

Results

The characteristics of our population are shown in Table 1. These two populations are neither comparable in terms of age nor in terms of the different studied scores, except for the GSES. Both populations have a comparable declared mastery of ICT tools.

Table 1 – Comparison between 2012 and 2017 midwife students (characteristics, self-efficacy, and acceptance scores)

	2012 Students (n=26)	**2017 Students (n=118)**	**p-value**
ICT control *median*	Good	Good	NS
Age *median (IQR)*	20(1)	22(1)	<0.001
GSES *mean (s.d.)*	2.97 (0.35)	2.97 (0.37)	NS
LMSSES *mean (s.d.)*	3.42 (0.36)	3.56 (0.43)	0.013
PEOU *mean score (s.d.)*	4.91 (1.06)	5.67 (1.06)	<0.001
PU *mean score (s.d.)*	4.19 (1.32)	5.18 (1.10)	<0.001
PA *mean score (s.d.)*	4.32 (1.17)	5.18 (1.16)	<0.001

Each tool had a satisfactory Cronbach's alpha (2012-GSES α=0.803; 2012-LMSSES α=0.744; 2012-TAM2 α=0.901; 2017-GSES α=0.764; 2017-LMSSES α=0.820; 2017-TAM2 α=0.906).

Concerning the theoretical model, correlations between acceptance and self-beliefs are shown in Figure 2. All components of the TAM2 model were correlated (0.4241<r<0.7293, p<0.01).

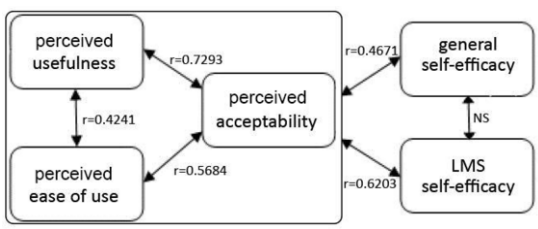

Figure 2– Theoretical model: correlation between acceptance and self-efficacy in 2012 students (p<0.01)

Upper-TAM2-score students presented better affirmed computer skills than lower-TAM2-score students (Good vs Deficient, p=0.005) and higher LMS-self-efficacy mean score (3.57 vs 3.2, p=0.003). These groups were similar in terms of mean age, sex, affirmed regular use of internet, and the mean general-self-efficacy score. Finally, there was no correlation between the TAM2-score of each group and their self-efficacy (r=-0.0405, p=0.8543).

With regard to the social representation of the LMS's job relevance (Fig. 3), the most significant core items were "organization" and "accessible". The most significant potential surrounding item with a negative value was "as during PACES".

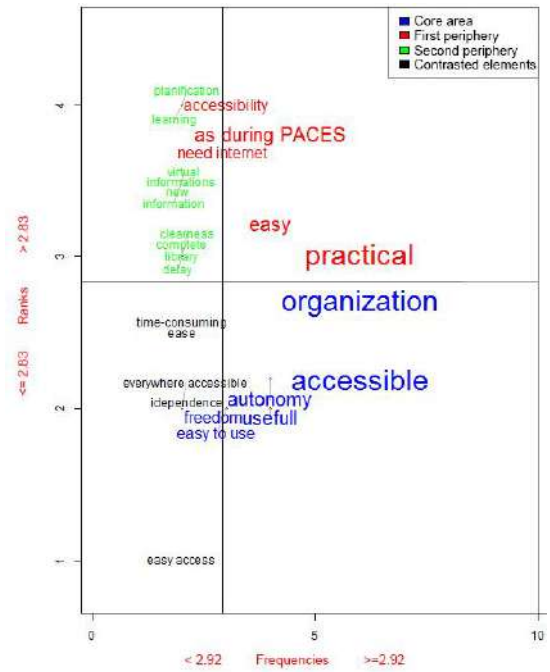

Figure 3– Prototypical analysis: social representation of LMS's job relevance

With regard to the social representation of the LMS's "results demonstrability" (Fig. 4), positive core items were "lengthy" and "organization". A potential surrounding item had a very negative value: "work alone".

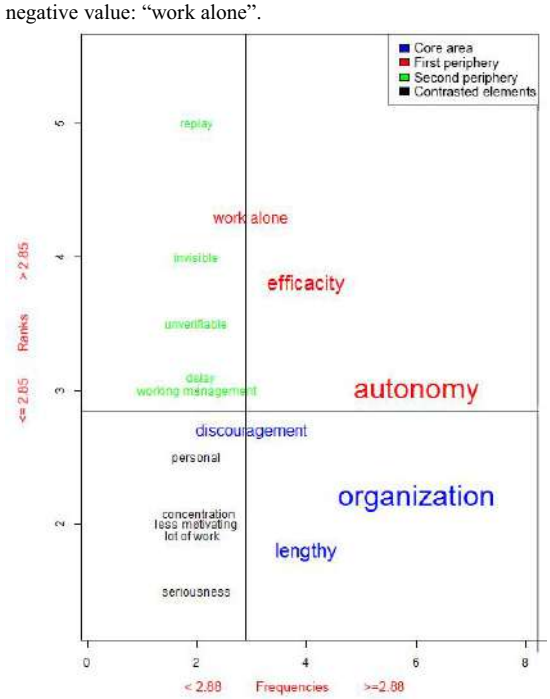

Figure 4– Prototypical analysis: social representation of LMS's "results demonstrability"

Discussion

Main results

Only one hypothese was deemed valid.

If the theoretical model is consistent, each sample does not have a link between acceptability and self-belief. It seems there is no link between students' acceptance of the LMS and their self-efficacy. Indeed, the general self-efficacy is not significantly different between students who identify the LMS as being less useful, less easy to use and less acceptable compared to students who identify the LMS as being more useful, more easy to use, and more acceptable. This is confirmed by the analysis of the 2017 population, who declared having a better technology acceptance, in all its dimensions, but had a similar general self-efficacy to the 2012 population.

The way to learn is negatively linked to the first year of health studies (PACES) because of the similarities between the LMS used during both years. It explains the fear of isolation, according to the surrounding item "work alone". But the social representation of the LMS proves that the system has many benefits, which are linked to the organization and the usefulness. Indeed, the LMS was created in that way to propose many features that facilitated the organization of study, including a learning-activities agenda, an online survey to ask questions to the lecturer while working on dematerialized lectures, and discussion forums. Moreover, these features were reinforced through the discussions with teaching staff and peer-experienced students, who explained each feature of the system and how students can organize their work.

Limitations of this study

This study has the following limitations. Only Year 2 students used the LMS, hence it was not possible to have a larger group in 2012 and therefore the group sizes are different. During the study period, user groups and attitudes probably changed, but it was necessary to analyze the GSES for the new generation. Scales used in our study are validated scales and reflect the measures in each group.

The choice of using TAM2 is also debatable. Some other technology acceptance models have been described (TAM, TAM3, UTAUT), but TAM2 has the advantages of being neither simplistic nor too complex and of having been validated within the framework of mandatory uses. Moreover, it presents precursors of perceived utility that were fundamentally interesting for our study ("job relevance" and "results demonstrability").

Internal validity

From 2012 to 2017, acceptance of the technology has increased significantly. This is probably due to enhancements of the LMS and changes in tutorship. Moreover, the 2017 population includes students older than that of the 2012 population. This could impact on declared perceived usefulness, ease of use, and acceptability as a confounding factor. Indeed, users' experience is linked to perceived usefulness[6]. This bias probably has a minor impact on our results because students' mean age also impacts on general self-efficacy; older students are skilled students, with some level of responsibilities at the hospital. Finally, cultural differences between student generations regarding acceptance of this particular technology could also be a confounding factor. The additional 5 years of experience with the LMS system probably increased students' perceived acceptability. However, the use of validated and contextual scales (TAM2, GSES, LMSSES) limits all of those biases.

External validity

In its entirety, the study linked the various concepts even if most of the correlations are moderate. The pedagogical method (not only the LMS as a tool) has already been evaluated [15] concerning its intention for use and the impact on learning strategies. The method is well accepted, but students have an intention to be too neutral in using the system, probably due to distractibility during lectures. So, we suggest improvements to make the LMS more acceptable for students, by (1) creating adapted types of interactive multimedia lectures (SCORM format activities for example) to be different from PACES and to have more rapidly perceived learning results [16][17]; (2) making changes in the presentation session of the LMS to improve the perceived ease of use of the tool.

Implication for health professional education

Our study showed that it is important to train students to use their learning environment. The intention to use a LMS and its acceptability are correlated to learners' satisfaction, which itself depends on quality of the transmitted information and ease of use [18][19]. Blended Learning is an interesting way of teaching healthcare [20]. It doesn't interfere with deep learning strategies[15]. These strategies are needed to help students make links between knowledge, skills, and habits. Our study showed that the LMS used in the method proposed by the Grenoble-Alpes University has a negative social perception for health students. To change this, the faculty of medicine must create an adapted context of use for this LMS, which would include new formats for courses (different than those used in PACES), and improved tutorship for using and understanding the method and the tool. Especially since students show an improvement in their computer skills after using an LMS [21].

Conclusions

Our study shows that the LMS is well considered by students concerning work organization, autonomy, and accessibility. Moreover, it seems that this rejected tool has no impact on students' self-efficacy. But since students are forced to use this LMS for their training, it is necessary to improve its conditions of use. This must involve creating learning objects different from those currently existing.

Acknowledgements

The authors are thankful to midwife students of Grenoble-Alpes University for their participation in this study. The authors are also thankful to Prof. Florence Martin, Prof, Ralf Schwarzer, Prof. Venkatesh, and Prof. Davis for their authorization to use their rating scales.

Development of a Digital Tool to Assist the Training of Health Professionals in the Determination of Brain Death

Carlos Eduardo Rochamedica Correia[a], Clécio de Oliveira Godeiro Junior[a]

[a] Department of Integrated Medicine, Rio Grande do Norte Federal University, Natal, RN, Brazil

Abstract

Due to technological advancement of medicine, patients have been maintained through mechanical ventilation and vasoactive drugs despite complete and irreversible brain injuries. Accurate diagnosis of brain death (BD) reduces costs, shortens family's suffering, and increases availability of intensive care beds and organs for transplantation. Guidelines were created to standardize BD diagnostic parameters, but knowledge of medical students and medical professionals has been demonstrated to be insufficient. To assist health professionals' in BD determination, a digital training tool that contained images, videos and interactive content was developed for desktops and mobile devices. Software to create and animate 3D models (MakeHuman™ and Blender™) and a game development platform (Unity) were used. Versions for all the major operating systems (iOS™, Android™, macOS™, Windows™ and Linux™) are being made available through online repositories and mobile application stores.

Keywords:

brain death; education, medical; mobile applications.

Introduction

Technological advances in the field of intensive care medicine, with artificial ventilatory support and use of vasoactive drugs, has contributed to the maintenance of hemodynamic and respiratory activity in patients with severe and irreversible central nervous system injury. Recognizing and diagnosing this situation is critical, since such therapeutic efforts can result in increased hospital costs, contributing to the shortage of intensive therapy beds, as well as prolonging the suffering of patients' families [1].

Additionally, patients with irreversible brain damage are recognized as potential organ and tissue donors. With the advent of transplantation in the 1960s, it is necessary to redefine the concept of death, avoiding controversies in obtaining organs [1].

Mollaret and Goulon, in their 1959 classic publication, were the first to define irreversible coma ("Le coma dépassé") [2]. In 1968, a committee created at Harvard Medical School established criteria for determining irreversible coma, with the definition of brain death (BD) [1]. The American Guidelines for Determination of Death, published in 1981, were based on Harvard Criteria [3]. The American Academy of Neurology published a review of the guidelines in 1995, and the more detailed descriptions of the steps of the examination specified parameters for the apnea test positivity, and six hour intervals between evaluations [4]. These latter guidelines are still valid.

Although there is some divergence, the American criteria are often referenced as guidelines in other countries. In 2002, Wijdicks reviewed the process for BD determination in 80 countries: 69% reported presence of legal standards on organ transplantation and 88% had practice guidelines for BD [5]. Some aspects varied among countries, such as the number of physicians needed to declare BD (more than 1 in 50%), apnea test (not performed in 24%), need for complementary diagnostic tests, observation time between examinations and the mandatory qualifications of the physicians. A 2015 publication found that among 91 countries, 70% had specific legislation, with institutional protocols established at 77%. Deviations in the guidelines from the American Academy of Neurology were observed in 53% of the countries [6].

In Brazil, Federal Council of Medicine published three resolutions with criteria to BD determination that were based on the American guidelines, most recently in December 2017. According to Brazilian law, the two clinical exams that are required, must be conducted with a minimum one hour interval hour, by different physicians, and consist of a confirmatory test proving absence of electrical or metabolic brain activity, or cerebral circulatory collapse. Physicians who perform the tests must have at least one year of experience in the care of patients in coma and follow or perform at least ten determinations of BD or participated in a training course [7].

Studies that evaluated the knowledge of physicians and medical students about BD diagnosis further demonstrate the need for training. Among the undergraduate students in Brazil, there is a lack of knowledge about BC, and few feel apt to perform the examination [8-11]. Other countries, such as South Africa [12] and the United States report similar challenges [13]. The knowledge of medical professionals also has been demonstrated to be insufficient, even those working within intensive or emergency units [14-17]. This low performance may be related to the limited number of opportunities to perform the exam during training, observed even among residents in neurology or neurosurgery [18].

This lack of practical experience can be reduced with the use of realistic simulation mannequins. The use of this didactic resource has been demonstrated to be effective in BD determination training, and has been positively rated by students [19]. The BD scenario is one of the most accessible in neurology for this modality of teaching, since BD requires testing of absent reflexes. The simulation of situations in which the findings would not be compatible requires the use of more advanced simulators that incorporate capacity for movement and pupillary reaction. The main barriers to the more frequent use of realistic simulation are cost, lack of structure (employees, physical space, supplies and technical support), longer time required for application, and lack of experience with the method. Cost remains the main barrier, as

only the high-fidelity, and more expensive, mannequins can simulate respiratory movements during the apnea test [20].

The use of computers to create virtual environments and virtual patients has emerged as a powerful educational alternative for health professionals. Training that is not dependent on face-to-face methodologies can reach a larger number of students, that may be in remote locations, without increasing costs [21].Additionally, there is increased opportunity for students to manage their own learning [22] with the growing availability of mobile devices, such as smartphones and tablets. Most students and physicians have a smartphone, and most of them use specific medical applications [23, 24]. Mobile devices can be used to quickly access scientific literature, self-assessment applications, calculators, and multimedia educational content, proving to be valuable tools in health education [25, 26].

Recognizing the educational gap in medical education about the diagnosis of BD, the use of a digital teaching tool that can be delivered through mobile devices, would be a valuable contribution to the training of health professionals. Thus, in this paper we review how we developed an application for computers and mobile devices that can assist the training of students and health professionals in BD determination.

Methods

Creating a Virtual Scenario

We used Blender ™ [27], a free and open source software, to create a virtual simulation experience consisting of three-dimensional (3D) models. Complex 3D figures can be created from basic geometric shapes (planes, cubes, spheres, cylinders, etc.), modified by the addition, subtraction or repositioning of vertices, edges and faces, and by combination with other shapes. Materials or textures can be assigned to the surfaces of the models providing color and brightness to the objects.

Using visual references as images searched on the Internet, 3D representations of object found in an intensive care unit were created. Examples included vital signs monitor, mechanical ventilator, hospital bed, infusion pumps, flow meters, cannula, as well as other equipment used in this hospital environment.

We found creating 3D human models to be a much more challenging task. We used MakeHuman™, also free and open source software, [28] to generate customized characters, Parameters that could be selected included gender, height, age, weight, skin and hair color. A male model was chosen as a patient and a female as a medical examiner. The created templates were exported to Blender™.

To demonstrate the clinical examination of BD a scene was created of an intensive care unit (see Figure 1). The male patient was placed on a hospital bed and wore a disposable diaper. The female medical examiner wore blue clothing and disposable gloves and was positioned on the left side of the bed. Medical equipment that was being used to monitor the patient included electrodes, oximeter, probe to measure esophageal temperature and was connected to a monitor, triple-lumen subclavian catheter, bladder catheter with urinary drainage bag and orotracheal tube connected to a mechanical ventilator. The final elements created for the scenario included walls and a floor, infusion pumps with intravenous administration sets and solutions bags, medical gas system (valves, flow meters, hoses and reservoirs), side table with material used in the examination (syringes, bowls, catheters, "cold" solution bottle, otoscope, flashlight and cotton swabs), negatoscope with tomography film, bed control, cover sheet and blanket, and clipboard inside a rack fixed to the bed. The final version of the file with both models and all of the objects totaled approximately 1.6 million vertices.

Figure 1 – Creation of Virtual Scenario of an Intensive Care Unit Using Blender ™

After adding light sources to the scene, Blender™ can be used to create a rendered image by calculating the color, shading and lighting of objects' surfaces, in a chosen angle of view of a virtual camera. Depending on the fidelity parameters, it can take several minutes on a typical home computer to create a single image. Thus, the time to process and obtain a single sample of the approximately 3,500 images used for the project would exceed 200 hours. The time render to images was reduced by 25 times due to the use of an useful Blender™ feature, that "bakes" an object's texture and color shading information, while maintaining quality of the images.

Creating Animations with 3D Models

Within Blender™, the process known of "rigging" allows for animations to be created through manipulations of 3D models., The changes to size, shape, or position of the 3D models in successive frames creates a perception of object movement.

To control the rigging process , the 3D models are given an "armature", which is a skeleton that can have its shape, size or location modified in relation to other objects. Human models are provided with more complex armatures, composed of several bones and joints, capable of reproducing a wide variety of poses.

More discrete movements such as breathing, blinking, and heartbeat are difficult to control through armatures. For these, we used the shape keys feature to generate various versions of the same object that can re-position in the different vertices.

In Blender's™ timeline windows, we could select different frames, numbered sequentially. By default, every 24 frames in the timeline equaled one second of animation. When modifying the armatures poses or the shape keys in different frames, Blender™ was set-up to automatically calculate the expected shape of the objects in the intermediate frames. The rendered images of each frame was combined in sequence to create a video.

Seven virtual cameras were used, with different viewing angles, to better visualize the steps of the examination (See Figure 2).

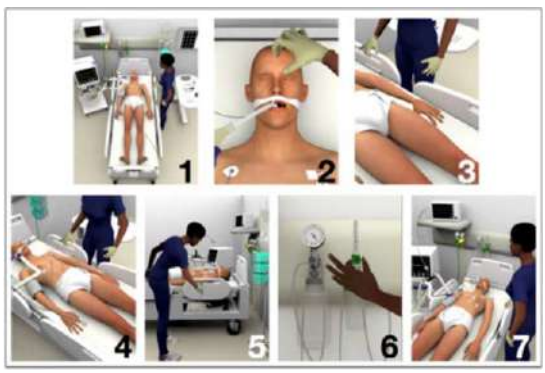

Figure 2 – Different Viewing Angles of Cameras Used in Animation Sequences

Creating and Editing Videos

Blender™ also provided a useful tool for creating and editing videos. The rendered images of all frames were combined and exported as video files (using H.264 MPEG-4 format), one video was created for each step of the clinical examination. The video editor allowed the addition of layers and transitions effects. The application of this feature was demonstrated in the development of the video for the apnea test, where an accelerated clock sequence was superimposed on the patient's image to represent the 10-minute observation time.

Editing Images

We used the GIMP™ (GNU Image Manipulation Program), a free and open source software [29], to edit and retouch the images used as textures in Blender™ and create the application (opening screen, icons, backgrounds, etc.).

Sample images of complementary exams were downloaded from Radiopaedia.org [30], a free collaborative radiology educational web resource. The images did not contain patients' data, and credit for reproductions followed Radiopaedia's user-contribution agreement.

Using a Game Engine

Developed by Unity Technologies, we used Unity™ (also known as Unity3D™ or Unity Engine™), as our cross-platform game engine [31]. Unity has a user-friendly interface and within a single project can generate application versions for all the major operating systems (Windows™, MacOS™, Linux™, iOS™ and Android™). Although it has paid subscriptions, it offers a free license for beginners whose project does not result in annual revenue over US $ 100,000 [32], fitting in with the proposal of our work.

For our project, Unity™ was used to create a game or application containing images, sounds, videos and 3D models (collectively called Assets), combined with user interface elements such as windows, text and buttons. These elements were divided into several scenes, which could be alternated according to the player's interaction with the elements on the screen.

A total of 20 scenes were created, with interactive elements that could be clicked (or touched) to display videos, text windows with relevant information or change to other scenes. Screens representing the Term of Declaration of Brain Death, similar to what was available within the Brazilian guidelines, played the role of "command center" in the application structure, from which all stages of the examination could be accessed through numbered icons. Users were allowed to revisit them as often as necessary to ensure understanding.

Some steps were chosen to be demonstrated in a more interactive way, requiring the user to perform gestures of clicking (or touching the screen of mobile devices) and dragging to interact with the content. Examples include:

- In the pupillary light reflex test, the user moved the examiner's hand with a flashlight to illuminate the patient's eyes, with fixed pupils. An icon with a question mark showed the expected response in normal situations, with reduction of pupil size to light exposure.
- In examining the corneal-eyelid reflex, the user moved the examiner's hand with a cotton swab to touch the patient's cornea, without reactivity to the stimulus. It was also possible to observe the normal find, with blinking as the response.
- In the oculocephalic reflex test, the user was instructed to horizontally drag the mouse pointer (or finger on the screen) to move the patient's head to the left or right. The patient's eyes followed the movement of the head. In the demonstration of the normal reflex, the eyes moved in the opposite direction of the head.

For more complex responses such as those shown in the steps described above, Unity requires the creation of scripts, text files containing commands written in programming language and instructions detailed to accomplish the task.

At the end of the work, executable files were created for the main operating systems. Only small differences could be seen between versions of application, such as screen resolution or some icons images (e.g. mouse pointer for computers and a drawing hand for mobile devices).

Results

The "Brain Death Determination: A Digital Guide" application beta version was created for Windows™, MacOS™, Linux™, iOS™ and Android™ operating systems.

The user is guided through the Brazilian Term of Declaration of Encephalic Death, from identification of the patient, definition of cause of coma, exclusion of confounding factors, measures for clinical stabilization of the patient, and all steps of the neurological examination with tutorials videos and interactive content. During the process, the user is alerted to important aspects and possible pitfalls during examination. In some stages it is possible to display the expected findings in normal patients. A brief explanation and sample image are given on the complementary tests used in the BD determination. At the end, the user is congratulated and invited to review the steps as many times as necessary. See Figure 3 for screenshots of examples of the application.

No images and videos of actual patients were used. This study was approved by the university ethics board (3.079.856).

The application is currently in the test period to evaluate bugs and area of improvements. Once testing is complete the application will be available for download in Internet repositories and mobile app stores (App Store™ and Google Play™).

Discussion

Knowledge concerning BD has proved insufficient among medical students and health professionals, highlighting the need for more effective teaching practices. A digital tool with multimedia tutorials, available in several platforms, could be a valuable tool to assist the training in the determination of BD.

With the lack of opportunities for students and residents to follow the BD examinations in practice, we choose a game-like approach to integrate content. We selected this approach for students based on its appeal, strength in experiencing of realistic simulation with mannequins, and frequent use as a methodology for training courses. The use of computers and mobile devices has the additional benefits of reaching a greater number of students with reduced cost.

The program could be easily adapted for use in other countries, with language modification and adjustments to the local guidelines. There is also the opportunity to provide updated versions to meet specific needs (e.g. providing a module for self-evaluation).

In recent years, similar applications have been used to assist in the training of different medical skills, proving to be valuable educational tools. A mobile application simulator has been demonstrated to be an effective education tool for of medical students, improving the performance in several operations and practical procedures, such as male urinary catheterization and chest tube insertion [33, 34]. For laparoscopic cholecystectomy, the same application was useful for learning cognitive aspects of procedure when used in combination with virtual reality in a multimodal training approach for general surgeons and medical students [35]. In a blinded randomized controlled study, the use of a web-based otoscopy simulator increased the diagnoses of otologic diseases by medical students, with a 24% higher score than the control group using standard otology lectures [36].

Limitations

The true potential of the application in practice still needs to be evaluated through a randomized blinded study that measures the impact of the acquisition of knowledge that involves a comparison of the application with other traditional teaching methodologies.

Conclusions

Using open-source software to create and animate 3D models (MakeHuman™ and Blender™), and a game development platform that offers free license for beginners (Unity), we were able to create a low-cost application to assist health professionals' training in BD determination. Available for all major operating systems (iOS™, Android™, macOS™, Windows™ and Linux™), this teaching tool can be used for students through their desktops or mobile devices.

Patterns of Interaction Between General Practitioners and Their Patients by Means of a Messaging System Within the Electronic Health Record Regarding Messages Asking for a Referral to a Specialist: A Descriptive Study

María Emilia Espósito[a], Santiago Esteban[a], Sergio Terrasa[a], Gabriel Villalón[a]

[a]Department of Family and Community Medicine, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina.

Abstract

The continuity of care is the relationship between a physician and a patient that extends throughout different episodes of illness. This care includes that in some opportunities the patient must consult a medical specialist. In this qualitative study, we set out to explore and describe the different requests for referral authorization to a specialist by patients affiliated with private health insurance, in order to understand the different patterns of interaction between general practitioners (GP) and their patients. The conversation analysis let us identify categories (structural and functional) after a critical reading of messages between GPs and their patients through an Electronic Health Records (EHR) messaging system. This work allowed us to know more in depth the process of continuity of care. In most cases, the doctor answered affirmatively to the request for a new referral to a specialist

Keywords:

Referral and consultation, electronic health records, continuity of patient care.

Introduction

In 2011, the World Organization of National Colleges, Academies and Academic Associations of General Practitioners / Family Physicians (WONCA) reviewed the definition and desirable attributes of GPs or family doctors. Some of these characteristics are a physician-patient relationship established over time through effective communication and the responsibility to provide longitudinal and continuous care, determined by the needs of the patient [1].

This last characteristic, the continuity of care, is defined as the relationship between a physician and patient that extends throughout different episodes of illness. It has a positive effect on the satisfaction of patients and doctors, for example, it is associated with greater adherence in people with chronic diseases, fewer consultations to emergency services and fewer hospitalizations [2-4].

Hospital Italiano de Buenos Aires, general practitioners and management of referrals to specialists

The Hospital Italiano de Buenos Aires (HIBA) is a private hospital that has a private health insurance (HI-HIBA) that is based on the concept of GPs as gatekeepers: if a patient needs or wants to have an appointment with a specialist, his GP has to allow that referral.

Regardless of the mechanism of access to the specialist, with few exceptions, it is desirable that the GP makes a formal assessment of the problem before the referral. Inappropriate referrals not only generate overload to the system, but they can condition unnecessary diagnostic cascades and harmful overdiagnoses for the patient, unnecessary expense of resources and delays in the care of patients that clearly would benefit from getting a quick consultation [5-7].

The decision to make a referral to a specialist is based on multiple factors: the disease to be treated, the recommendations of clinical practice guidelines or experts, the availability of specialists, the ability and predisposition of the GP to solve the problem, his satisfaction with his job and remuneration, etc [8].

In 2006, the HIBA began the Personal Health Portal project (PHP), designed to provide new functionalities to the people who are treated at the Hospital. The PHP is a Personal Health Record linked to the EHR hospital, which provides services and access to unified data in multiple devices, allowing patients to interact or consult their medical or administrative information. Within the tools provided by this system, there is a messenger that allows patients to write to their GP. This is one of the most frequent ways of requesting referral authorization. Patients also can send messages by calling a call-center.

Health Care Quality Improvement Program and its indicators in the Department of Family and Community Medicine of the Hospital Italiano de Buenos Aires

The Department of Family and Community Medicine of the HIBA (DFCM) has a Quality Improvement Program (QIP) that use certain indicators and economic incentives as main strategies. Since 2017, we began measuring two continuity of patient care indexes for each GP: the Usual Care Provider index (UPC) and an index developed by Bice & Boxerman (COC) [9]. Other indicators used by the QIP are related to the accessibility to scheduled appointments and the response to messages sent by patients through the PHP or call-center. This last indicator is operationalized as the rate at which a GP consult the EHR of patients who have sent messages asking for a referral during the previous seven days.

We consider that given that this indicator is measured purely quantitatively, without evaluating the quality of the responses provided by the GPs, it does not allow to distinguish the answers framed in the concept of "continuity of care" and those that are not.

With this study we set out to explore and describe the different requests for referral authorization to specialists from patients affiliated with the HI-HIBA, with the aim of understanding the different patterns of interaction between physicians and patients.

Methods

We made a qualitative and quantitative description of different requests for referral authorization made by patients and the answers provided by GPs working in the DFCM-HIBA.

Population, source and data collection

We defined a population of "requests for referral authorization". For the purposes of this investigation, the latter was operatively defined as the requests for referral authorization to specialists made by patients through the messenger service of the PHP in order to avoid extra payment.

First stage: identification of words most used by patients in the referral request messages

The research began by requesting a random sample of 150 patients who had sent a message to their GP between 01/01/2016 and 12/31/2016. This data was requested from the Information Management Area of the Research Department of the HIBA. The answers given by their GP during the first seven days after the first message was sent, were obtained from the EHR.

From the sample of 150 patients who had sent at least one message to their GP in the selected period, a total of 1019 exchange messages were obtained. Of these, 372 messages (36.5%) made reference to the request for referral authorizations. Of these 372, a total of 288 had been sent by the patients.

Of the total of 288 messages sent by patients for the request for referral authorization, 93 (32.2%) were generated using a structured option in the PHP and not as free text addressed to the GP. However, in the free texts of the messages, the following keywords were identified: *derivación* (referral), *derivaciones* (referrals), *especialidad* (speciality), *especialista* (specialist), *interconsulta* (interconsultation), *autorización* (authorization), *autorizar* (authorize), *hacer una orden* (make an order).

Second stage: searching messages specifically related to the request of referral to specialists through the roots of words identified in the previous step

Once the most used words were identified in referral requests, we made a second request to the Information Management Area with the roots of words found in the previous step, independently of the number of repetitions. We also requested the registration of the authorizations made by the GP in the EHR.

Table 1 - Roots of the words found during the first stage that were used during the second stage to identify the free text messages linked to the request for a referral

Root	Words
Deriv	*Derivación / Derivaciones / Derivar / Derivarme*
Interc	*Interconsulta / Interconsultas*
Autoriza	*Autorización / Autorizar*
Especiali	*Especialista / Especialidad*
Pase	*Pase*
Orden	*Orden*

In this second stage, we obtained a total of 2600 messages between patients and doctors, which allowed us to carry out a qualitative analysis of 214 conversations in which the patient had requested his or her GP to authorize a referral to a specialist. For this analysis, the main researcher reviewed the conversations between patients and physicians, as well as the clinical notes recorded in the EHR during the episodes of care. This analysis allowed us identifying patterns of interaction between GPs and their patients, making it possible to identify categories that were built from the critical reading and the discourse analysis.

Results

The qualitative analysis of 214 conversations related to the request for referral authorization to specialists allowed the elaboration of two types of categories: structural and functional.

Structural categories

Three categories were identified that refer to the structure of the analyzed conversations: a) the content of the message sent by the patient requesting the referral authorization; b) the answer made by the doctor; c) the referral authorization made by the doctor through the EHR.

a) The content of the message sent by the patient requesting the referral authorization to a specialist

The content of the message was defined as all the information included in the message sent by the patient to his/her GP requesting a referral authorization. There were identified 136 messages in which the only content detected was the request for referral authorization. Of these 136, 77 messages had been sent from the PHP messenger in a free text format, such as:

> Female, 61 years old: *"...hola Dr. le pido derivación para endocrinología y coloproctología..."* ("... hello Dr., I'm asking you for referral to endocrinology and coloproctology ...").

The other 59 messages were created from a "ask for referral authorization" structured option in the PHP, which sent an automatic message with the following text:

> *"El paciente (...) solicita renovar su derivación con el servicio de endocrinología ambulatoria".* ("The patient (...) requests to renew his referral to ambulatory endocrinology service".)

Other 78 messages with more content were identified, in which the reason for requesting the referral authorization was expressed. These messages were analyzed to identify the different reasons for referral request (see functional categories below).

b) The answer made by the doctor in response to the request for referral authorization

This category was defined as all the information contained in the message sent by the GP in response to the request for referral authorization.

It was observed that of the 214 requests, only 57 were answered by the GP through a message in the PHP and, in all these cases, the content of this messages was only the notification of the given authorization or a personal greeting to the patient, with the eventual addition of recommendation of a professional:

> 49 years old female GP to 20 years old female patient: *"...te dejo la derivación con Nutrición..."* ("... I leave you the referral authorization to Nutrition ...").
>
> 47 years old male GP to 72 years old male patient: *"...va a ser cuestión de tiempo la recuperación del olfato. Cualquier cosa, la Dra. XXX es de mi confianza..."* ("... it's going to be a matter of time the olfactory recovery. In any case, Dr. XXX is of my trust ...").

c) Referral authorization made by the doctor through the EHR

When analyzing the referral authorization made by the doctor through the EHR, we identified different possible scenarios and two possible responses: loading or not the authorization in the EHR.

In most cases, the GP performed the authorization. The only cases in which we observed that the authorization had not been carried out were in the context of requests for renewal of

previous referrals, when the authorization were already loaded and still valid in the EHR, in the presence of some acute symptom or when the GP decided to make an appointment with the patient.

Functional categories

We identified four functional categories that refer to the purpose of conversations between patients and physicians: a) the reason for requesting referral authorization expressed in the patient's message; b) the time of evolution of the health problem related to the request; c) the level of care where the health problem can be solved (primary care vs. not primary care); d) the trigger for the request for referral authorization.

a) The reason for requesting referral authorization expressed in the patient's message

From the total analyzed sample (214 conversations), 78 were identified where the reasons for requesting a referral could be detected.

One of the options in this category is when the reason given by the patient for requesting for a referral to the specialist is a new diagnosis made in the context of an unscheduled consultation in the emergency department:

> Male, 61 years old: *"...estoy con una tendinitis en el brazo derecho. Me estoy atendiendo con la guardia de traumatología pero ahora me derivaron a un especialista de mano. Necesitaría una derivación para esa especialidad..."* ("... I have a tendinitis in the right arm. I was dealing with it in the trauma emergency department but now I was referred to a hand specialist. I would need a referral authorization to that specialty ... ").

We also detected referral requests for health problems previously known to both the patient and his doctor and which had previously motivated consultations with a specialist:

> Female, 62 years old: *"...me enviarías una derivación para la Dra. de otorrino, es por mis acúfenos, tengo turno el 2 de junio..."* ("...would you send me a referral authorization to the otolaryngologist, it is because of my tinnitus, I have an appointment on June 2...").

Another option that we observed were cases in which the persistence of symptoms, having previously consulted the GP about this problem, make patients to request referral authorization to a specialist:

> Male, 72 years old: *"...todavía no recupere el sentido del olfato y el gusto, derivame por favor a un otorrinolaringólogo de tu confianza para evaluarme..."* ("... I still do not recover the sense of smell and taste, please refer me to an otolaryngologist from your trust to evaluate me ...").

Similarly, we observed that in some cases, a new or recurrent appearance of an acute symptom triggers a referral request:

> Male, 62 years old: *"...me resucitó el dolor de espalda. Hace días que no se va. No es demasiado intenso pero es persistente... Me podés derivar con alguien para verlo?"* ("... my back pain is back since days ago. It is not too intense but it is persistent... Can you refer me to someone to see it?").

Patients also usually express that they request for referral authorization to perform control of a specific health problem related to a speciality. This situation could be verified by reviewing the EHR:

> Male, 62 years old: *"... por favor solicito derivación a cardiología para poder asistir a control..."* ("... please, I request referral to cardiology to be able to attend to control...").

On other occasions, it was observed that the patient has been suggested by another person than the GP to consult with a specialist to evaluate the result of a complementary study (see further category "referral request trigger"):

> Male, 62 years old, referring to an electrocardiogram: *"...me piden que me haga la derivación para cardiología, por el informe del ECG tiene que verme un Cardiólogo..."* ("...they told me to ask you for the referral authorization to cardiology, for the EKG report a cardiologist has to see me...").

At last, as we expressed previously, in some cases the reason for requesting a referral was not expressed. This type of requests was frequent for dermatology, and somewhat less frequent for otorhinolaryngology, general traumatology and nutrition:

> Male, 52 years old: *"Hola, necesito una derivación para dermatología, ya que el dia 18/03 tengo un turno con el Dr. XX"* ("Hello, I need a referral to dermatology, because I have an appointment with Dr. XXX on the 18th of March").

b) The time of evolution of the health problem related to the request

In relation to the time of evolution of the health problem that motivated the referral request, we were able to differentiate acute evolution problems analyzing the messages and the EHR:

> Male, 43 years old: *"...me están doliendo muchos los tobillos y también las piernas, pienso que por el efecto del tobillo, qué especialista en pie me recomendás?"* ("... my ankles are hurting a lot and also my legs, I think that because of the ankle effect. Which foot specialist do you recommend me?").

We also recognized requests related to chronic problems:

> Female, 61 years old: *"Sería tan amable de hacerme una derivación a hipertensión. Es solo por control" ("Would you authorize me a referral to hypertensology? Is it just for a control").*

c) The level of care where the health problem can be solved (primary care vs. not primary care)

We documented referral requests to specialists for problems that could be handled in primary care by the GP. These situations could make us infer that the patient would not recognize the GP as someone with the capacity to solve that problem:

> Male, 52 years old, with a recent diagnosis of type II diabetes without pharmacological treatment: *"...me podrías dejar una derivación para consultar un especialista en diabetes"* ("...could you leave me a referral to consult a diabetes specialist?").

On the other hand, we have also identified health problems that exceed primary care capacities, such as some surgical problems:

Female, 62 years old: *"...estoy pensando en operarme la hernia umbilical. ¿A quién me recomendás? ¿Podrás hacerme una derivación?"* ("I'm thinking on solving my umbilical hernia. Who do you recommend? Can you authorize the referral?").

d) The trigger for the request for referral authorization

When analyzing the different conversations, who triggered the request for referral authorization was detected as a category. In most cases was the patient himself:

> Male, 29 years old: *"...este mes tengo turno para el dermatólogo por unos granitos en la cara que no se me van y con el otorrinolaringólogo ya que estoy constantemente, mes tras mes, con la garganta irritada. Me parece que necesito derivaciones para ambos..."* ("... this month I have appointments with a dermatologist because of some spots on my face that do not go away

and with the otorhinolaryngologist since I am constantly, month after month, with sore throat. It seems to me that I need referrals for both... ").

In other cases the patient requests a referral after a suggestion made in the past by the GP:

Male, 21 years old: *"Doctor, siguiendo su indicación, necesito que me haga una derivación a una nutricionista"* ("Doctor, following your instructions, I need you to refer me to a nutritionist").

Another possibility is that the referral has been suggested by another professional of some ambulatory specialty:

Male, 54 years old: *"Necesitaría una orden de derivación para cirugía plástica a quien me derivó el dermatólogo…"* ("I would need a referral authorization to plastic surgery to whom the dermatologist referred me…").

Also, the referral could be suggested by a physician in the emergency department:

Female, 51 years old: *"… tengo turno con un especialista en mano mañana por la tarde por una molestia, me lo indicaron en demanda espontánea. Me dicen que necesito que me ingreses una derivación…"* ("... I have an appointment with a hand specialist tomorrow afternoon, I have been referred in the emergency department. They told me that I need you to authorize the referral...").

Other health professionals previously involved in the patient's care, for example, a psychologist from another institution, could have made the referral:

Male, 26 years old: *"…me trato con un psicólogo particular. El mismo me sugirió comenzar tratamiento por depresión en el hospital. Ya tengo turno para la admisión. Necesito derivación a psiquiatría…" ("... I´m seeing a private psychologist. He suggested me to start treatment for depression in the hospital. I already have an appointment. I need a referral to psychiatry...").*

Also, a primary care physician could have referred a patient to a specialist during an emergency department consultation:

Male, 52 years old: *"…necesito la derivación para dermatología. Estuve el sábado en la guardia y me recomendaron ver al especialista..."* ("... I need the referral authorization to dermatology. I was on the emergency department on Saturday and they recommended me to see the specialist...").

Finally, it was identified that in some cases who triggers the referral request is a non-medical personnel, for example, an electrocardiograph technician:

Male, 62 years old, after an electrocardiogram requested by his GP: *"…me piden que me haga la derivación para Cardiología, por el informe que tiene que verme un Cardiólogo…"* ("... they asked me to make the referral for Cardiology, for the report a cardiologist has to see me ...").

Discussion

This study allowed us to deepen how the interaction between physicians and patients occurs regarding referral requests to specialists. From the qualitative analysis of the conversations, we were able to develop categories that allowed us to characterize conversations and to understand the process of continuity of patient's care.

It is striking that, contrary to what we thought, in most cases, the GP responds in an affirmative way to the request for a new referral to a specialist regardless of the speciality, the reason expressed in the message and the time of evolution of the health problem. This generates uncertainty regarding the role of the GP as "gatekeeper".

This controversy is also observed in countries with more rigid health systems in relation to the patient's contact with the second level of care [10]. Among the arguments in favour of the role of primary care physician as gatekeeper are: that promotes less use of the health system, a shorter delay in appointments with specialists, a greater system efficiency and less overdiagnosis and overtreatment. On the other hand, some of the arguments against are: the increase in costs due to delayed diagnosis, the lack of respect for the patient's choice, the increase in workload for primary care physicians and conflicts in the physician-patient relationship [11].

It is very likely that this controversy exists internally in GPs, being one of the factors that leads to respond affirmatively in almost all referral requests, jeopardizing the continuity of care. Another factor could be that GPs working in HIBA are used to referral many health problems that could be handled in primary care, such as dermatology or otorhinolaryngology issues.

On the other hand, some affirmative answers to the referral requests were adequate and framed in the continuity of care. For example, those requested for surgical specialities and specialities that perform procedures that are not usually carried out by GPs of the DFCM of the HIBA.

We consider that some requests for referral authorization are difficult to answer in a negative way. Such is the case of the request for referral to a specialist to follow up a diagnosis made in the emergency department, where the patient is evaluated by another doctor. The same applies to those referrals suggested by a specialist, by another health professional (for example a psychologist) and when the GP is licensed, and the replacement physician must answer the request.

Our study has certain limitations and weaknesses. We have not been able to adequately analyze the conversations in which the GP decides to communicate with the patient by telephone to assess the referral request. Most of these interactions are not recorded in the EHR.

We did not include in our protocol messages sent through the call-center service. This implies having left out of the analysis a certain population, mostly elderly, that does not use the messenger system of the PHP.

Despite the previous limitations, we have not been able to identify similar studies carried out in our country or in our region and we believe that this work constitutes a fundamental contribution to understand the process of referral requesting to specialists.

In the future, it would be interesting to know the opinion of patients about the role of the GP as gatekeepers, to evaluate their satisfaction with this system and to examine whether this function improves the quality of care of them.

Conclusions

This work allowed us to understand the process of referral requesting and the arrival of the patient to the appointment with the specialist. It lays the basis for new research on the continuity of patient care and the role of the general practitioner as a gatekeeper.

Training Leaders in Health Informatics

Susan H. Fenton, Angela Ross, Debora Simmons

The University of Texas School of Biomedical Informatics, Houston Texas, USA

Abstract

Despite the widespread adoption of electronic health records (EHRs) in the U.S. over the past decade, significant improvements, especially in patient safety, have yet to be realized. This finding, along with health informatics workforce data and an identified gap in the offerings of an educational program, led to a proposed professional doctorate in health informatics. Developed via stakeholder focus groups, the program was approved by the public university system, the state-level educational authority, and the regional accreditation body, with final approval in July 2018. Unique features of the program include a prolonged practice project demonstrating a return on investment, as well as online and face-to-face delivery components. This program aims to develop evidence-based professionals who improve the health of people and populations through the application of health informatics. Applications and interest in the first class are high.

Keywords:
Education, Health Informatics

Introduction

In 2004, President George W. Bush outlined a plan to ensure that most Americans would have electronic health records within the next 10 years. The President believed that better health information technology was essential to his vision of a health care system that puts the needs and the values of the patient first and gives patients the information they need to make clinical and economic decisions – in consultation with dedicated health care professionals [1].

President Barack Obama continued to support President Bush's mandate during his administration, including incentives for implementing electronic health records (EHRs) in the American Recovery and Reinvestment Act [2]. As a result of this, the health informatics industry has flourished with the need for an educated informatics workforce[3]. This workforce is needed to assess, design, implement and evaluate the electronic health record (EHR) and patient care technologies, as well as effectively utilize the data generated; all with the goal of preventing medical errors and providing the information needed to improve human health.

As of 2017, 96% of all U.S. Non-federal Acute Care Hospitals have adopted a certified EHR [4]. Documented benefits of EHRs include enhanced patient care; real-time, multi-user access to the patient record; alerts for medication errors and critical lab values, among others[5]. However, in spite of these benefits of the introduction and widespread use of EHRs in hospitals, medical errors are perceived to have increased and are estimated to be the nation's third leading cause of death[6]. These medical errors also include unanticipated and undesirable consequences from implementing an EHR. In 2016, Johns Hopkins researchers examined four separate studies that analyzed medical death rate data from 2000 to 2008. Then, using hospital admission rates from 2013, they extrapolated that based on a total of 35,416,020 hospitalizations, 251,454 deaths stemmed from a medical error, which the researchers say now translates to 9.5 percent of all deaths each year in the U.S[6]. In March 2019, Fortune magazine published "*Death by 1,000 Clicks"* describing multiple failures of EHRs, with even those who led the national U.S. effort stating EHRs "have not fulfilled their potential."[7]

The health care industry is in need of transformational change in the education required for executive-level health informaticists who practice at the most advanced levels. The 2019 Health Information Management Systems Society (HIMSS) Leadership and Workforce Survey found that 84% of all respondents reported to be in a management role, with 47% associating themselves with an "Executive Management" position[8]. The health informatics executives are an integral part of the health care team, providing the foundational technology infrastructure to support efficient, effective care. The recommendation that health informatics executives practicing at the highest levels should receive doctoral level preparation emerges from multiple factors evident by the expansion of scientific knowledge in health informatics and growing concerns regarding patient safety, the continued need for improved patient outcomes, and quality care delivery.

The 2019 Health Information Management Systems Society (HIMSS) U.S. Leadership and Workforce Survey ranked the following priority needs concerning quality care delivery and health informatics/health IT in health care organizations:

- Cybersecurity, Privacy, and Security
- Improving Quality Outcomes Through Health IT
- Clinical Informatics and Clinician Engagement
- Culture of Care and Care Coordination
- Process Improvement, Workflow, Change Management
- User Experience, Usability and User-Centered Design
- Data Science/Analytics/Clinical and Business Intelligence
- Leadership, Governance, Strategic Planning
- Safe Info and Tech Practices for Patient Care
- HIE, Interoperability, Data Integration and Standards[8]

It is worthwhile noting that leadership and user experience are new to the top 10 in 2019. The health informatics workforce data indicates there is an increased demand for health informatics in several health care delivery models. In 2017, HIMSS noted that efforts to advance clinical IT in non-Hospital Provider environments (ambulatory and long term Post-Acute care facilities) can be challenging when there is no educated, trained, and designated health IT workforce [9]. Both the 2018 and 2019 reports concluded that the influence of executive management health IT professionals continues to expand in organizations[8,10].

The United States has implemented the position of the Chief Medical Informatics Officer (CMIO), as well as the Chief Nursing Informatics Officer (CNIO), in its largest healthcare organizations. For the CMIO, the American Board of Medical Specialties administers the clinical informatics subspecialty exam for physicians[11]. Likewise, the American Nurses Credentialing Center administers an informatics nursing certification, the RN-BC[12]. In the UK, it appears that the position of Chief Clinical Information Officer (CCIO) is emerging[13]. The nursing certification content outline does not include management or leadership skills. The US subspecialty exam includes one item related to leadership needed for fostering change and managing large-scale information projects. The UK CCIO role is proposed as a leadership role with a clinical focus. While there is no doubt of the need for these clinical leadership roles in health informatics, they often do not include the techinical or management background needed for the chief information officer (CIO) or chief technology officer (CTO). In addition, while these clinical roles are essential in care delivery organizations, they may not be found in pharmaceutical or insurance or other health information technology organizations. The advent of digital health in the US and around the world will only expand the types and numbers of organizations engaging in the health informatics field. Effective informatics leaders are needed in all of them.

Therefore, **it is critical that the executive-level health informatics professional is educated and prepared to manage complex organizations across the continuum of care and throughout the healthcare industry**.

In addition to the available workforce data, the University of Texas School of Biomedical Informatics (SBMI) identified a gap in their current educational offerings after multiple applications for the doctor of philosophy degree from industry professionals who could not articulate a research area for their studies. These applicants felt the need to continue their education to a terminal degree, as is the case for the MD, PharmD, DNP, and DPT. However, historically, the only terminal degree option in the informatics field has been the PhD. With all of these issues in mind, a group of applied informatics faculty proposed the development of a practice doctorate, or professional degree, in health informatics (DHI).

Methods

The first step in the development of the DHI was approval of the concept at a faculty retreat. Following this, the task of developing the proposal was assigned to the Associate Dean for Academic Affairs, with assistance of the applied faculty and staff members. The process for public institutions in Texas necessitates several steps with the format of the proposal proscribed in regulation.

Development of the proposal began with submission of a letter of intent to develop a new degree program to the university and The University of Texas System administration. This was followed by the convening of focus groups of Texas Medical Center and other SBMI stakeholders. These stakeholders are persons who mentor SBMI master's degree students for capstone projects or have employed SBMI graduates or are SBMI alumni. Focus groups were held in early 2017 to ascertain whether the proposed program was needed, as well as determine topics that were deemed most important for health informatics executives and managers. Eleven (11) people either participated in the focus groups or were interviewed individually if the focus group meetings were not convenient. The titles of those participating are as follows:

- One Executive Officer with a nursing background from the U.S. Defense Health Agency
- Three Directors of Information Technology, Information Technology Development, and Information Systems Operations from large systems in the Texas Medical Center, respectively.
- One Vice President of Clinical Informatics for a large integrated health care system.
- One Division Director of Clinical Informatics for a multi-state health care delivery system
- One Vice President of Applied Clinical Informatics and Chief Nursing Informatics Officer from a tertiary care system.
- One Executive Director of Clinical Quality Informatics for a multi-hospital system
- One Director of Nursing Operations
- One Informatics Manager with a public health system.
- One Associate Chief Medical Informatics Officer

Once the focus group results were analyzed, development of the proposal began. The format required includes evidence related to Job Market Need; Existing Programs; Student Demand; Student Recruitment; Enrollment Projections; Accreditation; Admission Standards; Program Degree Requirements; Curriculum; Candidacy/Dissertation Requirements; Use of Distance Technologies; Program Evaluation Plans; Faculty Availability and Teaching Load; Student Financial Aid; Library and Other Teaching Resources; Support Staff; potential Proposal Evaluators; and a 5-year Financial Plan.

Results

Focus Group Results

The focus groups and persons interviewed individually were very supportive of the need for and subsequent development of a doctorate in health informatics (DHI). Selected comments include:

"There needs to be an understanding of analytics and linking that back to scientific inquiry to better collaborate with research Ph.D. students & make things workable for the end user. It is important to work in an evidence based space so we can continue to inform the community and fill the gap in this doctorate; fill the gap so people are trained appropriate in practical application."

"Terminal degree completion for specific specialties is important. Practice prepared topics can make the research information usable in the field and can provide real-time solutions."

"Practice based trends/evidence are important. Students should be driving things back to the researchers – feeding things back to Ph.D. researchers to identify trends and help validate their work."

"We are looking for someone with the ability to think strategically and be forward thinking to look at the impact of regulatory requirements. How can we leverage or utilize technology that addresses new needs that are coming in the future?"

"The number one skill needed is change management experience as we implement new systems. You need to be able to change a culture in an organization."

"While there is a discussion of workflow, formality and discipline, the structure is not there. How do you structure a proper workflow that is then communicated across the organization – it is just not there. Discipline is lacking. When you look at staff and come to see how they have become an "Informatician", background is lacking."

"Many informaticians are heavily focused on implementation and do not look back at the practice of it to do an evaluation or look for evidence-based practice."

The final proposal document with all required attachments totaled 62 pages.

The proposal was approved by The UT Board of Regents in August 2017. From there, it was submitted to the Texas Higher Education Coordinating Board (THECB). The THECB required a desk review of the proposal and later conducted a site visit with three external reviewers. Final approval was obtained in July 2018.

Program Development

The professional doctorate in health informatics is a degree sorely needed for the current and future success of health care across the globe. In the U.S., a master's degree extends what is learned at the bachelor's degree, but does not provide the depth of a doctoral degree. Many informatics professionals, currently holding master's in informatics degrees and working in health care organizations wish to continue their training. However, they do not wish to conduct the research necessary for a PhD. The only knowns professional doctorate in health informatics and the requirements are described herein.

The objectives of the program are to:

- Implement evidence-based practice to improve human health.
- Assume leadership positions throughout the healthcare industry having integrated health informatics with organizational leadership and ethics.
- Design, implement and evaluate health information technology quality improvement projects in health care systems.
- Synthesize health informatics and patient care technologies to effect improvements in health care delivery and patient safety.
- Employ effective communication and collaboration skills to identify and implement best practices in health care delivery.

Admission Standards

The admission standards include:

- Bachelor's degree with documented executive/management health care experience
- Master's degree preferred
- Personal statement that includes short and long-term goals after completion of the practice doctorate program
- Proposed area of interest for the translational practice project
- *Letter of Support from the health care organization willing to facilitate the translational practice project*
- Resume or curriculum vitae
- Three letters of recommendation from supervisors (two letters should be from supervisors), colleague etc.
- Interview with the SBMI Application, Progression, and Graduation Committee (APG) (by invitation upon review of application)
- Cumulative GPA of 3.0 or higher

The maximum number of students admitted to the first cohort will be thirty (30), with no set minimum. That is, if only 15 applicants are qualified for the program, only 15 students will be accepted into the first cohort.

Curriculum

The student learning objectives for the practice doctorate in health informatics are as follows:

1. The student will design and implement a project plan to address an operational health informatics problem.
2. The student will apply the appropriate scholarly foundations and evidence-based practices when designing and implementing the project.
3. The student demonstrates broad knowledge in the field of health informatics and advanced knowledge in a sub-discipline, such as privacy and security, data analytics, revenue cycle management, or other specified, in conjunction with the advisory committee.
4. The student will present and disseminate his/her project and the evaluation using strong verbal and written communication skills.

The curriculum is found in Table 1.

Table 1 - Curriculum

Course #	Course Title	Semester Credit Hours
Year 1 – Fall		
BMI 5300	Introduction to Biomedical Informatics	3
BMI 6324	Health Information Technology Policy	3
Year 1 – Spring		
BMI 6328	Healthcare Delivery in an EHR-enabled Environment	3
BMI 6311	Advanced Decision Analysis	3
Year 1 - Summer		
BMI 7350	Scholarly Foundations of Advanced Health Informatics Practice	3
Year 2 – Fall		
BMI 6305	Social Dynamics and Health Information	3

Course #	Course Title	Semester Credit Hours
BMI 6316	Change Management in Health Informatics	3
BMI 7170	Project Advisement	1
Year 2 - Spring		
BMI 7360	Advanced Project Management	3
BMI 7351	Evidence-Based Health Informatics Practice	3
BMI 7170	Project Advisement	1
Year 2 - Summer		
BMI 7361	Vendor Relations and Contract Negotiation	3
BMI 7170	Project Advisement	1
QUALIFYING EXAMINATION		
Year 3 – Until Graduation		
BMI 7070	Fellowship in Health Informatics	6
BMI 9950	Project Evaluation and Writing	6

The courses beginning with 6000 are electives in the master's and PhD degree programs. Those beginning with 7000 are unique to the DHI program. BMI 5300 is a leveling course required for all students new to SBMI. The selection of the additional courses was influenced and guided by the focus group feedback. As can be seen from the course titles, the program curriculum is focused on developing the skills needed for informatics managers and executives to implement evidence-based health informatics practices and technologies to improve care delivery and outcomes.

In addition, during their course of study, students will identify and seek a certification relevant to their translational practice project.

Translational Practice Project

The proposed practice doctorate will conclude with a project evaluation report to be written upon completion of a translational practice project. The proposed translational practice project requirements will consist of:

- Background and Review of Relevant Literature/Evidence
- Project Overview
- Theoretical Framework/Logic Model
- Purpose Statement/Significance of Project
- Evaluation Design, including Return on Investment
- Implementation/Gather Evidence
- Recommendations
- Future Implications

Program Delivery

The program was designed to be delivered executive-style. Thus, all of the didactic course content will be available online. However, students will be required to travel to Houston, Texas for onsite meetings. These will be held over long weekends, beginning on a Thursday and ending on a Saturday. This will enable cohort building, meetings with advisors, and value-add activities such as guest lectures from leaders in the field of health informatics. First year students will meet 5 times throughout the year, while second through fourth year students will meet on campus once per semester.

Program Evaluation

This program is the first of its kind in the country. As such, there is no accreditor for a practice doctorate in this discipline at this time.

During the first and second cohorts, formative evaluations in the form of student feedback sessions will be conducted. Course evaluations will also be reviewed. Longitudinally, the program will be evaluated as follows:

1. Acceptance rates each year and longitudinally – More applications for the program than available slots will be an indication of the demand for this type of program. Decreasing rates of acceptance as the number of slots available each year increases over the first five years will indicate strong need for the program.
2. Qualitative Assessment at 2 and 4 years – Graduates will be interviewed and surveyed by program faculty at 2 and 4 years after graduation to determine which skills and competencies learned in the program have proven useful and which have not.
3. Aggregate Return on Investment of practicum projects – Demonstrating the cost-effectiveness of the practicum projects demonstrates the benefit the program can provide to the health care industry.

In addition, the state of Texas requires an annual report from all doctoral programs and an external review every 7 years from external reviewers.

Discussion

The DHI has not yet been implemented. However, given the evaluation proposed and the inclusion of a Return on Investment as an essential component of the translational practice project, value is expected to be documented as soon as the first students complete their studies. Whether these savings are expressed in actual dollars saved or adverse patient events prevented or efficiencies in the application of health informatin technology remains to be seen.

Upon approval in the early fall of 2018, the school issued a press release and opened an application on the website. (https://sbmi.uth.edu/news/story.htm?id=61f010ca-127e-4778-ab02-d7925d562f7e) An informational webinar held in early October 2018 had 27 participants from across the U.S. and even overseas.

One of the ways to judge the perceived need for a program such as this is by the expressed interest. By the March 1, 2019 deadline, twenty-nine (29) persons had started applications and thirteen (13) had submitted completed applications for review. As of this submission, applicant interviews were underway to choose the initial cohort.

Conclusions

This is a new terminal degree program aiming to educate health informatics and information technology executives as they seek to become evidence-based professionals who improve the health of people and populations through the application of health informatics. To the knowledge of the authors and sponsoring school, this is the only degree of this type in the world. As such, the program seeks to advance standards of care and models of delivery and health care policy via the implementation of the translational health informatics practice project. This proposed program offer health informatics

executives a unique educational opportunity that is not currently offered anywhere else in the U.S. or the world. The practice doctorate program will serve diverse communities, as executives within the program will represent a variety of health care facilities, companies, and other organizations (such as insurance and pharmaceutical companies) throughout the Texas Medical Center and beyond. The in-depth translational projects will seek to advance quality of care in those facilities and improve health care delivery, while reducing costs, for patients, their families, clinicians and the sponsoring organizations. The level of interest to date suggests that the health care industry is ready for a practice doctorate of health informatics or DHI.

Acknowledgements

The authors have no conflicts. The outline of the program contained in this document is subject to change. The authors which to thank their faculty colleagues at SBMI, as well as the SBMI Office of Academic Affairs staff for their support in bringing this dream to reality.

Layered Privacy Language Pseudonymization Extension for Health Care

Armin Gerl[a], Felix Bölz[a]

[a] *Chair of Distributed Information Systems, University of Passau, Passau, Bavaria, Germany*

Abstract

Enforcement of General Data Protection Regulation strengthens privacy in Europe and especially emphasizes protection of special categories of data as required in health care. Layered Privacy Language intends to model privacy policies to enforce them. Hereby, a special focus lays on the Policy-based De-identification process, which is based on anonymization and privacy models. Motivated by a health care scenario, this work shows pseudonymization capabilities are essential for health care. An overview of pseudonymization methods is given, showing a great variety of methods for different use cases. Therefore, a pseudonymization extension for Layered Privacy Language is introduced to define several pseudonymization methods. Furthermore, pseudonymization is added to Policy-based De-identification process of the overarching privacy framework of Layered Privacy Language. An example policy configuration is given demonstrating the introduced pseudonymization extension on the given health care example. The results are discussed, concluded, and future work is introduced.

Keywords:

Anonyms and pseudonyms, confidentiality, privacy

Introduction

The enforcement of the General Data Protection Regulation (GDPR) in May 25th 2018 strengthens privacy in Europe. The legal principles of Privacy by Design and Privacy by Default postulate that privacy has to be taken into consideration during design of all technical systems and default settings (e.g. privacy policy in an electronic system) have to be privacy friendly by default [Art. 25, 1]. Special categories of personal data, e.g. data concerning health or genetic data, are hereby especially protected and must not be processed unless special conditions are met like a legal basis or explicit consent [Art. 9, 1]. The Layered Privacy Language (LPL), including its overarching framework, intends to model and enforce privacy policies 'from consent to processing' [2]. Hereby, LPL models privacy policies, which are presented and possibly personalized by the individual Data Subject. If agreement and/or consent is given on the privacy policy, it will be pre-processed and stored. On a request of personal data for a specific purpose the Policy-based De-identification process is conducted. This determines if the requesting entity is authorized to request the data and, if necessary, anonymizes the data. Thus, anonymization techniques like generalization, suppression, and deletion are used to enforce privacy models like k-anonymity [3], l-diversity [4], or diffential privacy [5].

In this work, we introduce a scenario that demonstrates that privacy models solely are not suitable for health care. In health care, capabilities for pseudonymization have to be introduced in LPL, section *'Data Analysis in Health Care'*. Therefore, we give an overview of pseudonymization techniques in section *'Pseudonymization'*. In section *'Integration in LPL'* we describe extension of LPL, as well as integration of the pseudonymization techniques within existing Policy-based De-identification process. Section *'Health Care Scenario Results'* discusses extension of LPL according to the introduced scenario. In *'Discussion'* possibilities and limitations of the approach are shown. Lastly, the work is summarized and future work given in *'Conclusion'*.

Data Analysis in Health Care

In health care, patients' personal data is stored and processed for different purposes like billing, analysis, or research. Especially, information on patients' condition, e.g. blood sugar, symptoms, diseases and treatments, which fall under the special categories of personal data [Art. 9, 1], are stored alongside regular personal data like name, age or address, of patients. In the following, we assume a scenario in which a dataset is analysed to identify a possible epidemic. Here, influenza, commonly known as 'the flu', is divided into different types. *Type A* is generally responsible for large flu epidemics, *Type B* is less harmful, and *Type C* does not cause epidemics. There are additional sub-types, which are irrelevant for this example.

Table 1– Example health care dataset describing influenza types for patients. Attributes are assigned to privacy categories.

Name (*EI*)	**Age (*QI*)**	**Zip Code (*QI*)**	**Virus (*SD*)**
John	28	94032	Flu Type C
Max	25	94032	Flu Type C
Mary	22	94034	Flu Type A
Harry	20	94032	Flu Type B
Theresa	24	94034	Flu Type C

We assume a health care dataset like shown in Table 1, consisting of attributes of different privacy categories. In general, data is classified in four categories. *Explicit Identifiers (EI)*, attributes which identify a person uniquely. *Quasi Identifiers (QI)* which in combination identify a person. *Sensitive Data (SD)*, consisting of sensitive but not identifiable information about the record owner. *Non-Sensitive Data (NSD)*, data not in any of the categories above [6]. Based on this classification, which is also present in LPL, privacy models anonymize a dataset. We assume in this case that we want to protect the identity and sensitive information, which could also be maliciously utilized for de-identification [4]. Therefore, a

privacy model like l-diversity could be choosen and applied on the dataset.

The *EI* in l-diversity is anonymized by deletion (denoted by '*'). The *QI* and *SD* are anonymized, such that each group (age, zip code, and symptom) contains at least three identical entries. The values for attribute 'age' are generalized by decades, which leads to generalization of each value (e.g. '20' to '20 – 29'). For zip code, suppression is applied beginning with the last character, which is suitable for German zip codes. Lastly, attribute 'virus' is generalized from specific to more general description, e.g. 'Flu Type A' to 'Flu'.

The resulting anonymized dataset (see Table 2) may be interpreted as an epidemic in the general area of 9403* despite original data shows only one case of influenza *Type A* in area 94034, and one case of influenza *Type B* in 94032. Therefore, original data does not indicate epidemic outbreak but anonymized dataset might indicate outbreak of influenza (which type is unspecified). Although not shown explicitly in this example, *EI* is especially important in time series data in which same patient has to be identified over several records. This would be completely destroyed or falsified by anonymization techniques [6].

Table 2– De-identified data set with applied 3-diversity.

Name (*EI*)	Age (*QI*)	Zip Code (*QI*)	Virus (*SD*)
*	20 - 29	9403*	Flu
*	20 - 29	9403*	Flu
*	20 - 29	9403*	Flu
*	20 - 29	9403*	Flu
*	20 - 29	9403*	Flu

This leads to the conclusion that anonymization techniques solely are not sufficient. Pseudonymization techniques, on which we give a broad overview in the next section, are required and have to be explored for LPL.

Pseudonymization

In general, original dataset *D* is pseudonymized to *D'*. It consists of previously mentioned categories of data.

$$D = (EI, QI, SD, NSD)$$

In *D'* attributes are replaced with uniquely identifiable pseudonyms. Depending on use case, only *EI* have to be pseudonymized. Application of the different categories of data depends on use case. Typically, *EI* and *QI* are pseudonymized. However, *SD* and *NSD* may be pseudonymized.

$$D' = (EI', QI' SD', NSD')$$

In the following, overview of pseudonymization methods is presented.

Tokenization

Tokenization swaps distinct values with a token. Generation of the token can vary and may include a pseudo-random seed [7] or facilitate keys [8]. A distinction is made between dependent and independent tokenization. Dependent tokenization retains a relationship with original data in contrast to independent tokenization.

$$Independent: TokenGenerator \rightarrow Token$$

$$Dependent: TokenGenerator(Value) \rightarrow Token$$

As a result, pseudonyms based on independent tokens are more secure, because re-identification with given pseudonyms only is not possible (e.g. injection attacks) [9]. In general, generation of token is based on random seeds, cryptographic methods, or hashing [6]. An overview is given in the following.

Random Seeds

A pseudonym can be generated based on (pseudo-) random seeds. Here, it is essential to prevent token collisions. To gain more privacy, the random seed can be combined with secret keys. An example is the patient ID generator by K. Pommerening [7].

Cryptographic Methods

Encryption approaches are either symmetric or asymmetric. Symetric approaches utilize same key for encryption and decryption. For example, Heurix-Neubauer et al. [8] and Noumeir et al. [10] utilize DES and AES. Asymmetric approaches encrypt with public key and decrypt with private key. Rottondi et al. [11] presented pseudonymization based on the RSA. The keys must be stored securely to sustain feasibility of this approach [8]. To definitively prevent de-pseudonymization the private key can be dropped. In general, the disadvantage of crypthographic methods is increased computational cost. Additionally, generated token may not be of fixed length and might get quite excessive.

Hashing

A hash function usually maps an input set to a smaller target set. Thus, most hash functions are not injective. Contrary to cryptographic methods, generated tokens have same size regardless of entrys' length. However, due to the hash function's nature, different inputs may become the same pseudonym. Therefore, collision-resistant hash algorithms are preferred for pseudonymization. Furthermore, hashing methods can be classified into keyed and non-keyed hashing. Noumeir et al. [10] and Brekne et al. [9] utilize non-keyed MDX and SHA-X algorithms. The disadvantage of non-keyed hashing is that generated tokens can be linked between different datasets if same hashing function is used. Keyed methods extend cryptographic based hashes by a key, e.g. hash message authentication code (HMAC) [12]. Assuming the key remains secret, dictionary attacks or similar attacks are prevented.

Value-Preserving Techniques

There are some further methods for tokenization, which preserve particular operations on de-identified datasets increasing utility. These algorithms are developed for specific use cases. Examples are prefix-preserving IP address anonymization [13] and distance-preserving pseudonymization [14].

Implementation Patterns

To gain additional features, like increased degree of privacy or possibility for de-pseudonymization, tokenization can be combined with additional methods. Note that the following methods comparatively perform very weak if they are used solely in a security perspective, especially for small datasets. Thus, they should always be combined with other approaches [9,15].

A *bijective mapping* stores generated token and the original value.

$$Value \leftrightarrow Token$$

Thus, it allows authorized de-pseudonymization of the token. Therefore, storage has to be encrypted to avoid unauthorized de-pseudonymization [7]. When new data entries are added to

D, which have to be pseudonymized, then each value will be looked up in the encrypted mapping store and replaced by corresponding token. If no corresponding token is found new mapping is created and appended. Therefore, *D* with less distinct values is processed faster than *D* with various distinct value. Processing performance during de-pseudonymization depends on used data structure for storage.

Limited token generation mimics original values by exclusively calculating pseudonyms with same character set and same structure. As a result, privacy increases. For instance, an input date will also result structured as date after pseudonymization [6]. *Data permutation* swaps entries based on permutation function. For each new entry, changes have to be tracked by simple mapping or by updating the function. The pseudonymization can be reverted if permutation is known [9]. *Noise addition* is used to gain more privacy by adding a pseudo-random noise to input entries [15]. However, anomaly detection or similar techniques may counter noise. *Salting* adds entropy (or salt) to token generation process to increase computing costs of insider dictionary attacks and therefore reduces risk of de-pseudonymization [12]. The salt value can either be generated deterministically from a given entry as in PBKDF2 (hashing) [12], or as a random value as in RSA-OAEP modification (encryption) [11]. For equal values salt is reused.

Reasoning for Various Pseudonymization Methods

Pseudonymization method has to be selected based on intended usage. Here, several aspects have to be considered. Beginning with properties of the data value, required utility of the token, and usage of hashing and encryption methods. The requirement for later de-pseudonymization using bijective mappings or usage one-way pseudonymization for increased security should also be taken into consideration. Moreover, multiple techniques can be added to reach the desired level of privacy/security. Due to various possibilities for pseudonymization we concluded the requirement for a general specification of pseudonymization methods within LPL and its overarching privacy framework, which we discuss in the following.

Integration in LPL

Layered Privacy Language (LPL) is intended to model privacy policies combining both legal and computer science views on privacy. The original LPL [2] has been further extended by a *UI Extension* to support privacy icons for personal privacy policy user interface [16] and *Art. 12-14 GDPR Extension* [17]. Furthermore, LPL is accommodated by an overarching privacy framework that enables *Policy-based De-identification* utilitzing anonymization methods and privacy models. To facilitate various pseudoynmization methods within LPL, both policy and *Policy-based De-identification* process have to be extended. This is shown in the following.

Pseudonymization Extension for LPL

In the following, we describe *Pseudonymization Extension* for LPL based on original formalization by Gerl et al. [2]. Note that *UI Extension* [16] and *Art. 12-14 GDPR Extension* [17] are not considered as they do not interfere with integration of pseudonymization in LPL. The root element of LPL is the *LayeredPrivacyPolicy*-element *lpp*, which remains unchanged.

$$lpp = (version, name, lang, ppURI, upp, ds, P)$$

It consists of LPL version number, privacy policies name, language defined to display descriptions, link to legal privacy policy, *UnderlyingPrivacyPolicy*-element, *DataSource*-element and a set of *Purpose*-elements.

The *Purpose*-element *p* is extended allowing definition of pseudonymization methods on specific sets of data.

$$p = (name, optOut, required, descr, DR, r, pm, D, PSM)$$

Therefore, the purpose consists of its name, status flag specifying if user can opt-out or opt-in on the purpose, a flag whether the purpose is required to be accepted, description in defined language *lang*, set of *DataRecipient*-elements *dr*, *Retention*-element *r*, *PrivacyModel*-element *pm*, and a set of *Data*-elements *d*. The set of *PseudonymizationMethod psm* is appended, which will be further detailed. Note that it is also possible to assign no *psm*, if no pseudonymization is required for the purpose.

A *PseudonymizationMethod psm* represents one pseudonymization configuration, which will be applied on the dataset.

$$psm = (name, attrName, NOD, descr, header, PSMA)$$

It is a tuple with the following attributes:

- *name*: Defines pseudonymization approach. Consists of pre-defined set of available methods.
- *attrName*: Textual representation of name for newly created attribute, which holds pseudonyms.
- *NOD*: Set of *Name*Of*Data*-elements *nod*, which represent attributes to be pseudonymized. It refers the *name* attribute of the *Data*-element. It must at least consist of one valid *name*.
- *descr*: Human-readable description of pseudonymization in defined language *lang*.
- *header*: Human-readable header of pseudonymization in defined language *lang*.
- *PSMA*: Set of *PseudonymizationMethodAttribute*-elements *psma* describing further configurations of pseudonymization approach.

Each *PseudonymizationMethodAttribute*-element *psma* configures the defined approach:

$$psma = (key; value)$$

This key-value tuple defines attributes necessary for all possible methods.

LPL has been extended by adding *PseudonymizationMethod*-element *psm*, and *PseudonymizationMethodAttribute*-element *psma*, which allows definition of various pseudonymization methods (see Figure 1). In the current state, the extension supports various hashing approaches (SHA-X, MDX), keyed hashing (HMAC SHA-X), keyed hashing with entropies and mapping (PBKDF2 HMAC SHA-X), symmetric cryptography (AES, DES, 3DES, RC4, Blowfish), and random seeds with mapping. Further approaches can easily be added by defining them as *psm* and *psma* elements.

Secrets, which can lead to re-identification, are not stored in the LPL model. According to GDPR, these information must be stored separately [Recital 29, 1]. The concrete key and secret management belongs to the controller, entity which administrates stored data.

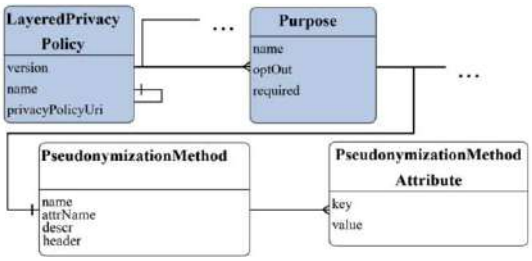

Figure 1– LPL structure extended by the pseudonymization elements. Further elements and attributes are omitted for the scope of this paper.

Policy-based De-identification

Policy-based De-identification based on LPL requires requesting entity to provide the purpose, a set of data , and set of data sources for the request. The requesting entity will then be authenticated. The purpose, entity and set of data will be authorized against properties of respective privacy policies *lpp* of the data sources. During *Minimum Anonymization* personalized privacy settings of each data source will be applied. Lastly, a common privacy model is derived from all related *lpp* and applied on the dataset.

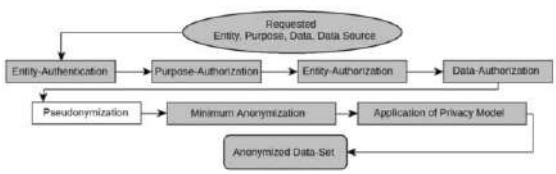

Figure 2– Modified Policy-based De-identification processes of the LPL framework when data is requested [2].

This process chain will be extended by adding the *Pseudonymization* process before *Minimum Anonymization* (see Figure 2). An inverted order, anonymization before pseudonymization, would result in less utility preservation, due to possible anonymization of values that should be preserved by tokenization with bijective mapping. Each pseudonymized *Data*-element will be altered after pseudonymization. For example, classification will be changed to *NDS* to avoid any further anonymization by later processes.

Health Care Scenario Results

With pseudonymization extension we can now de-identify the influenza dataset (see Table 1) and simultaneously add possibility of re-identification using bijective mappings. Patient names and virus type in the influenza example will both be stored as pseudonyms or IDs. For instance, if new insights regarding patients' health arise, IDs can be de-pseudonymized to deliver these new information to affected patients by gaining their identity and virus information.

The following configuration, using HMAC-SHA-1 algorithm and patient ID generator [7] combined with mappings, would achive such pseudonymization:

psm_0 = ("HMAC-SHA-1", "Name -ID", {"Name"}, "Description_0", "HMAC-SHA-1 pseudonymization", {})

psm_1 = ("PID", "Virus-ID", {"Virus"}, "Description_1", "PID pseudonymization", {})

It is noteworthy that the key, necessary for HMAC, and mapping are not defined within the LPL privacy policy to comply with GDPR [Recital 29, 1].

The results of the pseudonymization, applied on the raw data (see Table 1), defined by *psm_0* and *psm_1* are given in Table 3, which is accessible by the data analyist. Note that in Table 3 anonymization or privacy models are not applied. The mappings, necessary for re-identification, can be examined in Table 4, which should be secured and only be accessible by authorized personal. The extension also supports an AES encryption for mappings to increase security properties.

Table 3– De-identified dataset with pseudonymization. Pseudonyms shortened for better readability.

Name-ID (*NSD*)	Age (*QI*)	Zip Code (*QI*)	Virus-ID (*NSD*)
EA4B255	28	94032	KM93N2O
ADE0D85	25	94032	KM93N2O
2412F8F	22	94034	93I8M72
FF85768	20	94032	0O9INMW
71624DB	24	94034	KM93N2O

Table 4– Mappings which can restore content replaced by pseudonyms.

Name-ID	Name
EA4B255	John
ADE0D85	Max
2412F8F	Mary
FF85768	Harry
71624DB	Theresa

Virus-ID	Virus
93I8M72	Flu Type A
0O9INMW	Flu Type B
KM93N2O	Flu Type C

If we now compare anonymized data (see Table 2) and pseudonymized data (see Table 3), faulty conclusion cannot be made anymore. It can be observed that different types of viruses are present, which can uniquely be assigned to individuals. Still it can be seen that there is clustering. But with bijective mappings it can be shown that often appearing virus *KM93N2O* is the relatively harmless influenza *Type C*. Therefore, conclusion that there is no influenza epidemic, can be drawn. Furthermore, pseudonymization of SD can mitigate *attribute linkage* [4], identification by sensitive attribute. Due to pseudonymization, the attacker cannot infer privacy by identifying individuals by unique sensitive attributes or utilize external knowledge because provided information is not readable by the attacker.

Discussion

Based on verification of pseudonymization extension of LPL against introduced health care scenario, we conclude that anonymization methods and privacy models are insufficient for the given health care scenario. This is also valid for other anonymization techniques and privacy models. The application of pseudonymization methods tackles presented flaws by preserving essential data utility which would be lost otherwise. This has been exemplarily validated on the given scenario. To the extent of our knowledge, LPL is the first privacy language that models and enforces pseudonymization methods. Implementation is currently limited and in the state of work-in-progress. However, potentially various pseudonymization methods (which follow described configuration structure) may be added. For instance, asymmetric cryptographic functions and non-keyed hashing approaches with use of mappings for re-identification are appropriate additions. LPL certainly enables arbitrary combinations of pseudonymization and

anonymization. It is however important to choose suitable methods (pseudonymization, anonymization, privacy models) based on intended purpose, otherwise privacy may be broken. The selection of appropriate de-identification should be executed by an expert, e.g. trained data protection officer.

Conclusions

Privacy is an emerging topic which has to be considered within various fields. In health care it is especially necessary that data privacy is considered because processed data falls under the special categories of data. LPL intends to model privacy policies to inform *Data Subjects* and enforce privacy by design. In LPL, solely anonymization and privacy models were defined and used for de-identification. However, it was shown that pseudonymization is necessary for health care scenarios. *Pseudonymization Extension* of LPL offers possibility to define pseudonymization methods that have to be applied on the dataset. For example bijective mappings would allow an authorized de-identification, which is not possible for anonymization only techniques. Additionally, tokenization allows clear distinction of original values. *Policy-based De-identification* process joins pseudonymization, anonymization, and privacy models as a holistic approach. LPL and its overarching framework are continiously developed and researched. Evaluation of *Policy-based De-identification* process based on real health care data is sort after. Also, evaluation of LPL in other domains like *IoT*, *Cloud,* and *Mobility* are aimed for. The framework itself should be extended for fullfilment of *Data Subject Rights* to support *Data Protection Officers*. Suitable user interfaces for different domains and user groups (e.g. elderly or children) are developed to allow GDPR-compliant consent.

The Burden and Burnout in Documenting Patient Care: An Integrative Literature Review

Emily Gesner[a], Priscilla Gazarian[a], Patricia Dykes[b]

[a] *Department of Nursing, University of Massachusetts Boston, Boston, MA,*
[b] *Department of Medicine, Brigham and Women's Hospital, Boston, MA*

Abstract

The implementation of the electronic health record (EHR) across the globe has increased significantly in the last decade. Motivations for this trend include patient safety, regulatory requirements, and healthcare cost containment. However, the impact of regulatory requirements and new EHRs on clinicians has increased the incidence of documentation burden and may lead to burnout syndrome. It is important to understand the extent of documentation burden and potential solutions such as EHR user-interface redesign and the use of scribes to assist healthcare providers across the world.

Keywords:

Occupational Burnout, Electronic Health Records, Healthcare Providers

Introduction

The adoption of the electronic health record (EHR) in developed countries across the world has increased to almost 95% [1-3]. The motivation for health policies to implement the EHR is to improve the quality of care and reduce healthcare costs [4]. An example of a health policy that encourages EHR implementation is the Health Information Technology for Economic and Clinical Health (HITECH) Act in the United States (U.S.) [5]. One of the more significant programs within HITECH is the Promoting Interoperability (PI) Program which was formerly known as the Meaningful Use Program. The HITECH financial incentives and punitive measures were motivators for healthcare organizations to adopt EHR [5]. In addition, the World Health Organization (WHO) has encouraged the implementation of EHR in developing countries because of studies that show the improvement of patient outcomes [6].

The incidence of burnout syndrome in nurses in the U.S. ranges from 10% to 70% [7]. Also, more than half of physicians in the U.S. are reporting symptoms of burnout [8]. Studies have shown that the incidence of burnout syndrome is inversely proportional to patient outcomes [9]. Nursing and physicians are particularly vulnerable to burnout syndrome due to decreased job satisfaction, emotional, and physical exhaustion [10-12]. Clinicians report that they spend more than half of their day documenting patient care [13]. Studies also have found that when clinicians spend more time on clerical tasks, they have a decreased rate of job satisfaction which correlates to increased symptoms of burnout [11]. The purpose of this integrative review is to synthesize research evidence related to the extent of the documentation burden of healthcare providers and the potential solutions.

Methods

Using the strategies outlined by Whittemore & Knafl [14], four databases, (CINAHL, PubMed, ScienceDirect, and Web of Science) were searched as well as bibliographies of relevant articles and a broad internet search of the topic. The keywords used alone or in combination were "EHR documentation", "electronic documentation", "burden", "nursing", "nurse burnout", "physician burnout" and "clinician burnout", subject headings in CINAHL such as "burnout" were also used to broaden the search. All duplicate articles in the search were removed. Inclusion criteria included the following: Nursing and physician providers including Physician Assistants and Nurse Practitioners, EHR/electronic documentation of patient care, all healthcare settings. Due to the rapid change of technology and health policies throughout the world, we included research articles published between the years of 2013 and 2018. The types of studies included were experimental, quasi-experimental, descriptive, mixed-methods and qualitative. The exclusion criteria included any articles that focused on the process of transition from paper documentation to an EHR or from a legacy EHR to a new EHR system. Also excluded were non-physician/nursing providers (e.g. Chiropractors), news articles, articles not published in English and non-peer reviewed manuscripts.

Results

The initial search yielded 106 articles. After the inclusion/exclusion criteria were applied and duplicates removed, 26 articles remained. After the full-text articles were reviewed, a total of 10 articles [6; 11; 12; 15-21] were included in the final review (Figure 1). Common themes were identified from each article and tabulated (Table 1). A common theme identified in the articles is time pressure for documentation which relates to the increased stress clinicians experience when completing the time-consuming patient care documentation [11; 12; 15-20]. The main population found in the literature was physicians [6; 11; 12; 15-18; 20; 21]. Other populations identified in articles were advanced practice registered nurses (APRNs), ancillary care professionals in outpatient clinics and one article identified patients [6; 19; 21]. The solutions to documentation burnout identified were the use of clerical support or scribes to perform the documentation for clinicians [11; 12; 15-19], optimization of the EHR to enhance workflows [6; 12; 20] and additional training to improve documentation efficiency and quality [20].

Time Pressure for Documentation

All included articles [6; 11; 12; 15-21] discussed a possible link between the pressure or increased stress to document combined with the lack of time allocated for documentation and clinician burnout. Ehrenfeld & Wanderer [16] identified some evidence linking burnout to time pressure for documentation but not enough to characterize a strong link between the two. Most of the articles discussed the linkage between increased stress (e.g., documentation as one contributing factor to that stress) and the high rate of clinician burnout [11; 12; 15-19]. A common theme was that the requirements for data entry in the EHR took time away from patient care which led to poor job satisfaction [11; 12; 16-18]. Guo, Chen, & Mehta [20] discussed how decreasing "click-burden" or the amount of mouse clicks required in the EHR led to increased job satisfaction due to the decreased amount of time required to document.

Use of Clerical Support as a Solution

A proposed solution to increasing face-time and job satisfaction is the use of clerical support or "scribes" to perform the documentation for the clinician [11; 12; 15-19]. Four articles discussed how the increased amount of time required to document patient care could be relieved by simply assigning the task of documenting the care to another person who would observe the patient care along with the clinician [11; 15]. The use of scribes was identified only to assist physicians. Nurses were suggested as a possible staff member that could take the role of a scribe for the physicians [11; 16; 18]. There were no solutions offered in the articles related to assisting nurses with documentation burden.

Optimizing EHR Workflow through Education and Technical Enhancements

Jawhari et al. [6] discussed how lack of standardization increased documentation time which implied an increase in documentation burden. However, several articles [11; 12; 17; 22] suggested that education combined with technical enhancements in the EHR would improve the efficiency and quality of documentation. Robinson and Kersey [17] provided an educational intervention that improved the clinicians EHR workflow while also improving job satisfaction. Guo, Chen, & Mehta [20] provided a multi-faceted intervention which included technological options and EHR enhancements combined with a structured educational program. Studies that included interventions to improve the user-interface in combination with education showed significant improvement to an end user's documentation efficiency, quality of documentation and job satisfaction [17; 20].

Discussion

The main theme of the articles included in this review relates to how EHR documentation can contribute to burnout, and the potential solutions to mitigate this problem. Central to this theme was the discussion that increased documentation time takes away from providing direct patient care [6; 11; 12; 15-19; 22]. Solutions included the use of scribes, reconfiguration of the EHR, increased education about the EHR including education to improve clinician workflows, and utilizing technology in the EHR to assist with the completion of documentation.

Nurses at the Point of Patient Care

In terms of solutions for documentation burden, several articles discussed how nurses could be used as the scribes for the physicians [11; 16; 18] but this presents a greater problem [11]. Nurses must have the time to document their own care and would not have time to do documentation for the physicians. Nurses spend up to 60% of their shift documenting patient care and it is a considerable source of stress [10; 13; 23]. A recent study states that nurses have been shown to document up to 875 times per 12-hour shift which equates to documenting 1 data point per minute [24]. It is not feasible to add additional documentation responsibilities. Nurses are highly educated and over skilled for conducting only clerical work. Considering that the literature does suggest that higher amounts of required documentation increase the rate of burnout, it can be hypothesized that the rate of burnout syndrome in nursing would increase if their documentation requirements included documenting both nursing and medical care. The use of scribes may also affect the clinician-patient relationship by adding another person to listen and document during a patient's visit or in the patient's hospital room. Instead of adding more staff to fix the problem, the solutions may have to come from a modification of both regulatory requirements (e.g., lessen documentation requirements) and optimization of the EHR.

Emerging Technology to Decrease Burden

Another potential solution to the documentation burden presented in the literature was optimization of the EHR and education [20]. Emerging technology should be included in this category because of how innovations such as natural language processing (NLP) or artificial intelligence (AI) could address this growing problem (i.e., using NLP to integrate free text into clinical decision support). Though NLP has been used in various capacities in medicine, the application to clinical notes is still limited [24]. NLP could decrease documentation burden by allowing nurses or physicians to write a quick note which NLP would scan for information needed for clinical decision support (CDS) and convert unstructured data to structured data adequate for reporting to government agencies [25]. Artificial intelligence is currently being used to recognize progressions of disease in imaging but the possibilities to use AI in other capacities through machine learning to understand how the clinician documents and provide suggestions through algorithms or automate some documentation is conceivable [26; 27]. While AI or NLP may be possible interventions in the future, presently they may not be feasible for wide use due to software or financial constraints [28]. Based on this review, it is more feasible at this stage to optimize the EHR configuration to increase usability by decreasing the number of clicks and find low-technological ways to reduce documentation demand. Any reconfiguration of the EHR requires a well planned and structured education program for clinicians. The structured education program can provide communication regarding the changes to the EHR which may impact clinician workflows. The impacts may not be negative and provide a means to improve the quality and efficiency of documentation. The drive to implement the EHR and collect data has global implications which should be considered because it is these policies that have driven the EHR implementation for some of the major countries (e.g. China, France, Denmark, etc.) for the last decade [4].

International Health Policies surrounding EHR Documentation

The WHO identified that health outcomes and care efficiency are significantly impacted when an EHR is not implemented in a healthcare facility. They encouraged the implementation of the EHR in developed and developing countries. The motivation of the WHO to raise this topic on the global political agenda is to improve patient outcomes [22]. However, the downstream effect of this act may be that there is increased

pressure to perform more patient care documentation [11; 12; 15-20]. Health policies regarding the EHR and patient care documentation requirements vary. The articles reviewed did not discuss policies that may influence the type and amount of required patient documentation. The Commonwealth Fund profile on healthcare systems in nineteen countries discuss what policies influence the implementation of EHR documentation in each country but did not address the regulatory requirements surrounding documentation [4]. Studies evaluating international policies that encourage EHR implementation were not found during this literature review. However, that does not mean that they do not exist. It would be beneficial to analyze these policies for downstream effects especially as interoperability continues to expand into international space.

Conclusions

The studies included in this review have discussed the theme of documentation time pressure as a possible cause of clinician burnout syndrome. The possible solutions to relieve this pressure included the use of clerical support, EHR optimization and education. The focus of most of the studies to date involved physicians or APRNs. The evidence supports a link between documentation time pressure and burnout syndrome among all clinicians. The solution of using nurses as scribes may not be feasible due to their own documentation demands. It may be more reasonable to assess the EHR itself and possible technological innovations that can decrease documentation time burden. Despite any policies that may be in place across the globe, the problem of documentation burden is something that must be taken seriously as we continue to advance technology and monitor the incidence of clinician burnout syndrome.

Recommendations for Future Study

Future studies should include physicians and nurses in inpatient and outpatient settings. It should identify factors that can influence patient care documentation. It is important to discover if regulations and other health policies surrounding required documentation influence clinician burn out syndrome. Also, studies should include new technological interventions such as AI and NLP to understand if they make a positive or negative impact on the clinician's workflow and documentation time demands.

Tables

Table 1 – Articles reviewed

Author(s)/ year	Participants	Themes Identified	Proposed Solutions
Adnt, Beasley, Watkinson, & et al., (2017).	142 physicians in a single system in Wisconsin	Time required to use and document in the EMR; clerical burden	Use of Scribes Additional training for EHR documentation
Ehrenfeld & Wanderer (2018)	6 articles discussion the relationship between clinician burnout and the EHR	Clerical burden (e.g. burden of data entry)	Use of Scribes
Golob, Como, & Claridge (2015)	Trauma surgeons, orthopedic surgeons and neurosurgeons at a level 1 trauma center over the year of 2014	Time pressure for documentation	Clerical assistance for documentation (e.g. scribes), changes in workflow
Guo, Chen, & Mehta (2017)	Physicians at New York Presbyterian Hospital	EHR optimization	CDS (safety alerts) Use of EHR technology to optimize clinician workflow
Harris, Haskell, Cooper, Crouse, & Gardner (2018)	371 APRN's across Rhode Island	Time pressure for documentation	Use of clerical support staff (e.g. scribes).
Jawhari, J., Keenan, L., Zakus, D et al., (2016)	Outpatient clinic staff (physicians, nurses, etc.) in clinic in Kibera	Lack of EHR optimization	Optimize EHR; Providing training
Linzer, Poplau, Bobbit, et al., (2016)	Inpatient and outpatient physicians, nurse practitioners	Shorter visits, documentation time pressure, insufficient support staff	Use of Scribes IT Support and training
McMurray, Hicks, et al., (2013)	Outpatient clinic staff and 3 patients	Lack of EHR interoperability; Documentation burden	EHR optimization

Author(s)/ year	Participants	Themes Identified	Proposed Solutions
Robinson, Kersey (2018)	3500 physicians from 35 specialties	Lack of EHR optimization; education to improve documentation	Provide training for documentation best practice Optimize EHR workflow
Shanafelt, Dyrbye,Sinskey, et al, (2016)	Physicians in the U.S. across all specialties and settings	Time required to use and document in an EMR; clerical burden (e.g. data entry requirements)	Use Scribes Optimize EHR workflow Increase staff training

Experts Views on the Use of Mobile Devices to Support Patients with Mild Learning Disabilities During Clinical Consultations

Ryan Colin Gibson[a], Matt-Mouley Bouamrane[b], Mark Dunlop[a]

[a] *Department of Computer & Information Sciences, University of Strathclyde, Glasgow, United Kingdom*
[b] *Usher Institute of Population Health Sciences and Informatics, University of Edinburgh, Scotland*

Abstract

Due to several factors including time and budget constraints, General Practitioners (GPs) are often under-trained on the communication needs of patients with learning disabilities (LDs). As such, they may find it difficult to extract accurate information from these patients. Digital technologies have the potential to alleviate communication barriers, yet their use in this context remains vastly unexplored. Hence, we conducted 2 focus groups with 12 experts in LDs to investigate how tablet applications may be used to promote the information exchange process between GPs and patients with mild LDs. The experts identified an initial set of design criteria for the future implementation of these technologies and were enthusiastic about the potential impact they may have on primary care. In addition, they also discussed a potential model for extracting medical information from this population, which focused on breaking the overall consultation down into smaller, less cognitively challenging segments.

Keywords:

Mobile Applications; Intellectual Disability; Primary Health Care

Introduction

People with learning disabilities (LDs) are more susceptible to a range of conditions and comorbidities [1] and therefore have a higher demand for healthcare services compared to that of the general population. Despite this, the standard of care being provided is often inadequate [1] and this has a detrimental impact on both the length and quality of their lives.

To determine the overall scale of the problem, researchers at the University of Bristol conducted an inquiry into the premature deaths of people with LDs [1]. They examined the cause of death of 247 patients with LDs across 5 primary care trusts in the South West of England and found that approximately 50% were avoidable. Of these deaths, 27.5% were directly amenable to better care and this suggests that such patients are being subjected to serious health inequalities.

Previous studies [1–5] have investigated the various barriers to providing primary and secondary care for people with LDs, some of which may contribute to the findings made by Heslop et al. [1]. This literature covers a span of 2 decades, and with a number of barriers appearing consistently throughout, it is clear that effective support for this population has not been identified. Some of these obstacles include: difficulties identifying and accessing appropriate services; under-trained staff on the health and communication needs of patients with LDs; inflexible procedures; and insufficient collation and use of health care data.

Central to many of the identified barriers is communication. In primary care, this is extremely problematic since Howells suggests that "*the art of general practice lies in the ability to communicate with patients*" [6].

Nevertheless, patients with LDs have a number of impairments that affect their ability to convey medical information [2,3,7,8]. In addition, General Practitioners (GPs) often lack the skills required to adjust their consultation methods to limit the effect these impairments may have on the appointment [3,5].

Consequently, the overall goal of our research is to investigate the use of Alternative and Augmentative Communication (AAC) applications to promote the exchange of information between GPs and patients with mild LDs. AAC technologies are used to enhance an individual with disabilities capacity to communicate by offering those who cannot speak a platform to convey their needs (alternative), or by supplementing the vocabulary of those who can (augmentative). This contrasts with traditional information applications, which often treat accessibility as an afterthought.

Throughout the paper, we will present the results of an exploratory study in which 12 experts discussed how tablet AAC applications can improve consultations involving patients with mild LDs. The requirements listed will assist in the future development of medical AAC applications that target the needs of these stakeholders.

Background

In this section, we define the term "mild learning disability" and introduce some of the impairments common to this population that may have an adverse effect on the consultation process. We then discuss the available guidelines on how to communicate effectively with patients who have LDs, before giving an overview on the current use of digital technologies to promote the health of these patients.

Mild Learning Disability Characteristics

An individual may be diagnosed with a learning disability if they satisfy the following 3 criteria: their intellectual functioning is impaired; their social functioning is impaired; and the aforementioned conditions occur before adulthood [9]. LDs typically manifest across a scale ranging from mild to severe; however, those with mild LDs are generally able to communicate their everyday needs but may struggle with more complex concepts such as describing symptoms. A number of impairments tend to coexist with LDs that affect an individual's capacity to communicate their medical needs.

These include: cognitive impairments that affect vocabulary and sentence formulation skills, meaning the patient may not

possess the language required to accurately describe symptoms; reduced receptive skills that may affect their ability to understand the GP; limitations in their abstract thinking and long-term memory which may affect their ability to provide an accurate medical history; and a restricted knowledge of the human body, meaning they may not even recognise the presence of symptoms [2,3,7,8].

Guidelines in Consulting with Patients who have LDs

National and international guidelines e.g. [10] have been developed to assist medical professionals in conducting consultations with this population. Much of the advice regarding communication focuses on carrying out reasonable adjustments to cater to the individual needs of patients [10]. Some of the key recommendations include: extracting information directly from the patient; establishing the patient's preferred method of communication as early as possible e.g. by reviewing a clinical passport [11] if available; targeting a range of communication modalities based on the needs and preferences of the individual; and avoiding the use of medical jargon. GPs should also consider: utilizing gestures to emphasize communication; being vigilant for any additional information conveyed by the patient's body language; making sure the person has understood the information they have received; providing additional time for the patient to consider any information conveyed; and supplying information in advance of the consultation to help the patient prepare for the appointment.

Existing Health Applications for People with LDs

Researchers in the past have explored the use of digital technologies in a number of areas of health including: dentistry [12]; psychiatry [7]; and patient profiling [13]. Once again, this literature highlights the importance of exchanging information in a manner suited to the patient's individual needs. In particular, Menzies et al. recognized that the sole use of speech was not sufficient in conveying dental information to patients with cognitive disabilities [12]. Instead, they found that imagery/videos were particularly effective in describing the potential procedures to be carried out and the tools used within them. Furthermore, the professionals involved in this study requested features that assist in determining the patient's preferred method of communicating the terms "yes", "no" and "stop" – three aspects deemed crucial to their care. Prior et al's. study explored this functionality in further depth [13]. They developed a digital aid that extracts vital information from the patient (such as their communication needs, allergies etc.) prior to treatment. This information may then assist medical professionals in providing improved care, since they will be able to utilize the best practices when interacting with a patient. Bostrom & Eriksson investigated the possibility of providing healthcare data in advance of appointments [7]. They found that questionnaires could be successful in highlighting potential psychiatric conditions providing the information presented is accessible to stakeholders.

Methods

To determine the feasibility of embedding AAC applications in primary care, and to identify initial requirements that cater for the needs of patients with mild LDs, we conducted 2 focus groups with 12 experts in LDs (found in Table 1). We recruited experts in this study, as opposed to GPs, since they have extensive knowledge about the needs of people with LDs – a characteristic often not found in traditional medical professionals [5].

The LD nurses also understood the procedures involved in the consultation process, meaning the experts were better suited to identify how the proposed technology can support such patients. The set of features discussed will be expanded on during future studies that incorporate the views of both adults with mild LDs and GPs.

Table 1 – Expert Demographics

The focus groups were designed to achieve 2 goals: (1) improve the accessibility of co-design techniques that may be employed within future workshops; and (2) identify an initial set of features for the development of the application. This paper will primarily focus on the results pertaining to goal 2. All 12 participants were required to complete the 4 activities shown in Figure 1 - the details of which have been described in the "Data Collection" subsection. These activities were identified during a review of previous literature that aimed to explore the use of co-design processes with participants who have LDs. They were selected to address 3 specific aspects of the proposed application: appropriate imagery to capture medical symptoms; its overall functionality; and the design of the interface including the layout of each screen.

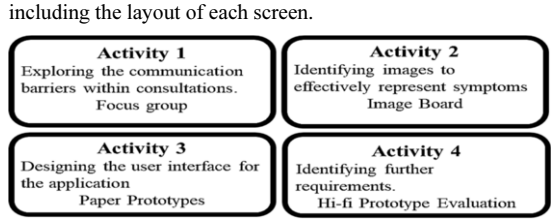

Figure 1 – The 4 Co-design Tasks Presented to the Experts

Invitations to participate in the study were issued (via email & telephone) to various charities, universities and hospitals throughout Scotland in May 2018. Seven experts from the city of Glasgow and 5 from Dundee consented to take part and formed focus groups 1 and 2 respectively. The focus groups were carried out in June 2018. Ethical approval to conduct this study was obtained from the Department of Computer and Information Sciences Ethics Committee at the University of Strathclyde.

Data Collection

The first task completed by the experts was a focus group that aimed to explore the primary barriers to effective health care for patients with LDs, as well as the potential use of digital technologies in mitigating these barriers.

The questions presented focused on the following 4 themes: (1) preparing for an appointment; (2) positive and negative encounters with GPs; (3) aptitude in using touch screen

technologies; and (4) how technology may be used to support the patient throughout the consultation.

Open-ended questions were primarily used to promote discussion and the session was conducted on a semi-structured basis to ensure the experts were able to raise, and expand upon, topics unforeseen by the authors [14].

The second task involved employing the image board methodology [15] to identify appropriate pictures to be included within the application. The experts were required to review images that depict common symptoms experienced by people with LDs and then separate these into one of two categories: those that accurately capture the condition; and those whose meaning is more obscure. A discussion then occurred as to why some images were more effective in capturing this information than others. Each symptom was portrayed using 3 separate styles of images - photorealistic, cartoon drawings, and simplistic black and white drawings to determine the style best suited to people with mild LDs. These styles were selected since they are often used in health-related resources for people with LDs.

The penultimate task consisted of a basic paper prototyping process. This involved placing/drawing elements onto a paper representation of a tablet based on the experts' views of the functionality and layout of each screen.

The fourth task involved the evaluation of a previously developed tablet application to try and discern the requirements that were not identified during task 3. This process was modelled around a "think-aloud" [16] session where the participants were required to complete 2 exercises and describe their reasons behind the actions being performed during real-time.

Data Analysis

The focus groups were recorded with participant consent and transcribed verbatim. The transcriptions were then subjected to a framework analysis to ensure a structured summary of the key features/requirements discussed was obtained. An initial thematic framework was developed by the first author based on the themes that emerged from a previous scoping review of the technologies used to support patients with mild LDs during clinical consultations.

The transcripts did not conform entirely to this framework and further codes were created to address this issue, at which point similar codes were grouped together to form overarching themes. The framework was reviewed by the second author and any discrepancies were resolved by the third author. The first author then tagged the transcriptions using the final framework and the relevant excerpts were transferred to their appropriate positions in the framework analysis table made available via the following doi: 10.15129/76f97730-a5fa-49da-973f-995373cee7ad. The requirements presented in the next section are based upon the main themes/sub-themes that emerged during this process.

Results

In this section, we present the key requirements identified by the experts. The quotes used to support these features are referred to using the participant ID listed in Table 1.

Simplifying the Consultation Process

The experts were of the opinion that the consultation process is often too complex for people with mild LDs.

Patients generally have to contemplate or provide information on aspects that are difficult to understand and must achieve this using methods that may be unsuited to their needs.

Consequently, the experts suggested developing technologies that help to break this process down into manageable sections, as discussed by participant 2.5:

"Could you not have something like that for the parts of the body - saying what part of the body the pain is in first of all? Once you've narrowed it down, have a different set of cards to say what type of pain is it? Is it hot pain? Does it [feel] cold? Is it sharp like a needle or something?

The participants in focus group 2 also recognised that the application should explore conditions that do not involve pain: participant 2.5:

"I suppose the problem is if [you] start with body parts and then go on to what's wrong with that body part, general symptoms of tiredness [for example] wouldn't be [picked up]. Do you know what I mean cause they might just feel totally drained all the time."

In summary, the experts suggested a potential model that may be utilized by GPs to explore the health of patients with LDs, as shown in Figure 2.

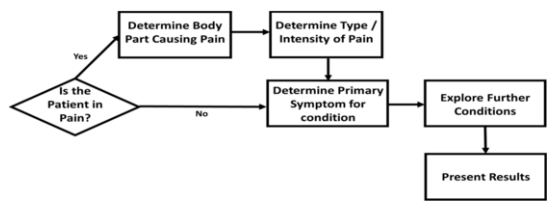

Figure 2 – Suggested Model for Diagnosing Patients with LDs

Utilizing Appropriate Modalities

The experts discussed two key strategies that may assist in promoting the accessibility of medical information, the first of which centres on the language used and the second focuses on the incorporation of images.

Comprehensible Language

Whilst describing appropriate language to be embedded within the application, the experts frequently cited common accessibility guidelines. This included: utilizing plain and simple language, along with short sentences that focus on solitary ideas; employing a minimum font size of 12; and offering the ability to playback textual information. In addition, the use of concrete examples was emphasized by participant 1.6 when describing particularly complex concepts. Finally, the experts in focus group 2 revealed that closed questions are most effective in extracting information from this population.

Identifiable Imagery

All experts throughout both focus groups emphasized the importance imagery may have in conveying medical information. Nevertheless, they were unable to agree upon the style of image that will be most effective in achieving this. For example, the participants in focus group 1 found that the more photorealistic images managed to capture the symptoms accurately, as described by participant 1.3:

"*I thought this tired one was quite good it was quite realistic - better than the sort of drawing of someone lying in their bed. I suppose that's a bit more cartoony, I think I prefer the actual person."*

In comparison, the experts in focus group 2 advocated for the use of the more simplistic black and white drawings, as discussed by participant 2.3:

"I prefer the egg head kind of ones 'cause they're not male or female. You know you might get a female with autism who's like that's not me 'cause [the picture is of a man]…And also,

less colour - just the black and white (colours) I think is more effective."

These excerpts suggest that a range of needs will have to be catered for by the images implemented within the application and this matches the views of participant 1.6:

"*It's quite difficult because when you think of people, some will really connect with some of them [the pictures] and some individuals will connect with others*."

Combining Modalities

In addition, the experts in focus group 1 revealed that the combination of text and images provided the most complete and accurate description of the symptoms presented as discussed by participant 1.4:

"You have headache at the bottom and I think if it didn't have headache at the bottom it would be quite confusing 'cause it could [mean something else]. So I think it's good with the headache heading."

Identifying Most Appropriate Communication Strategy

Participant 2.3 also discussed the benefits of using the application to identify the communication needs of the patient:

"My sister is a radiographer and sometimes there will be a little footnote somewhere [suggesting] some sort of learning disability and she's like "okay that's good to know but I want [more information]. You know, avoid saying this or use this approach".

This has the potential to increase communication significantly and matches the process described by both Menzies et al. [12] and Prior et al. [13].

Guiding the Patient

The experts in focus group 2 discussed two common scenarios that generate a heavy burden on healthcare services. Firstly, participant 2.4 suggested that some patients book medical appointments for the social experience as opposed to actually requiring treatment:

"*So [sometimes] they use health professionals inappropriately. You know, they make appointments with the doctor and they don't have any symptoms, they just want to talk to somebody. The doctor won't find the symptom cause there's not one there*."

The second involves patients prematurely booking appointments for conditions that have just occurred and will heal in due course, as discussed by participant 2.5:

"*For some of our clients, I don't see any point in [them] going to the GP. Sometimes it's something that's just happened and we expect it to be like that so [they shouldn't] go to the doctor."*

To overcome these issues, the experts discussed implementing a feature that makes use of the extracted information to suggest a course of action for the patient, as explained by participant 2.5:

"*Whether you can have solutions at the end to say well how long have you had a headache for? Right, try [taking] paracetamol or try drinking some water or a lie down or something. You know go and tell your care worker or your family first of all, so it could almost be like a filter*."

Consequently, the application could be used in the patient's home, before directing the individual to treatments out with primary care for minor ailments such as short-term headaches.

However, the app may also suggest that the individual contacts a medical professional, at which point the extracted information can be embedded in the consultation process.

Further Features

This subsection describes those features that were deemed to be important but do not fit into the previous 2 themes introduced.

In addition to presenting closed questions, participant 1.2 revealed that the amount of choice available should be limited, preferably to 2 options:

"I think as much as possible if you could have yes/no questions or like a tick and a cross to say is it painful [for example]. I think they might struggle if there's too many options."

The experts were also concerned about the user possessing the attentiveness required to complete the questionnaire, as discussed by participant 2.5:

"Even if they put down symptoms in different parts of the body and they gave up - if they take that to the GP, they could see some of things going on."

As such, they discussed the need to record the patient's progress to be completed at a later date or subsequently presented to the GP for review.

Discussion

Prior research has shown that digital technologies have the potential to increase the health of adults with LDs [7,12,13]. We add to this body of literature by highlighting the positive impact AAC applications may have within consultations involving this population. The experts were particularly enthusiastic about the technologies ability to support GPs in implementing many of the communication guidelines discussed in the "Background" section [10].

Previous research has explored extracting medical [7] or personal [11,13] information from the patient in advance of the appointment; however, the experts suggested that an application that combines both of these strategies should lead to optimal communication. Extracting medical information will enable practitioners to shape the questions to be presented, thus affording them more time to focus on aspects that may be crucial to a diagnosis. Furthermore, the patient may have more time to deliberate the questions being asked and subsequently construct an appropriate response. Obtaining personal information will enable the GP to utilize the strategies most suited to the patient's needs, which may ultimately increase their comprehension of the data being presented.

In accordance with the findings of previous literature [7,12,13,17,18], the experts highlighted the importance of combining images with accessible language to convey medical information. Nevertheless, they were unable to agree upon the style of image that captures this information best and instead revealed that a wide range of preferences must be catered for to meet the needs of people with mild LDs. Two strategies could be used to achieve this. First, several sets of images may be developed with the option to dynamically change between these sets e.g. when a user is unsure of the meaning conveyed by a particular image. However, this process may be cognitively challenging for people with LDs. As such, the second option involves the user completing an initial questionnaire that determines the most effective style of image to be embedded in the system, based on the individual's needs. Furthermore, the experts suggested that the application could assist in limiting the amount of unnecessary appointments attended by the patient.

This problem is also common throughout the general population, yet there is evidence to suggest that a higher percentage of people with LDs live with undiagnosed conditions e.g. [19]. Consequently, it is more important for these patients to seek medical care since more serious conditions may be the source of their current problem. The application can assist in this process by exploring all potential causes for the symptoms extracted, before suggesting a course of action.

A plethora of guidelines are available e.g. [10] to assist practitioners in conducting consultations with patients who have LDs, yet little research has been conducted into the specific questions to ask such patients. The experts discussed a potential model to achieve this by breaking down what is essentially a difficult process into more manageable parts. This process is shown in Figure 2 and consists of deducing whether the patient is pain; extracting the primary symptom causing their condition; and finally exploring any additional symptoms that may be present.

Conclusions

In this paper, we have presented one of the first studies to explore the potential use of tablet AAC applications to support patients with mild LDs during clinical consultations. Twelve experts in LDs participated in 2 focus groups throughout Scotland and subsequently identified a set of design criteria for the future development of such technologies. Developers will therefore be able to consider a variety of complex needs required by people with LDs and this criteria may be expanded on during future research with target stakeholders. In addition, this process has resulted in a potential model that may be utilized by GPs to extract symptoms from patients with mild LDs.

A Mobile Application for Patient Engagement to Support Interdisciplinary Care

Christian Haux, Julia Lutyj, Max Seitz, Petra Knaup

Institute for Medical Biometry and Informatics, University of Heidelberg, Heidelberg, Germany

Abstract

There is evidence on interrelationships between several dental and chronic diseases. However, dentists and general practitioners often lack information when treating such multimorbid patients. Engagement of the patient in the decision making process may help to fill this gap and improve intersectoral care. The Dent@Prevent project therefore aims to develop a mobile application that can be used by patients to report information about their health status for interdisciplinary care. In this paper, the user interface concept and evaluation of the prototype of this mobile application is presented.

Keywords:

Patient Participation, Mobile Applications, Intersectoral Collaboration

Introduction

Empirical evidence indicates interrelationships between dental diseases and chronic-systemic diseases, particularly between periodontitis and diabetes [1,2]. For example, it has been shown that the treatment of periodontitis can lead to a better glycemic control in diabetics [3].

This makes obvious that interprofessional collaboration between dentists and general practitioners (GPs) is important to provide good health care. However, interprofessional collaboration is often limited. In Germany, these professions are organizationally separated, and dentists and GPs often lack information about the general or oral health status of the patient from the other profession. For example, the oral health status is often not known to the GP [4]. Supporting interprofessional collaboration between dentists and GPs might enable an encompassing view of the patients' health status.

EHealth services and systems (e.g., referral portals and electronic health records) can support communication between health care providers. Nevertheless, there are no established or optimized solutions to support collaboration between dentists and GPs. This is necessary for conveying essential information as Electronic health records in general can lead to information overload for physicians [5].

Better involvement of the patient in the decision-making process may help to fill this gap and improve interprofessional care. Patient-reported outcome measures (PROMs) are gaining importance to measure outcomes of health care. Self-anamnesis and patient-centered parameters are used to get information about the general and oral health status of the patient. Patient-reported experience measures (PREMs) are used to measure patients' experiences with health care services [6].

The Dent@Prevent project aims to develop a mobile application for the collection of such patient-centered parameters [7]. The aim is to provide this data to dentists and GPs during the treatment process in order to improve interdisciplinary care. Further, the mobile application can be used to provide patients with additional individualized information about their general and oral health status and to make them aware of the interrelationships between diseases.

To support interdisciplinary care among dentists and GPs, PROMs and PREMs from both areas have to be requested from patients. This leads to a considerable amount of questions for the mobile application. It is crucial for the success of this project that the patient stays motivated during reporting parameters. Further, the application must be designed to meet the requirements of the intended user groups.

In this paper, the development and testing of a user interface concept and prototype of a mobile application for patients to report patient-centered parameters for interdisciplinary care of dentists and GPs is presented.

Methods

The application was developed in a five phases process.

First, the preliminary content of the application was determined in a scoping literature review [8,9]. The aim of the scoping review was to identify patient-centered parameters that are potentially relevant in the context of interrelationships between chronic-systemic and dental diseases.

The results of the scoping review were evaluated by dentists, GPs, scientists, and patients in an Online Delphi survey afterwards. The participants assessed the relevance of the preliminary patient-centered parameters, suggested changes, and determined the final parameters to be recorded by the patient with the mobile application.

A requirement analysis for the user interface concept was conducted subsequently. For this, personas were developed on the basis of a review of case reports in scientific literature that reflect the intended user groups. The case reports were found with a PubMed search using the search terms (((“case reports”[Publication Type]) AND “periodontitis”[Title/Abstract]) AND “diabetes”).

General information about the patients reported in the case reports was taken from the case reports to create the personas. Personas are an established method for representing a concrete model of a user [10]. The developed personas were used to deduct requirements for the user interface of the mobile application for the Dent@Prevent project. The requirements were differentiated into functional requirements and non functional requirements.

The user interface concept was designed using the prototyping tool Axure RP 8.1.0 [11]. The prototype that was developed with this tool was fully functional, so that it could be evaluated with users afterwards in a focus group discussion.

The objective of the focus group discussion was to evaluate the usability of the user interface concept. The participants were recruited in the department of endocrinology and metabolism at Heidelberg University Hospital and a pharmacy in Heidelberg. The user interface concept was installed on tablet PCs so that the participants of the focus group could test the application. Afterwards, the feedback was discussed with the participants. An interview guideline was created using questions from the System Usability Scale (SUS) [12]. Unlike the SUS questionnaires, the questions were asked by the moderator. Further, the experiences of the participants with the interdisciplinary cooperation between dentists and GPs were discussed during the focus group. The answers of the participants were recorded in writing.

The feedback from the participants of the focus group was incorporated in the user interface concept and a prototype of the mobile application was developed. The application was implemented for the operating systems Android and iOS. The framework, ResearchKit, was used to develop the application for iOS [13] and the framework, ResearchStack, was used to develop the application for Android [14]. ResearchKit is an open source framework for medical research that was released in 2015. ResearchStack is a similar framework for Android. The frameworks provide predefined modules and templates that can be adapted and customized for individual studies.

Results

The scoping literature review resulted in 23 publications that concern patient-centered parameters for the intersect of oral and chronic systemic diseases and interprofessional collaboration between dentists and GPs [8]. Nineteen patient-centered parameters were selected from the results for the Online Delphi, in which 22 GPs, dentists, scientists, and patients participated. The Online Delphi resulted in selecting 16 relevant patient-centered parameters.

The application contains 33 questions for anamnesis. They can be recorded with the mobile application to get information about the general and oral health status of the patient. For example, the patient is asked about existing diseases like diabetes and periodontitis. Further, the application contains validated risk questionnaires. To assess the risk for diabetes, questions from the FindRisk questionnaire [15] were included. To assess the risk for periodontitis, questions from the Periodontitis risk score [16] were included. Finally, the application contains parameters concerning patients perception on intersectoral care. Among others the patient is asked, which data he regards as important to be exchanged between dentists and GPs.

The PubMed search resulted in identification of 30 case reports. Using these, two personas were developed for the requirement analysis. The first persona covers younger patients, aged 20 to 40, that only suffer from either diabetes or periodontitis. The second persona covers multimorbid and older patients, aged greater than 40.

The functional and non-functional requirements that were deduced from these personas are depicted in table 1. One requirement for the application is that it should have a high usability for older users. Therefore, care was taken to ensure good readability by presenting the questions in a clear and uncluttered way.

Each question is displayed on a separate screen. Small font sizes were avoided as well as long texts, as they not only hamper the readability, but also cause a longer answer time. The most used answer formats are single-choice or multiple-choice answers and free text to supplement uncovered replies. Some questions used a Likert scale or an EQ-visual analogue scale (EQ-VAS). Answer options were vertically aligned to use the space on the smartphone display optimally. For navigation, a toolbar was integrated in the user interface. The users could switch backwards and forwards between questions. Further, they had the option to quit the survey and discard the results at any time.

The user interface concept was subsequently evaluated in a focus group discussion at the Heidelberg University Hospital in summer 2018. Six partly multimorbid participants joined the discussion. The feedback on the usability of the application was positive. The participants found the application intuitive and easy to use. Further, they found the time needed to answer the questions acceptable. However, the participants also provided some criticism. First, they stated that the preview of the next question at the bottom of the screen was distracting. Therefore, it was removed when the prototype of the application was developed (figure 1).

Table 1– Functional and non functional requirements for the mobile application

No.	Requirement	Description
Functional requirements		
1	Application for iOS and Android	The application should be available for iOS and Android
2	Start screen	The application should contain a start screen that contains a description of the study and the option to start the survey.
3	Informed consent	The application needs to support the collection of the informed consent of the patient.
4	Options when taking the survey	It should be possible to quit the survey at any time. All answers that were given so far must then be deleted. Questions should be skippable. Further, the user should have the option to switch between questions and correct answers.
Non functional requirements		
1	High usability	The application should be easy to use for different age groups. The font and font size should be easy to read.
2	Visualization	The questions should be presented in a clear and uncluttered way.
3	Self-descriptiveness	The application should be simple and easy to understand and allow intuitive operation.

Further, they found some questions difficult to answer. For example, the FindRisk questionnaire contains questions concerning waist circumference and body mass index (BMI). The participants assumed that some patients might not know their waist circumference or BMI. Therefore, the question concerning BMI was changed to allow users to enter their height and weight, and BMI is calculated from these parameters.

When asking the participants about their experiences with the interdisciplinary cooperation between dentists and GPs, they stated that dentists lack information about the patients' general diseases and vice versa. The participants assumed that better patient engagement in the process may help to improve the information exchange, and that they would use such a mobile application in their daily life. They appreciated if the mobile application could be used to provide information concerning the interrelationships between chronic and dental diseases to them.

The feedback from the focus groups was adopted in the prototype that was implemented using the ResearchKit framework for iOS and the ResearchStack framework for Android. The application consists of three modules. First, users give informed consent. Second, they fill in the questions for the patient-centered parameters. A third module that contains questions from the SUS was added to evaluate final application in dental practices. The defaults of the framework almost fit the specifications of the user interface concept. Some of the features of the user interface concept could not be implemented in the Android application using ResearchStack because the framework was lacking the corresponding features. For example, it was not possible to use a slider bar for the EQ-VAS answer formats. Instead, the input of a number was chosen (figure 2).

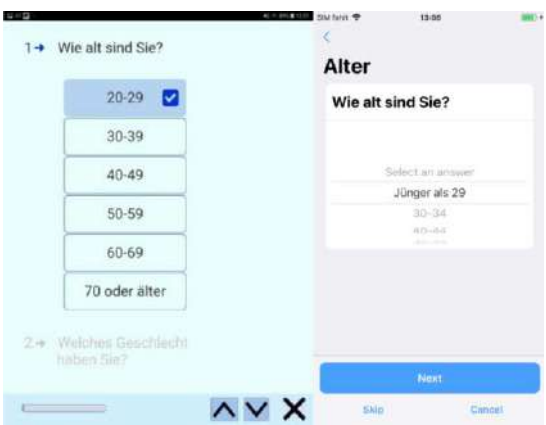

Figure 1– Example question of the user interface concept in Axure (left) and the prototype of the mobile application using ResearchKit (right). The preview of the next question at the bottom of the screen was removed in the prototype.

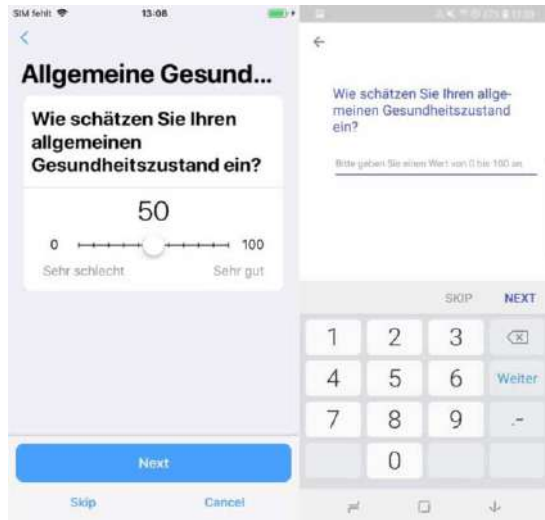

Figure 2– Difference between the ResearchKit framework (left) and the ResearchStack framework (right).

Discussion

The interprofessional collaboration between dentists and GPs is limited despite evidence on interrelationships between dental and chronic systemic diseases. Active patient involvement can play an important role in the implementation of an improved interdisciplinary treatment process.

This paper has described the development of a mobile application for patient engagement. By having a multi-step approach with designing first a user interface concept, having it be evaluated by users in the focus group, and implementing the prototype of the application, it was possible to integrate the feedback of users at an early stage of the development process to ensure that the application fits the requirements of its users.

Axure RP has proven a very comprehensive and complex prototyping tool for the user interface concept. The development of the user interface was rather time-consuming with the tool. The final development of the prototype using the ResearchKit and ResearchStack frameworks was done in a much shorter time. Therefore, it would have been possible to implement the user interface concept directly with the ResearchKit and ResearchStack frameworks for our application.

The choice to involve intended users in the focus group was advantageous – the users were integrated at an early stage, they could test the user interface concept on a device, and could give direct feedback. Further, problems or questions could be solved immediately when they raised during the discussion. However, it also had the disadvantage that the responsiveness of the users was different. As the moderator asked the questions to all participants in the group, some of the participants answered more than others. Therefore, the opinion of all users could not be collected completely, and users may have influenced each other [17]. Individual interviews with each participant may solve this issue.

By choosing the ResearchKit and ResearchStack frameworks for the development of the prototype, it was possible to save time during the development of the prototype because many of

the predefined modules and templates could be used directly. However, in some cases it was not possible to realize every aspect of the user interface concept with the defaults. Further, the functionality between the ResearchKit framework and the ResearchStack framework differ. For example, the ResearchStack framework lacks answer formats. Such limitations were solved by choosing a different answer type in the Android application. Another advantage of using these frameworks is that they are not dependent on any data storage or data exchange service.

The developed prototype will be tested in dental and general practices in the near future. Patients will be asked to fill in the questionnaire and rate the usability of the application afterwards. The answers of the participants will be stored locally on the mobile device in an aggregated way. Thus, data protection requirements can be adhered to.

Conclusions

The prototype of the mobile application for patient engagement to improve the interprofessional collaboration between dentists and GPs was successfully developed. The prototype will subsequently be tested by patients in dental and general practices.

How Do General-Purpose Sentiment Analyzers Perform when Applied to Health-Related Online Social Media Data?

Lu He, Kai Zheng

Department of Informatics, University of California, Irvine, City Irvine, CA, USA

Abstract

Sentiment analysis has been increasingly used to analyze online social media data such as tweets and health forum posts. However, previous studies often adopted existing, general-purpose sentiment analyzers developed in non-healthcare domains, without assessing their validity and without customizing them for the specific study context. In this work, we empirically evaluated three general-purpose sentiment analyzers popularly used in previous studies (Stanford Core NLP Sentiment Analysis, TextBlob, and VADER), based on two online health datasets and a general-purpose dataset as the baseline. We illustrate that none of these general-purpose sentiment analyzers were able to produce satisfactory classifications of sentiment polarity. Further, these sentiment analyzers generated inconsistent results when applied to the same dataset, and their performance varies to a great extent across the two health datasets. Significant future work is therefore needed to develop context-specific sentiment analysis tools for analyzing online health data.

Social Media; Computing Methodologies

Introduction

Increasingly, patients use the internet to ask questions related to their health conditions and write about their experience coping with diseases. According to a survey conducted by the Pew Internet Project, in the U.S., one in five patients' living with chronic diseases participated in creating online content about their health or medical issues through social media websites [1]. As such content is readily available and contains rich information and insights, researchers have started to utilize it as a new source of data to conduct novel research studies. In this paper, we refer to such content hereafter as "online health data."

Sentiment analysis, also known as opinion mining, is a branch of natural language processing (NLP) for describing emotions from text. It provides a computational means to automatically classify positive, negative, or neutral attitude toward a subject (e.g. a movie) based on the opinions expressed in a piece of text (e.g. a movie review). In health-related disciplines, sentiment analysis has been widely applied to analyze online health data to investigate in topics such as public opinions of health policies (e.g. the Affordable Care Act) [2], patient attitudes toward a medical treatment or intervention (e.g. vaccination) [3,4], consumer rating of healthcare services or products (e.g. hospital services; drugs and cosmetic products) [5,6] and patient journeys (e.g. stigmatization related to Alzheimer's Disease) [7].

The proliferation of research work that has applied sentiment analysis to online health data is attributable in part to the availability of several general-purpose sentiment analyzers (e.g. Stanford Core NLP Sentiment Analysis). However, all of these analyzers were initially developed in non-healthcare contexts; and were trained on non-healthcare datasets. It is therefore imperative to evaluate their validity before applying them to analyze online health data. Unfortunately, in reviewing the relevant literature, we found that previous studies used these general-purpose sentiment analyzers in a rather arbitrary manner. Most of the studies did not provide adequate justifications as to why a particular sentiment analyzer was chosen; whether it was appropriate for a study context; and whether other analyzers might produce better results.

In this paper, we aimed to address this gap by empirically evaluating the performance of three general-purpose sentiment analyzers that have been most popularly used in previous studies: Stanford Core NLP Sentiment Analysis, TextBlob, and VADER. We applied these sentiment analyzers on two datasets, representing two typical analytical scenarios with online health data: public opinions regarding health interventions and healthcare policy. We also used a non-domain specific twitter dataset to serve as the baseline and compared the performances of the analyzers on the baseline dataset with the other two health-related datasets. Through the empirical evaluation, we aimed to answer the following research questions:

1. 1. Do different sentiment analyzers produce consistent results when applied to the same online health dataset?
2. 2. Does the same general-purpose sentiment analyzer perform differently when applied to different online health datasets concerning different health topics?
3. 3. Are these general-purpose sentiment analyzers adequate enough to generate useful results without retuning for online health data?

Answering these questions may help the research community establish an evidence base as regards the validity of these general-purpose analyzers when applied in studies that involve online health data. The results may also provide insights into how to properly select the right sentiment analyzer for a particular study context, and how to improve their performance in future research.

Related Work

Most of the existing sentiment analyzers and lexicons were developed based on movie reviews or product reviews, possibly

because of the availability of large amounts of labeled data for training. The Hu&Liu sentiment lexicon, one of the earliest tools for sentiment analysis, was curated by manually grouping words contained in e-Commerce product reviews into different sentiment categories [8]. Similarly, the most popularly used sentiment analyzer, the Stanford CoreNLP Sentiment Analysis tool, based its sentiment treebank and model training on a movie review dataset [9,10].

In health-related studies, Korkontzelos et al. used sentiment analysis to detect adverse drug reaction (ADR) based on twitter data, and demonstrated a higher level of accuracy as compared to conventional approaches [11]. Davis et al. used a sentiment lexicon named labMT15 to assess public opinions expressed in tweets regarding the Affordable Care Act (ACA), and showed that the results were highly consistent with what could only be obtainable previously through expensive polls [2]. In another study, Du et al. used the supervised machine-learning method to automatically classify tweets based on the sentiments toward HPV, and to study the evolution of the sentiments over time using a time series analysis [3]. More recently, Burnap et al. incorporated sentiment scores into their feature sets to develop supervised machine learning models that automatically detect suicide-related tweets [12]; and Ji et al. extracted negative sentiments from online social media data to understand public health concerns regarding disease epidemics [13].

While researchers may opt to train machine-learning classifiers on their own datasets, doing so requires a significant amount of manually annotated data, in addition to sophisticated skills in developing, training, and testing machine learning models. As a result, most of the previous studies leveraged existing, general-purpose sentiment analyzers that are readily available and are relatively easy to adopt. However, as it has been previously demonstrated, sentiment analysis models trained in one domain may perform poorly when applied in another domain without adaptation. In a study on Ebola-related social media discussions, Lu et al. noticed a significant level of disagreement between the results generated by different sentiment analyzers that they experimented with [14]. In reviewing the previous studies, we also found that there was generally a lack of discussions on the rationale of choosing a particular sentiment analyzer; and very few studies validated the analyzer chosen before applying it to their datasets. It thus remains unknown whether the results reported in these studies, based on general-purpose sentiment analyzers developed in non-healthcare domains, are reliable and repeatable.

Methods

Sentiment Analyzers Studied

In this paper, we evaluated three sentiment analyzers that had been most popularly used in previous studies: Stanford Core NLP Sentiment Analysis, TextBlob, and VADER.

The Stanford Core NLP Sentiment Analysis tool was developed by the Stanford NLP group as a module in the Stanford Core NLP toolkit [9]. Its sentiment analysis model was trained using a recursive neural tensor network on a movie review dataset made available by Pang and Lee [10]. Unlike earlier sentiment analyzers, in which bag of words was used and word orders were ignored, the Stanford Sentiment Analysis tool parses input text into sentiment trees, where each leaf node refers to a word; every word in the input text is thus represented as a vector. Instead of producing numerical sentiment score, the results generated by the Stanford Sentiment Analysis tool are in the form of discrete categories, namely “very negative,” “neutral,” “positive,” and “very positive.”

TextBlob is a widely distributed Python Library with an easy-to-use API that can be called upon by other programs to analyze sentiments of text, in addition to performing other common NLP tasks such as part-of-speech tagging and tokenization [15]. Its sentiment analyzer has two implementations: one based on a collection of semantic patterns; and the other based on a Naïve Bayes learning module. TextBlob returns sentiment analysis results in the form of numerical polarity ranging from -1 (most negative) to 1 (most positive). It also produces a companion subjectivity score in the range of 0 (very objective) to 1 (very subjective).

VADER, which stands for Valence Aware Dictionary and sEntiment Reasoner, is an open-source sentiment analyzer developed and maintained by Hutto and Gilbert. VADER is a lexicon and rule-based tool optimized for classifying sentiments expressed in user-generated text in social media [16]. The rules it utilizes are heuristics derived from a manual review of a set of tweets by multiple independent human judges. The authors have also incorporated many features that are not found in other sentiment analyzers, such as punctuation, capitalization, slangs, emoticons, and degree modifiers. The results produced by VADER are in the form of sentiment polarity (positive vs. negative), and a numeric sentiment intensity score on a scale from -4 (extremely negative) to +4 (extremely positive).

Annotated Datasets for Evaluation

To evaluate the performance of these general-purpose sentiment analyzers, we leveraged two publicly available online health datasets that were annotated in previous studies for the purposes of understanding public opinions of the Health Care Reform (hereafter referred to as the “HCR” dataset) and public opinions of HPV (the “HPV” dataset), respectively. We also used a general-purpose twitter dataset to serve as the baseline.

The first dataset, or the HCR dataset, contains tweets that include the hashtag “#hcr” in March 2010. The original annotated dataset also includes 8 different targets, for instance, Obama, HCR, Liberals, etc. The annotated sentiments include 5 categories, positive, negative, neutral, irrelevant and unsure. For our study purpose, we only included the tweets that targeted on HCR and those that expressed positive, negative or neutral sentiments. This resulted in a total of 961 tweets, with 290 of them (30%) being labeled as positive, 422 (44%) being labeled as negative and 249 (26%) being labeled as neutral.

The second dataset used in this study was curated and made available by Du et al. This dataset was created by three human annotators in an attempt to discover hierarchical sentiment categories of public opinions regarding the HPV vaccination [3]. The manually annotated results consist of three major categories: “negative,” “positive/neutral,” and “unrelated.” The original dataset contained a total of 6,000 tweet IDs. After removing invalid tweet IDs (e.g. those that were deleted, or are no longer publicly accessible), 4,616 tweets are available to use in this study. As our study focused on sentiment analysis, we further excluded those tweets that were labeled as “unrelated,” which left us 3,211 tweets to work with. Among these tweets, 1,084 (34%) were annotated as negative, and 998 (31%) were positive and 1129 (35%) were neutral.

The baseline dataset contains non-domain specific tweets that have been annotated. It includes tweets regarding products (e.g., “am loving new malcolm gladwell book - outliers”), personal experiences or feelings (e.g., “so tired. I didn't sleep well at all last night.”), opinions (e.g., “If Google's self-driving

car is the future, I don't want to be a part of it. #savethemanuals"). It contains 381 positive tweets (38.9%), 387 negative tweets (39.5%) and 212 neutral tweets (21.6%).

Study Design

We separately applied the three sentiment analyzers to each of the annotated datasets. To answer the first research question ("do different sentiment analyzers produce consistent results when applied to the same online health dataset"), we calculated the inter-rater agreement rate between the results generated by different sentiment analyzers when applied to the same dataset. To answer the second research question ("does the same general-purpose sentiment analyzer perform differently when applied to different online health datasets concerning different health topics"), we computed the precision-recall-F1 metrics of the sentiment analyzers across the two annotated datasets. We then compared the classification results (i.e. sentiment polarity) to the ground truth—human annotations, to answer the third research question ("are these general-purpose sentiment analyzers adequate enough to generate useful results without retuning for online health data"). Last, we performed term frequency-inverse document frequency (TF-IDF) analysis to extract and compare the important words in each sentiment category across the three datasets.

Results

The overall results - the precision, recall, F1-measure metrics of each sentiment analyzer on each dataset are reported in Table 1, Table2 and Table 3. The recall measure should be interpreted with caution, as with skewed datasets it is easy to achieve a high recall by incorrectly labeling the data. Stanford NLP sentiment analyzer performed poorly on both the HCR and the HPV dataset, compared to the baseline dataset, as it has extremely low precision (e.g., 11%, 7.3%) in detecting positive sentiments on the HCR dataset and the HPV dataset. VADER performed fine on the HCR and the HPV dataset with around 42 % to 51% F1-measures in each sentiment category, however, the performance on the baseline dataset (65%~74%) still beats these numbers. TextBlob performed the worst in distinguishing sentiment classes, especially that it assigned most labels as neutral. It performed equally poorly on the HCR and the HPV dataset with extremely low precision for the positive and negative sentiment class, but had decent performance on the baseline dataset. Therefore, the three sentiment analyzers all performed poorly on the two health-related datasets, but had satisfying performance (i.e., most having a precision or a recall higher than 60% in detecting the three sentiment categories) on the baseline dataset that is non-domain specific.

Table 1- Precision, recall, F1-measure, Stanford NLP

		Dataset		
Class	**Metric**	**Baseline**	**HCR**	**HPV**
Positive	Precision	54%	11%	7.3%
	Recall	73%	62.7%	47%
	F1-measure	62%	18.8%	12.7%
Negative	Precision	39%	47.2%	58.2%
	Recall	71%	46.5%	35.8%
	F1-measure	51%	46.8%	44.3%
Neutral	Precision	74%	38.6%	39%
	Recall	34%	20%	34%
	F1-measure	47%	26.3%	36.6%

Table 2-Precision, recall, F1-measure, VADER

		Dataset		
Class	**Metric**	**Baseline**	**HCR**	**HPV**
Positive	Precision	82.6%	54.8%	39%
	Recall	67.6%	38.2%	45%
	F1-measure	74%	45%	42%
Negative	Precision	64.7%	35.4%	57%
	Recall	90.7%	56.4%	49%
	F1-measure	75.5%	43.5%	53%
Neutral	Precision	68.8%	46.6%	50%
	Recall	62%	41.4%	51%
	F1-measure	65.3%	43.9%	51%

Table 3-Precision, Recall, F1-measure, TextBlob

		Dataset		
Class	**Metric**	**Baseline**	**HCR**	**HPV**
Positive	Precision	59%	7.6%	3%
	Recall	72%	40.7%	49%
	F1-measure	65%	12.8%	5.9%
Negative	Precision	40%	2.6%	3.8%
	Recall	90%	68.8%	65%
	F1-measure	55%	5%	7.1%
Neutral	Precision	82%	96.8%	97.6%
	Recall	36.8%	27%	36%
	F1-measure	51%	42.2%	52%

Table 4 reports the inter-rater agreement rates when applying these sentiment analyzers to the first annotated dataset (HCR). Among the three sentiment analyzers, Stanford NLP and TextBlob exhibit a high degree of agreement with each other, 46.68%; while the results obtained by the VADER Sentiment Analysis tool correlate poorly with the other two analyzers, for instance, Stanford NLP in particular (29.88%). Shown in Table 5 are inter-rater agreement rates when applying each of the three sentiment analyzers to the second annotated dataset (HPV). Similarly, Stanford NLP and TextBlob have the highest agreement (39.3%). However, the results produced by VADER and by the Stanford NLP Sentiment Analysis tool are poorly correlated; the inter-rater agreement ratio is only 38.0%. In Table 6 we present the inter-rater agreement rates of the three sentiment analyzers on the baseline dataset. While the agreement rates are higher than those of the HPV and the HCR datasets, they are still unsatisfying with only around 50% agreement ratios of each pair of the three sentiment analyzers.

Table 4-Inter-rate agreement rates, the HCR dataset

Analyzer A	**Analyzer B**	**Agreement Ratio**
Stanford	TextBlob	46.68%
Stanford	VADER	29.88%
VADER	TextBlob	34.95%

Table 5-Inter-rate agreement rates, the HPV dataset

Analyzer A	**Analyzer B**	**Agreement Ratio**
Stanford	TextBlob	39.3%
Stanford	VADER	38.0%
VADER	TextBlob	38.5%

Table 6-Inter-rate agreement rates, the Baseline dataset

Analyzer A	Analyzer B	Agreement Ratio
Stanford	TextBlob	51.0 %
Stanford	VADER	42.6%
VADER	TextBlob	42.7%

To further explore possible reasons why general-purpose sentiment analyzers perform significantly worse on health-related datasets than on baseline, non-domain specific dataset, and how different health-related datasets are from the non-domain specific dataset, we used term frequency-inverse document frequency (TF-IDF) analysis. Table 7 to Table 9 present the top-5 weighted TF-IDF unigrams of the three datasets for each sentiment category.

Table 7: Top-5 positive unigrams

Baseline	HCR	HPV
love	Passthedamnbill	Act2015
happy	Affordable	availability
Lebron	Human	post2015
earlier	Petition	saving
seats	stupakpitts	literally

Table 8: Top-5 negative unigrams

Baseline	HCR	HPV
fucking	handsoff	neutral
warner	takeover	trigger
fuck	killthebill	victim
driverless	tax	injury
cable	codered	danish

Table 9: Top-5 neutral unigrams

Baseline	HCR	HPV
Driving	defazio	slightly
deflategate	holding	stance
Google	schedule	callaghan
Check	breaking	heather
flight	association	project

The TF-IDF analysis may in part explain why the sentiment analyzers tend to assign too many neutral labels and fail to recognize negative and positive sentiment classes. For instance, words and phrases such as "danish" itself is neutral, but tweets that express negative sentiments toward HPV often include such words to form their arguments. However, the three sentiment analyzers failed to recognize them as negative, because without a proper context, they are neutral. A sample tweet "Vaccines trigger genetically modified diseases" is labeled as neutral by VADER and TextBlob. While we do not have space to include the top-10 unigrams and bigrams of the baseline dataset, we observed that the top-10 weighted unigrams are sentiment words such as "love", "happy", "amazing", "better", "thank", etc, which do not appear in the unigrams in both the HCR and the HPV datasets. Therefore, the significant differences in performance of the three sentiment analyzers on health-related datasets and general datasets that are not in health-domain may be explained in part by the different ways of sentiment expression – in health-related social media data, people use words that are neutral to form arguments and express negative or positive sentiments, and such expressions cannot be accurately captured by general-purpose sentiment analyzers. We also noticed that for the HCR dataset, many of the combined word phrases such as "passthedamnbill" and "killthebill" are used to express sentiments, however current NLP tools may have difficulties parsing and splitting those combined words, and therefore makes it hard to sentiment analyzers to detect the underlying sentiments.

Discussion

Our results indicate that the three general-purpose sentiment analyzers popularly used in previous studies produced inconsistent classification results when applied to the same online health dataset, and their performance varies to a great extent across different datasets. Among these three analyzers, VADER and the Stanford Sentiment Analysis tool have the lowest degree of inter-rater agreement. This may be due to the fact that these two sentiment analyzers were developed from distinct domains: VADER drew its lexicon and rules primarily from social media data (tweets); while the Stanford Sentiment Analysis tool was developed based on movie reviews. This finding indicates that in sentiment analysis, the utility of a high-performing sentiment analyzer trained in one domain may not be transferable to other domains. Thus, when deciding what sentiment lexicons or sentiment analyzers to use, researchers should be aware of the contexts in which they were originally developed, in addition to its underlying classification mechanisms.

Overall, the performance of these three general-purpose sentiment analyzers is unsatisfactory (e.g., having extremely low precision in detecting positive sentiments or falsely labeling tweets as neutral) when applied to online health data, while they have decent performance on non-health related social media data. The Stanford Core NLP Sentiment Analysis tool may fall short because of the nature of user-generated content online, especially tweets, that contain an excessive number of anonyms, abbreviations, hashtags, and URLs; as compared to movie reviews that are generally well structured. However, this does not explain why tools such as VADER, which was specifically designed to process social media data, missed a vast majority of the text containing negative sentiments in the HPV dataset and HCR dataset. It is possible that "negativity," "positivity," and "neutrality" of sentiments expressed in the context of health-related discussions may be interpreted differently by human annotators, in contrast to sentiments conveyed in other types of social media exchanges, demonstrated by the TF-IDF analysis above. Thus, it is critical for health sciences researchers to be mindful of the limitation of the sentiment analyzer(s) that they choose to use.

The findings from this study provide insights into future work on how to improve the utility of sentiment analysis in studies that involve online health data. First, based on our review of previous work, it appears that a lack of comprehensive understanding of the state-of-the-art of sentiment analysis tools impedes researchers from picking the right tool for their studies, and from providing adequate rationale to justify their choices. Therefore, it will be very valuable to have a "road map" of the history and recent development of sentiment analyzers and lexicons, especially their context of development, working mechanisms, and intended use. Second, the existing general-purpose sentiment analyzers need to be significantly adapted when used to analyze online health data. This requires a thorough understanding of the nature of health-related social media discussions, and of the specific health-related topic being studied; for example, the algorithm and lexicon appropriate for determining sentiment polarity in detection of drug side effects

can be very different from what is appropriate for use in understanding the public's opinions toward a health policy. Future work is thus called for to explore how to develop context-specific lexicons and sentiment analyzers that are optimized for analyzing different types of online health data. Third, pre-study validation and post- study error analysis are essential to understand the utility and limitation of an existing sentiment analyzer, which should be performed and reported in every study that involves sentiment analysis. Unfortunately, most of the previous studies that we reviewed simply reported the results produced by a general-purpose sentiment analyzer, without conducting any assessment of the validity of the results. Lastly, knowing that sentiment analyzers usually do not perform well when applied across domains, the research community may consider developing domain adaptation techniques that can be readily applied to extend the capability of existing general-purpose sentiment analyzers, e.g., by means of re-training sentiment analysis models, adjusting heuristics and rules, or swapping lexicons.

Conclusion

In this study, we empirically evaluated the performance of three general-purpose sentiment analyzers on two different online health datasets. The results show that these general-purpose sentiment analyzers were unable to produce consistent results when applied to the same dataset, and their performance varies when applied to different datasets. These findings suggest that general-purpose sentiment analyzers developed in non-healthcare domains may perform poorly on online health data. Future work is thus needed to identify ways to tailor them, or develop new sentiment analyzers optimized for the health context.

Abstract

Redesigning Electronic Medical Record (EMR) systems is needed to improve their usefulness and usability. For user-centered redesign, designers should consider which EMR features are the most important to the users. However, prioritizing the EMR features is complicated because: (i) EMR systems involve multiple users with different, and sometimes conflicting, priorities and (ii) targeting one feature will affect other features of the EMR system. In this work, we propose a method for prioritizing the features to target when redesigning an EMR system. The method takes into consideration the different priorities of the users and the relationships between the different features. We illustrate the method through a case study on redesigning EMR systems in Japanese antenatal care settings. Our results show the importance of considering the different types of EMR users and the relationships between different EMR features. Designers could use the proposed method as a decision-aid tool in EMR redesign projects.

Keywords:

Electronic Medical Records, Design, Decision Aids

Introduction

Electronic Medical Record (EMR) systems are increasingly implemented in clinics. Their main purpose is to support healthcare provision processes by making them more efficient, effective, and data driven [1,2]. However, healthcare providers had voiced concerns over EMR systems disrupting their workflows [3] and affecting their communication with their patients [4]. These concerns may be due to the low levels of usability and usefulness of existing EMR systems [5].

Previous studies have proposed multiple redesign opportunities to improve EMR systems such as: integrating them better into work practices [6–8], making it easier to navigate and find information inside of them [9–11], extending their functionalities to support all the tasks of the healthcare providers [12–14], improving their interoperability [15], and improving their usability and learnability [16], among others.

When redesigning an EMR system, multiple redesign opportunities exist. Usually, designers cannot act upon all of them due to their limited available resources. Therefore, designers have to make a choice over which EMR features to target. To make that choice, designers have to prioritize EMR features i.e., know which EMR features are the most important to work on.

Following a user-centered design approach, the designers would prioritize the EMR features based on the priorities of their users [17]. However, EMR systems have different users with different, and sometimes contradicting, priorities. For example: some patients may think it is important to have access to their EMRs while their providers may think it is not important at all. Taking into consideration the priorities of all the users is necessary to provide optimal designs.

Moreover, targeting one feature could affect other features of the EMR system. For example: adding more functionalities to the EMR system might make it less usable. As another example, making the EMR system easier to learn might make it easier to use. Thus, the overall effect of targeting one EMR feature consists of a *direct effect* i.e., the effect it has on the targeted feature and a *cascade effect* i.e., the effect it has on the other features.

In this paper, we propose a method to prioritize EMR features to target during redesign projects. The method takes into consideration the priorities of the different users and the relationships between the different EMR features. The method allows EMR designers to rank different EMR features based on their importance to the users and the overall effect of targeting them.

To illustrate the method, we conduct a case study where we prioritize EMR features to redesign in Japanese antenatal care settings.

Methods

Our method consists of four steps, as shown in Figure 1.

In *Step 1,* the designers identify the level of importance of the different EMR features to the users.

In *Step 2*, the designers analyze the relationships between the different EMR features.

In *Step 3*, the designers compute the overall effect of modifying each EMR feature.

In *Step 4*, the priority score for redesigning the different EMR features is calculated. The priority scores are used to identify the most strategic EMR features to redesign.

1- Identifying the importance of different EMR features to the users

Previous work identified multiple features of EMR systems in Japanese antenatal care settings [16]. To identify the importance of the different EMR features, we surveyed five obstetricians, ten midwives, and 413 pregnant women in Japan. We asked the respondents about the importance of each EMR feature to them. The respondents reported the importance of the different EMR features on a 4-point Likert scale of "Very Important (4)," "Important (3)," "Slightly Important (2)," "Not important at all (1)."

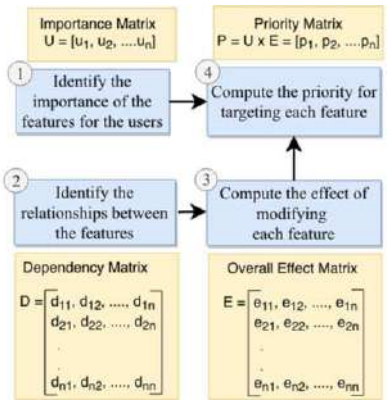

Figure 1- Four steps to prioritize EMR features to redesign

Using the survey results, we created the features' *importance matrix* as follows:

Suppose we have *n* features F = {$f_1, f_2, ..., f_n$} and *l* respondents R ={$r_1, r_2, ..., r_l$} who indicated the importance of each feature using the 4-point Likert scale. By aggregating the *l* respondents' answers, we obtain the features' *importance matrix* $U = [u_i]_n$ using:

$$u_i = \frac{1}{l}\sum_{k=1}^{l} u_i^k \quad i = 1,2,\dots,n$$

where u_i^k represents the answer of respondent r_k on the importance of feature f_i and u_i represents the importance score of feature f_i to the group of users.

We created the feature *importance matrix* separately for three different user groups: Obstetricians (U_o), Midwives (U_m), and Pregnant women (U_p).

Certain EMR features could only be experienced by the obstetricians and midwives, for example: the automatic collection of data from the medical devices used in the clinic. For these features, we did not ask the opinion of the pregnant women. Their importance scores were assigned as the average importance score given by the pregnant women for the other EMR features. The reasons and the consequences of this decision are discussed in the Discussion section.

By giving equal weight to the opinions of the three user groups, the feature *importance matrix* $U = [u_i]_n$ was calculated as:

$$U = \frac{1}{3}(U_o + U_m + U_p)$$

where u_i is the importance score of feature f_i.

2- Identifying the relationship between the EMR features

Multiple EMR features could be redesigned. One way to prioritize the EMR features to redesign is based on the users' priorities as identified in *Step 1*. However, the different EMR features are interdependent. In other terms, modifying one EMR feature could affect other features. Therefore, taking into consideration the interdependency of the features is needed to strategically prioritize them for redesign.

To identify the relationships between the EMR features, an analysis was conducted by three of the authors of this paper. We assumed that feature f_i has a negative influence on feature f_j when an improvement of f_i leads to a deterioration of f_j. Similarly, we assumed that feature f_i has a positive influence on feature f_j when an improvement of f_i leads to an improvement of f_j.

In the analysis, we rated the degree of influence between the different features. The direct influence of feature f_i on feature f_j was rated using a scale of "Very strong negative influence (-0.9)," "Moderate negative influence (-0.6)," "Weak negative influence (-0.3)," "Weak positive influence (+0.3)," "Moderate positive influence (+0.6)," "Strong positive influence (+0.9)."

Once the authors agreed over the influence ratings, the *feature dependence matrix* was formed as $D = [d_{ij}]_{n\times n}$ where all principal diagonal elements are equal to zero and d_{ij} represents the degree to which feature f_i has as influence on feature f_j.

3- Computing the overall effect of modifying each feature

In this step, we aim to calculate the overall effect of redesigning each EMR feature. The overall effect of modifying a feature f_i consists of the direct effect on f_i and the indirect effect on the other EMR features.

Let $A = [a_{ij}]_{n*n}$ be the *direct effect matrix* where a_{ij} is the direct effect that modifying feature f_i has on feature f_j. All the principal diagonal elements of A are equal to 1 and $a_{ij} = 0$ *where* $i \neq j$.

The *overall effect matrix* E is computed by summing the direct effects and the indirect effects of modifying the different EMR features as follows:

$$E = A + A \times D + A \times D^2 + \cdots + A \times D^h \,, \qquad h \to \infty$$

$E = [e_{ij}]_{n*n}$ where e_{ij} is the overall effect that modifying feature f_i has on feature f_j.

4- Computing the priority for targeting each EMR feature

To identify which features are more important to target, we take into consideration two factors: (i) the importance of the EMR features based on the users' opinions, and (ii) the overall effect of targeting the different EMR features.

Therefore, the *priority matrix* is computed by multiplying the *importance matrix* by the *overall effect matrix* : $P = U \times E$. The computation will result in $P = [p_i]_n$ where p_i represents the priority score of redesigning feature f_i.

Example to illustrate the method

Step 1.

Supposing we have two EMR features f_1 and f_2 that we could target in a redesign project.

Supposing that $\boldsymbol{U} = [\mathbf{2} \quad \mathbf{3}]$ is the *importance matrix* for features f_1 and f_2. This importance matrix indicates that the users think that f_2 is more important than f_1. Following a user-centered design approach, redesigning f_2 has a higher priority than redesigning f_1.

Step 2.

Supposing that $\boldsymbol{D} = \begin{bmatrix} \mathbf{0} & \mathbf{+0.6} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}$ is the *dependency matrix* of f_1 and f_2 based on the designers' analysis. In this case, f_1 has a moderate positive influence of f_2, and f_2 has no influence on f_1.

Step 3.

$\boldsymbol{A} = \begin{bmatrix} \mathbf{1} & \mathbf{0} \\ \mathbf{0} & \mathbf{1} \end{bmatrix}$ is the *direct effect matrix*.

Consequently, $\boldsymbol{E} = \begin{bmatrix} \mathbf{1} & \mathbf{0.6} \\ \mathbf{0} & \mathbf{1} \end{bmatrix}$ is the *overall effect matrix*. This means that modifying f_1 has a moderate indirect influence on f_2, while modifying f_2 has no influence on f_1.

Step 4.

Consequently, we obtain $\boldsymbol{P} = \boldsymbol{U} \times \boldsymbol{E} = [\mathbf{3.8} \quad \mathbf{3}]$ as the final *priority matrix*.

The priority scores in the final *priority matrix* indicate that redesigning f_1 has a higher priority than redesigning f_2. This

change in priorities between *Step 1* and *Step 4* shows the importance of considering the interdependency of the features when redesigning EMR systems.

Results

Importance of the different EMR features to the users

From previous work conducted on EMR systems in Japanese antenatal care settings [16], we identified fourteen EMR features. Based on the responses to the user surveys, we identified the importance of the different EMR features to the users.

Table 1 shows the EMR features, their assigned code names, and their importance to the users. The features are initially ranked based on their importance scores (**IR**) from highest to lowest.

U_o , U_m, and **U_p** represent the importance scores given by the obstetricians, midwives, and pregnant women, respectively. **U** is the aggregation of the scores for the three user groups.

The users agreed on importance of twelve out of fourteen features. However, the pregnant women reported that viewing their EMRs during and after the check-ups was important to them. On the other hand, the antenatal care providers did not report that feature to be important.

The overall top priorities for EMR users in Japanese antenatal care settings were: (1) *the use of the EMR system to exchange information between the antenatal care providers*, (2) *the EMR system being easy to use*, and (3) *the EMR system providing them with a quick summary of the pregnancy course*.

The overall lowest priorities for EMR users were (13) *the pregnant women viewing the EMR screen during the check-ups* and (14) *the pregnant women viewing their EMRs online*.

Relationships between the EMR features

Through the analysis conducted in *Step 2*, we identified the interdependency between the different EMR features. Figure 2 shows the map of interdependencies.

The nodes in the map represent the different EMR features. Inside the nodes, the EMR features are named using their corresponding code name shown in Table 1.

The weighted arrows connecting the nodes represent our judgement of the degree to which feature f_i influences feature f_j. The interdependence matrix $D = [d_{ij}]_{n\times n}$ was formed according to the map shown in Figure 2. Matrix D is not shown due to space constraints.

Priority for targeting each EMR feature

Through the computations conducted in *Step 3 and Step 4,* the final priority matrix was calculated. The final priority scores converged at h=10, as shown in Figure 3.

Table 1- The importance of different EMR features to the users

Code name	EMR feature	IR	U_o	U_m	U_p	U
EXCHANGE	EMR system is used to exchange information between the providers	**1**	3.8	4.0	3.46	3.75
EASY USE	EMR system is easy to use	**2**	4.0	4.0	2.67*	3.56
SUMMARY	EMR system can provide a quick summary of the pregnancy	**3**	3.8	4.0	2.76	3.52
EASY LEARN	EMR system is easy to learn	**4**	3.8	3.9	2.67*	3.46
INTEGRT	EMR system is well integrated with the medical devices in the clinic	**5**	3.8	3.6	2.67*	3.36
PSYCHO-SOCIAL	Sensitive psycho-social information is documented in detail in the EMR	**6**	3.4	3.6	2.75	3.25
NOT INT COMM	EMR system does not interrupt the communication	**7**	3.2	3.8	2.73	3.24
PREP	EMR system is used to prepare for the check-ups	**8**	3.4	3.5	2.67*	3.19
SCHEDULE	EMR system is used to manage the antenatal care appointments	**9**	3.4	3.8	2.37	3.19
NOT INT PROCESS	EMR system does not interrupt the clinical process	**10**	3.2	3.6	2.67*	3.16
EXPLN	EMR system supports the explanation	**11**	2.8	2.9	2.40	2.7
PAUSE SCREEN	EMR system is used to pause the communication when needed	**12**	2.4	2.4	2.67*	2.49
SCREEN ACCESS	EMR screen can be seen by the pregnant women during check-ups	**13**	1.6	2.3	2.61	2.17
WEB ACCESS	EMR can be accessed online by the pregnant women	**14**	1.0	2.3	2.30	1.87

* Importance scores were calculated by averaging the other importance scores reported by the pregnant women

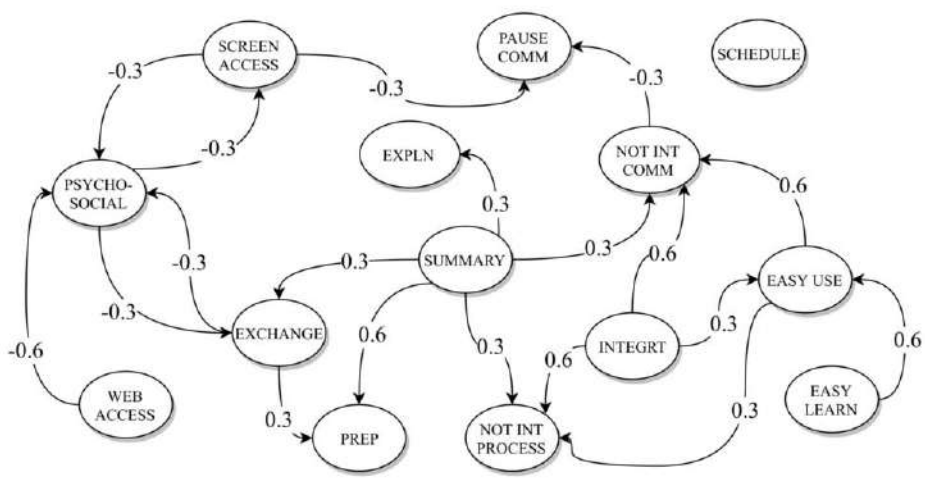

Figure 2- The map of interdependencies between the EMR feature

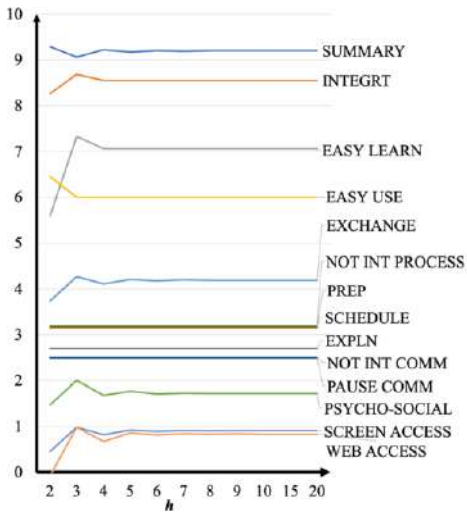

Figure 3- Convergence of the final importance scores

Table 2 shows the final priority scores (**P**) for the different EMR features after considering the feature interdependency. **IR** represents the initial ranking of the features based on the importance scores of the users. **FR** represents the final ranking of the features based on the final priority scores. **Change** represents the change in feature ranks after taking into consideration the features interdependency.

Table 2- Final ranking of EMR feature to redesign

Feature code	P	IR	FR	Change
EXCHANGE	4.19	**1**	**5**	**-4**
EASY USE	6	**2**	**4**	**-2**
SUMMARY	9.19	**3**	**1**	**+2**
EASY LEARN	7.06	**4**	**3**	**+1**
INTEGRT	8.55	**5**	**2**	**+3**
PREP	1.72	**6**	**12**	**-6**
NOT INT PROCESS	2.5	**7**	**10**	**-3**
PSYCHO-SOCIAL	3.19	**8**	**6**	**+2**
NOT INT COMM	3.19	**9**	**7**	**+2**
SCHEDULE	3.16	**10**	**8**	**+2**

PAUSE COMM	2.49	**12**	**11**	**+1**
SCREEN ACCESS	0.91	**13**	**13**	**0**
WEB ACCESS	0.84	**14**	**14**	**0**

After taking into consideration the interdependency of the features, the priority ranks of the EMR features changed. The top priority EMR features to redesign in Japanese antenatal care settings was identified as (1) *the implementation of automatic summary generation in EMR systems.* The second, third, and fourth priorities were (2) *the integration of EMR systems with the used medical devices,* (3) *the improvement of the learnability of the EMR systems* and (4) *the improvement of the usability of EMR systems.*

The lowest priority EMR features to redesign were (13) *granting the pregnant viewing access to the EMR screen during the check-ups* and (14) *granting the pregnant women online viewing access to their EMR.*

Discussion

In this work, we proposed a method that allows the designers to prioritize EMR features to redesign. The method takes into consideration the priorities of the different users. By doing so, the method fits into the user-centered design paradigm where design activities respect the preferences and aspirations of the users. The method goes beyond the users' priorities and takes into consideration the relationships between the different EMR features. By doing so, the method regards EMR systems as complex dynamic systems.

We applied the method in a case study of redesigning EMR systems in Japanese antenatal care settings. In our case study, we considered three different types of users: the obstetricians, the midwives, and the pregnant women. The results of the survey showed that the three user groups have mostly overlapping priorities. However, the *ability of the pregnant women to access their EMRs* was viewed differently by the healthcare providers and the pregnant women. This shows the importance of considering the opinions of the different users when redesigning EMR systems.

The survey results showed that *the exchange of information between the different antenatal care providers* was the highest priority EMR feature for the three user groups. However, after considering the relationships between the different features, the highest priority EMR feature to redesign was found to be *the generation of summaries from EMR notes*. This change in priorities shows the importance of considering the relationships between the different features when redesigning EMR systems.

In the following paragraphs, we discuss the different design choices that we made in our case study and how these choices affected the end results.

Giving weights to the opinions of the different user groups

In our case study, we gave equal weights to the opinions of the three user groups. Some may argue that this choice is not patient-centered and that the opinions of the pregnant women should have a larger weight. For example, we could have considered the obstetricians and the midwives as one group of users: the antenatal care providers. Consequently, we could have given equal weights to the opinions of two user groups: the antenatal care providers, and the pregnant women. In this case, another question arises: how should the weights be distributed within the antenatal care providers' group? Therefore, the question of the weight for the different user groups remains open. We believe that the designers can decide on the weights depending on what they see best in their target situations.

Dealing with the missing data

As mentioned in the methods section, some EMR features cannot be experienced by the pregnant women. For these features, we did not ask for the opinions of the pregnant women in the survey. The importance score was assigned as the average of the other importance scores provided by the pregnant women for the other features. Other approaches could have been employed to address the missing scores issue. For example: we could have given those features the lowest possible importance score or only considered the opinions of the obstetricians and the midwives for these features. However, we decided to consider these features as neutral for the pregnant women by assigning them the average importance score that they have given for the other features. This decision was mainly driven by the fact that antenatal care providers gave higher importance scores on average. The other possible approaches in this case would have majorly biased the final priority scores.

Deciding on the relationships between the EMR features

Three of the authors of this paper conducted an analysis of the relationships between the features and reached an agreement. Based on their analysis, the final priorities were computed. Clearly, different designers could have come up with different

relationships, resulting in different priorities. The subjectivity of the designers is a limitation of this method. However, we argue that any design process is usually tainted with the subjectivity of the designers. Therefore, their subjectivity cannot be completely avoided, but could be reduced by defining stricter criteria on how to model and rate the influences between the different features. Further research is needed to develop a set of guidelines for designers to follow when modeling the interdependency of the features.

In other respects, the users may have considered some features' dependencies when answering the survey questions. For example, some respondents may have considered the effect of integrating the devices with the EMR system when rating its importance. Therefore, some interdependencies may be accounted for twice. Further consideration is needed to counter this effect when applying the method.

In other respects, deciding on which features to redesign could include other important criteria such as: the cost of the redesign activity, the difficulty of the redesign activity, and the alignment of the redesign activity with other pre-existing strategies. This method provides the designers with information about which feature redesign could have the largest user-desired effect on the system. Further work is needed to incorporate this method into a larger scope method that allows the designers to take into consideration other decision-making criteria when redesigning EMR systems.

Through the case study, we showed the importance of considering the different users and the feature interdependency. To understand the practical value of this method, it is important to further evaluate the method as a decision-aid tool for designers in redesign projects.

Finally, even though this method was proposed to prioritize EMR features, it can be used by designers of other complex systems with multiple user groups and interdependent features.

Conclusion

We presented a method to prioritize EMR features to redesign. The method takes into consideration the priorities of the different users and the relationships between the different EMR features. The method allows the designers to rank features based on the direct and indirect effects of targeting them. We applied the method in Japanese antenatal care settings. The top priority features to redesign were (i) the implementation of automatic summary generators in EMR systems and (ii) the integration of EMR systems with the used medical devices. The results showed the importance of taking into consideration the priorities of the different users and the interdependency of the EMR features. The proposed method could be used as a tool to support designers in making strategic decisions during the initial system redesign phase.

Abstract

This paper describes the methodology and developments towards the TIGER International Recommendation Framework of Core Competencies in Health Informatics 2.0. This Framework is meant to augment the scope from nursing towards a series of six other professional roles, i.e. direct patient care, health information management, executives, chief information officers, engineers and health IT specialists and researchers and educators. Health informatics core competency areas were compiled from various sources that had integrated the literature and were grouped into consistent clusters. The relevance of these core competency areas was rated in a survey by 718 professional experts from 51 countries. Furthermore, 22 local case studies illustrated the competencies and gave insight into examples of local educational practice. The Framework contributes to the overall discourse on how to shape health informatics education to improve quality and safety of care by enabling useful and successful health information systems.

Introduction

The notion that health information systems success does not only depend on good technology but also on capable users has been accepted for many years in the context of participatory systems design [1] and the task-technology-individual models [2]. However, it has received momentum only in the last decade with increasing health IT adoption rates world wide [3]. Thus, realistic scenarios for using IT on a large scale emerged and necessitate a competent workforce. While clinical end users and their practical skills are widely discussed, health informatics competencies of IT decision makers, often at the board level, have only recently received attention [4]. Hence, health informatics covers a wide field of competencies for all different types of professionals in the healthcare arena, at different levels, and is connected with the need for life long learning. Against this backdrop, national and international professional and scientific associations are undertaking great efforts to develop [5-7] and update educational recommendations [8]. TIGER (Technology Informatics Guiding Education Reform) started issuing recommendations for basic IT competencies for nurses [9] and moved on to develop a comprehensive framework of recommendations of health informatics. This framework accounts for the increasing complexity and sophistication of competencies needed for different roles in nursing [10]. However, it is restricted to nursing and does not include other professions. The primary goal of this study, therefore, was to extend the scope of the framework of recommendations of health informatics core competencies beyond nursing and to include further professional roles that contribute to the success of health information systems. Hereby, the relevance of pertinent core competency areas for the different roles should be designated and illustrated. The secondary goal was to reconcile the global perspective on educational recommendations with the local perspective reflecting an in-depth view and practical experience. As the approach for this framework should pursue a very similar rationale and methodology we decided to call it "International Recommendation Framework of Core Competencies in Health Informatics 2.0". This paper describes major milestones towards this framework.

Methods

The development of the International Recommendation Framework of Core Competencies in Health Informatics 2.0 was performed under the umbrella of the EU Horizon 2020 project EU*US_eHealth_Work addressing workforce development and of TIGER (Technology Informatics Guiding Education Reform). TIGER is a grassroots initiative formalised in 2006 within the nursing community before transitioning to the Healthcare Information and Management Systems Society (HIMSS) in 2014 with members in 26 countries worldwide. TIGER now embraces an interprofessional focus that covers a great field of different health care professionals. In order to address the **first goal**, six professional roles were identified that belong to the communities of either IT users, IT decision makers, IT technologists or IT researchers & educators. Knowing that these communities overlap we more specifically defined the roles as (1) direct patient care (mainly physicians, nurses, therapists) and (2) health information managers belonging to the users, (3) executives (clinical and administrative) representing the decision makers, (4) chief information officers (technical and clinical) in their dual position as decision makers and technologists, (5) engineers and health IT specialists as members of technologists, and

finally (6) science & education forming the group of researchers and educators. The core competencies that should be assigned to the professional roles were compiled from the Recommendation Framework for nurses, which integrated existing recommendations of well-known scientific and professional associations, e.g. IMIA [5] and AMIA [7], and from the HITCOMP tool [11]. In comparison to the Recommendation Framework for nurses the following new competency areas were included: public health informatics, consumer health informatics and learning techniques. In addition, other competency areas were now marked as separate areas, i.e. communication, healthcare processes & IT integration, legal issues, interoperability & integration, and life cycle mangement. Previously these areas had been subsumed under other areas in the Framework for nurses. Information and communication technology was split into two areas: applications and architectures. Finally, three areas were rephrased to be more general. These changes were made to adapt the list to the broader professional scope. This adaptation was performed by four experts that mapped both competency lists, i.e. the nursing one [10] and the one from the HITCOMP tool [11], and finally agreed on utilising 33 core competency areas for the Framework 2.0 (see Table 1).

Table 1 – Core Competency Areas in Alphabetical Order

Applied computer science	Interoperability and integration
Assistive technology	IT risk management
Change/stakeholder management	Leadership
Clinical decision support by IT	Learning techniques
Communication	Legal issues in health IT
Consumer health informatics	Medical technology
Data analytics	Principles of health informatics
Data protection and security	Principles of management
Documentation	Process management
e/mHealth, telematics, telehealth	Project management
Ethics in health IT	Public health informatics
Financial management	Quality and safety management
Care processes and IT integration	Resource planning & management
ICT / systems (applications)	Strategic management
ICT / systems (architectures)	System lifecycle management
Information management research	Teaching, training, education
Information and knowledge management in patient care	

In order to obtain the relevance ratings for the core competence areas, a questionnaire was developed that amongst others included a section on competencies. Initially, twelve different roles were distingushed that were then grouped to match the six different roles of healthcare professionals mentioned above. Similar to the Framework for nurses, relevance ratings could range from 0 to 100. The survey participants rated the relevance of competencies for those professional roles they were competent to speak to. Explanations of what the core competency areas embraced were included in the questionnaire. After pretesting, the survey was finally made available online from the middle of February to the end of June 2017. As the relevance rating should yield a global picture, the survey link was deployed via 60 global listservs comprised of individuals and international, European and North American organisations that represent healthcare professionals. The organizations were asked to share it amongst their members. Due to this deployment policy the people who were invited could not be exactly specified by number. As the same data had been used to analyse options for interprofessional education, the survey methodology had been described also in [12] with a slightly different focus and with clusters of professions that partly varied from this approach.

The **second goal** of this study was to exemplify and illustrate the global findings with a local perspective. To this end, case studies from different countries were identified to illustrate the core competence areas by practical and detailed descriptions of individual competencies. As it was necessary to obtain comparable descriptions with a similar focus and structure, a template for reporting the case was developed that incorporated the principles of case studies [13]. The template was divided into sub-sections for: author, organisation, background, status of current developments, activities and measures, changes, results and outlook and lessons learnt. There was a checklist of eHealth topics alligned with the list of core competency areas of the questionnaire, e.g. process and workflow management, consumers and populations, research, data science, ethics, legal and data protection. The template also included a checklist to aid the case study authors referring to crucial areas, e.g. teaching the teachers, integrating health informatics into traditional curricula and motivating clinicans and managers.

In order to obtain authentic and first hand information, it was decided that the case descriptions should be provided by the persons who were actually involved in this case, e.g. as developer of the educational programme and/or as teacher in this programme. The recruitment of case study authors was initialised by an open call that was launched in July 2017 and closed in January 2018. The call was made public via HIMSS community listservs, the European Health Telematics Association (EHTEL) and other EU*US_eHealth_Work project members. A total of 214 individuals from all around the world were personally invited aiming at experts affiliated with major leading institutions in their field. In addition, general invitations via the HIMSS listservs, national and international conferences, e.g. MEDINFO 2017, were made public. Upon receipt of the case study manuscript the descriptions were edited by authors of this paper (TS, BE, UH) in cooperation with the case study authors.

Results

Goal 1: Relevance of core competency areas. A total of 718 experts from 51 countries provided answers to the questions on health informatics competencies. The 51 countries were composed of 28 European countries, 10 Asian countries, 8 countries from Middle and South America, 2 African countries, the USA, Canada and Australia (see [4] for further demographics). These answers corresponded with 1,571 relevance ratings for professional roles. Out of these answers, 27 were excluded either because they addressed health professions not meant to be focused on in this Recommendation Framework or received not enough answers, e.g. pharmacists. Table 2 gives an overview of the top 10 core competency areas and their mean relevance for the six professional roles. Relevance means were high among the top 10 across all roles ranging from 96.4 to 81.1. Each role was characterised by a unique pattern of top 10 competency areas out of which the first three were separately marked (see Table 2). Communication appeared in all six roles among the top 3. Other core competency areas in the top 3 were more role specific. Direct patient care for example was further featured by documentation and information & knowledge management while the executive role was characterised by leadership and quality & safety management. Beyond the rather distinct role profiles it is noteworthy that some core competency areas were shared by a majority of the roles: Among the top 10, leadership and ethics in health IT appeared in all six roles, quality & safety management, documentation and care processes & IT integration in four out of the six roles. All other competency areas were more specific and described only three or fewer roles. As the absolute relevance ratings ranged in a rather small interval from about 10 points per role (e.g. for direct patient care from 92.4. to 81.1) among the top 10, there were sometimes only minimal

differences between one rank and the next one. For example in the role of engineers and health IT specialists, documentation on rank 9 received a mean relevance of 82.1 and process management on rank 10 had a mean value of 82.0.

Table 2- Top 10 Core Competency Areas in the Six Roles and Related Mean Relevance (REL - 0…100)

	Direct patient care (DPC) (nurses/physicians/therapists)	
	Core competencies	***REL ± SD***
1	*Communication* [n=335]	92.4 ± 14.5
2	*Documentation* [n=337]	91.7 ± 17.2
3	*Information & knowledge management in patient care* [n=335]	90.0 ± 17.5
4	Quality & safety management [n=333]	87.5 ± 18.9
5	Leadership [n=336]	86.2 ± 19.0
6	Learning techniques [n=334]	85.6 ± 18.8
7	Teaching, training & education in healthcare [n=333]	84.4 ± 21.0
8	Ethics in health IT [n=334]	83.8 ± 23.0
9	Information & communication technology (applications) [n=332]	81.6 ± 20.5
10	Care processes & IT integration [n=333]	81.1 ± 21.3
	Health information management (HIM)	
	Core competency area	***REL ± SD***
1	*Communication* [n=184]	90.1 ± 19.0
2	*Documentation* [n=184]	87.7 ± 18.0
3	*Data analytics* [n=183]	87.7 ± 17.9
4	Leadership [n=184]	87.0 ± 19.0
5	Data protection & security [n=184]	86.9 ± 19.3
6	Information & knowledge management in patient care [n=182]	86.2 ± 19.4
7	Ethics in health IT [n=184]	85.6 ± 20.2
8	Principles of health informatics [n=182]	85.1 ± 18.4
9	Care processes & IT integration [n=183]	84.8 ± 19.1
10	Learning techniques [n=184]	84.2 ± 20.2
	Executives (EXC) (clinical and administrative)	
	Core competency area	***REL ± SD***
1	*Leadership* [n=55]	96.4 ± 7.8
2	*Communication* [n=55]	95.8 ± 8.3
3	*Quality & safety management* [n=55]	90.4 ± 16.1
4	Information & knowledge management in patient care [n=55]	89.2 ± 16.9
5	Strategic management [n=55]	89.1 ± 21.0
6	Principles of management [n=55]	88.6 ± 20.ß
7	Legal issues in health IT [n=55]	87.6 ± 16.3
8	Process management [n=55]	87.5 ± 16.4
9	Resource planning & management [n=55]	87.3 ± 21.7
10	Ethics in health IT [n=55]	87.0 ± 18.3
	Chief information officers (CIO) (clinical and technical)	
	Core competency area	***REL ± SD***
1	*Leadership* [n=62]	93.8 ± 9.6
2	*Communication* [n=62]	93.2 ± 10.7
3	*Care processes & IT integration* [n=62]	91.8 ± 13.7
4	Principles of management [n=61]	90.8 ± 12.2
5	Quality & safety management [n=61]	90.5 ± 12.7
6	Strategic management [n=61]	90.0 ± 13.4
7	Process management [n=62]	89.6 ± 13.6
8	Change & stakeholder management [n=61]	89.6 ± 12.6
9	Ethics in health IT [n=61]	88.7 ± 18.0
10	Resource planning & management [n=61]	88.4 ± 18.7
	Engineering or health IT specialist (ENG)	
	Core competency area	***REL ± SD***
1	*Communication* [n=172]	91.3 ± 14.3
2	*Care processes & IT integration* [n=171]	87.5 ± 18.9
3	*Information & communication technology (applications)* [n=171]	87.2 ± 18.0
4	Leadership [n=172]	86.1 ± 17.8
5	Project management [n=172]	85.4 ± 19.7
6	Data protection & security [n=171]	84.3 ± 22.6
7	Ethics in health IT [n=170]	83.4 ± 22.2
8	Interoperability & integration [n=172]	83.0 ± 21.7
9	Documentation [n=172]	82.1 ± 22.6
10	Process management [n=172]	82.0 ± 21.7
	Science and education (S&E)	
	Core competency area	***REL ± SD***
1	*Communication* [n=218]	91.6 ± 16.1
2	*Teaching, training & education in health care* [n=220]	89.2 ± 17.9
3	*Leadership* [n=218]	88.2 ± 17.3
4	Learning techniques [n=218]	88.1 ± 18.8
5	Ethics in health IT [n=219]	86.5 ± 21.3
6	Documentation [n=222]	86.3 ± 21.2
7	Information & knowledge management in patient care [n=221]	86.3 ± 20.2
8	Principles of health informatics [n=218]	83.3 ± 23.2
9	Quality & safety management [n=220]	83.1 ± 22.9
10	Data analytics [n=218]	81.9 ± 23.6

In order to further group the core competency areas, clusters used in the Recommendation Framework for nurses were tested for consistency and adapted if needed. Table 3 shows the Cronbach's alpha values for the six roles and seven clusters, i.e. data/information/knowledge (DIK), information exchange/ information sharing (IEIS), ethical/legal issues (EL), systems/ system principles (SYS), management (MAN), technology (TECH) and teaching/learning (LRN). Only data analytics (STAT) was not assigned to any of the clusters and stands on its own. Thus, a consistency check was not necessary. The great majority of alphas received acceptable values, well above or very close to 0.7, hinting at consistent clusters. This held not true only for three role cluster combinations. The clusters were constructed with some overlap [10], e.g. public health informatics was assigned to DIK and IEIS.

Table 3 - Cronbach's Alpha Values for the Roles and Clusters (No. Core Competency Areas)

Clusters	**Roles**					
	DPC	ENG	HIM	EXC	CIO	S&E
DIK (8)	0.86	0.88	0.90	0.86	0.82	0.92
n	322	161	174	54	61	211
IEIS (8)	0.88	0.88	0.91	0.91	0.88	0.92
n	321	160	171	54	59	207
EL (3)	0.82	0.87	0.90	0.79	0.87	0.89
n	330	169	182	55	61	217
SYS (4)	0.85	0.85	0.88	0.90	0.85	0.91
n	324	167	176	54	61	212
MAN (10)	0.92	0.92	0.95	0.92	0.92	0.95
n	326	166	175	54	61	212
TECH (2)	0.49	0.71	0.65	0.68	0.73	0.76
n	325	163	175	55	59	211
LRN (2)	0.68	0.57	0.83	0.63	0.81	0.80
n	332	166	181	54	62	218

Goal 2: Illustration of the core competency areas. So far a total of 22 case studies from 19 countries were obtained which covered the views from universities (15), from hospitals, (3) from the perspective of countries (3) and one from an educational IT system (decision support). The university courses described offered education at the level of Bachelor, Master and continuing education programmes. The educational activities of hospitals targeted workforce development while the country perspectives reflected needs and national programmes to establish and deepen health informatics education. Due to the nature of health informatics, all case studies blended technical and health topics, however, with various foci and targeting different roles. The majority (17) addressed students and professionals in Direct Patient Care (DPC) either as the only role or in combination with a different role. Six case studies covered the Executive role (EXC) and four the Chief Information Officer role (CIO) either alone or in

combination. Two cases exemplified a curriculum focusing on engineers/health IT specialists together with other roles. Finally, one case study described the need for health informatics in general irrespectively of a dedicated role. Currently all 22 case studies are available from [14]. There were 7 dedicated interprofessional cases and others also stressed the importance of mutual exchange between the students and professionals. In the following some examples are given to show how the case studies illustrate the core competency areas and break them down into individual competencies.

Case Study 1: Indiana University School of Informatics and Computing, Indianapolis, Indiana, United States (Josette Jones)

Case study 1 describes a module-based flexible workforce training program with 21 one-credit modules for anyone who needs training in health informatics, in particular students from health professional programs (e.g. physicians, nurses, public health), professional health care staff members (e.g. from patient centred medical homes, community health centres). It thus addresses all professional roles of this Framework. The following competencies belong to the areas systems/system principles (SYS) and data/information/ knowledge (DIK):

EHR systems development & implementation: Identify the range of clinical decision support (CDS) tools within the EHR; determine which tool is appropriate for specific situations; analyze how to develop and implement CDS tools to adhere to meaningful use criteria. Describe the processes of developing or selecting an EHR system, preparing and supporting clinicians for system implementation and evaluating system effectiveness. Clinical data and clinical process modeling; Technical security applications and issues; Systems testing and evaluation.

Case Study 2: Laurea University of Applied Sciences and Arcada University of Applied Sciences, Finland; Tartu Health Care College, Estonia; Red Cross Medical College of Rīga Stradiņš University, Latvia (Outi Ahonen, Jonas Tana, Gun-Britt Lejonqvist, Marge Mahla, Sanita Marnauza, Elina Rajalahti)

The curriculum, whose development was funded by the EU Central Baltic Program 2014-2020, is multi-professional and combines health and welfare with IT and service design. In the three study units (15 credit points), future professionals from different fields of study (IT, social care, economics and health care) are developing their own unique competencies according to the pedagogical principle "learning by developing". The following example of competencies is taken from unit 2 that focuses on the cluster ethical/legal issues (EL):

Understand ethical theories, safety procedures, principles and laws affecting digital health and welfare as well as customer privacy. Have the skills to practice ethical and high quality customer service taking responsibility for the safety and integrity of the client.

Case Study 3: Assuta Medical Centers, Israel (Rachelle Kaye)

The main drivers at Assuta Medical Centers, the largest private hospital system in Israel, for process changes and associated skills and capabilities, including eHealth competencies, is the striving to steadily improve the quality of care. Continuing education, hereby, is devided into developing basic, intermediate and advanced skills and competencies and is meant to reach all professionals within Assuta. Assuta, which publishes a professional journal, therefore emphasises analytical competencies (STAT) as the following example taken from advanced skills and capabilities shows:

Research and Data Analytics: Perform digitally supported research and database research, or data analytics, design database for research purposes, on-going management and patient care improvement.

The three case studies were chosen against the background to illustrate and reflect ongoing activities to increase the health informatics competencies of all healthcare professionals in a process of life long learning. The case studies were also selected on the basis to represent countries with a high adoption rate of health IT.

Discussion

The current state of the "International Recommendation Framework of Core Competencies in Health Informatics 2.0" developed by TIGER within the EU*US_eHealth_Work project utilizes a robust methodology of surveying healthcare stakeholders across countries worldwide about the relevance of core competency areas and is grounded on a rigorous method to obtain comparable local exemplar case study descriptions. The methodolody was rooted in the approach pursued by the Recommendation Framework for nurses [10] and was further developed regarding the breadth of core competency areas included, the outreach to obtain views from all around the world including Africa and the highly systematised manner of case study descriptions. The recommendation framework is meant to serve as a compass for teachers, students and healthcare organisations to identify patterns of core competency areas and practical advice how the competencies are embedded in a curriculum and realised in a local setting.

The relevance findings point to the paramount importance of communication as the connecting link between different stakeholders with various interests (silo mentality), different settings (primary, secondary vs. tertiary care) and other types of fragmentation. Communication is coupled with leadership, another competency area that runs like a golden thread through the relevance ratings across the roles. It is noteworthy that leadership is not only esteemed relevant at the board level but at all levels and goes along with different professional scopes. This finding matches the increasing awareness of intrapreneurship [15] as a key factor for health IT success. It describes the capability of individuals to assume responsibility, initiate projects and become an innovation champion. Communication and leadership as drivers for health IT correspond with the knowledge about the ethical constraints and skills how to balance diverging interests. Ethics in health IT was thus also found relevant for all roles and is illustrated by the Finish, Estonian and Latvian curriculum that dedicated one out of 3 modules to this topic.

At a more aggregated level, these results concur with four out of the ten foundational domains identified by the latest AMIA white paper on core competencies at master's degree level [8] that revolve around social and behavioural science/aspects and leadership. The IMIA recommendations from 2010 [5] mentioned socio-organizational and socio-technical issues and ethical and security issues as two areas from a list of 19 biomedical/health informatics core knowledge and skill areas for IT users and biomedical and health informatics specialists.

Among the information systems core competency areas care processes & IT integration was found to be essential not only for technically oriented roles but also for direct patient care. This demonstrates that the stakeholders must possess knowledge that crosses the health – technology boarder. Data analytics seems to be an emerging field in the age of Big Data,

however, not yet found central for all roles. In countries with a complete adoption of electronic health records, data analytics is just the next step in digitisation. The comprehensive utilisation of the data is very well illustrated by case study 3 from Israel.

A question that often arises in the context of education is whether interprofessional courses are meaningful. Judging by the core competency areas shared across the professional roles, interprofessional approaches seem feasible and are current practice as a series of the case studies demonstrated. A specific analysis on this topic based on the same data [12] had shown that the relevance ratings between nurses and physicians did not differ significantly, thus supporting this option. Also many of the case studies addressing direct patient care did not specifically distinguish between the professions working directly with patients. This discussion is further fueled by the demand of joining health and social care [16] in particular for the elderly and other vulnerable groups.

There are some limitations that need to be deliberated. Although the survey findings embraced the voice of experts from 51 countries, the very large majority came from North America and Europe. Thus, a bias towards industrialised countries cannot be excluded. This bias can be partly mitigated by including case studies from as many countries as possible. Indeed, it was possible to garner case descriptions from China, India, Saudi Arabia and Nigeria amonst others. However, more insight into local educational practice is required to complete the Framework. These case studies should not only represent more countries but also cover all professional roles in an even manner. Similar to the Framework for nurses an expert workshop with discussions on the roles, the core competency areas and the relevance ratings is desirable. These activities constitute the next steps towards finalising the Framework.

Conclusions

The TIGER International Recommendation Framework of Core Competencies in Health Informatics 2.0 is based on a proven methodology and well on its way with global findings and local exemplar case studies. It contributes to the overall discourse how to shape health informatics education. Furthermore, these findings should help stimulating the discussion within IMIA's work on educational recommendations.

Acknowledgements

This study was funded by the European Union's Horizon 2020 (grant: 727552 EUUSEHEALTHWORK) and by the German BMBF (grant: 16OH21026 KeGL). We wish to thank the case study authors for their invaluable contributions in particular Outi Ahonen, Elske Ammenwerth, Juris Bārzdiņš, Alexandrina Maria Ramos Cardoso, Jan Florin, Theofanis Fotis, Josette Jones, Taghreed Justina, Rachelle Kaye, Ulla-Mari Kinnunen, Gun-Britt Lejonqvist, Jessica Liston, Inge Madsen, Marge Mahla, Sanita Marnauza, Anne Moen, Lynn Nagle, Siobhán O'Connor, Omotayo Omojola, Elina Rajalahti, Ann Kristin Rotegård, Sabu K M, Paulino Souza, Jonas Tana, Helena Blažun Vošner and Zhuang Yiyu. In addition, we thank Rachelle Blake for integrating the HITCOMP perspective into this work.

Abstract

Community health workers in primary care programs increasingly use Mobile Health Data Collection Systems (MDCSs) to report their activities and conduct health surveys, replacing paper-based approaches. The mHealth systems are inherently privacy invasive, thus informing individuals and obtaining their consent is important to protect their rights to privacy. In this paper, we introduce an e-Consent tool tailored for MDCSs. It is developed based on the requirement analysis of consent management for data privacy and built upon the solutions of Participant-Centered Consent toolkit and Consent Receipt specification. The e-Consent solution has been evaluated in a usability study. The study results show that the design is useful for informing individuals on the nature of data processing, allowing them to make informed decisions.

Keywords:

Mobile health, Privacy, Public surveillance

Introduction

Privacy protection of personal data (or "data privacy") is fundamental for developing sustainable mobile health (mHealth) technologies – the use of mobile devices to support the delivery of healthcare. This is particularly important for the initiatives in low- and middle-income countries where hundreds of mHealth projects have been developed to support the care of HIV, malaria, tuberculosis, diabetes and antenatal care [1]. As these projects involve the processing of highly sensitive personal data at a large scale, data privacy becomes one of the main challenges for gaining public trust, deploying and scaling-up systems [2].

The research field of privacy and data protection has evolved dramatically in the past decades, in both legal and technical terms, and has drawn attention to healthcare applications. Most recently, the European General Data Protection Regulation (GDPR) [3] has advanced the safeguards of people's right to privacy in the digital world. Privacy-enhancing technologies have been developed to improve transparency, intervenability, and security of the digital systems.

While the adoption of mHealth systems in low- and middle-income countries is growing, researchers have pointed out that a knowledge gap exists in the realms of privacy and mHealth [2][4]. What seems to be missing are more concrete examples on *how* to integrate best practices of data privacy in the existing mHealth initiatives. That is, providing mHealth practitioners with realistic recommendations on how to adhere to privacy laws, as well as how to engineer privacy and use existing privacy-enhancing technologies into their systems.

The research in this paper addresses the needs to support consent for data privacy in mHealth. Consent is traditionally a legal requirement for healthcare interventions and clinical trials, embodying the respect for patients' autonomy and dignity. This has been extended to the digital world to safeguard people's right to privacy. The GDPR uses the concept of "informed consent" as one of the main legal grounds for processing of personal data, i.e., data subjects should be able to determine when, how, and to what extent their information is communicated to others. Informed consent enables people to make decisions before any personal data is collected. More specifically, we have investigated an electronic consent (e-Consent) solution to support the consent management for Mobile Health Data Collection Systems (MDCSs). MDCSs have been widely used for conducting health surveys and surveillance in the primary care [5]. They are used by Community Health Workers (CHWs) to gather and report data as part of their care activities. Tablet- and smartphone-based systems (e.g., GeoHealth MDCS, Open Data Kit, Open Smart Registration platform) [5] have been developed to streamline the data collection to replace the paper-based approaches in many countries. This move has raised a particular challenge in technology design to support the consent process.

In this paper, we present our work in the design of an e-Consent solution to support informed consent in MDCSs. We first review related work and describe our research methods. We then analyse existing legal and technical requirements. We focus on presenting the e-Consent design which addresses the strategies on how to inform the data subject and how to handle and store the consent. We then present the usability study and results. Our work contributes to the research of protection of personal data with an e-Consent design which can be integrated into MDCSs and used by CHWs in primary care.

Related Work

Innovative solutions have been proposed to safeguard people's privacy when giving consent in digital applications. One of them is the Participant-Centered Consent (PCC) toolkit [6] which is designed to obtain informed consent from research participants. The interface guides the users through the consent process to allow them to make an informed decision. The toolkit has been incorporated in the Apple's ResearchKit and used by various application developers. The consent also needs to be captured in an appropriate data structure and managed by the data collection platform (e.g., MDCS). To do so, the Consent Receipt specification [7] defines a record of consent granted by an authority. This record can be portrayed in a human-readable and machine-readable format. The Consent Receipt includes a link to the existing privacy policy as well as a description of what information has been or will be col-

lected. It also states the purposes for data collection and relevant information about how that information will be processed or disclosed, and how long it is valid (i.e., expiration date). As a result, the Consent Receipt specification promotes interoperability with a data structure for representing consent in compliance with current privacy and data protection laws.

To the best of our knowledge, the development of e-Consent for MDCSs is relatively unexplored. Our work leverages on the PCC toolkit and the Consent Receipt specification. However, the PCC toolkit is designed primarily for app-mediated research and MDCSs require a more sophisticated consent interface which the existing PCC toolkit does not provide. That is especially in terms of selective consent and withdrawal, allowing data subjects to agree only to specific purposes. The Consent Receipt specification also needs to be extended to allow consent on behalf of minors (e.g., by a parental figure) or on behalf of people unable to give consent due to mental or physical limitations (e.g., by a guardian or health worker).

Methods

Our research had two main phases: the design of the e-Consent, and the usability evaluation of the e-Consent. During the first phase, the e-Consent interface was designed through an iterative approach. Based on prior work on MDCSs [5] and current privacy law (GDPR [3]), the legal and technical requirements for the e-Consent were first defined. This was followed by an investigation of how to use Consent Receipts [7] as a data structure to handle consent in the system. The e-Consent mock-up interfaces were then developed using the Mockplus prototyping tool. During the second phase, the e-Consent interface was evaluated in a usability study (approved by CSIRO's Human Research Ethics Committee Nr: 117/18). The study used a mixed method of cognitive walkthrough [8], questionnaire and interview in an experimental setting. Participants were researchers in a lab and had related experience in digital technologies in healthcare. Potential participants were invited to participate via email. Each experimental session involved one participant. During the cognitive walkthrough, the participants interacted with the interface by playing a role of patient or family member being enrolled in the primary care program and giving consent. After the walkthrough, each participant completed a paper-based questionnaire and attended a debrief interview session to talk about their experience with the interface. The questions asked in the questionnaire and interviews focused on assessing the e-Consent interface regarding the principles of informed consent as defined by Friedman *et al* [9], including information disclosure, comprehension, voluntariness and agreement. Table 1 summarizes a series of statements in the questionnaire which used 5-point Likert scale. The questionnaire also included a knowledge comprehension quiz in which the participants were asked 5 questions (Table 2) to reflect their understanding on the information provided in the e-Consent interface.

Results

Legal and Technical Requirements

The analysis of the legal and technical requirements for consent has served as the first step and foundation for our design, outlined in this section. The GDPR [3] introduces a higher standard for consent. Its Article 4(11) defines it as: *'consent' of the data subject means any freely given, specific, informed and unambiguous indication of the data subject's wishes by which he or she, by a statement or by a clear affirmative action, signifies agreement to the processing of personal data relating to him or her*. If compared to the Friedman's principles of informed consent [9], *freely given* refers to *voluntariness* and *agreement*, while *specific*, *informed* and *unambiguous* relates to *information disclosure* and *comprehension*. In addition, according to Art. 7 GDPR [3], the conditions for consent are: the controller has to demonstrate that the data subject has consented (i.e., burden of proof); the request for consent must be clearly distinguishable from other matters; the data subject shall have the right to withdraw his or her consent at any time; the performance of a contract may not be made dependent upon the consent to process further personal data, which is not needed for the performance of that contract (e.g., "prohibition of coupling" of consent). The GDPR also includes other recitals and articles, covering: conditions for consent for scientific research, child's consent, freely given consent, and burden of proof (GDPR Recitals (32, 33, 38, 42, 43) [3]).

Table 1 – Questionnaire Part 1: Principles

Information disclosure	**[Data]** I know what personal information will be collected by the system. **[Use]** I know how my personal information will be used. **[Access]** I know who will have access to my personal information. **[Retention]** I know for how long my information will be stored or archived in the systems. **[Protection]** I know how they will protect my information.
Voluntariness	**[Forced]** I felt like forced or coerced to provide consent. **[Inf. Manip.]** I could identify some forms of manipulation in the options and information provided. **[Psy. Manip.]** I could identify some forms of psychological manipulation during the process.
Agreement	**[Accept/Decline]** It is clear whether I can accept or decline the consent. **[Withdraw]** It is clear that I can revoke or withdraw consent any time.

Table 2 – Questionnaire Part 2: Comprehension Quiz

Comprehension	What is (are) the purpose(s) of collecting my personal health data? (**3 points**) **[P1]** Support primary care teams in the provision of health care (Yes or No) **[P2]** Support public health programs (Yes or No) **[P3]** Support research in public health and clinical practice (Yes or No) **[Access]** My personal data can only be accessed by authorised personnel. (**1 point**, Yes or No) **[Sharing]** I can choose to share my data with qualified researchers. (**1 point**, Yes or No) **[Skip]** I will be able to skip any question during the surveys. (**1 point**, Yes or No) **[Stop]** I will be able to stop participating at any time. (**1 point**, Yes or No)

Besides legal requirements, we also elicited technical requirements based on our experiences with MDCSs [4, 5]. The current e-Consent tool was designed considering the Brazilian Community-Based Primary Health Care (CBPHC) program, Family Health Strategy [10], in which MDCSs have been increasingly adopted. CBPHC programs often rely on a broad and implicit consent for the processing of personal data. By receiving the CHWs at their homes, the families implicitly accept the health service and agree with the data collection. However, Art. 9 2. (a) requires explicit consent for the pro-

cessing of special categories of personal data (e.g., health data). This is a specific consent for data processing of personal data which differs from the traditional informed consent for receiving a medical treatment. Based on the existing literature and group discussions, we generated the requirement analysis for e-Consent in MDCS as shown in Table 3. These requirements not only address the current consent issue of the CBPHC program but also the challenges for consent under the GDPR and in the context of MDCSs.

Table 3 – Main Legal and Technical Requirements

No threat of disadvantage – Corresponds to freely given. Consent should not be required for the provision of care.
Provide information – Information about the personal data processing should be provided orally or in writing. It is important to consider the cases of illiterate people.
Information easy to understand – The information that is provided should be concise and easy to understand.
Support CHWs – The application should support the CHWs with all the information necessary regarding consent.
No additional hardware – Consent should be received without requiring the use of any computer technology on the part of the data subjects (i.e., may not have or afford a device).
Registration and consent – Allow consent to be obtained while the CHW is visiting the family or if a family member comes to the health unit and enrols in the program.
Selective consent and selective withdraw – Data subjects should be able to give or withdraw consent to specific purposes of data processing.
Consent withdrawing – Data subjects should have an interface to review and/or to withdraw consent (e.g., website portal, talk to CHWs, call Basic Health Unit).
Consent signing – Data subjects should be able to sign the consent (e.g., digital or wet signature) as otherwise consent would not be explicit.
Child's consent – Child's consent should be given or authorised by "the holder of parental responsibility".
Consent witnessing – If data subject is unable to sign, the health worker should sign the consent as a witness; and the consent should be marked as 'unable to sign'.
Consent receipt – A copy of the consent should be available in the system and sent to the data subject (e.g., via email).
Managing consents – Modified or revoked consents should be archived for the duration necessary for verification or provenance purposes.
Auditing and compliance – A process for paper trail (a written record, history, or collection of evidence) should be designed and implemented to demonstrate compliance.
Secure storage and transmission – Since the consent may contain sensitive personal information, the consent receipts should be securely stored and transmitted.

Design Considerations

Although the existing solutions (e.g., PCC toolkit) offer a strong starting point, adaptions were required to fit the e-Consent design into the particular context of the MDCSs. The PCC toolkit is designed mainly for app-mediated research, i.e., participate in research through smartphones, and share data with researchers. MDCSs are used primarily for the health care purposes (i.e., offering care and treatment, and meaningful use of health data), although they might also be used for secondary purposes (e.g., research and statistics). The range of data collected with MDCSs is also much larger, requiring better information about the data processing.

MDCSs also have a much broader range of purposes for data processing, so that, data subjects should be able to selectively consent (whenever possible) to the purposes that they agree and to selectively withdraw. For instance, because MDCSs are used to support public health, the data controller is normally the government and they can carry out processing activities without consent. That is, there are other lawful bases for data processing, such as the performance of a public tasks, to fulfil a contract, or on the legitimate interest of the data subjects (i.e., for their own health benefits). However, some MDCSs can also be used for secondary purposes, which should be made optional to data subjects, for instance, if linking their personal data to other electronic health records or disclosing it for research and statistics outside the public health sphere. In summary, the specification of purposes is more complex for MDCSs and the interface for consent must reflect such conditions, particularly with respect to selective consent and withdraw per purpose.

In addition, a particular context in the CBPHC consent setting is that the Tablet devices used for MDCSs are carried by the CHWs. This is different to PCC which is designed to run at the individuals' mobile phones. CHWs can help individuals to use the consent application, walking them through the consent process. Information can be provided orally and in writing, and data subjects can ask questions directly to CHWs before signing the consent. That also enables options for dynamic consent, i.e., asking individuals again for consent in case data should later be used for another purpose, or allowing them to change their consent over time. The design should allow the consent to be changed or withdrawn during the CHWs visits or by contacting the basic health unit, considering that consent revocation should be as easy as giving consent.

Consent Interface

Based on the elicited requirements, we defined the steps and information that should be conveyed by the e-Consent tool. The resulting consent interface (Figure 1) provides the data subjects (e.g., family members) with appropriate information about the primary care program and the MDCSs. Each page contains a short explanation about main aspects of the privacy policy. As recommended in [6], the interface uses two layers of information together with appropriate icons to reinforce its content. Users can access the second layer of information by clicking in *"learn more"* link. The consent interface includes the following steps and information:

Description about Primary Care: explains the primary care program offered by the government and the CHWs' tasks.

Data handling and use: explains the categories of personal data collected, emphasizing the highly sensitive data.

Selective consent and withdrawal: lists purposes of personal data processing, whether they are compulsory (e.g., public task) or optional (e.g., data linkage and sharing for research).

Overview on privacy and data protection: describes the data protection mechanisms yet also stressing privacy risks.

Your rights and choices: reminds data subjects that they can skip survey questions, revoke consent and determine to what extent they want to share their data.

Review and consent: informs about the data controller and gives a summary of the consent to be agreed and signed.

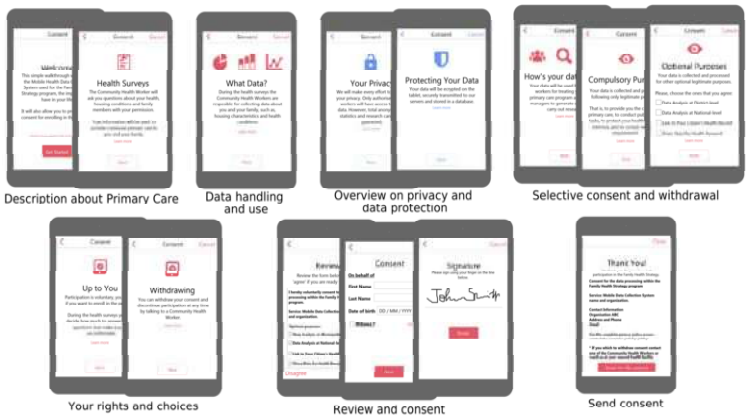

Figure 1 – Main Interfaces for the Consent Application

Send consent: allowing data subjects to send a copy of the consent in a human-readable format to their email address.

Generating Consent Receipts

To generate the Consent Receipt, the e-Consent application should create a signed data structure in a JSON Web Token format with all necessary attributes. This string can be represented in human- and machine-readable formats. Consent Receipts can also have a date; triggering an automatic revocation and requiring re-consent (e.g., every two years). However, the Consent Receipt does not support in its data structures the consent "on behalf of" other people that are unable to give consent. The data structure should therefore be extended to include not only the data subject but also a second individual that consents on behalf of the data subject. Developers can also decide how to handle the Consent Receipts, e.g., a JSON object can be associated to the data subject's record and stored in the database. Consent Receipts may however contain personal data. Thus, it is assumed that the MDCSs use security mechanisms (e.g., [11]) to protect the receipts as well.

Usability Evaluation

A total of 10 participants participated in the usability evaluation. They were researchers working in human-computer interaction, health informatics, and computer security. Their years of experience ranged from 3 to 35 years. Participants were positive on the design related to the principles of informed consent in their questionnaire responses (Figure 2). They reflected positively about their experience, such as recalling what data was being collected and how it would be used; did not feel forced, coerced or manipulated to give consent; options for accepting, declining, and withdrawing consent were clear to them. Nonetheless, the participants' satisfaction on some aspects of information disclosure, such as data *Access*, *Retention* and *Protection*, was lower than the satisfaction on voluntariness and agreement. Questionnaire results also showed that all participants understood what they were consenting to (Figure 3). On average, participants marked 5, 9 out of 7, 0 points in this quiz. Only the question regarding the right to *Skip* questions during health surveys seemed to be misunderstood.

Key findings of the interviews are summarized below.

Information disclosure – Participants (n=9) understood what data is disclosed, the purposes of data processing, and who has access to their data. They stated that *"[the e-Consent] gives*

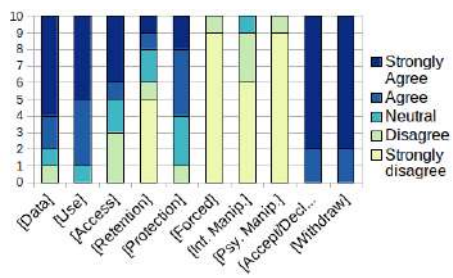

Figure 2 – Results from the First Part of the Questionnaire (information disclosure, voluntariness and agreement). Note that, disagreeing is beneficial for columns 6-8 (Forced, Inf Manip, Psy Manip), i.e., did not feel forced/manipulated.

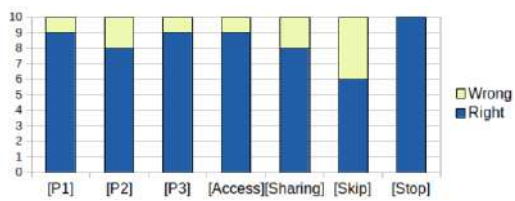

Figure 3 – Results for the Comprehension Test

me all the information I care about", and *"[y]eah, I think that is quite clear, laid out pretty simply, it's very concise"*.

However, one of the participants said that he/she did not *"remember reading how to withdraw the consent"*, and another participant also admitted: *"I'd say that I haven't read all the 'learn more' things. […] Maybe if people have time to read it properly, they can get all the information"*.

Comprehension – Although the participants' average score in the comprehension test was positive, some participants commented that specifically on data *Retention* the e-Consent needed to provide more information about what happened to their data when consent was withdrawn or changed (e.g., disable data sharing for health research).

Voluntariness – Most participants did not feel forced, coerced or manipulated to provide consent (n=9). They mentioned, *"[n]o, I didn't get any feeling of this kind of thing [i.e., manipulation]. There's no impression that something is dodgy.*

It's clear to me". Just one participant, stated that he/she *"felt [coerced] a small amount. If I were to declined consent that I would not receive healthcare [...]"*. Another participant added, *"I feel that the information maybe too much for me. That would've stopped me rather than coerced"*. Regarding manipulation, specifically, one participant stressed that he/she did not feel any kind of manipulation *"because there was not a lot of talking from you [e.g., the CHW]"*. That is, the e-Consent may not contain any manipulative content, but health workers should be trained to not attempt to talk people into something that they do not want to do.

Agreement – All the participants (n=10) stated that the options to accept or decline consent were clear, and they understood that it was possible to withdraw the consent. They mentioned, that they *"never felt that I didn't have a choice"* and *"[y]es, it was pretty clear whether I should accept or decline, even after completing the consent form I realized that I can withdraw"*.

Participants also provided general feedback and suggestions. Examples included: the second layer of information was text-heavy (n=7); more attractive/engaging buttons and links could be used (n=6); some terms used were too technical (n=6); some patients or family members might want more information on privacy aspects (n=5); the pressure of giving consent "on spot" could be a concern (n=4); and, a "progress bar" would be useful to show the steps and progress (n=2).

Discussions

Data privacy is challenging in the context of primary care programs (e.g., CBPHC) which often involve vulnerable populations that can be susceptible to stigmatization and discrimination caused by privacy violations. This, combined with the increase use of mHealth, has led to our exploration of providing appropriate solutions to the e-Consent process. Although preliminary results are positive, further design considerations and improvements can be discussed.

Privacy and protection of personal information needs to be well described in the e-Consent. This is particularly important to inform the aspects regarding data *Access* and *Retention*. We also found that participants were not fully aware that during the health surveys carried out by CHWs, that they have the option of not answering some questions unless it is a mandatory question. This needs to be more clearly stressed in the interface using clear and short statements and details need to be emphasized in the "learn more" link. Furthermore, the "quiz" can be potentially introduced as part of the e-Consent as an additional step before reaching the agreement and signature steps. We found that some participants missed important information either because they felt pressure to finish or thought they already knew it. Depending on the application and scenario, data subjects could be required to pass the comprehension test before providing consent.

The proposed e-Consent offers a simple solution with flexibility for technology refinements. The Consent Receipt specification already offers the minimum viable data structure. It is left to developers to provide more sophisticated solutions for authorisation mechanism (e.g., OAuth, UMA, and XACML). Ideally, data subjects would have access to a personalised web portal where they can access their information and see all records of consent, but providing such system interface can increase the costs of development and infrastructure. Finally, and importantly, the usefulness of the e-Consent designs will need to be assessed with the actual users (e.g., family members and CHWs) and in the real-world setting.

Conclusions

Addressing privacy is a priority for mHealth practitioners [2]. Informed consent is one of the grounds to safeguard individuals' privacy rights, giving back their autonomy and enabling informed decisions before starting the data collection. We have presented the design and evaluation of an e-Consent tool tailored to MDCSs in the context of public health surveys and disease surveillance. Early findings suggest that it has the potential to enhance system's transparency and give individuals more control over their data. Moreover, our requirement analysis, design considerations and usability study findings have implications for other mHealth applications in which data privacy and informed consent are crucial.

Abstract

Unhealthy behaviors are a socioeconomic burden and lead to the development of chronic diseases. Relapse is a common issue that most individuals deal with as they adopt and sustain a positive healthy lifestyle. Proper identification of behavioral transitions can help design agile, adaptive, and just-in-time interventions. In this paper, we present a methodology that integrates qualitative coding, machine learning, and formal data analysis using stage transition probabilities and linguistics-based text analysis to track shifts in stages of behavior change as embedded in journal entries recorded by users in an online community for tobacco cessation. Results indicate that our semi-automated stage identification method has an accuracy of 90%. Further analysis revealed stage-specific language features and transition probabilities. Implications for targeted social interventions are discussed.

Health behavior , social media, machine learning

Introduction

Poor lifestyle choices and unhealthy behaviors such as smoking, alcohol consumption, poor diet, and physical inactivity affects the development and management of chronic diseases, like obesity, Type 2 diabetes mellitus, hypertension, cardiovascular diseases, and several types of cancer [1]. Chronic diseases kill 38 million people every year and hence their prevention is important [1]. Efficient self-management of chronic illnesses and adoption of positive health behaviors has shown to be related to overall better physical and psychological health outcomes [2]. However, such self-management is not driven by individuals solely but rather in a social context which includes formal health care providers, informal social peers, and their physical surroundings [3]. Behavior change can be a daunting task, and oftentimes individuals relapse as they attempt to embrace and sustain a positive health change.

Behavioral transitions are important to sustain lasting and improved health outcomes [4]. Several theories have been postulated to define and model these transitions and changes in behavior. Specifically, the Transtheoretical Model (TTM) of Change has been used to conceptualize the process of intentional behavior change by its two main components: stages and processes of change [5]. Stages explore the temporality of behavior change, while processes encompass cognitive and behavioral concepts such as decisional balance, self-efficacy, and rewards management [5]. It is important to identify these stages of change so that appropriate lifestyle interventions can be prescribed to individuals who are willing to quit an unhealthy habit and modify their behaviors. Many mobile interventions have been modeled after TTM. Adapting theory-driven interventions to the changing needs of individuals can help sustain positive health changes long-term [5].

Emerging research has shown that agile and adaptive interventions that respond to stage transitions can be effective tools of behavior change in real-time settings [6]. However, it is difficult to monitor stage transitions using traditional behavior modeling approaches at scale. Online communication forums, which form the dominant means of communication in the digital era, provide an opportunity to understand human behavior change at nuanced levels. According to the Global Digital Report 2018 the number of social media users worldwide is about 3.2 billion [7]. The electronic archival of digital interactions provide us with rich data sources that afford the opportunity to understand intricate processes and stages of behavior change. Emerging research suggests that online social media analysis can help us understand patterns of social factors underlying behavior change and help in the development of network interventions for health behavior changes [8]. Thus far, social media analysis has focused on (a) understanding the structure of social ties [9], (b) assigning peer-to-peer communication events to various social support categories [10]. However, prior research on health-related social networks has not merged theoretically-driven content-based approaches with machine learning methods to facilitate stage-based user behavior and transition classification. Such understanding can have important implications for the design of interventions that aim to enhance self-management behavior.

In this paper, we present a new methodology to understand an individual's behavior transitions using recorded journal entries in online communities. Our study has three major components: (a) qualitative analysis to manually label the user-generated data for different stages of behavior change, (b) automated categorization using machine learning models to scale the labeling of stages of behavior change to a large social media dataset, and (c) characterization of stage-specific language features and transition rates to enable personalized intervention refinement and technology development in scalable online settings. Our research described in this paper will help answer the following questions: 1) How can we adapt existing informatics approaches to automate stage identification in digital health platforms? 2) What are the relationship characteristics between user engagement on these platforms, behavior transitions, and language features?

Such an understanding can help in identifying the triggers for relapse and designing appropriate interventions for the users at risk for relapse or in need of more social support for long-term sustenance [11]. We apply our methodology to characterizing behavioral transitions among the users of an online community for tobacco cessation.

Methods

QuitNet is an online social communication forum that promotes smoking cessation amongst its members thereby leading to behavior change and health promotion [12]. It has been in existence from the past 16 years and has over 100,000 new registrants per year. The members of this platform are usually smokers who are willing to quit or ex-smokers who are willing to stay abstinent. Graham et al. [13] have shown a strong correlation of individual's participation in online community with abstinence compared to individuals who do not participate in such communities. The dataset used in this study consisted of de-identified journal text entries, spanning from 1999-2015 including 26,441 individuals, and 111,004 journal text entries. The journal text entries that were marked as public by the QuitNet users were used for this analysis. This study is exempted from human subjects review by the Institutional Review Board at the University of Texas Health Science Center at Houston.

Qualitative analysis

Firstly, we developed the annotation guidelines to inform the coding process and ensure objectivity in stage assignment. Table 1 shows the annotation guidelines that were adopted in our analysis. We used the TTM model to label every journal text entry with its associated stage of change. The TTM model defines Precontemplation, Contemplation, Preparation, Action, Maintenance, and Termination as the six stages of change, where each stage involves a process of progress (Figure 1). Fivehundred out of the 111,004 journal text entries were randomly selected and coded manually by two independent researchers by performing a line by-line analysis on the text entries to derive the stages of change codes from the data. The codes they assigned to the text entries had a Cohen's Kappa measure of 97%. Disagreement between the researchers was resolved through discussion.

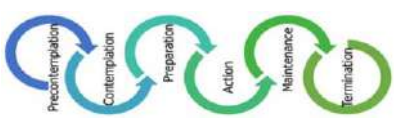

Figure 1– Stages of behavior change

Automated Text Analysis

Using the labeled dataset of 500 journal text entries, we first performed a feature inspection to get a better understanding of our textual data. The dataset was then cleaned using the following techniques - (a) tokenizing the text to split sentences into individual words, (b) removing the stop words to get rid of words that occur too frequently or infrequently as well as punctuation, (c) stemming the text to address word variants, and (d) vectorizing words since we needed to convert words into mathematical representations to feed them into various machine learning models. Latent Dirichlet Allocation (LDA) and word2vec models [14, 15] were trained using default parameters to create feature vectors and extract sensible feature data from the journal text entries. LDA is a probalistic topic model that creates probabilities on the word level, while word2vec is a deep learning method that creates feature vectors for the words in the text corpus [15]. After this we applied a few supervised classifiers to be able to predict what stage belongs to each journal text entry. The labeled dataset was split into a train and test set and a ten fold cross validation was performed. We used the features that were previously created to train three machine learning models: Logistic Regression (LR), Support Vector Machine (SVM) (linear), and Random Forest (RF). These models were chosen, given their performance on similar classification tasks [15]. We used recall, precision, and F-measure as our accuracy metrics to evaluate the machine learning algorithms used in this study. We selected the model with the highest accuracy to make final predictions on the unlabeled dataset. Scikit-Learn package was used for analysis [16].

Data Analysis

User level analysis was performed to map transitions between stages of behavior change. Pearson Correlation coefficient was calculated to identify if there was any correlation between user engagement and stage transition rates (the numbers of messages posted and the number of transitions from one stage to another). A Markov model was used to estimate the stage membership probabilities and the stage transition probabilities of movement from one stage to another. Stage membership probabilities indicate the prevalence of each stage and transition probabilities indicate the probability of stage movements conditional on the stage membership at the previous time point [17]. Further, we applied The Linguistic Inquiry and Word Count (LIWC) [18] dictionary that comprises of psychologically meaningful word categories, and whose output includes the percentage of words within a given text that belong to each stage of change. Applying this technique allows for a direct comparison of text features across various stage-specific journal entries.

Table 1– Annotation guidelines

Stage in TTM model	Characteristics of this stage as per TTM model	Patient's View / State of mind
Pre-contemplation (Not Ready)	People in this stage are not ready to change in the foreseeable future like for another 6 months.	Not thinking about change, Feeling of no control, Denial: does not believe it applies to self
Contemplation (Getting Ready)	People in this stage have the intention to change in the next 6 months.	Weighing benefits and costs of behavior, proposed change
Preparation (Ready)	People in this stage are ready to make a change immediately, they have a plan of action in place.	Experimenting with small changes
Action	In this stage people have made specific overt modifications in their lifestyles within the past six months.	Not all modifications count as Action in this model. Total abstinence is what counts as an action compared to switching to low nicotine cigarettes.
Maintenance	In this stage people have made specific overt modifications in their lifestyles and are working to prevent a relapse.	Maintaining a new behavior over time, has quit for over 6 months
Relapse	People in this stage have started smoking again following a quit attempt.	Experiencing a normal part of the process of change, usually feels demoralized

Results

On an average, a user posted four text entries. Table 2 below shows some of the textual characteristics of the unlabeled journal text entry corpus.

Table 2– Characteristics of an unlabeled text corpus

Characteristics of the corpus	Frequency
Total number of journal text entries	111,004
Total number of unique users	26,441
Mean age of the users	40.3 years
Total number of females	18,614 (~71%)
Total number of males	7,614 (~29%)
Average length of the journal entry	150 words

Qualitative Analysis

Table 3 shows examples of some of journal text entries and their associated stage of change as coded manually by the researchers. In the first example - as the individual was in the process of deciding to undertake the quit process and still thinking about it- the entry was coded as 'Contemplation'. The second example entry was coded as 'Preparation' since the individual specifically mentioned that they plan to quit smoking in 5 days. The last example entry was coded as 'Action' since the individual mentioned being smoke free for a certain amount of time, with a past quit date.

Table 3– Journal text entries labeled by manual coding

Stage of Change	Journal text entry example
Contemplation	I had originally set my quit date at Feb. 7 2003. I got to thinking about it and decided why wait?
Preparation	I was going to quit early but something upset me and I ran to the store. Ugh! Will I ever quit. I'm Quitting in 5 days!
Action	Tough day! Made it through! No slips today.4 days, 5 hours, 55 minutes and 17 seconds smoke free. 85 cigarettes not smoked. $33.60 and 15 hours of my life saved! My quit date: 8/15/2011 2:00:00 PM

Our dataset lacked examples of the 'Pre-contemplation', 'Maintenance' and 'Termination' stage and had limited examples of the 'Contemplation' stage (n=21). There were 210 text entries which were coded as 'Preparation' and 268 text entries which were coded as 'Action'. There was one text entry which was coded as 'NA' (Not Applicable).

Automated Text Analysis

Table 4 shows the accuracy of various machine learning models used for making predictions on the unlabeled dataset using 10-fold cross validation. Since the Random Forest Model gave the highest accuracy, this model was chosen to make the final predictions on unlabeled dataset.

Table 4– Classification report for machine learning models

Machine Learning Models	Precision	Recall	F1-score
LR	0.69	0.70	0.69
SVM (Linear)	0.71	0.72	0.72
RF	0.91	0.90	0.90

62% of the total entries were labeled as 'Action' (n=68,947) and 38% were labeled as 'Preparation' (n=42,041). Very few entries were labeled as 'Contemplation' (n=15) and 'NA' (n=1). Table 5 shows some example journal text entries that were labeled using the RF machine learning model.

Table 5– Journal text entries labeled by the Random Forest model

Stage of Change	Journal text entry example
Contemplation	just hooked up on the quitnet today... checking the site out... seeing what's available... so far so good... let my younger brother know i'd joined up by sending him a q-card... maybe he'll join up too...
Preparation	Reasonable nights sleep. crazy day. headache, a few cravings. no exercise. just work until 6 p.m. 1 nic gum.
Action	last night was bad; no sleep; up every freakin hour...hope day 2 is better. 1 day, 14 hours, 6 minutes and 31 seconds smoke free. 24 cigarettes not smoked. $5.62 and 4 hours of my life saved! my quit date: 7/26/2010

Data Analysis

Because a limited number of samples were coded to be in the 'Contemplation' stage, we conducted further data analysis with only those journal text entries that were labeled as either 'Action' or 'Preparation' by the machine learning model. The highest number of journal text entries posted by an individual was 418 and the number of transitions made by this particular individual was 95 from one to stage of behavior change to another. The Pearson Correlation coefficient between the number of journal text entries posted by the users and their transitions between the stages of change calculated was 0.857 (Figure 2).

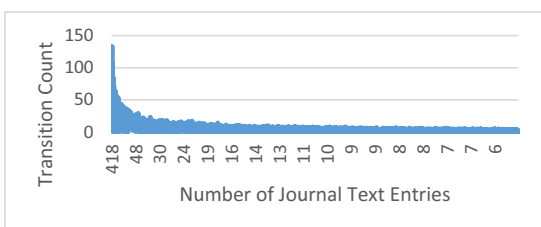

Figure 2– Line graph showing the relationship between the journal text entries posted and transitions between stages of change

This value showed that the higher the frequency of journaling by an individual, the higher the number of behavioral transitions for that individual, which may occur in either a positive direction (Preparation to Action) or a negative

direction (Action to Preparation). This engagement phenomena may indicate that the denser the digital footprint of an individual in a digital platform like QuitNet, the higher the probability to identify behavioral transitions.

Figure 3 shows a Markov chain model representing the movement pattern between the two stages of change – 'Preparation' and 'Action'. The membership probabilities for 'Preparation' is 0.37 and for 'Action' is 0.32. The transition probabilities from 'Preparation to Action' is 0.27 and from 'Action to Preparation' is 0.21.

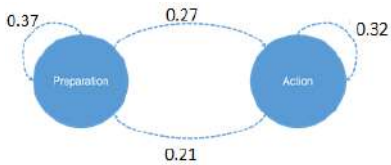

Figure 3– A two-state Markov chain representing the transition between stages of behavior change

As can be seen from the figure above, the probability of an individual staying in the 'Preparation' stage is higher compared to an individual staying in the 'Action' stage. The probability of transitioning from 'Preparation' to 'Action' stage is higher compared to transitioning from 'Action' to 'Preparation' stage.

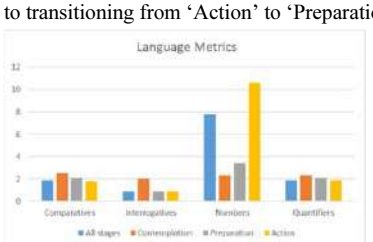

Figure 4- Comparison of means for language metrics

Exploratory text analysis using LIWC revealed specific language features that were prominent within the 'Preparation' and 'Action' stages. As can be seen in Figure 4, interrogatives were prevalent in the 'Contemplation' stage (e.g seeking information), while numbers were highly used in the 'Action' stage, which is probably expected due to expressing quantities of both time of abstinence and cigarettes not smoked (e.g. demonstrating progress). Figure 5 indicates specific foci of journal entries within each stage of change. For example, in the 'Contemplation' stage language with individual drives and needs, achievement, power, and reward were shown to be common. Sense of achievement and work- induced stress (obstacles to quitting) were emphasized in the 'Action' stage.

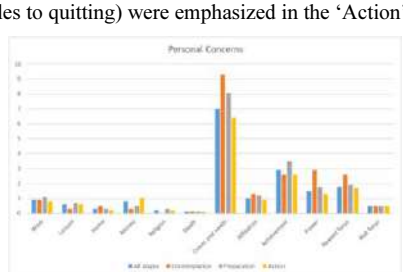

Figure 5- Comparison of means for personal communication topics in different stages of behavior change

Discussion

Technologies like online communities provide support for individuals to modify their behavior for better health outcomes. On the other hand, there are theory-driven principles and processes that work best at every stage of behavior change to reduce resistance, facilitate progress, and prevent relapse. It is important to develop advanced analytic tools to integrate theory and technology, which can result in enhanced just-in-time support infrastructure for sustained behavior change. Such an ecosystem will ultimately lead to a greater understanding of the ways in which such social phenomena mediate behavior change at individual and community levels, thereby providing us with the opportunity to develop superior and scalable interventions. This to further assist the development of multilevel systems that harness behavior change mechanisms aimed at augmenting the support for individuals attempting to achieve their health goals [19].

To the best of our knowledge, the research reported in this paper is among the few studies that have attempted to apply various machine learning models in the context of online communities and social journaling to understand and characterize stages of behavior change in tobacco cessation. Our work provides new techniques to analyze user generated unstructured health data to understand an individual's behavior transition over a period of time. Our model was able to label the stages of behavior change with an accuracy of 90% in journal text entries. The word2vec based approach described in this paper allows for the extension of human-intensive qualitative analysis to large social media datasets.

We found that people who engaged more in journaling had higher transition flags, which may indicate (a) desired or undesired stage shifts, and (b) higher chances of being flagged for stage transitions. In either case, better support infrastructure through adaptive and personalized means aimed at increasing user engagement may ultimately lead to better health outcomes. Further, we have seen that there is a higher probability of an individual staying in the 'Preparation' stage and targeted interventions should be developed to encourage such individuals to move to the 'Action' stage and attain a positive behavior change. The individuals undergoing relapse can be identified based on their stage transitions and appropriate interventions can be designed for them – encouraging them to pick a new quit date or helping them form new relationships online so that they can stay on the path of quitting.

Specific language traits revealed using LIWC analysis, while preliminary in nature, still highlight the authenticity and individual drive embedded in journal entries highlighting the need to understand emotional tone, speech intentions, and cognitive focus within each stage of behavior change. Our study can provide new directions for developing network interventions [20] for tobacco cessation and health promotion by focusing on content-based, targeted behavior change strategies while addressing stage-specific constraints and associations simultaneously.

One of the limitations of our work was the limited number journal text entries that were coded manually to identify stages of change. To improve the generalizability of our results, it is important to have higher number of journal text entries in the qualitative sample so that higher training accuracy of machine learning models can be achieved. It is possible,given the low fraction of journal text entries coded for stages of behavior change, that the distribution of various stages may not have been accurately represented. It is important that a larger number of journal text entries are coded to reach stage

saturation. Also, the content of the journal text entries plays an important role during the predictions made by machine learning models. For example, an individual who has just started the 'Action' but has provided lots of detail about the 'Preparation' could have led the classifier to make a wrong stage prediction. Individual-specific linguistic features and demographics should also be considered when analyzing journal entries. There are also some limitations inherent to the TTM such as a lack of consideration of the social context, biological, and environmental issues related to changes in health behaviors [21], that should be considered when understanding behavior transitions. Another limitation of our study is focusing only on tobacco cessation. Future work should extend these methodologies to datasets in other areas such as diabetes, cancer prevention and survivorship, etc. A more formal social network analysis that utilizes peer interactions with journal entries needs to be performed so that content specific network-patterns can be identified as they have implications in the design of behavioral support systems to promote public health and wellness.

Conclusions

Risky health behaviors contribute to a large number of preventable deaths around the world. The ubiquity of online social platforms allows us to examine inter- and intra-personal processes and stages of health behaviors among individuals. In this paper, we described a mixed methods approach that combines qualitative coding and automated text analysis to provide deeper insight into the mechanisms underlying behavior change through the utilization of digital footprints in the form of online journaling. It is very important to develop scalable methods to help health researchers and professionals analyze large amounts of textual data generated from online communities in today's digital era. Such techniques can help design personalized and targeted interventions that persuade people to initiate or adhere to a positive behavior change. This can help in establishing novel digital and translational interventions in public health and behavioral sciences.

Abstract

For those specialized in geriatric medicine, telemedicine innovations provide a new alternative to in-person follow-up care, allowing clinicians to connect and treat patients with more convenience. Telemedicine will likely play a vital role in reaching underserved populations in remote areas. This study investigates first impressions of a telemedicine-based delirium assessment tool. The overall response from participants is positive, supporting the theory that these types of tools will be welcome within the geriatric patient population. Feedback surrounding interactions with the interface are also positive, showing that while many elderly patients may refrain from working with tablets daily, they can successful interact with the tool when needed for care reasons. While this study and sample size are not all-inclusive regarding the diversity of patients and distinct challenges, it serves as a preliminary step towards future research exploring the feasibility and acceptability of such tools within this specific population.

Keywords:

Telemedicine, Critical Care, Aged

Introduction

Challenges in caring for geriatric populations, individuals older than 60 years of age who are receiving care [1], persist in the US health system. Similar to other vulnerable populations, the population of geriatric patients is growing in number as the baby boomer generation ages, often bringing with them complex diagnoses requiring the cooperation of many different follow-up plans and treatment specialists [2]. Primary care has struggled to keep up with the complex nature of geriatric care, as well as the growing number of patients requiring attention [2]. This is further compounded by the increasing shortage of medical professionals specializing in geriatric medicine [3,4]. Attributes of geriatric care often hinder traditional in-person care methods The development of telemedicine, particularly telecommunication platforms with patient-centered features, provide a possible solution to the unique challenges faced within the demand of this medical specialty. Telemedicine allows clinicians to connect and evaluate patients remotely and is ideally suited to help improve overall care outcomes within this population as well as address access issues.

A pilot study gathered preliminary evidence of geriatric patient satisfaction while using computer systems for follow-up care in the home [5]. This small pilot referred to these visits as "electronic house calls" and demonstrated that most geriatric patients are comfortable with computer-assisted follow-up care. It also revealed that patients did not believe the computer to negatively impact their clinician relationship with their physician [5,6]. While this study employed personal computers, as telemedicine technology has advanced, it has opened opportunities for health informatics research to further study the satisfaction and feasibility of other remote tools. These remote telemedicine-focused platforms can enhance the interaction between patient and clinician, offering a "new kind of service relationship" by providing direct and personal care with more convenience [6].

Telemedicine has been incorporated into ICU patient care and education. These new technologies allow for critical care patients to be treated by health professionals remotely [7,8]. ICU telemedicine interventions have demonstrated a reduction in hospital cost, patient mortality and patient length of stay [8,9,10]. While many benefits of telemedicine in the ICU are financially related, telemedicine has most prominently allowed for more efficient care to critically ill patients. Faster response time to alarms and the capturing of performance data for review and education has helped this improvement [8]. For ICU settings in rural or underserved areas, telemedicine has been a welcome addition, helping staff to monitor patients during their stay and to provide relief to physicians and nurses, in the event of workforce shortages [11]. ICU telemedicine interventions have been instrumental in clinical improvement and this continues to be an arguing force for the adoption of telemedicine platforms in hospital ICU settings across the country [9].

As opposed to previous generations of geriatric patients, individuals currently aging into this population group now have had some exposure to telecommunication or connected devices at some point in their lifetime [12]. Videoconferencing with patients as a form of follow-up care has already shown to be successful with this population [2]. These sessions are comparable to face-to-face encounters in terms of satisfaction, reliability and usability [12]. Furthermore, telemedicine can also potentially alleviate clinical access issues for geriatric patients in rural and remote locations. Barriers related to technology, such as information overload, lack of devices and or infrastructure, and cost, are still real concerns for geriatric patients [13]. Evidence to support telemedicine's effective deployment and sustainability in such areas is still being researched [14]. However, there will likely be an increase in the number of jobs that focus specifically on the coordination of telemedicine technology for patient use. This will potentially assist diffusion of telemedicine practices across clinical systems and regions, especially as service areas continue to grow in scope [6]. For our study, we investigate the feasibility of using a remote telemedicine tool for follow-up post-acute care within the geriatric population.

Methods

Thirty (n=30) participants from an inpatient geriatric specialty unit in North Carolina were selected for this study. Daily patient schedules were reviewed to identify potential study participants. Participants were English-speaking and 65 years of age

or older. This study was completed in partnership with another observational study gathering preliminary data on a new telemedicine delirium diagnostic tool. Participants were initially evaluated to determine their baseline cognitive state [15]. Those who screened positive for dementia as defined by an abnormal Mini-Cog test or had a documented history of dementia and/or brain abnormalities, as well as those unable to give informed consent, were excluded. Participants were given a tablet and instructions to complete the new delirium assessment. Once this assessment concluded, participants completed a usability questionnaire to detail their impressions of the new tool. The usability data, detailed in this paper, will be used to support hypothesis of a positive potential feasibility and patient acceptability of remote tablet devices in care settings outside of the hospital.

To evaluate the new assessment tool, participants completed the Questionnaire for User Interface Satisfaction (QUIS), a short form survey designed to uncover useful impressions from initial participant interactions. Participants answered questions about their overall reactions, the design, terminology used, and understanding of the system - both overall and when directed to complete a task. The final section of the questionnaire, system capabilities, was not applicable to this study.

Participants' responses for each question of the QUIS were determined from a bipolar Likert scale ranging from 0 to 9. These individual data points were averaged into four overarching categories of the QUIS for each participant: overall reaction, overall screen, terminology and system information, and meaning. A one-way ANOVA was performed in order to test for significant differences in the mean scores for these four categories by age group (60-69 years, 70-79 years, and 80+ years).

Results

Of the 30 participants recruited for the study, 26 (87%) were female. 100% of the participants were white and non-Hispanic. Participants ranged from 67 to 92 years old, with an average age of 77.80 years. Four participants (13.3%) were 60-69 years old, 14 participants (46.7%) were 70-79 years old, and 12 participants (40%) were 80 years old or older.

Overall Satisfaction Results

Questions focused on four different factors of the tablet experience, which were collapsed into four average scores for each of the 30 participants. The domains were overall reaction to the software, screen, terminology and system information, and learning. Questions to which participants responded "NA" were not included in the analysis.

Participants' responses—as determined from a bipolar Likert scale ranging from 0 to 9—were averaged across the four main categories to create a mean score for each participant for each category. These individual means were then averaged into overall means for each category, which ranged from 8.16 to 8.72. See Table 1 for descriptive statistics for all four domains.

Age and Satisfaction

An alpha level of .05 was used to assess statistical significance. A one-way ANOVA was used to assess whether responses varied by age category. There was no significant difference in mean responses found in any domain by age category. See Figure 1 for the mean average scores across age categories.

The 60-69-year-old age group had the highest mean score for the Overall Reaction, with a mean value of 8.90. The 80+ year-old age group had the lowest mean score with 7.98. The 60-69 age group also had the highest mean score for the Screen domain, with a mean value of 8.94. In this domain, the 70-79-year-old age group had the lowest mean score of 8.45. Conversely, the 80+ age group had the highest mean scores for the Terminology and System Information and Learning domains, with mean values of 8.72 and 8.85, respectively. The 60-69-year-old age group had the lowest scores for these two domains, with means of 8.42 and 8.25, respectively. However, it should be noted that the range between the highest- and lowest-scoring age categories for each domain is small, ranging from 0.30 to 0.92. See Table 2 for the mean scores of the four domains by age category.

Table 1—Summary of Mean Scores for the Four Domains of Interface Satisfaction Survey

Mean Score	N	Minimum	Maximum	Mean	SD
Overall Reaction Mean Score	30	6.00	9.00	8.16	1.66
Overall Screen Mean Score	30	6.25	9.00	8.60	0.72
Terminology and System Information Mean Score	30	6.66	9.00	8.58	0.85
Learning Mean Score	30	6.00	9.00	8.72	0.69

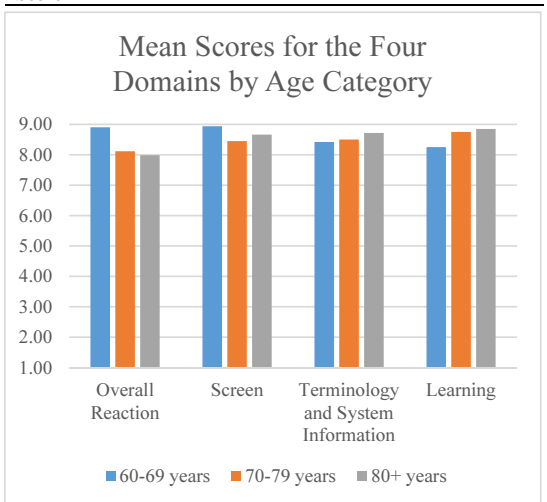

Figure 1—Mean Scores for Four Domains by Age Category

Additionally, we broke down the four domains into their various indicators. Though a one-way ANOVA of the indicators by age group found no significant differences in score by age category, the mean scores for the different indicators in each domain are highlighted in the rest of this section to note overall trends between age categories.

The Overall Reaction domain was broken down into its indicators, which can be seen in Table 3. Overall Reaction scores were high, ranging from 7.67 to 9.00. For most of the indicators, the 60-69-year-old age group scored the highest, followed by the 70-79 group and then the 80+ group. The "Rigid or Flexible" indicator is the only one which does not follow this pattern, with the 80+ group having a higher mean score than the 70-79 group, with mean scores of 8.08 and 7.79, respectively.

Table 2—Summary of Mean Scores for the Four Domains of Interface Satisfaction Survey by Age Group

Domain	60-69 Years Mean Score	70-79 Years Mean Score	80+ Years Mean Score
Overall Reaction	8.90	8.11	7.98
Overall Screen	8.94	8.45	8.66
Terminology and System Information	8.42	8.50	8.72
Learning	8.25	8.75	8.85

Table 3—Summary of Mean Scores for Overall Reaction Domain by Age Group

Domain	60-69 Years Mean Score	70-79 Years Mean Score	80+ Years Mean Score
Terrible or Wonderful	8.50	8.07	7.83
Difficult or Easy	9.00	8.36	7.67
Frustrating or Satisfying	9.00	8.14	8.17
Inadequate or Adequate	9.00	8.21	8.17
Rigid or Flexible	9.00	7.79	8.08

The Overall Screen domain was broken down into its indicators, which can be seen in Table 4. Scores for these indicators mirrored those in the Overall Reaction domain, ranging from 7.86 to 9.00. Contrary to the Overall Reaction domain, while the 60-69 group scored the highest across all indicators, here the 80+ group scored higher than the 70-79 group. The exception to this is the "Reading Characters on Screen" indicator, where the 70-79 group scored higher than the 80+.

Table 4—Summary of Mean Scores for Overall Screen Domain by Age Group

Domain	60-69 Years Mean Score	70-79 Years Mean Score	80+ Years Mean Score
Reading Characters on Screen	9.00	8.90	8.83
Organization of Information	8.67	8.54	8.73
Sequence of Screens	9.00	8.54	9.00
Help Messages on the Screen	9.00	7.86	8.17

The Terminology and System Information domain was broken down into its indicators, which can be seen in Table 5. For three of these indicators—Use of Terms Throughout the System, Position of Messages on Screen, and Prompts for Input—again the 60-69 age group scores the highest. However, for Error Messages and Information Accessibility, this group scored the lowest. This is mostly due to the small N for the 60-69 group for these indicators (N = 3), with most respondents in this age category choosing "Not Applicable". One participant rated the system a 2 for both of these indicators, decreasing the respective mean scores significantly. For the other indicators, the 60-69 group is followed by the 80+ group and then the 70-79, mirroring that of the Overall Screen domain.

Table 5—Summary of Mean Scores for Terminology and System Information Domain by Age Group

Domain	60-69 Years Mean Score	70-79 Years Mean Score	80+ Years Mean Score
Use of Terms Throughout the System	9.00	8.78	9.00
Position of Messages on Screen	9.00	8.78	8.89
Prompts for Input	9.00	8.31	8.64
Error Messages	5.50	8.20	8.33
Information Accessibility	7.25	8.50	8.83

The Learning Domain was broken down into its indicators, which can be seen in Table 6. Analyses of this domain were hindered by the high number of participants who gave a "Not Applicable" rating for various indicators, most notably the Exploring New Features by Trial and Error and Reference Materials. This is likely because many participants did not opt to explore features on the telemedicine tool and were not instructed to by researchers. Additionally, reference materials were not readily provided for participants. For the other indicators, Remembering Commands and Straightforwardness of Tasks were scored the highest by the 60-69 group followed by the 70-79 group and then the 80+ group. Most notably, Learning to Operate the System exhibited the opposite pattern, with the 80+ group rating this the highest and the 60-69 group rating it the lowest, with mean scores of 9.00 and 8.50, respectively.

Table 6—Summary of Mean Scores for Learning Domain by Age Group

Domain	60-69 Years Mean Score	70-79 Years Mean Score	80+ Years Mean Score
Learning to Operate the System	8.50	8.75	9.00
Exploring New Features by Trial and Error	N/A	7.67	8.33
Remembering Commands	9.00	8.61	8.58
Straightforwardness of Tasks	9.00	8.85	8.83
Reference Materials	N/A	8.20	8.50

Discussion

Overall, participants were very satisfied with the interface, with an overall reaction mean score of 8.16. The other three domains exhibited similarly high scores, ranging from means of 8.58 to 8.72. A one-way ANOVA failed to find a statistically significant difference in scores by age category, suggesting that even the eldest of this geriatric population did not react differently

from the youngest age category. We demonstrate that for three of the four domains, the domain means actually increased between the 60-69 group and the 80+ group. Together, these results suggest that geriatric populations are highly satisfied with the telemedicine software, indicating that it could be feasible and acceptable for this population to use.

The development of telemedicine, particularly telecommunication platforms with patient-centered features, provide a possible solution to some of the challenges associated with providing geriatric care, especially as the proportion of the population who are older grows. Telemedicine platforms can be utilized to improve primary care by allowing providers to follow-up with their geriatric patients in a time and place that is most convenient for both groups. This could be especially convenient for scheduling follow-ups with rural patients or for those without access to reliable transportation to and from their appointments. Though these individuals have generally had some exposure to connected devices [12], previous studies found that older participants exhibited a lower overall reaction mean score. Though this study did not focus on patients and instead solicited results from community members [16].

Our study contradicts some of the results from a previous study that found that older participants were less satisfied with telemedicine platforms. However, this is the first study to look at the experience of in-patient geriatric populations in relation to telemedicine platforms [16]. Future research is needed to truly assess the acceptability and feasibility of telemedicine platforms for the geriatric population. Most ICU specific research regarding telemedicine interventions detail support for adoption of these platforms via financial incentives [9,10]. While many show greater contribution margins once this technology is implemented within ICU processes, other research demonstrates better clinical outcomes, such as decreased mortality, as a result of more acute monitoring and intensivist involvement via telemedicine platforms [8]. Conversely, our study looks at the patient side of telemedicine in the ICU. Our preliminary findings show that from a patient perspective, telemedicine is a welcome and useful tool during their treatment.

Over time, rural counties have received a net influx of people over the age of 50, suggesting that many geriatric people are opting to move into rural locations [17]. In light of this, future studies are needed to focus on the satisfaction and feasibility of telemedicine software for rural, geriatric populations who may face different barriers than their peers in urban areas. As this is a potentially vulnerable population, researchers must ensure that the usage of telemedicine software as a form of follow-up care does not also interfere with medical comprehension.

At this time, this research suggests that telemedicine software is a viable solution to overcoming barriers to reaching geriatric populations. As the population of the United States ages and this population tends to require more medical care, telemedicine allows primary care physicians the ability to follow-up with these patients in a manner that is convenient for both parties. Offering telemedicine platforms as an option for geriatric populations can reduce the burden on the patient and the physician and provide greater access to patients who may otherwise have difficulty traveling to appointments.

Limitations

The main limitation of this study is the sample size of 30 participants, all of whom are English speakers. Participants did vary in age, however all participants were white and not Hispanic/Latino. Additionally, the vast majority of patients were women. As this group is not representative of the demographics of the area, it is likely that this is not a representative sample. Finally, patients who had tested positive for dementia or had a documented history of dementia and/or brain abnormalities were excluded, so our sample is not representative of the entire geriatric population.

Conclusions

Telemedicine can potentially alleviate access and availability issues for geriatric patients. However, previous research found that older populations were less likely to be satisfied with telemedicine software [5]. This study focused on how geriatric patients reacted to the telemedicine software in terms of receiving follow-up care outside of the hospital setting.

Results found that telemedicine software is an effective tool for receiving follow-up care, with no differences in mean satisfaction between age categories. Future research is needed to study how rural geriatric patients respond to telemedicine software.

Abstract

Many studies use eye-tracker to analyse the socio-technical system, also in medical research. Only a few articles describe the use of eye-tracker to examine human-computer interaction in a critical care environment, especially in the field of anaesthesia or surgery. Therefore, we have tested in a feasibility study head-mounted eye-tracker of three different manufactures in a simulated anesthesia surrounding with mankind patient simulators. The research question was to analyse whether the field scene camera of the eye-tracker can be used in the light conditions and changes in brightness of the operating room. In addition, it was tested whether the eye-tracker was still calibrated and held on the subject's head during the resuscitation movement. All eye-trackers tested had a good adaptation on changing light or changing distances.

Keywords:

Patient Simulation, Anesthesia, Patient Safety

Introduction

Anesthesia as a medical discipline in hospitals include anaesthesiology, which includes all medical procedures such as intensive care, pain therapy and emergency medicine. Within intensive care, procedures such as intubation in the operating theatre are omnipresent. The anesthesiologist's work is characterized by the use of various technical devices such as ventilators and a high stress level due to medical emergencies. Errors at the level of human-computer interaction or human-human communication can lead to errors that impair patient safety. For this reason, the anaesthetic area is also a safety-critical area, which is the subject of research.

The main aspects of safety-critical systems are characterized by interactions and rules between people (teamwork), (medical-) devices and are influenced by organizational conditions. In case of an adverse event, the cause can usually occur on several levels of the socio-technical system. An analysis of this system is therefore necessary to increase patient safety. It depends also on human-machine-interaction. Especially in emergency medicine, a risk for patient safety arises from situations with a lot of stress, changing teams and complex human-machine interaction. The perception, attention and education level of each team member is important for patient safety. Loss of attention, insufficient teamwork or problems in human-human-interaction can be a reason of making wrong decisions or insufficient troubleshooting[1].

The identification of risk-based human-machine interactions and usability are a core component of the research project in which this pilot study is embedded. For this purpose, this pilot study determines whether eye-tracker can be used as a measuring system for analysing part of the socio-technical system and its limitations. So far, eye-tracker has been used as a measuring instrument for the determination of visual attention, perception and decision making [2]. Currently, they are used in emergency and intensive care medicine to analyze the surgeon's vigilance by measuring their gazes [3]. The anesthetist's distribution of visual attention [4], the mental workload [5], the anesthetists' experience [6] and the eye behaviour between novice and expert are being investigated with eye-tracker [7–9]. However, the applicability of eye-tracking as a measuring instrument for the identification of risks in human-machine interaction in the anesthesiological area is still missing [10].

The aim of this pilot study is to test the feasibility and effectiveness of eye-tracker in emergency and intensive care medicine. The suitability of eye-tracker is tested under real-world conditions, which in particular address the context factors such as light and brightness differences. This study is part of a larger future research project to analyse the entire socio-technical system in medicine.

The following research questions are answered in this study:

- Is the eye-tracker applicable in anesthesia workspaces?
- Do the video data of the eye-tracker allow an analysis afterwards of the scene?
- Do the video data of the eye-tracker represent the scene and its objects in a realistic way corresponding to the perception of the person wearing the eye-tracker glasses?
- Is the eye-tracker still attached to the head and calibrated after rapid head movements (resuscitation)?
- Are there any limitations in the use of eye-tracker in these environments?

Methods

Study Design

In this study, three eye-trackers were tested for use in the operating room and in intensive care medicine. The test referred to the practical applicability of Eye-Tracking technology in intensive care unit environments. For this purpose, three scenarios were selected in which the research question was answered.

The operation rooms are characterized by large brightness und distance differences. It should be tested if the video material provided by the field scene camera of the eye-tracker depicts adequately and correctly the crucial areas such as monitor, glottis and patient simulator. The correct representation of the objects is crucial for the subsequent qualitative analysis of the risky actions in emergency medicine. The detection of vital signs on the monitor or the perception of the glottis during intubation must be realistically reproduced by the eye-tracker to ensure a successional analysis of the video material. For future use of the eye-tracker as a measuring instrument in the socio-technical system, the comparison between the perception of the subject and the recorded video material must take place

in order to be able to use qualitative analysis methods. In addition, it must be found out if the glottis lying in a dark hole can be recognized as a Region of Interest (ROI) by the eye-tracker. The recognition of the glottis is an important criterion for correct intubation. Therefore, it must be checked whether the glottis can be taken as Region of Interest (ROI).

The domain-specific environment has yielded in to three research questions (see the research questions assigned to the scenario Table 1.

Table 1 – Research Goals Assigned to the Scenarios

Research Goal	Scenario and Requirement
Detection of different objects (ROI) with different luminous intensity	Scenario1 Changing Gaze: Accurate changing gaze e.g. to monitor with different backlights in greater distances
Recognition of the glottis	Scenario 2 Intubation: Accurate detection with very low light intensity and low distance
The calibration of the eye-tracker remains stable after heavy movement of the head (resuscitation)	Scenario 3 Resuscitation: Freedom to move your head and continue to recognize the objects in the room

The study was performed in an operating room with a patient simulator. An anesthesiologist performed the scenarios with the three eye-trackers according to a given protocol. A study leader was present and directed the process of the study. Before each test, the eye-tracker was calibrated. Once the eye-tracker worked, each scenario was performed and the video data were recorded. First, the scenario "changing gaze" was performed on all three eye-trackers. Thereafter, the intubation scenario and the resuscitation scenario were performed. The analysis of the video data was carried out by two raters (anesthetist and computer scientist) who defined the evaluation criteria. The analysis process took place by consensus.

Material

Table 2 – Used Equipment and Material

eye-tracker	Ergoneers Dikablis Eye Tracking Glasses	SMI Eyetracking Glasses 2.0	Tobii Pro Glasses 2
Software	Avidemux 2.6.18	BeGaze 3.6 build 52	Tobii Pro Lab 55.5126

Evaluation Criteria

This evaluation is based on an analysis of the video material. Two raters evaluate the recording due to the time of recognizability (sharpness) of the objects (ROI) in the video. By using the timer and frame-to-frame-function of the video software we measured the time from beginning of fixation to the end of adjustment (mean values). We choose the frame where the objects were very cleary depicted. The raters assess the recognizability of objects subjectively.

The applicability of eye-tracker in intensive care medicine must meet the following requirements:

- Rapid focus adaptation and rapid adaptation when brightness changed.
  - Anaesthesiologists always have to change their gazes. Changing of gaze is always combined with changing of brightness and changing of distance.
- Good correlation between the real scene and the recorded video frame
  - The look into the orifice of the body (e.g. laryngoscopy) is often combined with loss of brightness and cramped visibility conditions, a special point of view or a special angle of vision.
- The eye-tracker must stay fixed on the head and stay calibrated during the resuscitation
  - During the resuscitation intense movement of the head occurs.
- Are the values visible on the screens with different backlighting? In order to recognize the ROI, the objects must be clearly recorded. Monitors with different lighting systems are often used in anesthesia.
  - Here we have selected the categories "recognizable", "partially recognizable" and "not recognizable".

Simulation Environment

The study takes place in an operation theatre to have a realistic environment. We use a patient simulator (Laerdal, Resusci Anne Advanced SkillTrainer). The patient simulator and the monitoring machine were connected to display the simulated physiological parameters. This patient simulator was lying on the operation table. The operation lamp was focused on the thorax of this patient simulator. We simulated different scenarios to test the properties of the following products: Ergoneers Dikablis Eye-tracking Glasses Professional (Ergoneers GmbH), SMI Eyetracking Glasses 2.0 (SensoMotoric Instruments GmbH) Tobii Pro Glasses 2 (Tobii AB).

The operating theatre was 5m x 5m with an operation table placed in the middle of the room (Figure 1). At the end of the head the anaesthesia machine was on the right side with a light background (Primus, Dräger). The distance was nearly 70 cm. On the right side of the anaesthesia machine was the patient monitor with a black background (Datex Ohmeda).

Scenario 1: Changing Gaze

We defined four different Regions of Interest (ROI) reflecting the tasks during the medical procedure.

- ROI 1: Face of Patient Simulator,
- ROI 2: Display of Patient Monitoring
- ROI 3: Display of the Aaesthesia Machine

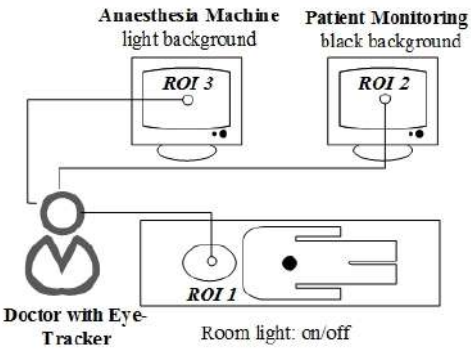

Figure 1 – This figure shows a model of the operation theater (5m x 5m) to depict the scenario more easily.

The anesthesiologist focussed all of the ROI two times (displays) up to 4 times (patient simulator and through the room). After each change of the gaze, he had to fix the ROI for at least 10 seconds, so we could measure the time for the adjustment of the eye-trackers. This was performed with the light switched on and off.

Scenario 2: Oral Intubation

The anesthesiologist did the laryngoscopy. If he could see the epiglottis, arytenoid cartilage, vocal chords and subglottic area he gave a sign to find this scene on the video later. We looked for the typical anatomical structures on the video at the time the anaesthesiologist saw all structures in real field of vision.

Scenario 3: Resuscitation

The anesthesiologist performed a heart pressure massage for 1 minute. Calibration of the eye-tracker was measured by using a target disc (Figure 2) before and after the heart pressure massage. The centre of this target disc was placed at a height of 170 cm, the distance to the disc was 100 cm. The deviation was analysed on the recorded video.

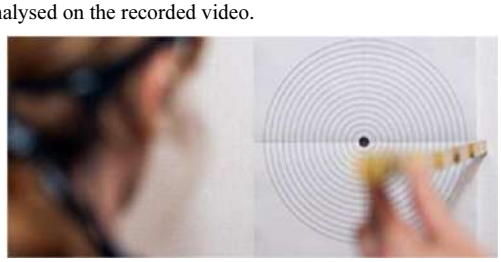

Figure 2 – After 1 minute resuscitation the deviation of calibrated eye-tracker was tested with the help of a target disc.

Results

Scenario 1: Changing Gaze

The face of the patient simulator was depicted clearly in the video material of all three eye-trackers in under one minute (

Table 3). When the light was turned off, it took a little longer for the eye-tracker to be in focus or to see something on the video. Nevertheless, the eye-tracker took less than a second to focus.

Table 3 –ROI 1-Face of Patient Simulator with Room Light Switched On and Off. It depicted the time of adaption till the video of the eye-tracker was focused.

	Ergoneers	Tobii	SMI
Light On	0,11 sec	0,70 sec	0,40 sec
Light Off	0,39 sec	0,90 sec	0,53 sec

In ROI 2, the eye-trackers should record the monitor to determine what can still be seen when the light is switched on and off. The monitor background colour is black. The ability to see details on the monitor strongly depends on the colour background of the monitor and the ambient light. With the light on, it takes less than a second to focus the eye-trackers. Only with the Ergoneer eye-tracker the contents of the monitor are fully recognizable (Table 4 and Figure 3).

With the light switched off, all eye-tracker needs more time to focus. Nevertheless, the highest setting time is just 1,01 second (Ergoneers eye-tracker). In this experiment, SMI's Eye Tracker had the shortest set-up time and the objects on the patient monitor screen were all clearly visible (Table 5 and Figure 4).

Table 4 – ROI 2: Display of Patient Monitoring with Room Light Switched On. .It depicts the time of adaption

	Ergoneers	Tobii	SMI
Light On	0,48 sec	0,96 sec	0,34 sec
	everything recognizable	partly recognizable	partly recognizable

Figure 3 – Screenshot of the Patient Monitor with Room Light On. The first monitor is seen with the Ergoneer eye-tracker, the second with Tobii and the third with SMI.

Table 5 – ROI 2-Display of Patient Monitoring with Room Light Switched Off. It depicted the time of adaption

	Ergoneers	Tobii	SMI
Light Off	1,01 sec	0,84 sec	0,78 sec
	partly recognizable	partly recognizable	everything recognizable

Figure 4 – Screenshot of the Patient Monitor with Room Light Off. The first monitor is seen with the Ergoneer eye-tracker, the second with Tobii and the third with SMI.

In ROI 3 the eye-trackers should record the ventilator (anesthesia machine) with background light to determine what can still be seen when the light is switched on and off. The ability to see details on the ventilator strongly depends on the background colour of the ventilator and the ambient light (Figure 5 and Figure 6).

In total, all eye-trackers needed the longest time to focus the scene with the light on and a backlight monitor. The eye-tracker from Tobii took with 1,42 sec. the longest time. With the Ergoneers and SMI eye-tracker the contents of the screen have been displayed in detail and can be recognized. With the light switched off, it took less than a second to focus again. However, the objects on the monitor are either barely visible or not at all (Table 6 and Table 7).

Table 6 – ROI 3-Display of the Anesthesia Machine with Room Light Switched On.

	Ergoneers	Tobii	SMI
Light On	0,52 sec	1,42 sec	0,58 sec
	everything recognizable	partly recognizable	everything recognizable

Figure 5 – Screenshot of the Anaesthesia Machine Display with Room Light On. The first monitor is seen with the Ergoneer eye-tracker, the second with Tobii and the third with SMI.

Table 7 – ROI 3-Display of the Anesthesia Machine with Room Light Switched Off.

	Ergoneers	Tobii	SMI
Light Off	0,75 sec	0,90 sec	0,58 sec
	nothing recognizable	partly recognizable	nothing recognizable

Figure 6 – Screenshot of the Anaesthesia Machine Display with Room Light Off. The first monitor is seen with the Ergoneer eye-tracker, the second with Tobii and the third with SMI.

Scenario 2: Oral Intubation

During a laryngoscopy the arytenoid is fully visible on all eye-tracker video data. The vocal cord is partially recognized by the Tobii eye-tracker but the other eye-trackers do not display it sufficiently. The glottis is completely recognized by Tobbii and SMI but only partially by Tobii. With all eye-trackers the sections of the scene camera and the real view of the test person were different (Figure 7 and Table 8).

Figure 7 – Screenshots of the Direct Laryngoscopy. The first monitor is seen with the Ergoneer eye-tracker, the second with Tobii and the third with SMI.

Table 8 – Scenario 2 Oral Intubation.

	Ergoneers	Tobii	SMI
Arytenoid cartilage	recognizable	recognizable	recognizable
Vocal chords	not recognizable	partly recognizable	not recognizable
Subglottic area	partly recognizable	recognizable	recognizable

Scenario 3: Resuscitation

Rapid head movements during a cardiac compression changed the calibration of the eye-tracker of Ergoneers (2 rings, 16mm) and SMI (7 rings, 56 mm). The eye-tracker of Tobii had the best fixation in our test without any changing of calibration (Table 9).

Table 9 – Scenario 3 - Deviation After Cardiac Compression

	Ergoneers	Tobii	SMI
Mm	16 mm	0 mm	56 mm
α-Angle	0,92 deg		3,21 deg

Discussion

The aim of the "Changing Gaze" experiment was to analyze the image and video quality of eye-tracker cameras in different light conditions and with different screen backgrounds. Only if the ROI is also recognizable, a subsequent video analysis can be carried out. On average, all Eye Trackers have adapted to the environment and lighting conditions in less than a second. On average it took them a little longer to focus in the dark. Regardless of how the camera is focused, object detection is not always possible. On the display with a dark background, the contents are partially or completely visible when the light is switched off and on. In contrast, the objects on the screen with backlight and the light switched on are almost all recognizable. However, when the light is switched off, the background lighting outshines the contents of the display, so that almost nothing is visible.

During oral intubation, the light conditions between the surroundings and the oral cavity are very high in contrast. The angle at which the subject looks into the oral cavity is small, so that the subject's view is different from that of the scene camera. The exact adjustment of the scene camera must be ensured without disturbing the subject during intubation.

The position at the head and the calibration of the eye-tracker were measured during the resuscitation. The strong head movement led to a slight shift in the calibration of two eye-trackers (Ergoneers and SMI). One eye-tracker was still calibrated afterwards (Tobii). All the eye-trackers sat tight on the subject's head. A change of the calibration can make a subsequent analysis impossible, so that data sets cannot be used [7]. In a qualitative feedback, the subjects said that they would wear the eye trackers during resuscitation [11]. On the other hand, wearing the eye tracker and the restriction of mobility by the eye tracker was perceived as marginal disturbing [5].

There are many reasons for data loss or poor data quality with eye-trackers. The data loss for eye-trackers was approx. 27%, whereby the causes were calibration, poor focus and hard contact lenses in the test person [12]. The quality of recording depends on one hand on the subject that can lead to noisy video material [3]. Poor recordings can also be caused by hard- and software issues of the eye-tracker like equipment failure and poor tracking quality [13] or technical problems [4]. The reasons for poor data quality have not yet been sufficiently investigated, since data quality has never been the goal of the

studies, but always only one aspect of limitation. In addition to the technology, the environment such as lighting conditions and monitor background are also responsible for the quality of the recorded material.

Limitations

Activities and procedures in emergency medicine and anesthetics are crucial for patient safety. To analyze aspects of the sociotechnical systems, the measuring systems have to be proved. Extremely changing light conditions caused by surgical lights, also procedures that look at "dark holes" e.g. the glottis and almost extreme head movements such as resuscitation, necessitate a feasibility analysis of the eye-trackers with regard to efficiency and effectiveness. The limitation of this pilot study is the limited number of rooms in which the study took place. Other operating theatres may have different light conditions and other arrangements of the devices, which may have an effect on the recordings of the eye-tracker.

Conclusions

The aim of this study was the applicability of eye-tracker in anesthesia, which is characterized by changing light conditions, displays with many values and different background illumination. Three eye-trackers are used, but they are not in competition. The measured values and qualitative results do not allow a decision on a winner. All eye-trackers are suitable for use in anesthesia and have their advantages and disadvantages. The Tobii Eye Tracker was the only one that didn't have a shift of the calibration for tight head movements, but took the longest time for the focus position. The Ergoneers and SMI needed the same average time to capture the videos, but with strong head movement the calibration was slightly shifted. All in all, the eye-trackers differ in the display of the objects on the screens. SMI and Ergoneers displayed objects very clearly or not at all, while Tobi Eye Tracker always displayed something, but often a little blurred.

Abstract

In the present study, we intended to solve identification problems in analyzing the results of microbiology by proactive man-machine interaction. We modified the analytics software MOMO so that it flags laboratory results containing textual elements unknown to the thesaurus, and a human expert assigns the elements to the respective existing thesaurus elements or creates new ones. In 773,309 laboratory results, roughly 2.6% contained unassigned elements and would have been ignored in thesaurus-based analyses for purposes other than simply reporting microbiological findings to physicians. In current use, the thesaurus is kept up to date with synonyms, syntactic deviations, misspellings, and entries not contained earlier, with man-machine interaction of 2–3 hours per week. This approach helps to accommodate both up-to-date clinical reporting for immediate patient care as well as up-to-date queries for infection surveillance and epidemiology, outbreak management, quality control and benchmarking, and antimicrobial stewardship.

Data Analytics; Software; Microbiology

Introduction

Why are clinical information technology (IT) solutions – despite high sophistication and the latest IT standards [1] – sometimes not well accepted by users? This question has been addressed in extensive clinical informatics studies [e.g., 2-4] as well as studies focused on our topic [5, 6], and is still impeding the optimal use of IT tools in clinical and laboratory medicine. A common feature of all studies cited above is the attempt to overcome shortcomings in daily routine outputs which could be allocated to insufficient involvement of human experts during the execution of IT tasks.

In the course of our long-standing involvement in fully automated IT-assisted analysis of microbiological and clinical data, we learned that strict adherence to coded data alone is not enough to avoid deficits in IT analysis [7]. We looked into the discrepancies that emerged when comparing the results of automated IT analyses with the respective gold standards. The search for the root cause led us to elements and terms in our clinical reporting scheme which were not allocated to the thesaurus (terminology coding of the laboratory information system (LIS)), and therefore could not be recognized by our software. In many instances, simple misspellings or orthographic variants were the cause. In other cases, a number, or even whole arrays, of different entities were allocated to a single code, which is why a distinction by code was no longer feasible. So far, such deficits – provided they are detected at all – could explain mistrust in automated IT tools and call for a scrupulous check of each data entry and manual thesaurus allocation of missing terms by human experts. This hardship may be accepted for a research study but is not a realistic approach for a reliable routine IT clinical reporting tool.

Two aspects should be mentioned here: First, free-text entries have been introduced by the users of the microbiology LIS (with arguments discussed later in this paper), thus "invading" the LIS which originally had been focused on merely coded entries and results. Second, microbiology findings play an important role not only in immediate patient treatment but also in contributory disciplines, such as infection surveillance, outbreak management, and antimicrobial stewardship. Hence, microbiology reports and the respective meta-analyses/queries are significant and must therefore be concise, correct, and – last but not least – timely.

The aim of this study was to enhance the precision of our automated analytics and clinical software by adding and augmenting man-machine interaction. In detail, we aimed to solve ambiguity and identification problems in digital reports of clinical microbiology by proactive man-machine intervention.

Methods

General

We modified our automated analytics software so that it flagged laboratory reports which contained elements unknown to the thesaurus and forwarded these to a human expert on a regular basis. The expert then assigned the textual elements to the respective existing entities or created new ones. Thus, we "trained" the thesaurus on a regular basis to recognize possible synonyms, syntactic deviations and misspellings, and thus be extended by new entries.

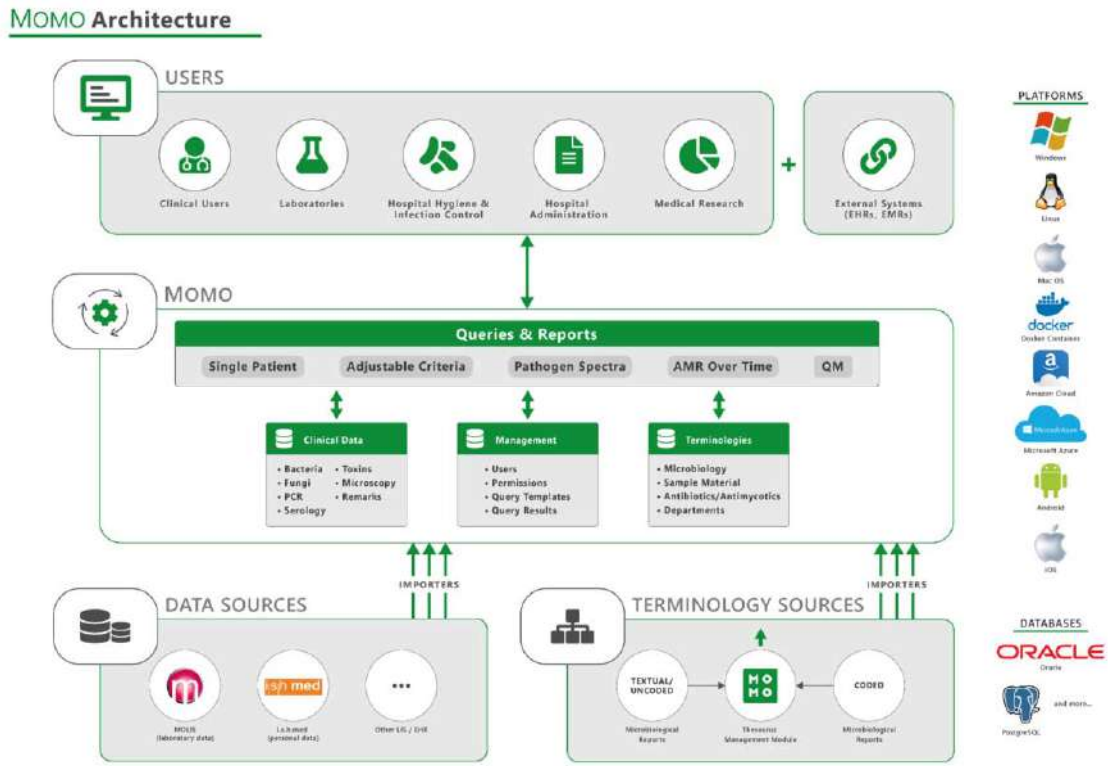

Figure 1 – MOMO is a multifunctional tool for analyzing, monitoring, and reporting pathogens and antimicrobial resistance. It receives 58 different parameters from the microbiology laboratory; four of them are based on terminologies. Most data are structured or coded, some are textual. The latter include not only several comments or report additions, but also microbiological terminology such as bacteria, fungi, PCR, serology, toxins, and microscopy.

Study Setting and Design

We performed a retrospective single-center analysis of validated clinical microbiology results from Vienna General Hospital (VGH), Austria – a 1,900-bed tertiary-care and teaching hospital. Laboratory data were obtained through systematic interrogation of MOLIS (Modular Open Laboratory Information System, Compu Group Medical (CGM) LAB Belgium S.A., Barchon, Belgium) [8] from patients of all VGH clinics from July 4, 2013 to February 16, 2018. MOLIS is designed for IT support of laboratory processes and issues laboratory findings in digital reports, which are delivered as pdf files to the requesters.

Microbiology laboratory data were imported and analyzed by the use of MOMO (Monitoring of Microorganisms, Medexter Healthcare, Vienna, Austria) [9], a microbiology analytics tool for generating analyses of pathogens, spectra, and antimicrobial resistances from routine microbiology results. In addition, MOMO provides immediate answers to questions related to microbiology results for single patients. This feature is now routinely employed by clinicians at their offices and at the bedside. Figure 1 shows the principal architecture of MOMO. MOMO automatically checks incoming textual identifiers (e.g., specimen, detection method, microbes, antibiotics) for compatibility with existing thesaurus entries, and provides different analysis options. It employs four thesaurus categories: requester/department, specimen type, microbiology, and antibiotics/antimycotics.

Thesaurus Management

MOMO uses software elements which check all incoming entities against the thesaurus they belong to. Importantly, each thesaurus may identify entities either by code or by text depending on its configuration. Due to the structure of MOLIS, MOMO's thesauri for requester/department, specimen type, and antibiotics/antimycotics are based on the entities' respective codes. On the other hand, MOMO's thesaurus for microbiology identifies all entities by their texts because the respective codes in MOLIS were frequently inconclusive or missing.

Regarding the microbiology thesaurus, each of its entries (concepts) consists of an internally generated number and the corresponding textual label/name. Externally provided codes can be attached. MOMO's thesaurus management permits the definition of synonyms for each concept or the creation of new concepts (see Figure 2). The concepts may be organized hierarchically into superordinate and subordinate concepts across several levels (e.g., family, genus, species of bacteria). Concepts may possess more than one parent element. *Staphylococcus aureus*, for instance, is a species of the genus *Staphylococcus* within the family of Staphylococcaceae (parent 1); under the distinction of Gram staining, *Staphylococcus aureus* possesses

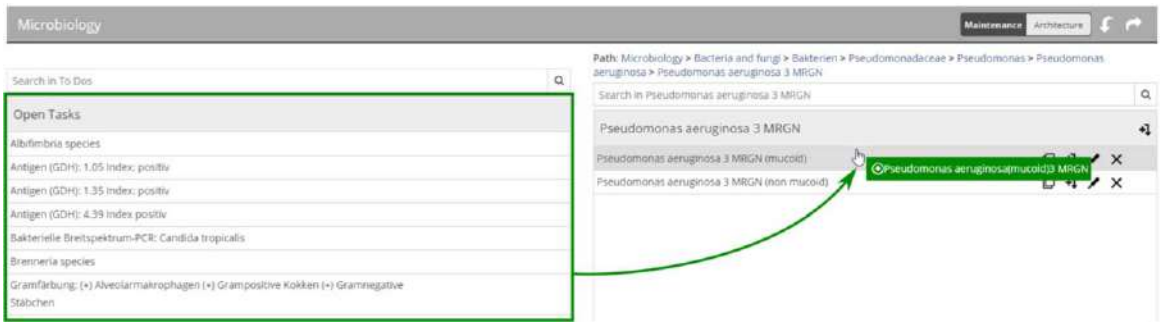

Figure 2 – MOMO thesaurus management – Within MOMO, concepts that cannot be automatically allocated to existing concepts are collected as "open tasks". During thesaurus maintenance these concepts become distinct concepts within the thesaurus hierarchy or will be allocated to an existing concept as a new synonym.

a Gram stain retaining cell wall and is therefore attributed to the Gram-positive group of bacteria (parent 2).

A particular advantage of identifying microbiological results by their texts instead of their codes is that they may be incorporated into the thesaurus immediately, although they may not yet have an officially defined and assigned code [3].

Thus, any microbiology result will be allocated to the respective concept in the thesaurus, or a new concept will be introduced, which is from then on available in clinical as well as secondary query results. Concepts representing misspellings, orthographic variants, or completely new elements must initially be allocated manually; thereafter these texts will be found automatically.

Results

In the investigation period from July 4, 2013 (the day on which the data transfer from MOLIS to MOMO commenced) to February 16, 2018, altogether 773,309 laboratory results were available for analysis. As shown in Table 1, the yearly yield ranged from 154,079 to 209,290, indicating a rising trend. The 2013 and 2018 batches of results were truncated by the respective start and ending dates of the study period.

Table 1 – Imported and analyzed microbiology results by year

Year	Number
2013	25,645
2014	157,627
2015	154,079
2016	196,203
2017	209,290
2018	30,465
Total	773,309

Fractions of Laboratory Results Containing Elements Unknown to the Thesaurus

We started counting the elements unknown to the microbiology thesaurus after the study period had started and can only give an estimate of their total numbers (Table 2).

Roughly 2.6% of all results contained unknown elements and would therefore have been ignored in MOMO analyses based on correctly sorted concepts alone. The types of incompatibility with existing thesaurus concepts were manifold and ranged from typos to completely new elements. Two-thirds required allocation to new sub-concepts under existing concepts. One third of the required actions were the allocation of synonyms or textual variants.

Table 2 – Required thesaurus adaptations after import of 773,309 microbiology results

Type of incompatibility	N*	Fraction
Entries requiring manual allocation	20,000	2.6% of total number
Thereof		
– New species	100	0.5% of N
– New synonym or textual variants	6,900	34.5% of N
– Allocation of new sub-concepts under already existing concepts (especially for serology and microscopy)	13,000	65% of N

* estimated

A prospectively conducted analysis of unassigned microbiology concepts gave a deeper view of the number of concepts allocated to one of the categories within the microbiology thesaurus (Table 3). This analysis includes 89,973 microbiology results from October 30, 2018 to March 12, 2019. Of these, 1,663 (approximately 1.9%) concepts had to be assigned manually. As presented in Table 3, the majority fell into the categories culture, serology, and microscopy.

Table 3 – Current figures for 1,663 manually allocated microbiology concepts between October 30, 2018 and March 12, 2019

Category	N	Fraction
Culture	311	18.7%
PCR	130	7.8%
Serology	525	31,6%
Toxins	72	4.3%
Microscopy	422	25.4%
Miscellaneous	203	12.2%
Total	1,663	100.0%

Effect of the Intervention

On completion of the allocation of unknown elements, 100% of the microbiological results in the trial period became accessible for MOMO analyses.

Manpower Expenditure

In the current use of MOMO, two to three hours per week are required to keep up with changes in laboratory as well as clinical routine. We call this the "man-machine terminology interface". The work is done by persons who are familiar with the MOMO thesaurus as well as clinical and microbiological terms. Top-level clinical or microbiological experts need to be contacted only on rare occasions.

Discussion

Free text entries are known sources of typing errors, misspellings, and unwanted inaccuracies. For this reason, they are "banned" from many modern clinical IT applications, and health care workers are familiar with mandatory coded entries. However, textual descriptions can be more meaningful and may fit individual characteristics better. User-friendly "colloquial" terminologies [2, 4] are indispensable in attracting the use of IT tools by medical professionals.

In the microbiology LIS at the VGH, we were confronted with user demands for free-text elements, which in the course of years of use had become significantly inaccurate. An extraordinary example was a two-digit code connected with 83 – mostly unrelated – entities in the thesaurus. Discrepancies between codes and text were one of the reasons, which had led us to the decision that MOMO should access text rather than codes in the analysis of microbiology terms.

As it turned out, the ambiguity of terms was not an immediate problem for the clinical recipients of microbiology reports, but rather for users relying on MOMO query results, as they would have had to manually select all hidden variations. Hence, the quota of coding incompatibilities observed in our study was more or less irrelevant from the immediate clinical standpoint, but a crucial factor in creating analyses for infection surveillance or outbreak management, where missing results are unacceptable.

As described by de Quirós et al. [2], we had to deal with different acronyms and synonyms for the same clinical finding. For the generation of concise query results, it was necessary to allocate those different terms to the same concept. In contrast to [2], however, we did not have to provide standardized codes based on our thesaurus. Nevertheless, it would be possible to incorporate codes and terms of official terminologies (e.g., SNOMED) as synonyms for those terms that are now available in the microbiology thesaurus.

For this study, we decided not to create a thesaurus based primarily on a so-called reference terminology (e.g., SNOMED as proposed by Rosenbloom et al. [4]) which provides the users with a set of terms as complete as possible. On the contrary, we included only those terms in the thesaurus for which at least one microbiological result was available. Thus, users implicitly know what they may query and do not have to create "test" queries to see whether results are available for certain entries of the thesaurus.

Compliant with, and supplementary to, FAIR principles (code sets are required to be Findable, Accessible, Interoperable, and Reusable) [10], the observations of our study trigger the following microbiology-specific discussion:

Why admit free text entries in lab requests or in (microbiological) lab reports at all?

1. In clinical reporting, we need procedures to deal with inevitable and unanticipated advents of new communication and knowledge elements, which are not yet included in the ordering schemata of the system. This concerns input (emerging clinical demands and laboratory methods) as well as output (new report details or messages). Even brand-new knowledge must be reported precisely and on time, irrespective of the status of the reporting system. This not only applies to microbiology reports for the ordering clinician (which may contain free text information or even handwritten information), but equally to IT analyses and meta-analyses built on microbiology reports, especially if they serve (hospital) epidemiology and outbreak management.
2. Therapeutic imperative: Lab reports must be released a.s.a.p. to facilitate the earliest possible start of appropriate therapy (or adaptation of current therapy) – ideally in a matter of hours. In contrast, as stated by [3], the construction of clinical code sets is usually a time-consuming activity. Thus, the required codes may not be available at the time they are requested.
3. In the man-machine terminology interface, concepts based on free text are organized in a structured manner. This makes them accessible to automated analysis without additional coding.

Following this, the second question pertaining to the analyses of content in microbiology reports is whether they should be based on codes or on free text entries. An analysis based on codes is a plain approach to fully automated analyses; non-coded entries are more difficult to handle and need not be excluded from automated analysis. In free-text-based analyses, each data entry is available for analysis, but the procedure may be time consuming because it requires the scrutiny of hitherto unknown entries.

Neither of the two approaches meets all demands. And, if we agree that non-coded entries have a place in clinical reporting, we ought to provide IT supplements which capture this type of "wild characters" as well.

Our results support two basic recommendations:

1. Optimal and timely thesaurus maintenance is an indispensable provision for all fully automated and rapid IT analyses, the results of which must be trustworthy in terms of their conciseness and correctness.
2. IT systems which draw on codes when appropriate and on free text when appropriate – as MOMO does – provide comfort, speed, and conciseness.

As a result, in thesaurus management high priority is given to capturing synonyms, syntactic deviations and misspellings, which in our analyses were predominant causes of missed entities or misinterpreted reports.

Of similar importance is the ability to capture clinical and microbiological free text comments in laboratory reports which provide special knowledge aimed at new/improved diagnosis and therapy, and which address epidemiology. The ability of a system to communicate such high-level information supports the proficiency/professionality of the daily dialog between laboratory, clinicians and hospital epidemiologists.

Finally, this type of IT tool may serve as an internal knowledge engine for the clinical microbiology laboratory striving for continuous knowledge acquisition and its provision in routine microbiological work.

This topic also encompasses the notorious question: can analyses of routine clinical reporting be accepted for research purposes, especially in epidemiology and public health matters?

This question was discussed extensively in the process of establishing international benchmarking networks (e.g., HELICS [11], IPSE [12], and EARSS [13], which were forerunners of the present European Centre for Disease Prevention and Control networks HAI-net [14] and EARS-net [15]). In the end, it was agreed that routine laboratory data are indispensable for this purpose, despite the fact that they may be generated under missing or unknown scientific standards. There is no other way of obtaining the required information, because impeccable scientific studies of appropriate size and duration are not feasible. In our study, we present a new focus as well as a software solution to bring analysis data from routine clinical reporting closer to the desired degree of conciseness, reliability, and relevance.

Conclusions

In our opinion, clinical IT solutions must focus on a good balance between full automation and man-machine interactivity for successful clinician-laboratory dialog, which in turn supports patient care and infection control.

Given this balance, we may expect considerable progress from such IT solutions in microbiology-related "Good Clinical Practice" as well as in infection prevention and control. Other areas that will benefit from such progress are research in clinical microbiology, healthcare-associated infection prevention and control, epidemiology, and public health!

"When used properly, informatics tools can help the clinical microbiology laboratory to do more with less while improving the quality of patient and public health care" [1].

Acknowledgments

The authors are indebted to Wolfgang Barousch for his fruitful help and discussions.

Abstract

Open Access provides researchers another opportunity of publishing, besides the traditional publication in subscription-based journals. Providing higher dissemination and therefore visibility as well as better accessibility, among others, Open Access helps to fulfil changed needs of authors and readers in our information and communication society of today. Though this publication model provides a lot of advantages both for readers and authors, there are also some obstacles. In order to identify the incentives that can lead scientists of medical informatics to an Open-Access-publication, we conducted a study consisting of group discussions, interviews, and surveys. This tripartite evaluation starts in its first part with group discussions and interviews. First results of them show that, among others, the higher visibility, indexing, Impact Factor and better accessibility are factors for an Open-Access-publication.

Keywords:

Open Access Publishing, Motivation, Focus Groups

Introduction

Within the last decade, a creeping alteration in the publication landscape can be observed. Due to the changed needs of researchers, in the role of readers as well as authors, in regard to the modified information and communication society, a new publication model has been developed. Open Access (OA) seems to fulfill these needs better than the traditional subscription-based model [1-3]. The internet allows the publication of journal articles, whole journals, or books online and within the OA model without any barriers such as paywalls. This means that everyone with an internet connection can freely access content and depending on the license, distribute, use, and modify it. In recent years many governments, research funding organizations and universities have changed their policies demanding to publish funded research outcomes in OA [4, 5]. For financing this new publication model, a shift of costs from readers to authors can often be found. For publication of accepted manuscripts, they have to pay a so-called "Article Publication Charge" (APC).

Today nearly all journals offer their authors the option to publish their article in OA. There is also a growing number of genuine OA journals, though this depends on the discipline, in which Medical Informatics authors can only choose from a small number of pure OA journals [6]. Another issue is that only a few authors make use of this publication model so far and only about 13% of research papers are published OA [7]. This is effected by concerns connected to OA. Besides the assumed positive characteristics of the publication model as, for example, better visibility and increased citation rates, there are also some significant barriers. An often-higher effort for authors, for example in terms of administrative tasks and the above-mentioned publication charges, is to refrain from OA publishing [8, 9].

The factors that influence researchers in their decision on where or how to publish their research results have not been sufficiently investigated yet. In order to identify them, among others, we are conducting the project "Trans-O-MIM" (full title "Strategies, models and evaluation metrics for the goal-oriented, stepwise, sustainable and fair transformation of established subscription-based scientific journals into open-access-based journals with *Methods of Information in Medicine as example*") [10, 11], funded by the German Research Foundation (DFG). The results are intended to help traditional subscription-based journals transform successfully into OA-based journals. Within the framework of this project, we applied them on the concrete transformation of *Methods of Information in Medicine*.

Therefore, the goal of this study is the exploration of factors influencing researchers in the role of authors both positively and negatively in regards to OA publishing. For the construction of a successful and sustainable business model, it is essential to understand and consider the needs and wishes of authors. So the overall aim of the Trans-O-MIM-Incentives-Study (full title "Study on the Identification of Influencing Factors Regarding the Decision For or Against an Open Access Publication of Scientists of Biomedical and Health Informatics") is to determine what lead researchers to publish their research results to be freely available in OA. The sub-goals are:

- The identification of incentives and/or incentive systems for scientists with regard to a publication in OA (motivators of the use of OA).
- Also of interest is the determination of obstacles and barriers for scientists relating to an OA publication (motivators of the disuse of OA).

- In addition, also the superordinate level needs to be discussed, namely how the scientific system should be shaped for OA and what or how publication service providers can contribute to the promotion of OA from the scientists' point of view.

In the subsequent sections, we described the research method for this study and its composition, its conduction and preliminary results with a special focus on the first phase of the Trans-O-MIM-Incentives-Study. Afterward, we discussed these first findings and future perspectives of the study followed by a conclusion in the last section.

Methods

The main focus of this paper is on the first phase of the Trans-O-MIM-Incentives-Study, though altogether it consists of three parts:

1. Qualitative phase with guide-based group discussions and interviews with selected scientists in the field of biomedical and health informatics.
2. Quantitative phase with a standardized survey of representatives of scientific organizations in the field of biomedical and health informatics.
3. Quantitative phase with a standardized survey of members of scientific organizations in the field of biomedical and health informatics.

All three phases of the study are run in close collaboration with IMIA, the International Medical Informatics Association.

In preparation of the study we designed a questionnaire regarding the incentivizing of OA publications for a short survey that was conducted at HEC 2016 (Health Exploring Complexity: An Interdisciplinary Systems Approach; GMDS & DGEpi & IEA-EEF annual meeting, Medical Informatics Europe – MIE2016; 28 August – 2 September 2016, Munich, Germany), one of the main international conferences in the field of medical informatics, biometry and epidemiology [12]. Based on these not very productive and satisfactory results we decided not to choose mixed methods for the intended study in order to gather more detailed and in-depth information. This leads us to the previous explained study design consisting out of three phases with qualitative and quantitative methods.

Phase 1: Guide-based group discussions and interviews

The guide-based group discussions and interviews are intended to serve as a qualitative pre-stage of the subsequent surveys of scientific organizations and their members. The goal is to make participants narrate and create a discussion that develops its own dynamic in order to gain new and disregarded aspects pertaining to the wishes and needs of scientists in respect of OA publishing. In addition, it is to be reasoned which aspects should be taken into account in the subsequent survey of scientific organizations regarding country differences in OA. This first phase of the Trans-O-MIM-Incentives-Study started in July 2018 and was completed by the last interviews in February 2019.

Taking the results of the preparational survey into account, we created a guide for semi-structured group discussions. The guide serves as a framework and does not have to be followed rigidly, but rather provides the topics that need to be covered. It consists of six theme groups each containing one central question and several in-depth questions (see Table 1). The central questions serve as an introduction to different areas of interest and allow participants an unconfined statement of thoughts and opinions. In-depth questions are used if certain aspects need to be inquired, if answers are not sufficient or if the discussion has haltered. The theme groups are the attitude towards OA, reception behavior at OA articles, publication behavior of scientists, motivators of the use or disuse of OA, positive/negative external influence and promotion of OA.

Table 1– Questions included in the guide

Central questions	Most used in-depth questions
What are the participants thinking about OA?	• How do participants define OA? • Do participants advocate a change of the publication system to OA – and why or why not?
How do the participants read OA articles?	• Where do participants inform themselves about new articles and do they differ between subscription-based articles and OA articles? • How do participants experience new functionalities and evaluation tools, as Altmetrics?
What is the participant's procedure for publishing their research results?	• According to what criteria do participants choose a journal in which they want to publish? • Have the participants already published OA and how was their experience compared to a subscription-based publication? If not: why?
What leads the participants to publish their research results in OA and what deters them from it?	• What do participants think about the licenses that are used for OA? Are they well versed in the various Creative Commons licenses? • To what extent do participants feel constricted by the OA policy of many funding organizations in terms of their publication freedom?
Whereby do publication service providers and the scientific system promote or impede OA in the participant's point of view?	• What offers of publication service providers have a positive/negative influence on the decision for/against OA? • In what way does the scientific system have any structures that support/deter participants in an OA publication?
With what or rather whereby can OA publications be promoted in the participant's opinion?	• What changes pertaining to the scientists are necessary to reach more OA publications? • How will OA develop within the next five years?

For the group discussions, the sample consists of single members of IMIA who are suggested by IMIA for participation. It was planned to include 36 scientists categorized in the IMIA regionalities (North America, Latin America and the Caribbean, Europe, Middle East, Asia and the Pacific, Africa) and three seniority levels (scientists with long experience (e.g. department chairs), scientists with intermediate experience (e.g. postdocs), early scientists (e.g. Ph.D. students)), divided into six groups for discussions via video conference. Due to the difficulty of finding enough participants for group discussions we decided to conduct

additional interviews based on the same guide. Therefore corresponding authors of papers in *Methods of Information in Medicine*'s OA track *Methods Open* were invited for interviews. Additional interviews were held at conferences as for example on APAMI 2018 (APAMI 2018 - 10th Biennial Conference of the Asia Pacific Association for Medical Informatics; 09 – 11 November 2018, Colombo, Sri Lanka).

For the video conferences and non-face-to-face interviews, we used the video conference software of DFN, the German National Research and Education Network, based on Adobe Connect. The discussions and interviews were scheduled to last for an hour each. For an exact evaluation, the soundtrack and video (where available) were recorded. A method of analysis for the group discussions and interviews, the qualitative structuring content analysis of Mayring is chosen. Their data is categorized in accordance to previously determined criteria by use and preparation of a coding scheme (containing e.g. values, variables, and dimensions) and a coding guideline (containing e.g. coding rules and a collection of anchor examples for orientation). After determination of the content-analytical analysis unit, i.e. the coding unit and context unit, the coding of all group discussions and interviews is conducted by marking the discovery points according to the variables [13]. Therefore a transcription of all data in a pure verbatim protocol in connection with special characters is conducted. As not all data is collected at the time of preparing this paper, a preliminary evaluation is based on a comprehensive protocol.

Phase 2: Survey of scientific organizations

This first quantitative phase of the study conduces to capture the various conditions of OA in individual countries. Though prerequisites for publications in OA are obviously heterogeneous, the differences are not yet known in detail. Therefore we want to ascertain them by means of a standardized survey of the respective scientific organizations.

The questionnaire asked for various aspects regarding OA in the country of the respective scientific organization with the main focus on the current situation. Taking into account the findings of the group discussions and interviews, the survey will mainly cover the following aspects:

- In which countries the scientific organization operates
- If they mainly follow the green or gold road to OA and how the sentiment of scientists is
- If the government has provided guidance or recommendations concerning OA and if funding organizations have provided regulations or requirements
- If research institutions (e.g. universities) have OA policies
- How the development of OA is predicted in the next five years

The sampling frame for the survey consists of all scientific organizations that are member societies of IMIA. The target group has already been informed about the upcoming survey during a presentation at APAMI 2018. For convenience, we will conduct an online survey by using the software tool "eSurvey Creator" [https://www.esurveycreator.com]. The online survey is in preparation (see Figure 1) and will take place in April and May 2019. For participation, an e-mail containing a link to the survey will be sent to representatives of several scientific organizations. Upon the data received a quantitative evaluation will be conducted.

Phase 3: Survey of members of scientific organizations

This third part corresponds to the second quantitative phase of the study and builds on the guide-based group discussions and interviews. Herewith it is intended to complete the picture of wishes and needs of scientific authors with regard to OA publishing. While the first phase provides comprehensive and deep insights into the subject, the survey will reach the broad mass of scientists of biomedical and health informatics.

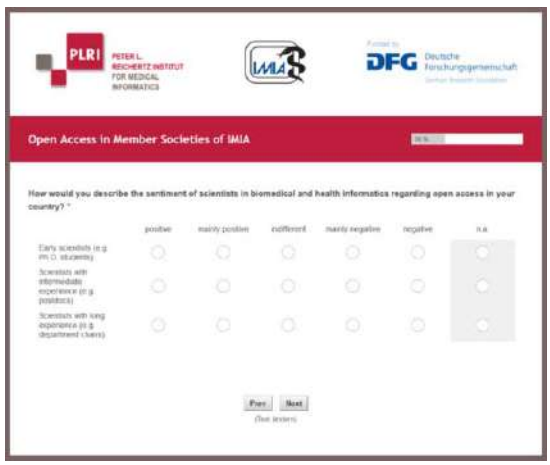

Figure 1– Exemplary page of the online survey

The questionnaire will partially use conjoint analysis to implement various scenarios from which respondents can choose the preferred ones. The questions are divided into various question complexes, according to the guide for group discussions and interviews.

The sampling frame for the standardized survey consists of all members of scientific organizations, who are member societies of IMIA, which currently corresponds to approximately 60,000 people. For greater reach, it will also be conducted as an online survey in May 2019.

Results

This analysis includes the data from 34 participants and was gathered in

- six group discussions with 18 participants suggested by IMIA representatives
- eleven interviews with participants also suggested by IMIA representatives
- five interviews with corresponding authors of a paper in *Methods Open*

Altogether 93 scientists of biomedical and health informatics have been invited for group discussions and interviews, so the participation quote is 36,56 %.

Attitude towards OA

The knowledge regarding OA is very heterogeneous but the whole sample has already heard from it. Most of the participants have a positive and open meaning regarding OA. The broad majority also welcomes a change of the publication system to OA. Thereby many mentioned that a complete

change seems unlikely and that they prefer the coexistence of the traditional system and OA. In this context also the freedom of choice between the publication models was stated as important.

Reception behavior at OA articles

The general tenor of responses to the question about possible differences in the way the participants inform themselves about new print or OA articles is that they do not exist. Some only annotated that OA articles are mostly not included in the subscribed table of contents or alerts, that is a popular information source. Others also outlined that they generally prefer OA articles as they are easier to access even if institutional subscriptions are available. In the way, articles are read no differences have been discovered. The opinion on new functionalities and evaluation metrics is divided and often these tools are still unknown. While some welcome it as a necessary innovation others describe it as insignificant.

Publication behavior of scientists

Asking the participants according to what criteria they choose a journal to publish in following key determinants have been discovered: a suitable scope of the journal to reach the targeted audience, a fast processing time, a high-quality review process and the Impact Factor. Also often mentioned was the cost of publication. The copyright issue by the use of Creative Commons is of little relevance and knowledge to scientists.

The question if participants in the role of authors have already published a paper in OA was affirmed by about half of the sample. Though it needs to be mentioned that only very few differentiated between Green and Gold OA, while about a third knew about the hybrid model. A previous non-publication in OA was often explained with missing funds or experience in publishing.

Motivators of the use or disuse of OA

The answers with respect to the motivators of the use and also the disuse of OA as a publication model show the previously anticipated factors but also new and unforeseen aspects, as presented in Table 2.

Relating to a constriction in their publication freedom due to OA policies of many funding organizations and universities the participants consistently stated that they do not feel restricted. They endorse these policies if existent and do not see any disadvantages.

Table 2– Factors for or against OA publications

Motivators for OA	Motivators against OA
• Faster processing time and publishing of articles	• High costs, for example, Article Publication Charges (APC)
• Higher visibility and therefore more citations	• Lower or initially missing impact factor
• Free accessibility and availability	• Missing reputation of (new) journals
• Indexation in renowned registers	• The distinction between serious and untrustworthy or predatory journals is sometimes difficult
• Better rights on personal use for authors	
• Fulfillment of requirements of funding organizations	• Financing problems, esp. in structurally weaker countries
• Better publication opportunities for scientists from structurally weaker countries	• Fixed/traditional publication structures in the departments
	• There are only a few pure OA journals in the subject area
• Strengthening of the competition for traditional journals	

Positive/negative external influence on OA

Most of the participants had difficulties in answering the questions what offer of publication service providers would have a positive/negative influence on OA and how the scientific system could enhance or impede it. With regard to publication service providers, no concrete ideas for desired offers have been mentioned while the financing policy has been broadly criticized. In this context, it was discovered that nearly no author has made use of waiver systems or even knew about them, though often provided by publication service providers. Identified demanding framework conditions are: facilitation of the financing of articles in OA journals, initiation of new ways/methods for peer review, orientation away from the Impact Factor, production of scientific journals away from commercial publishing houses, and guide to choosing the right OA journal.

Promotion of OA

Regarding the further promotion of OA, no more findings have been gathered. Asking what changes pertaining to the scientists would be necessary most participants responded that they think most researchers are ready for the OA publication model. Some mentioned that senior researchers tend to have more reservations compared to the younger generation.

On the question of how the near future for OA will look like the whole sample predicts a positive development. Most are convinced that the proportion of OA articles will rise steadily but until the transformation is complete (if ever possible) it will still take a long time.

Discussion

The results show that OA has not yet reached the awareness of the majority of researchers of biomedical and health informatics. The findings regarding the attitude towards OA demonstrate accordingly that the topic is not considered in-depth and differentiated by many participants. Moreover, a missing distinction between OA and electronic publications is widely spread. Though a difference between young and senior researchers can be observed. While younger scientists often have only cursory knowledge and experience they are very open-minded on this still young publication model. Senior scientists, in turn, are often more focussed on political aspects of OA publishing.

The reception and publication behavior seems barely influenced by the underlying publication model. This corresponds with the findings that researchers in most cases are not very interested in publication issues and in consequence, are also not aware of them. Interestingly OA articles are not only preferred in structurally weak regions lacking of journal subscriptions but also by well-equipped researchers due to the generally easier accessibility and sometimes also due to the literature search methods. With

regard to the criteria for choosing a journal for publication, it is noteworthy that the scope of the journal is mentioned first and not the Impact Factor. Thereby young researchers often have or want to adhere to the specifications of their principals regarding the choice of journal, so finally, it is their stipulation where and how a paper will be published.

The most mentioned positive and negative motivators for OA are better visibility and accessibility/availability, indexing, more citations, faster processing time and on the downside costs, reputation, Impact Factor and lack of funding. Besides these factors, many participants also provided more detailed factors that can often be attributed to the respondent's seniority or origin. This can also be observed at answers on questions relating to the external influence on OA. On the other hand, only a few findings on further promotion could have been collected, which also seems to correlate with the often found disinterest in publication issues as thoughts regarding this topic have not been made yet.

Future perspectives

As already described in the preceding sections the group discussions and interviews will be followed by two online surveys to gain even deeper insights. The results show that a survey of scientific organizations is necessary in order to clear what influence the origin of participants has on their answers and opinions. A survey of members of the scientific organizations is important to gain a greater sample. This allows a check if the gained findings can be transferred to all scientists of biomedical and health informatics.

Limitations

A limitation to the in this paper focussed the first phase is that not all interviews are conducted yet and therefore a complete analysis and relative frequencies in the results section are missing. However, the sample size has nearly been reached what leads us to the conclusion that a comprehensive picture of factors regarding the decision for or against an OA publication can already be presented. A further limitation to the Trans-O-MIM-Incentives-Study is that this research can not or only limited be transferred to other fields as there are huge differences between several disciplines. Therefore further research for example in disciplines of the social sciences is necessary for comparison.

Conclusions

Through group discussions and interviews provided us with various new insights with regard to the incentives and obstacles of an OA publication, the answers also contain many well-known influence factors. The upcoming surveys will show if there are more, so far unconsidered, advantages and disadvantages of OA. It remains a question of why researchers seem prevalently disinterested in the conscious choice of a publication model. As factors for or against OA are now broadly discovered within this survey, in the next step it might be interesting to find out how researchers can be made aware of the OA publication model in general. This might round up the factors that need to be taken into account for a successful transformation of well-established subscription-based journals into OA-based journals.

Acknowledgments

This research has been supported by Deutsche Forschungsgemeinschaft under grant HA 1438/17-1.

We would like to thank IMIA and its members for supporting this study in various ways.

Clinical Leaders' Self-Perceived eHealth Competencies in the Implementation of New eHealth Services

Abstract

The training and competence of healthcare professionals are key factors in adopting new eHealth services. The scope of eHealth is broadening from information systems to eHealth services such as patient portals supporting self-management, which create a need for new competencies. In this study, we evaluated clinical leaders' eHealth competencies and training needs in two public healthcare organizations in Finland. The target organizations' goal was to increase the number of patients' eHealth services and clinical leaders were seen as critical in this change. Data were collected through an online survey of 98 clinical leaders working in two healthcare organizations. The results imply that managing change and planning implementation are challenging to clinical leaders. They need more information about eHealth services, their possibilities, and benefits in order to support their subordinates and patients. The clinical leaders seem to be in a critical role in supporting healthcare professionals and avoiding resistance to change.

Keywords:
eHealth, Competence, Implementation

Introduction

The training and competence of healthcare professionals have been identified as key factors in adopting Health Information Technologies [1]. Healthcare professionals are end-users operating applications and services, and thus, they need varying competencies for applying the technologies in their work or otherwise the benefits of new technology are not realized.

Previous research has focused especially on students' and nurses' ICT skills and informatics competence [2,3]. The Technology Informatics Guiding Educational Reform (TIGER) [4] identifies three categories of competencies in nursing informatics: basic computer competencies, information literacy, and information management.

While the level of healthcare professionals' basic computer skills is improving, the scope of eHealth is broadening from information systems to eHealth services. By eHealth services, we mean online services such as patient portals that support patients with self-managing their health. Increasingly, eHealth services are used to invite patients to take a more active role in the maintenance of their health [5]. For example, patients may have access to personal health information, educational materials, appointment scheduling, and patient-provider communication tools. Consequently, new eHealth competencies of healthcare professionals have been identified [6]. For example, professionals are in a critical role in motivating and guiding patients to use eHealth services and they need to be able to communicate with patients via a computer.

In addition to training, a champion or a superuser who is an enthusiastic visioneer willing to initiate and drive services forward is good in motivating and supporting staff [7,8]. On the other hand, common barriers to successful adoption of eHealth are negative effects on health professionals' workload, workflow, and roles [9]. Thus, it is not only about individual healthcare professionals' eHealth competencies to use eHealth services that are important, but professionals need to be also motivated and supported in adopting new eHealth services. In addition, work organizations and teams need to plan and adopt new workflows, roles, responsibilities, and care processes.

Leaders have a major role in motivating and supporting healthcare professionals and providing favorable conditions for them when new eHealth services are implemented to their organization. Indeed, there is plenty of existing evidence that effective leadership and change management contribute to the successful implementation of eHealth [10–14]. For example, according to Ingebrigtsen et al. [15] leaders should communicate a clear vision and goals for new eHealth services, provide leadership support, arrange training to healthcare professionals, identify and appoint champions, address work process change, and follow up the implementation.

The leadership activities are important as healthcare professionals and their attitudes are critical in preventing resistance and ensuring the active use of new innovations [16–18]. The good implementation practices that are related to successful implementation of eHealth services are well identified [11,17,19–22]. However, these good practices do not seem to be well known or used in healthcare organizations [23,24]

It should not be considered self-evident that leaders know how to support healthcare professionals. Even if they had good traditional leadership skills, the number of new technologies and eHealth services is constantly increasing and changing the care work. Especially patient empowerment and self-management related to the new eHealth services are changing the traditional expert role of healthcare professionals and creating tension as the control needs to be shared with patients [25,26]. Furthermore, as the new services are also used by patients, they should be informed, motivated and supported.

Patient work needs to be also redesigned in a way that new eHealth services support traditional health care and services efficiently.

In this study, we examine the current state of eHealth competencies of clinical leaders in two public healthcare organizations in Finland. Ingebrigtsen et al. [15] define clinical leaders as leaders responsible for leadership within an organization that delivers care. Clinical leaders include division and department directors, and personnel in designated leader positions in frontline units (e.g., wards, outpatient clinics, primary care practices, etc.) [15].

The identification of deficits in eHealth competencies helps in developing training and support for clinical leaders. We consider eHealth competencies broadly including use, implementation and the organizational change related to the new eHealth services. Thus, we are interested in what kind of challenges clinical leader experience in new eHealth services and their perceptions of the quality of implementation practices used in their units.

The strategy of the target health organizations is to use eHealth services widely, and organizations have already provided a set of self-management services to patients. The organizations' goal is to increase the number of eHealth services provided to patients so that patients initiate their care through eHealth services. In the organizations, clinical leaders' role was perceived as important in supporting healthcare professionals, and the identification of training and support needs was considered essential.

Methods

An online questionnaire was developed to assess the eHealth competencies of both healthcare professionals, including nurses, social workers, and physicians, and their supervisors and leaders. The leaders had their own version of the questionnaire and in this paper, we focus on their responses. The survey contained questions about demographics, self-perceived eHealth competencies, training, and support needs, challenges related to eHealth services, and the use of the recommended implementation practices.

Self-perceived eHealth competencies were assessed as in previous studies [6,27] using multiple-choice questions with competence statements with a five-point Likert scale. The scale ranged from 1 (fully disagree) to 4 (fully agree) and included a fifth option, 5 (I don't know), that was removed from the analysis. Seven statements were selected to broadly represent different eHealth competence areas identified in the literature and found important for leaders (see Table 1).

Also, the use of the recommended implementation practices was assessed using the multiple-choice questions as in our previous study [23,24] and with the same five-point Likert scale. In addition, respondents were asked open-ended questions with regard to training and support needs and challenges related to eHealth services. The quantitative data were analyzed using descriptive statistics and the responses to the open questions were content-analyzed.

The survey study was carried out between June and August 2017 in the South Savo and between October and November in 2017 in the East Savo Social and Health Care Authority. Both authorities are public healthcare organizations in Finland. The healthcare organizations already had eHealth services in use and the goal was to use the services widely.

The survey study was introduced in the intranet news page of the organization and an invitation was sent to participants by their work email. The invitation letter included a description of the target group and the purpose of the survey. Although participation was anonymous, respondents could submit their email address at the end of the survey to participate in a draw of movie tickets and two wireless computer mice.

Results

A total of 98 clinical leaders filled in the questionnaire; the response rates were 24% and 20% of the total healthcare personnel in the studied organizations. The mean age of the respondents was 50.1 years (*SD* = 8.5), 86.5% of them were females and they had worked for an average of 7.7 years (*SD*=7.2) in similar tasks. Most of the respondents were nurse leaders (32%). In addition, respondents included social worker leaders (25%), physician and dentist leaders (11%), other leaders (13%), and managers (19%).

Table 1 shows the self-perceived level of competencies. The healthcare organizations had recently offered training on the security and privacy protection and this competence was evaluated to be the strongest one, 98.8% of the respondents agreed or fully agreed that they are able to work based on the principles. Most of the respondents were also confident that they can use eHealth applications and services and do traditional leading tasks such as leading a change and supporting their subordinates' competence. The respondents had the least confidence in communicating about the new eHealth services to patients, developing services in a customer-centered way and planning an implementation of a new eHealth service.

Table 1– Percentage of clinical leaders agreeing with the competence statements. Scale from 1 (Fully disagree) to 4 (Fully agree).

Competence statement	M	S.D.	Respondents agree (%)
I can work based on the principles of information security and privacy protection.	3.7	.63	98.9
I can use eHealth applications and services.	3.3	.73	92.9
I can support the competence of my subordinates	3.0	.77	89.5
I can lead the change when new services are implemented	2.9	.70	84.2
I can communicate about the eHealth services to patients	3.0	.73	81.5
I can develop services in a customer-centered way	2.8	.78	80.0
I can plan the implementation of a new eHealth service	2.4	.88	52.2

Of the respondents, 42 took the opportunity to answer the open-ended question about their training and support needs. Most frequently, the respondents wanted more information about eHealth services, their possibilities and benefits (10 mentions). In addition, they wished to learn technical skills (4 mentions) and receive information about the contact and responsible

persons (3 mentions). The respondents also realized that they need skills to guide colleagues and customers (2 mentions). The need to learn the customer-centered development work (3 mentions) and implementation skills (2 mentions) were also mentioned.

74 respondents described the challenges of eHealth services. Most commonly, they were concerned about the competence of the healthcare professionals (12 mentions) and how to train, engage and commit the healthcare professionals to use new eHealth services (31 mentions).

Many pointed out challenges related to patients (18), how to guide them and how all different patient groups, especially elderly people, are able to use the services. The shortage of resources, concerning both time and equipment were perceived as challenging (16 mentions) as well as the usability, interoperability, and functioning of the services (14 mentions). The respondents were also unsure how to plan and renew the operations and services (8 mentions) and afraid of the negative attitudes of the professionals and their resistance to change (6 mentions).

Table 2– Percentage of clinical leaders agreeing with the statements of good implementation practices. Scale from 1 (Fully disagree) to 4 (Fully agree).

Competence statement	M	S.D.	Respondents agree (%)
New services are planned to be part of the work process	2.9	.89	69.2
The personnel will be informed enough about the new eHealth services	2.7	.87	67.3
The benefits of new eHealth services are told to the personnel	2.7	.91	62.1
My unit has a person who is responsible for the implementation of the eHealth services	2.7	1.1	62.0
There is enough training for using new eHealth services	2.7	.93	62.0
In our unit, we set goals for the implementation of new eHealth services	2.7	.86	58.7
Our unit has a person who encourages others to use eHealth services	2.7	1.0	58.3
The impact of the new eHealth services to our work is evaluated	2.6	.99	55.7
The personnel has the possibility to participate in the planning of new services	2.6	.97	54.9
We set measures for monitoring the implementation of new services in our unit	2.4	.86	46.9
The personnel is given allocated work time for adopting services	2.3	1.1	40.3

Table 2 presents the respondents' evaluations of how good implementation practices were used in their unit. The results resonate with the fact that almost half of the respondents experienced that they do not know how to plan the implementation of a new eHealth service. One-third of the respondents did not believe that the personnel is not informed enough about the new eHealth services or the benefits of the services. Even fewer respondents agreed that there is a person who is responsible for the implementation or would encourage others to use eHealth services. Almost half of the respondents did not agree that the personnel has the possibility to participate in the planning of new services. Less than half of the respondents' agreed that the implementation of new services is monitored using measures or the personnel is given allocated work time for adopting services as recommended.

Discussion

The results of the clinical leaders' eHealth competence survey in two healthcare organizations show that clinical leaders are in a pressure of many demands and changing environment. They need to support healthcare professionals in the change, organize workflows, make sure that patients are informed and guided, and that the quality of new eHealth services is good enough. They also perceived that the shortage of resources, regarding both time and devices, is challenging.

Many clinical leaders did not feel confident in their tasks indicating that they need more support and training. Especially, they requested more information about eHealth services, their possibilities, and benefits. They can't support their subordinates and patients without knowing about the new eHealth services by themselves.

Majority of the clinical leaders evaluated that they were able to use the new eHealth services, but one-fifth of them felt less confident in new tasks such as communicating about the new eHealth services to patients and developing services in a customer-centered way. Almost half of the leaders perceived that they are not able to plan the implementation of a new eHealth service. It is probable that leaders have not received training of these activities during their basic education and the organizations do not yet have traditions and practices for handling these tasks.

Consistent with the identified lack of implementation skills, the survey results imply that good implementation practices were not systematically used in the organizations. All leaders did not even know who is responsible for the implementation of the eHealth services in their organizations. The benefits of the new services and the goals of the implementation were not clear to all either.

The results suggest that clinical leaders should be better informed about the new eHealth services and their implementations. Many clinical leaders did not know whether the new implementations are well planned and good implementation practices are used. Still, the successful implementation does not only depend on the strategic level of management, but also the operational and frontline levels should participate [15,28].

All leadership levels have an important role in informing, motivating and engaging healthcare professionals. The responses to the open question about the challenges related to eHealth services reveal that the leaders are especially concerned about how to do these tasks for avoiding health professionals' resistance to change.

The results imply that managing change and planning implementations are particularly challenging to clinical leaders. We recommend healthcare organizations to improve the training of clinical leaders on these tasks. In addition, the identified training needs should be considered in the design of continuing education and degree programs.

Informing and engaging numerous health professionals is a challenging task and clinical leaders are in a critical role in this work. Trained clinical champions have been found to be successful in motivating and supporting healthcare professionals [8,11,15] and one potential strategy to healthcare organizations is to train frontline leaders to act as champions in their work units.

The limitation of the study is a small number of respondents in only two healthcare organizations in one country. Thus, the results are not well generalizable, but they are more preliminary in nature. The findings give insights about the potential competence needs and pain points of eHealth leaders. Future studies are needed to test the results in wider settings. However, the studied health organizations can be considered as forerunners as they already have used new kinds of eHealth services supporting self-management and they had the willingness to train and support both leaders and professionals.

Conclusions

In this study, we identified clinical leaders' eHealth competencies focusing on new eHealth services supporting patients self-care and self-management. The results provide insights into the clinical leaders' training and support needs. The new training needs are especially related to managing change, planning implementations of new eHealth services. The clinical leaders are in a critical role in supporting healthcare professionals in order to avoid the resistance to change and ensure that the adoption of new eHealth services is successful.

It Needs More Than Just User Participation: Combining Perspectives of Clinical Leaders and Chief Information Officers on Determinants of Hospitals' IT Innovativeness

Jan-David Liebe[a], Moritz Esdar[a], Jens Rauch[a] and Ursula Hübner[a]

[a]*Health Informatics Research Group, Osnabrück University AS, Germany*

Abstract

Although user participation may facilitate the realisation of IT innovations, various literature analyses show only minimal to moderate evidence for such effects possibly due to disregard of mediating factors. Against this background, this study examines the extent to which joint intrapreneurship of clinical leaders and IT leaders as well as a distinct innovation culture mediate the effect of user participation on hospitals' IT innovativeness. IT innovativeness was measured by the availability and usability of IT functions and by the perceived 'innovative power' of a hospital. An empirical model was developed and tested with data from 168 clinical leaders and IT leaders who participated pairwise in a survey representing 84 German hospitals. Three parallel mediation analyses indicated that the participation of users could only lead to IT innovativeness if they were accompanied by intrapreneurial leadership on the part of clinical directors and IT leaders and if a pronounced innovation culture prevailed.

Keywords:

User participation, intrapreneurship, innovation culture, diffusion of innovation, organisational culture

Introduction

Research has repeatedly shown that user participation can facilitate the realisation of IT innovations by blending the technical expertise of the information management department with the system-related functional expertise of users [1]. User participation can refer to various information management activities that take place during IT related innovation processes, ranging from identification of user requirements, implementation and deployment of new applications, to training of colleagues and regular system evaluations [2].

The basic idea behind user participation is to increase the acceptance and motivation of the users and thus contribute to maintaining long-term relationships between the system and its users. In addition to these rather psychological benefits, user participation is expected to generate a number of management-related, methodological and cultural benefits that, taken together, increase an organisations ability to innovate also regarding health IT [3].

Despite this theoretical potential, various literature analyses on the benefits of user participation provide only limited evidence of such effects. Bano and Zowghi [4], for example, conclude in their review of 87 studies that user participation is a double-edged sword which, if not handled properly, can cause more problems than benefits. Frequently cited difficulties that led to misalignments of participatory IT projects included disagreement with project objectives and conflicts about the extent to which users, IT staff and the top management should be empowered to make decisions [4]. Furthermore, He & King [3] showed in a review of 82 studies that the direct effects of user participation on the successful implementation of IT projects are rather minimal to moderate [2]. One reason for the lack of directly measured effects is seen in the fact that mediation factors are widely ignored. A second reason is seen in the different outcome measures with which the effect of user participation is investigated [2-4].

In hospitals, which often are highly specialised, fragmented expert organisations with complex hierarchies, two determinants in particular may mediate the effect of user participation on the ability to innovate regarding health IT: On the one hand, there is the extent to which clinical leaders and IT leaders jointly value IT innovations and therefore promote and demand user participation (top-down mediation). On the other hand, it is the degree of an innovation friendly organisational culture, which enables change through flexible and agile organisational processes and which is characterised by a clear vision of the future, defining the path for corresponding changes and thus facilitating the realisation of user participation (bottom-up mediation) [5].

Against this background, our study explores the following research questions: (1.) To what extent is the effect of user participation on the hospitals' IT innovativeness mediated by the attiudes of the clinical leaders and IT leaders and (2.) to what extent is the effect mediated by the organisational culture.

In theory, these so called top-down and bottom-up mediators can be described with the concepts of intrapreneurship and innovation culture. Intrapreneurship refers to acting on one's own responsibility on behalf of the organisation or part of the organisation, taking risks and anticipating the impact of one's actions, whereby corresponding initiatives and actions mainly concern the development of new products or the reorganisation and optimisation of existing practices [6]. In hospitals, intrapreneurship among executives is seen as an essential precondition of innovation [7]. Corresponding leadership types are characterised as "boundary spanners", constantly looking for innovative optimisation approaches within the hospital (across professional boundaries) and outside the hospital incorporating these approaches into their strategic actions [5,8]. At the same time, intrapreneurial leaders, especially in medium-sized and larger organisations such as hospitals, cannot drive innovative optimisations on their own. They rather rely on interdisciplinary teams that can work together in a purposeful manner to implement innovative concepts [7]. Against this background, it can be assumed that clinical leaders and IT leaders with strong intrapreneurship personalities encourage their employees to work together closely, constructively and therefore innovatively. Thus, we posit:

H1. *The more pronounced intrapreneurship is at the level of clinical leaders and IT leaders the more likely is a positive effect of* user *on a hospital's ability to innovate ~~in~~ health IT.*

Innovation culture can be defined as the extent to which an organisation's values and norms focus on the steady

introduction of new and improved practices and products [8]. Hence, a distinctive innovation culture is characterised by the fact that corresponding optimisation approaches are facilitated by a versatile organisational environment and that they are at the same time guided by an organisation-wide vision of the hospital's future [5]. Previous research suggests that organisational culture in hospitals also has a strong influence on the degree to which IT innovations are disseminated [9]. On the basis of prior studies, that already touched on the association between innovation culture and user participation [10], it is assumed that the nature of the organisational culture (innovation-oriented or not) also determines the direction of user participation (innovation-oriented or not). Thus, we posit:

H2. *The more pronounced the innovation culture of a hospital is, the more likely it is that* user participation *will have a positive effect on a hospital's ability to innovate ~~in~~ health IT.*

Figure 1 displays the research model in which the indirect effects of user participation on the IT innovativeness of a hospital are to be tested. It is assumed that joint intrapreneurship and innovation culture interact in parallel. In order to verify the indirect effect of these mediators, a total of three outcome variables were tested, which together characterise the different facets of IT innovativeness of a hospital. These were a) the availability of a selected set of IT functions, b) the usability of these IT functions and c) the perceived IT related innovation power. The hypothesis H1 is represented by the indirect paths a_1 and b_1 (top-down mediation). Complementarily, hypothesis H2 is represented by the indirect paths a_2 and b_2 (bottom-up mediation). The mediated, direct effect of user participation on innovation power is represented by the path c`.

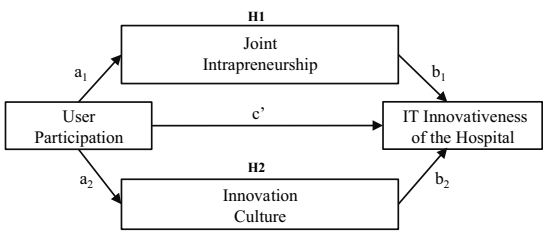

Figure 1 – Research model

Method

The research model was tested with data from 84 German hospitals. One clinical leader and one IT leader of each hospital took part jointly in a survey conducted by the IT Report Healthcare [11]. The IT Report Healthcare consists of a series of surveys that regularly invites IT stakeholders and other key players in all German hospitals to answer questions on topics such as IT maturity and information management.

To test the research model, we conducted three parallel multiple mediator analyses. Parallel mediation analysis allows the simultaneous testing for more than one mediator while accounting for the shared association between them. Model 1 examined the mediating effect of joint intrapreneurship and innovation culture on IT-related innovation power. Model 2 assessed the same mediating effects on the availability of IT functions and Model 3 gauged the mediating effects on the usability of these IT functions.

User participation was measured by asking the clinical leaders to assess the extent to which clinical staff (e.g. physicians / nurses) were involved in IT issues in the hospital on a scale ranging from 1 = "no participation at all" to 10 = intensive participation". The user participation scale comprised seven items that refer to different activities along a typical IT related innovation process in hospitals (starting with participation in IT strategy development, requirements analysis and system selection followed by user training and system evaluation).

Joint intrapreneurship was assessed by both, the clinical leader and the IT leader with regard to three aspects: (1.) to what extent they regularly take the time to think about IT-supported optimisations of hospital operations, (2.) to what extent they regularly exchange information about new IT solutions with external parties (e.g. suppliers, other IT managers, researchers), and (3.) to what extent they stimulate IT-related innovation. In a fourth item, the clinicial leaders were asked to assess the extent to which they regularly seek talks with the IT leader in order to discuss strategic IT issues. Correspondingly, the IT leaders were asked to what extent they seek regular talks on strategic IT issues with clinical leaders. The rating was made on a five-point Likert scale ranging from 1 = "do not agree at all" to 5 = "totally agree".

Innovation culture was also measured by a combined assessment of IT leaders and clinical leaders. Two items were identical in their wording and assessed (1.) the degree to which the hospital, in the participants' opinion, was agile and flexible when it came to the use of new IT solutions and (2.) the extent to which the hospital had a vision of the future that explicitly included the use of IT. In a third item, clinicial leaders should assess the scope to which the IT department was visible in their hospital. In a complementary manner, the IT leaders should rate the degree to which they regularly exchange information with clinical departments. The rating was made on a five-point Likert Scale ranging from 1 = "do not agree at all" to 5 = "totally agree".

Availability of IT functions was assessed solely by the IT leaders. The scale covered eight IT functions in four functional classes that primarily cover advanced IT functions: clinical decision support functions (i.e. medication therapy, alerting, clinical reminders), functions that address patient safety (i.e. electronic tracking of medication loop from ordering to administration), decision support functions (i.e. access to clinical databases) and clinical documentation functions (i.e. discharge letter, electronic nursing records, electronic ICU records). The availability was calculated on a five-point Likert scale ranging from 1 = "No, the IT function does not yet exist and an implementation is not planned" to 5 = "The IT function is completely implemented in all units".

Usability of the IT functions was assessed by the clinical leaders: They were asked to rate how well each of the eight abovementioned functions supported the corresponding documentation tasks and clinical processes. The rating was based on a 10-point Likert scale ranging from 1 = "not satisfied at all" to 10 = "completely satisfied".

Finally, IT-related innovative power was measured by a combined assessment of the clinical leaers and the IT leaders. Therefore, the participants of both groups evaluated how innovative they generally considered the hospital to be in terms of the use of IT on a scale from 1 = "not at all innovative" to 10 = "very innovative". The scales used had already been validated in other studies [9-12]. However, since the answers from two groups were combined for three of the six main variables (joint intrapreneurship, innovation culture and innovation power) and since the item sets deviated slightly from the original scales, we recalculated Cronbach's α to check their internal consistency.

We used PROCESS Version 3.1 for the calculations of the mediation models which utilises an ordinary least squares based path-analytical framework to test for both direct and indirect effects [13]. Since PROCESS does not allow testing the statistical assumptions of the data (i.e. linearity, homoscedasticity, normality of the estimation error and

multicolliniarity), we additionally calculated eleven simple regression models (one for each path in the three mediation models) and three multiple regression models (taking into account all main variables in the three mediation models). Based on these calculations, we furthermore tested the basic requirements for mediation modelling following Baron and Kenny [14]. According to this test procedure, four criteria must be met to determine mediation effects. The first condition is that there is a significant influence of the independent variable on the dependent variable (path c', see Fig. 1). The second condition is that there is a significant influence of the independent variable on the mediator(s) (path a_1 and a_2). The third condition is that there is a significant influence of the mediator(s) on the dependent variable, taking into account the independent variable (path b_1 and b_2). The final condition is that, taking into account the mediator(s), the effect of the independent variable on the dependent variable (path c') disappears or at least decreases.

After testing all model assumptions and the basic requirements for mediation modelling, we calculated the three mediation models with PROCESS. Statistical significance of indirect effects was assessed using bootstrapped bias-corrected percentile based confidence intervals, based on 10.000 bootstrap samples as recommended by Hayes [13]. Lastly, we calculated 95% confidence intervalls for the indirect and total regression coefficents and for the differences between the indirect effects.

Results

Table 1 shows the mean values, standard deviations and Cronbach's α of the six main variables (all values were scaled to range between 1 and 10 to improve comparability) as well as their intercorrelations. Cronbach's α indicated a satisfactory internal consistency for all scales, whereby the value for innovation power was slightly below .6 and was therefore marginally accaptable.

Table 1– Descriptive statistics, α and intercorrelations *(*p < .01) UP - user participation, JIP - joint intrapreneurship, IC - innovation culture, IP - innovation power, AIF - availability of IT functions, UIF - usability of IT functions*

	$\bar{x}$	$\sigma_{\bar{x}}$	α	1	2	3	4	5
1UP	6.2	1.6	.92					.
2JIP	7.3	1.2	.82	.57*				
3IC	7.1	1.4	.79	.49*	.60*			
4IP	6.4	1.8	.59	.43*	.59*	.72*		
5AIF	7.7	1.5	.76	.33*	.54*	.53*	.60*	
6UIF	7.2	1.8	.87	.34*	.48*	.28*	.36*	.26*

The examination of the model assumptions showed that the relationship of the independent and dependent variables could be regarded as linear in all regression models and thus also in the indirect pathes. Estimation errors were distributed relatively evenly over the predicted Y-values in all models and thus no heteroscedasticity was found. Q-Q plots yielded that the estimation errors of the calculated models were normally distributed. The calculated VIF values were all below 2.0, indicating no multicollinearity. On the basis of the four test criteria according to Baron and Kenny [16], it could be assumed that the basic requirements for mediation modelling were met.

The results of the three parallel mediation analyses together generally confirmed the hypothesized model. In all models the effect of user participation was mediated by joint intrapreneurship and in two models additionally mediated by the innovation culture. The direct effect of the user participation on the dependent variables (path c') disappeared in all models, indicating complete mediations. Together, user participation, joint intrapreneurship and innovation culture were able to explain 53.5 % of the variance of innovation power and 33.6 % of the variance of the availability of IT functions. Explained variance of the usability of IT functions amounted to 21.1%. Figure 2 shows the standardised regression coefficients for the relationship between user participation and IT-related innovation power, as it was mediated by joint intrapreneurship and innovation culture with the corrected R^2 displayed at the top right. The standardised regression coefficient between user participation and IT-related innovation power, controlling for the two mediators, is presented in parentheses. As the model demonstrates, user participation was significantly associated with joint intrapreneurship (a_1), and a high degree of joint intrapreneurship was significantly associated with a higher IT-related innovation power (b_1). The standardised indirect effect mediated by joint intrapreneurship (a_1b_1) was (.57)(.25) = .14 (see also indirect effects Tab. 2). Figure 2 furthermore shows that user participation was also significantly associated with innovation culture (a_2), and a high degree of innovation culture was significantly associated with a higher IT-related innovation power (b_2). The standardised indirect effect mediated via innovation culture (a_2b_2) was (.49)(.56) = .27 (Tab. 2). Figures 3 and 4 can be read in the same way by presenting the standardised regression coefficients for the direct and indirect effects of user participation on the availability respectively the usability of IT functions.

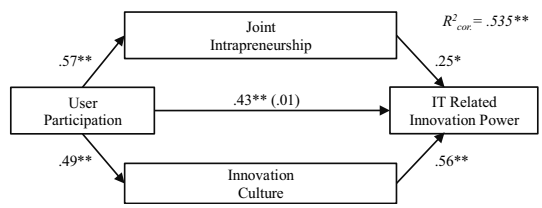

*Figure 2 – Mediation model 1 (*p < .05, **p < .01)*

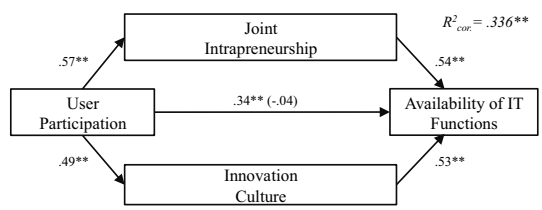

*Figure 3 – Mediation model 2 (**p < .01)*

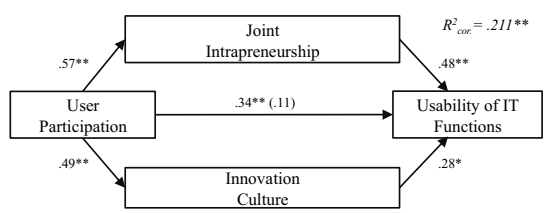

*Figure 4 – Mediation model 3 (**p < .01)*

Table 2 presents the total and indirect effects of user participation on the IT-related innovation power, availability of IT functions and usability of IT functions. In addition, the 95% bias-corrected confidence intervals based on 10.000 bootstrap samples are displayed. The lower bound of the 95% confidence interval (LCI) via joint intrapreneurship was above zero in all models and therefore significant. The same was true for the

indirect effect via innovation culture in models 1 and 2. The difference between the coefficients was not significant in all models (LCI to UCI) in Model 1: -.41 to .06; LCI to UCI in Model 2: -.16 to .23.

Table 2– Total and indirect effects with bias corrected 95% confidence intervals (CI) from bootstrapping. UP - user participation, JIP - joint intrapreneurship, IC - innovation culture, IP - innovation power, AIF - availability of IT functions, UIF - usability of IT functions

Discussion

With the increasing potential of information technologies to meet the general challenges of efficent and safe health care delivery, the importance of management practices that make IT adoption processes in hospitals smoother and sustainable increases as well. Against this background, user participation is regarded as a promising imperative in information management. Despite this, only moderate empirical evidence of corresponding effects have been provided to date [2-4].

In order to explain the discrepancy between expected and actually proven effects, various mediation factors are discussed in the literature. These range from the complexity and scope of the workflows at hand and the number of IT stakeholders involved in the change process to the complexity of the technology itself and the competencies and attitudes of the users [3]. In addition, some studies point to a mediating effect of leadership behaviour and organisational culture [2-4]. For the hospital environment, in which the latter aspects could be of particular importance due to partially inflexible hierarchies and fragmented organisational structures [5,8], these mediator effects on user participation have not yet been tested on a broad empirical basis.

The present study is a first approach to close this knowledge gap by investigating the mediating effect of intrapreneural leadership and innovation culture on hospitals' IT innovativeness. The chosen study design had two major advantages: on the one hand, it combined the perspective of clinical leaders and IT leaders, so that the multi-professional character of user participation was taken into account. On the other hand, the assumed mediation effects are examined not only in relation to one, but to three outcome variables. This made possible to test whether the mediation effects considered occur independently of the choosen outcome variable.

The results of the mediation analysis confirmed the hypothesis model. It could be shown that there is less of a direct effect of user participation on the IT innovativeness of hospitals, but that this effect mainly occurs when clinical leaders and IT leaders have a strong intrapreneurship personality and when a distinct innovation culture prevails. It could also be shown that the indirect effects explain up to half of the variance of IT innovation, depending on how it is operationalised.

In order to further explain the critical role of intrapreneurial leadership, the findings can be linked to the results of previous studies and existing leadership theories. Two aspects seem to be particularly important. The first one concerns the connection between intrapreneurship and transformative leadership. The results indicate that intrapreneurial leaders are able to achieve a high degree of IT innovativeness on their own by regularly and proactively thinking about optimisation possibilities and searching for suitable ideas inside and outside the organisation. At the same time, intrapreneurial leaders seem to have the ability to transfer this intrapreneurial thinking and acting to their employees. Corresponding indications are already given by Lega [7], who argues that intrapreneurial leaders must have a team behind them in order to implement their innovative approaches. This mechanism of an interpreneurial feedback loop from the leadership level to the employees can be explained by the concept of transformative leadership. Transformative leaders are characterised by the desire to intrinsically motivate their employees. They therefore provide promising visions of the future, offer suitable ways to achieve corresponding goals, act as role models and promote individual employee developments [15]. As such, they are able to forge alliances and propel a sense of communal spirit so that creative momentum from user participation can be transformed for the good of the organisation.

The second important aspect that emerges from the results relates to the joint appearance of intrapreneurship at the leadership level. Since the operationalization of joint intrapreneurship was designed in such a way that high values can only be achieved if both the clinical leader and the IT leader have a pronounced intrapreneurship personality, it can be assumed that positive effects of user participation occur to a lower degree if only one of the two leaders thinks and acts intrapreneurially. Conversely, this also means that participation should not take place at the user level alone if innovations are to be successfully implemented. Rather, participation must reach into the management level, where clinical leaders seek exchange with IT leaders and vice versa. These findings go hand in hand with previous studies that examined the effectiveness of hospital CIOs and concluded that a close connection to the hospital board goes hand in hand with IT performance and IT innovation [5]. Above all, however, the results regarding intrapreneurship highlight the decisive role that clinical leaders can play for the implementation of IT innovations. They act as agents and representatives of the users and close the gap to IT. To put it simply: If clinical leaders are removed from the equation, the greatest organisational efforts, including user participation, will not lead to successful IT innovations [7].

In order to interpret the demonstrated indirect effect of innovation culture, a closer look at the way in which user participation was captured appears to be helpful. The user participation scale measures the extent to which clinical users are involved in information management tasks, which in turn relate to a typical IT innovation process in an organsation - ranging from the identification and selection of new IT solutions to the participation in implementation projects and the conduct of user training and evaluation studys. The results of this study now indicate that these tasks can be carried out more effectively if they are supported by agile and flexible organisational structures. This finding is largely consistent with previous studies which have identified a low level of bureaucracy, low and permeable hierarchies and a low level of formalisation as basic prerequisites for innovative employee activities [8]. The great importance of a common vision of the

future for innovative employee activities has also been identified in other studies [16]. Last but not least, user participation seems to unfold positive effects on the hospital's innovativeness, if it is accompanied by a strong motivation for interprofessional exchange on the part of the clinical units and the IT department.

Finally, the results indicate that the effect size of joint intrapreneurship and innovation culture does not substantially differ. At the same time, the indirect effect of user participation via innovation culture was significant in only two of the three models. Taken together, it can therefore be concluded that without the observed top-down and bottom-up mediators, user participation will have little effect.

The present study has some limitations which also point to further research needs. Although the sample size can be considered sufficiently big taking into account the calculated regression coefficients [17], the examined effects should be retested in order to validate our results. Here, moderating factors such as hospital size or ownership could also be factored in. These characteristics are regarded as structural determinants of the hospital's IT innovativeness, but were not taken into account in the analyses due to the small group sizes of the individual characteristics. As the results suggest that transformational leadership may be the missing link between intrapreneurial leaders and user participation, this could be explicitly tested in future research. In the present study only the joint impact of intrapreneurship was considered, as it was assumed that both groups involved in participation (users and IT) need leadership. The study primarily used quantitative methods to answer the research questions, therefore the results should be further elaborated through a qualitative approach. Finally, the results demonsrate that joint intrapreneurship and innovation culture correlate. Even if no multicollinarity was found in the mediation models, this correlation could be investigated more closely. An innovative culture could, for example, promote the rise of intrapreneurial leaders, who would then be able to lead parts of the organisation to faster change.

Conclusions

This study investigated to what extent joint intrapreneurship and innovation culture mediate the effect of user participation on the IT innovativeness of hospitals. The results indicate that these so-called top-down and bottom-up mediators are not only sufficient but necessary conditions for successful user participation. In summary, the findings consolidate the network of possible preconditions for the hospital's IT innovativeness and - perhaps even more interestingly - contributes to the order of these preconditions.

SNOMEDtxt: Natural Language Generation from SNOMED Ontology

Olga Lyudovyk[a], Chunhua Weng[a]

[a] *Department of Biomedical Informatics, Columbia University, New York, NY, USA*

Abstract

SNOMED Clinical Terms (SNOMED CT) defines over 70,000 diseases, including many rare ones. Meanwhile, descriptions of rare conditions are missing from online educational resources. SNOMEDtxt converts ontological concept definitions and relations contained in SNOMED CT into narrative disease descriptions using Natural Language Generation techniques. Generated text is evaluated using both computational methods and clinician and lay user feedback. User evaluations indicate that lay people prefer generated text to the original SNOMED content, find it more informative, and understand it significantly better. This method promises to improve access to clinical knowledge for patients and the medical community and to assist in ontology auditing through natural language descriptions.

Keywords:

Systematized Nomenclature of Medicine, Natural Language Processing, Access to Information

Introduction

SNOMED CT is the world's most comprehensive clinical terminology [1]. The March 2018 release of the US version contains 347,231 unique concepts, including 78,561 diseases, and defines 1,088,068 unique active relationships between these concepts [2]. In contrast, the largest professional medical reference source, Medscape (medscape.com), contains 7,600 diseases, representing less than 10% of the diseases defined in SNOMED CT, and the largest consumer health resource, Mayo Clinic (mayoclinic.org), describes 2,215 diseases. Disease descriptions in these resources are manually curated, thus limiting the number of diseases which can be covered. Topics may be chosen according to popularity in search results [3], thus rare diseases are often excluded from these resources. Counts of disease concepts in major medical information sources are shown in Figure 1. Google Knowledge Graph for diseases is not available, but since it is curated from the sources listed in Figure 1, it is likely on the same order of magnitude.

While extensive, SNOMED CT is not easily accessible to the public and is known to be difficult to use even for clinicians without training in ontologies [4,5]. Like other structured ontologies, SNOMED CT is not designed to be used directly by lay people. The US version of SNOMED CT contains only 4,372 text definitions easily interpretable by untrained personnel, covering 2,608 diseases, corresponding to 1.3% of all SNOMED CT concepts and 3.3% of disease concepts.

We propose a method called SNOMEDtxt to automatically generate disease descriptions from SNOMED CT in order to make available to both patients and the medical community the valuable clinical knowledge contained in SNOMED CT.

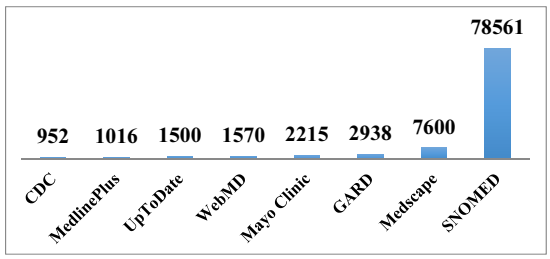

Figure 1– Counts of Diseases in cdc.gov, medlineplus.gov, uptodate.com, webmd.com, mayoclinic.org, rarediseases.info.nih.gov, medscape.com, SNOMED [2] (Nov. 10, 2018)

An additional use case for SNOMEDtxt is to enable clinicians and domain experts without specialised technical training or experience working with structured terminologies to review and critique clinical knowledge defined in SNOMED CT. This task is critically important as biomedical knowledge is growing exponentially with numerous data types and tools emerging rapidly on the daily basis. For example, Campbell et al. reported that the absence of a robust granular ontology represents a barrier to capturing and analyzing data in the field of cancer research and precision medicine [6], while Fung et al. made a similar observation in the area of rare diseases [7]. However, ontology auditing or quality ascertainment is largely performed by knowledge engineers with specialized training in ontology design and maintenance. The workforce of this profession is rare, hence creating a bottleneck for enabling scalable ontology expansion or for crowdsourcing ontology auditing. SNOMEDtxt allows representation of concepts and related information in natural text, thus expanding the group of potential reviewers to include any medical professionals who are not necessarily familiar with structured ontologies. Wider review of SNOMED CT by clinicians can be expected to improve accuracy, reduce missing information, and enable faster SNOMED CT evolution as the body of clinical knowledge expands.

Natural Language Generation (NLG) is a technology utilizing advanced computational methods to generate natural language descriptions from structured knowledge or data representation. Attempts to apply NLG to generate text from SNOMED CT have been reported by Liang et al. [8] and Kanhov et al. [9]. Liang and colleagues developed OntoVerbal, a generic tool for ontology verbalization that was then applied to SNOMED CT. While Kanhov and colleagues utilized an off-the-shelf natural language generator, they developed a methodology for user evaluation of the fluidity and readability of NLG texts in the Biomedical domain. OntoVerbal was developed as a Protégé 4.2 plugin and is not available in more recent Protégé versions

or as a standalone application. The NLG system developed by Kanhov et al. was not made available for download or use.

OntoVerbal implements a generic verbalization approach for ontologies, with an emphasis on the ability to handle any OWL ontology and generate natural language descriptions for any entity type in that ontology [8]. This approach restricts handling of relationships, or ontology axioms, to generic lexical choices and results in some redundant and inelegant phrases, such as "*chronic disease of the genitourinary system … has a finding site in a structure of the genitourinary system*." In contrast, our method trades off generalizability for improved readability and comprehensibility through more specific verbalizations of SNOMED CT axioms and simplifying structures tailored to SNOMED CT concepts, so that the same construct is simplified by SNOMEDtxt as "*… affects the genitourinary system*." Moreover, OntoVerbal takes the generic approach to ordering information from simpler sentences to more complex ones, whereas SNOMEDtxt follows the common flow of information found in disease descriptions in reference medical texts: definition is followed by possible causes, presentation, diagnosis, clinical course, and finally additional information.

SNOMEDtxt is a novel NLG engine and interface, intended to evolve and improve over time with user feedback. The current version focuses specifically on disease concepts and can be easily extended to summarize procedures, treatments, and other information contained within SNOMED CT and relevant to the wider audience.

Methods

SNOMEDtxt follows a 4-step framework outlined in Figure 2 to generate a disease description for a given disease.

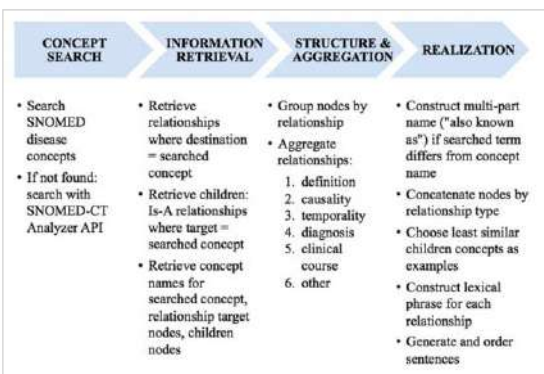

Figure 2 – Framework for Disease Description Generation

Concept Search And Information Retrieval

The current implementation of SNOMEDtxt is based on the 03/01/2018 release of SNOMED CT terminology, US edition, Snapshot version, available for download from the SNOMED CT website [2]. SNOMEDtxt uses a local copy of this database.

The system has the capability to randomly sample diseases from SNOMED CT and to search for disease names entered by a user. The search is undertaken in two steps: first, a simple match on concept names and synonyms in SNOMED CT database is attempted. If the search term is not found, the system then uses SNOMED CT Analyzer API (snomedct.t3as.org) to search for the term, provided that the API site is online.

Concepts are the key component of SNOMED CT. They are organized in a polyhierarchical structure with "Is-A" (parent-child) relationship and can be additionally defined or described through other relationships. Each relationship has a type, a source concept, and a destination concept. Once a disease Concept ID is found, relevant relationships are retrieved from SNOMED CT database:

- Relationships where the searched disease Concept ID is the source
- Is-A relationships where the searched disease Concept ID is the destination: the source concepts represent subtypes or examples of the disease and are included in the definition

Concept names are then retrieved for the corresponding target concepts. The generated text is the product of concept names arranged in lexical patterns corresponding to types of relationship between these concepts. Concept names undergo minimal string cleaning to remove non-informative structures such as "(Disorder)" and "(Body Structure)".

Structure And Aggregation

In order to produce fluid and coherent text and avoid redundancy wherever possible, SNOMEDtxt aggregates and structures information in three steps: Firstly, it groups all target nodes for the same relationship; secondly, it organizes relationships in broad logical groups; thirdly, it orders relationships within each group and the groups themselves following a typical flow of information in a disease description in medical reference texts. This stepwise grouping of relationships is a simplified application of the Rhetorical Structure Theory [10] that describes a recursive approach to organizing relationships in a text.

Table 1 – Organizing Relationships

Group	Relationship	Lexical Pattern
Definition	IS-A	"is a kind of"
	Finding site	"that affects the"
	Has definitional manifestation	"It manifests itself in"
	Associated morphology	"The associated morphology is"
	Pathological process	"Pathological process associated with … is"
	Children: IS-A, searched term=destination	"An example of … is" / "Examples of … are"
Causality	Causative agent	"is caused by"
	Due to	"occurs due to"
	Associated with	"is associated with"
Tempora-lity	Occurrence	"presents in" (period)
	During/Following/ After	"can occur during / following / after"
	Temporally related	"can be temporally related to"
Diagnosis	Finding method	"is discovered by"
	Finding informer	"<is discovered> through"
Clinical Course	Clinical course	"Clinical course is"
	Severity	"The severity of … is"
	Episodicity	"The episodicity of … is"
Other	Interprets	"interprets or evaluates"
	Has interpretation	"… as"
	Other	"Other related concepts include…"

Text Realization

The first task SNOMEDtxt undertakes in the Text Realization phase is constructing an informative disease name. If the search term is significantly different from the preferred term for the disease concept, as measured by Jaro-Winkler string distance [11], the disease description will combine both in the form of "<Preferred disease concept name> (also known as <searched term>)", e.g. "Influenza (also known as flu)".

Additionally, SNOMEDtxt concatenates all target nodes for the same relationship type which were aggregated in the previous step by following the "A and B", "A, B, and C" format. When concatenating examples of a given disease, SNOMEDtxt selects a maximum of three examples, based on the largest string dissimilarity with the given disease name, as a tradeoff between completeness and relevancy.

Finally, relationship types are converted into corresponding lexical patterns (see Table 1) and sentences are generated. For the sake of conciseness, relationships in the same group are combined into one sentence wherever this approach produces fluid text. For example, the Is-A and the Finding site relationships are combined into one sentence that forms the concise definition of the disease: "*Asthma is a kind of Respiratory disorder that affects the Airway*". Sentences are then ordered according to the order of relationships in Table 1.

Results

User Interface of SNOMEDtxt

A simple user interface is implemented in RShiny and is available online at https://sno2eng.shinyapps.io/sno2Eng.

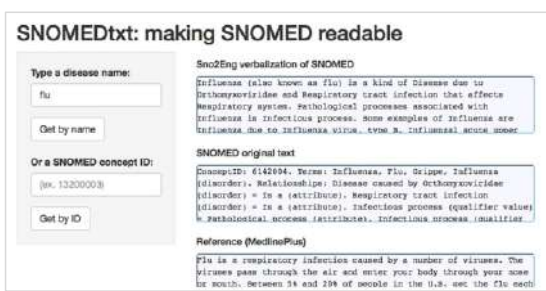

Figure 3 – Screenshot of SNOMEDtxt Interface

An example disease description generated by SNOMEDtxt and the corresponding concatenated SNOMED CT content are illustrated below.

SNOMEDtxt Disease Description

Lupus erythematosus (also known as Lupus) is a kind of Autoimmune disease and Connective tissue disease that affects Connective tissue. Some examples of Lupus erythematosus are Systemic lupus erythematosus, Drug-induced lupus erythematosus, and Neonatal lupus erythematosus. Pathological process associated with Lupus erythematosus is AI - autoimmune. Other related concepts are Cutaneous lupus erythematosus, Lupus erythematosus profundus, and Discoid lupus erythematosus of eyelid.

SNOMED CT Content

ConceptID: 200936003. Terms: Lupus erythematosus, LE - Lupus erythematosus, Lupus, Lupus erythematosus (disorder). Relationships: Disorder of connective tissue (disorder) = Is a (attribute). Connective tissue structure (body structure) = Finding site (attribute). Autoimmune disease (disorder) = Is a (attribute). Autoimmune (qualifier value) = Pathological process (attribute). Related concepts: Systemic lupus erythematosus (disorder) - Is a (attribute). Drug-induced lupus erythematosus (disorder) - Is a (attribute). Neonatal lupus erythematosus (disorder) - Is a (attribute). Discoid lupus erythematosus (disorder) - Due to (attribute).

We evaluated disease descriptions generated by SNOMEDtxt against the concatenated SNOMED CT content using computed metrics and user evaluations. Both sets of evaluations indicate that SNOMEDtxt succeeds in making SNOMED CT content more readable and comprehensible.

Computed Metrics

We computed readability and redundancy metrics for disease definitions of the top 20 most searched diseases in 2017 [13] and of 20 diseases randomly retrieved from SNOMED CT:

1. Readability: Flesch-Kincaid grade level (FK) and Automated Readability Index (ARI) estimate the number of years of education needed to understand a text. We calculated both with sylcount R package [12].
2. Redundancy: calculated as the ratio of unique word count to total word count after removing stop words.

Full summaries of health concepts retrieved from Medline Plus web service (MedlinePlus.org) were used as reference for the first set of disease concepts. Since only 4 out of 20 randomly sampled disease concepts had a reference health topic in Medline Plus, comparison with reference is not provided for the second set.

Table 2 – Evaluation with Computed Metrics

	Readability		Redundancy	
	FK	**ARI**	**Words**	**Unique/All**
Top 20 most searched diseases				
SNOMEDtxt	14.3	12.0	49.3	0.74
SNOMED CT	17.9	15.0	64.1	0.55
Reference	6.6	6.1	263	0.77
Random 20 SNOMED CT disease concepts				
SNOMEDtxt	11.7	9.7	47.3	0.69
SNOMED CT	15.7	13.8	69.7	0.56

For both measures of readability, a lower score indicates a lower grade of education needed to understand the text and therefore better readability. These metrics indicate that SNOMEDtxt texts are more readable than the original SNOMED CT content. For the 20 most searched diseases, the average FK score for SNOMEDtxt texts (14.3) is equivalent to the second year of undergraduate degree, and FK for SNOMED CT content (17.9) corresponds to the graduate school level. ARI score of 12.0 for SNOMEDtxt is equivalent to twelfth grade, while ARI of 15.0 for SNOMED CT content indicates that the text is appropriate for readers at the Professor level. Readability scores for the MedlinePlus reference texts are significantly lower, indicating that they can be read by a much wider audience than either SNOMEDtxt or the original SNOMED CT content.

SNOMEDtxt texts also improve on the redundancy metric compared to SNOMED CT content for the top 20 searched diseases (0.74 vs. 0.55) and for the 20 randomly sampled diseases (0.69 vs. 0.56).

User Evaluation

A survey evaluating results of SNOMEDtxt was conducted among 51 lay people recruited using Amazon Mechanical Turk (MTurk) and 6 clinicians from Columbia University Medical Center. MTurk is a crowdsourcing marketplace that enables outsourcing tasks like surveys to a distributed workforce for a small reward. Evaluations of all MTurk taskers that applied and did not self-identify as clinicians were included in the results. Evaluations of all 6 clinicians who responded to the survey were included in the results. All evaluators were provided with a basic description of the project, but were not aware of the study design or the research question.

We randomly selected a set of 20 disease concepts from SNOMED CT for evaluating readability, preference, accuracy, and completeness (set 1). Helpfulness was evaluated on a set of 20 disease concepts for which a medical reference text was available (set 2). Questions probing the degree of understanding were constructed for 10 diseases with sufficient information selected from 40 randomly sampled disease concepts (set 3). Comparison with OntoVerbal was restricted to 4 diseases for which OntoVerbal description was available in [8] (set 4). For all 4 sets, we generated a SNOMEDtxt disease description and a concatenation of SNOMED CT content. The survey was conducted using Qualtrics survey platform (www.qualtrics.com) and included randomization: each evaluator was presented with 3 randomly selected diseases from set 1, 2 from set 2, 2 from set 3, and 1 from set 4.

In order to assess readability and general preference, we presented evaluators with SNOMEDtxt disease descriptions and the SNOMED CT content for 3 diseases from set 1 and asked whether one or the other was more readable or generally preferred, or there was no difference. Evaluators were not informed which text represented SNOMEDtxt output. Lay people found 76.5% of SNOMEDtxt disease descriptions easier to read than the SNOMED CT content, and preferred 69% of SNOMEDtxt descriptions to SNOMED CT content. Clinicians found 83% of SNOMEDtxt descriptions easier to read and preferred 44% of them to the SNOMED CT content.

We tested understanding by presenting the evaluators with either the SNOMEDtxt description or the SNOMED CT content for a concept, followed by a multiple choice question designed to test whether the evaluator understood the text; we then compared the number of correct answers given when presented with SNOMEDtxt description or with the SNOMED content. SNOMEDtxt format appeared to be significantly easier to understand for lay users: they gave the correct answer 72% of the time when presented with SNOMEDtxt description and only 51% when presented with SNOMED CT original content. There was no difference for clinicians: they gave the correct answer 100% of the time regardless of what text they were presented with.

To evaluate helpfulness, we presented evaluators with the SNOMEDtxt description, the SNOMED CT content, and a description of the same concept from either Medline Plus or Google Knowledge Graph as a reference and asked "How helpful was the terminology content compared to" the reference, on a scale from 1 to 10. Lay people found SNOMEDtxt descriptions more helpful: the average helpfulness score for SNOMEDtxt texts was 5.7, compared to 4.8 for SNOMED CT content. On the other hand, clinicians found SNOMEDtxt descriptions on average minimally less helpful than SNOMED CT content (3.50 versus 3.58).

Clinician evaluators were also asked to assess accuracy and completeness for disease concepts from set 1. In most cases clinicians thought the SNOMEDtxt descriptions were as accurate (72%) and as complete (78%) as the original content, while they found 28% of descriptions to be somewhat less accurate, 6% somewhat less complete, and 17% significantly less complete.

Table 3 – User Evaluation: SNOMEDtxt vs. SNOMED

Readability and Preference

	SNOMEDtxt	SNOMED CT	No Difference
Lay Audience (n=51)			
Easier to read	76.5%	14.4%	9.2%
Preferred	68.6%	21.6%	9.8%
Clinicians (n=6)			
Easier to read	83%	11%	6%
Preferred	44%	28%	28%

Helpfulness and Understanding

	SNOMEDtxt	SNOMED CT
Lay Audience (n=51)		
Helpful (1-10)	5.7	4.8
Correctly understood	72.1%	51%
Clinicians (n=6)		
Helpful (1-10)	3.50	3.58
Correctly understood	100%	100%

Accuracy and Completeness

SNOMEDtxt vs. SNOMED CT	Significantly Worse	Somewhat Worse	Same
Clinicians (n=6)			
Accuracy	0%	28%	72%
Completeness	17%	6%	78%

A conclusive comparison between OntoVerbal and SNOMEDtxt was not feasible since only 4 disease descriptions were available for OntoVerbal. We conducted a limited comparison by presenting all evaluators with the SNOMED CT content and with a disease description from either OntoVerbal or SNOMEDtxt for the same disease (evaluators were unaware of the source of each text). All evaluators were asked which text they found easier to read and generally preferred; clinicians were additionally asked whether the text description was less accurate / complete than (denoted in Table 4 as "Worse") or as accurate / complete as (denoted as "Same") the SNOMED CT content. This limited comparative evaluation points to a preference for SNOMEDtxt disease descriptions with the same or better performance on readability, accuracy, and completeness.

Table 4 – User Evaluation: Comparison with OntoVerbal

	SNOMEDtxt	Onto Verbal	SNOMED CT	No Difference
Lay Audience (n=51)				
Easier to read	49%	43%	3.9%	3.9%
Preferred	52%	31%	11.8%	3.9%
Clinicians (n=6)				
Easier to read	50%	50%	0%	0%
Preferred	50%	17%	17%	17%
	SNOMEDtxt vs. SNOMED CT		**OntoVerbal vs. SNOMED CT**	
Clinicians (n=6)	**Worse**	**Same**	**Worse**	**Same**
Accuracy	0%	45%	27%	27%
Completeness	18%	37%	18%	27%

User evaluation demonstrates potential utility of SNOMEDtxt for lay users: they find the generated disease descriptions more readable and easier to understand than the structured SNOMED

CT content. The accuracy and completeness of SNOMEDtxt's natural language descriptions is close to the original SNOMED CT content. The use case of assisting in SNOMED CT content review would require some adjustments to SNOMEDtxt design in order to produce more faithful representations of the SNOMED CT content.

Discussion

We introduce a method to generate disease descriptions directly from the SNOMED CT ontology for two main applications: providing access to definitions of rare diseases or disease variants not described in clinical reference resources and enabling easier comprehension of SNOMED CT content for those reviewing, verifying, and extending the ontology.

In the design of SNOMEDtxt, we have made several choices that favor fluidity and ease of comprehension over faithful and complete representation of information, at the risk of possible loss of information. The human evaluation of results confirms that we achieved the goal. However, these choices may not be appropriate when SNOMEDtxt output is used to verify content of SNOMED CT. It may be desirable to provide users with configurations such as "more precise" and "easier to understand" when generating the natural language texts. Another tradeoff made in the design of SNOMEDtxt was readability at the expense of generalizability. In order to extend SNOMEDtxt to other types of concepts or to other terminologies, verbalizations of relationships and handling of aggregated sentence structures would need to be adjusted.

A significant limitation to the use of SNOMEDtxt for the wider audience is the amount of content available for each disease concept in SNOMED CT. Expanding, i.e. explaining, some related nodes, for example parent disease node or finding site, may add meaningful and relevant information to the generated disease descriptions. A navigable user interface where a user could click on confusing terms and see them explained would be an alternative approach to this challenge. Developing APIs to access SNOMEDtxt would enable integration of textual disease descriptions into other electronic resources and reference materials, such as EHR help function or patient portals. The search functionality in the current implementation is limited to exact string match with either the SNOMED term name or any of the term's synonyms and can be further improved with string search algorithms.

Results of the evaluation by lay people and clinicians presented in this paper are encouraging for the potential use of SNOMEDtxt in making SNOMED CT content more accessible and easier to review; however, a more rigorous evaluation with a larger audience and a greater number of tested concepts is recommended.

Finally, to allow the system to continuously learn and evolve, evaluation and feedback elicitation can be bulit into the user interface. Presenting users with different verbalization options at random and gathering user feedback would enable the system to learn verbalization patterns favored by users and evolve the NLG engine accordingly.

Conclusion

This work presents an ontology verbalizer for SNOMED CT disease concepts: a tool that generates natural language concept descriptions balancing completeness and accuracy with the ease of human comprehension. User evaluation shows that lay people prefer to read natural text instead of structured ontologies and understand textual descriptions better.

More broadly, natural langauge processing is growing in importance with many potential applications in Healthcare systems. NLG involves several important tradeoffs, which should be made with a specific application in mind. Two such tradeoffs are balancing completeness and accuracy on one hand with fluidity and comprehensibility on the other; and generalizability versus linguistic polish and expressiveness.

Abstract

Unhealthy behaviors, such as tobacco use, increase individual health risk while also creating a global economic burden on the healthcare system. Social ties have been seen as an important, yet complex factor, to sustain abstinence from these modifiable risk behaviors. However, the underlying social mechanisms are still opaque and poorly understood. Digital health communities provide opportunities to understand social dependencies of behavior change because peer interactions in these platforms are digitized. In this paper, we present a novel approach that integrates theories of behavior change and Exponential Random Graph Models (ERGMs) to understand structural dependencies between users of an online community and the behavior change techniques that are manifested in their communication using an affiliation network. Results indicate population specific traits in terms of individuals' engagement in peer communication embed behavior change techniques in online social settings. Implications for personalized health promotion technologies are discussed.

Keywords:

Health Communities, Social networks, Tobacco cessation

Introduction and Background

According to the World Health Organization (WHO), tobacco use is one of the leading causes of preventable death, causing over seven million deaths worldwide annually. Further exposure to second-hand smoke alone leads to 600,000 deaths. Tobacco use causes various chronic conditions such as cancer, heart disease, stroke, lung diseases, diabetes and Chronic Obstructive Pulmonary Disease (COPD), which collectively account for an estimated $1.7 trillion a year leading to an economic burden on the global healthcare system [1]. Several interventions have been suggested and implemented to address tobacco use around the world – use of behavior counseling and nicotine replacement therapy [2]. Despite ongoing public health campaigns, tobacco use rates are still concerning. It is imperative for us to uncover mechanisms of behavior change to design scalable interventions that support cessation [3].

Studies indicate that social support and networks can have complex relationships with health behaviors and health outcomes [4]. For example, being married to a non-smoker and having a lower number of non-smokers in one's social network are associated with greater rates of smoking cessation. Christakis and Fowler demonstrated that quit attempts occurred within social clusters and that a variety of network variables were predictive of cessation, including the smoking cessation of a spouse, sibling, friend and co-worker [5]. Researchers have investigated these effects through a multitude of methods grounded in socio-behavioral theories and network science methods [3,6]. However, our understanding of the network dynamics of behavior change is still developing.

Advances in information and communication technologies have revolutionized the way in which individuals seek peer support to adopt and sustain positive health behaviors. Social media platforms have increasingly been used as behavior change venus where users reach out to their peers for support and guidance [7]. Analysis of peer interactions in these digital platforms can provide us with a deeper understanding of how social influence impacts users to quit tobacco use and stay abstinent. Consequently, this has raised interest in understanding how users of these platforms communicate with one another about health behavior change in these supportive settings. In this vein, previous work has primarily employed methods of content analysis including qualitative analysis [6], automated text analysis [8] and simulation-based effects [9] which enable identification of communication topics that could be linked to theoretical constructs and behavioral outcomes like abstinence and relapse rates. Although insightful, the problem with these approaches is that they remain agnostic to the structure of relationships that underlies the communication environment and interdependent nature of communicative choices [7]. For example, what one talks about the characteristics of those users, and their ongoing patterns of interaction is rarely integrated [6].

More recently, advances in social media analytics and social network modeling provide opportunities to extract the relational infrastructure of online communication forums like those supporting healthy behavior change, to uncover the social processes that bring structure to that communication, and to account for the interdependencies in those data. In this paper, we draw on these techniques to examine QuitNet, an online community for tobacco cessation. We conceptualize this environment as a bipartite (or two-mode) network, comprised of two sets of nodes–QuitNet users and the behavior change techniques they adopt and talk about in their communication threads –with edges between node sets representing a technique adoption tie. Then, using a class of statistical network models, the exponential random graph models (ERGMs), we investigate the degree to which the attributes of QuitNet users, namely their gender and age, organize the structure of their communication behavior change techniques. Findings from this analysis will reveal patterns of engagement with behavior change techniques that constitute online support structures for community members in online settings.

Methods and Materials

Data Site and Sample

QuitNet is a social media platform designed to help people quit smoking through peer support and pragmatic engagement. It is one of the first online social networks for health behavior change and has been in continuous existence since 1995 [10]. QuitNet offers various forms of social support. Users communicate with their peers in one of the following ways – one to many messages in threaded forums, through synchronous channels such as chat rooms or through asynchronous channels (e.g., private internal e-mail). Previous studies show that participation in QuitNet is associated with abstinence [3]. The primary mode of communication is through forum interactions. For the purpose of this study, we examined communication of 126 highly engaged QuitNet users in 2014 and 2015. In total, these 126 users exchanged 17,451 messages. This research project was reviewed and exempted by the Institutional Review Board at the University of Texas Health Science Center at Houston.

Qualitative Analysis

Two independent researchers coded 900 messages from this dataset, selected at random using the taxonomy of behavior change techniques (BCT taxonomy) [11] to ensure objectivity of the coding process and identify theoretical manifestations in QuitNet interactions. We used Cohen's Kappa to measure inter-rater reliability of the qualitative coding. The BCT taxonomy consists of 93 theory-linked techniques grouped into 16 classes. A single behavior change technique can be related to similar behavior change processes from multiple behavior change theories such as the Health Belief Model, Transtheoretical Model, Social Cognitive Theory and Social Change Theory [12]. Each message was coded appropriately to one or more techniques that were linked to a particular behavior (for example, smoking), focusing on a particular population (for example, QuitNet users). The definition of each technique can be found in [11] with illustrative examples.

Automated Classification System

Using methods from distributional semantics and machine learning, we developed an automated classification system to scale up the BCT annotation to the remaining messages in the dataset. To generate vector representations of messages, we used neural word embeddings, specifically the Skipgram-with-Negative-Sampling (SGNS) algorithm developed by Mikolov and colleagues [13], as implemented in the open source semantic vectors [14] package for distributional semantics. Additionally, Wikipedia was used as a background corpus. Our Wikipedia corpus contains 1.9 billion words in more than 4.4 million articles, and 500-dimensional Wikipedia-derived term vectors were obtained by applying the SGNS algorithm to the Wikipedia background corpus. This decision was motivated in part by the terse nature of the messages exchanged in QuitNet user forums, which often do not provide enough contextual information to train a distributional model [6, 8, 15]. We first superposed (added together) the Wikipedia term vectors for the terms that occur in each QuitNet message to obtain Wikipedia-based QuitNet message vectors. We then composed term vectors for the terms that occur in QuitNet by adding QuitNet message vectors for each message in which a given term in QuitNet occurred. As such, these term vectors encode distributional information from Wikipedia and from QuitNet-specific contextual use of terms. Finally, QuitNet message vectors were generated by superposing these term vectors. The components of the vectors generated in this way were used as feature vectors for supervised machine learning that was conducted using the widely used Waikato Environment for Knowledge Analysis (WEKA) open source package for machine learning [16]. Each of the techniques of behavior change taxonomy was used as a target for classification. We used only eight techniques due to sparse representation in qualitative coding. Ten-fold cross validation was applied using the random forest classifier to evaluate a binary classifier for each of the themes. Each of the trained validated classification models was then used to classify the entire dataset.

Two-Mode Network Analysis

We dichotomized the messages exchanged by a QuitNet user based on whether or not the message is assigned a specific behavior change technique during our text analysis (presence of a technique: 1, else: 0). From this, we were able to create a user to behavior change technique, binary network.

Data were thus analyzed using two-mode network analysis by creating an affiliation network composed of two sets (or nodes) of actors – users of the QuitNet platform (N=126) and the BCT techniques embedded in their QuitNet posts (N=8). Ties are defined only between members of each set but not within sets of nodes [17]. For this reason, the network is comprised only of user-to-technique ties; ties connecting QuitNet users to one another or ties connecting behavior change techniques to one another are not explored.

We then used a class of statistical models for social networks called Exponential Random Graph Models (ERGMs) [18, 19], which allow us to account for the interdependencies in mentions of behavior change techniques among users of the same platform. ERGMs have been applied to a wide array of fields as diverse as epidemiology [20], political science [21],communication studies [22], biological sciences [23] and archeology [24]. As described in previously published work [25], ERGMs permit inferences about how network connections emerge by estimating the likelihood of a tie being present (or absent) in the network as a function of small local tie-based configurations (or patterns). Each configuration represents a distinct social process, such as reciprocity or balance, and corresponds to a specific parameter in the model. From this perspective, ERGMs adopt a logic similar to logistic regression, in which a binary outcome like the adoption of behavior (or the presence of a tie in ERGMs) is modeled as a function of selected, predictor variables (or local configurations in ERGMs) that are thought to explain the observed outcome.The configurations modeled in ERGMs can emerge from endogenous processes – i.e., when actors form ties in response to the other ties being made in their social environment (e.g., when frequently mentioned behavior change techniques continue to be mentioned by more QuitNet users) or in response to exogenous properties that exist outside the network like the attributes of other QuitNet users (e.g., when male QuitNet users tend to adopt the same behavior change techniques).

In statistical terms, the effect of each parameter is estimated by determining the prevalence of the modeled configurations in the observed network and then assessing their statistical likelihood above what would occur by chance alone [19]. A parameter estimate that is positive and significant indicates that ties are more likely to occur within the configuration tested than by chance alone. Conversely, parameter estimates that are negative and significant suggest that ties are less likely to occur within the configuration tested than by chance alone. ERGMs are deemed acceptable when the parameters converge, which occurs when the convergence t-ratios for each parameter

reaches <0.10. Details about the specification, estimation, and simulation of ERGMs can be found here [26, 27].

Selecting which parameters to be included in an ERGM should be grounded in which distinct theories of interaction one wants to test or the research questions one wants to explore. Given that the focus of this analysis centers on the relationship between demographic attributes of QuitNet users and their patterns of communication about behavior change techniques, our estimation focuses on the effects of five attribute-based parameters to determine whether they were more likely to occur than expected by chance alone. Figure 1 illustrates the corresponding configurations of these effects

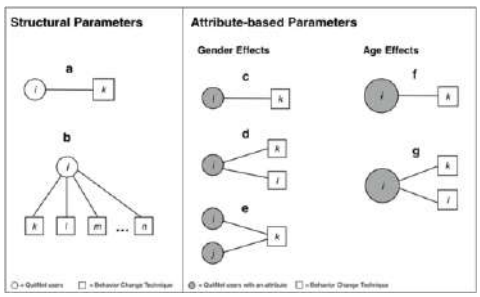

Figure 1. Parameterized Local Configurations among QuitNet Users a and j and Behavior Change Techniques k, l, m, and n. The parameters represent the following processes: (a) the likelihood of QuitNet users mentioning a behavior change technique, (b) the likelihood of QuitNet users mentioning multiple behavior change techniques, (c) the likelihood of male QuitNet users mentioning a behavior change technique, (d) the likelihood of male QuitNet users mentioning multiple behavior change techniques, (e) the likelihood of male QuitNet users mentioning the same behavior change technique, (f) the likelihood of older QuitNet users mentioning a behavior change technique, and (g) the likelihood of older QuitNet users mentioning multiple behavior change techniques.

First, to account for endogenous aspects of network emergence, we include two purely structural (or non-attribute) effects. The endogenous edge parameter (Figure 1a) is a required parameter and represents the overall propensity for QuitNet users to mention behavior change techniques in their posts. We also included the Alternating K-star parameter (Figure 1b), which represents the tendency for QuitNet users to mention multiple behavior change techniques and, therefore, corresponds to the variance in the distribution of technique mentions among QuitNet users.

With respect to our main interest -- attribute-based effects -- we parameterize several configurations that test the effects of gender and age on QuitNet users' patterns of communication about behavior change techniques. Specifically, we include parameters that represent the likelihood of male QuitNet users mentioning a behavior change technique (Figure 1c), the likelihood of male QuitNet users mentioning multiple behavior change techniques (Figure 1d), the likelihood of male QuitNet users mentioning the same behavior change technique (Figure 1e), the likelihood of older QuitNet users mentioning a behavior change technique (Figure 1f), and the likelihood of older QuitNet users mentioning multiple behavior change techniques (Figure 1g). Modeling results were implemented using MPNet, a network estimation program designed for one-mode, two-mode and multilevel network data [17-18].

Results

Qualitative Analysis

Table 1 provides sample QuitNet messages and the BCT techniques (and their definitions) assigned to them during manual coding. Of the manually coded messages, 32% were related to feedback and monitoring, 29% were related to social support, 21% were goals and planning, followed by rewards, natural consequences, associations, self belief and comparison of behavior and outcomes, repetition, and substitution.

Table 1. Illustration of QuitNet Messages and Assigned Behavior Change Technique

Quit message	Assigned technique
To tell you the truth, it's a new experience for me NOT to cough (I smoked for 38 or so years - YUK!). Good luck to you.	Natural consequences
Wow!!! xyxx is correct. You control your attitude. Deep breathing, chew gum, take a walk (or maybe a hike:-) Hang in there. This is not easy, your an addict.	Repetetion and substitution
At this point in your Quit it may be best to look at more immediate gains such as money saved or improved self esteem or better health. My dollar savings are $5,293 and that is real and for now. My life saved is an unrealized 15 weeks and 20 minutes that may never happen.	Comparison of outcomes

Automated Classification System

Due to insufficient positive examples in the training set, we disregarded eight of the 16 techniques of the taxonomy for final classification. For the remaining eight techniques, the precision, recall, and f-measure using Random forest classifier were 0.76, 0.74, and 0.78, respectively. The themes considered for further analysis were goals and planning, feedback and monitoring, social support, natural consequences, comparison of behavior, comparison of outcomes, rewards and threat, and self-belief. Based on the automated classification, we found that each of the users exchanged messages that embedded at least one behavior change technique and up to eight techniques. On average from the full sample, we see that far fewer users (13%) mention goals and planning. 55% of the users mention outcomes, 27% mention comparison of behavior, 53% users mention feedback and monitoring, 32% users mention natural consequence, self belief is mentioned by 33% of the users and social support is mentioned by 37% of users and finally 46% of users mention reward and threat. Table 2 shows the frequencies of each behavior change technique. Among the 126 users, 36 (29%) are men and 90 (71%) are women.

Table 2. Descriptive Statistics of Users and the Behavior Change Techniques within the QuitNet Forum

Behavior Change Techniques	Full user Sample (N=126)	Men (N=36)	Women (N=90)
Outcomes	70(55)	22(61)	48(53)
Feedback and monitoring	67(53)	19(53)	48(53)
Reward and threat	58(46)	17(47)	41(45)
Social support	47(37)	15(42)	32(35)
Self belief	42(33)	10(28)	32(35)
Natural consequence	40(32)	10(28)	30(33)
Comparison of behavior	34(27)	5(14)	29(32)
Goals and planning	17(13)	3(8)	14(15)

The bias towards females in the sample is a result of the inherent skewness in the utility of online social interventions such as QuitNet [6]. In the comparison of means tests not shown here, we find no significant differences between men and women with respect to the types of behavior change techniques they mention in their posts.

Figure 2. illustrates the two-mode affiliation network of 126 QuitNet users and eight behavior change techniques. QuitNet users are depicted as circles and the techniques are depicted as squares. The BCT technique nodes (squares) are sized by the number of mentions they received. Between node sets, there are a total of 375 ties, representing users' mentions of behavior change techniques in their QuitNet posts. Users mentioned on average 2.98 behavior change techniques and each technique had on average 46.88 mentions.

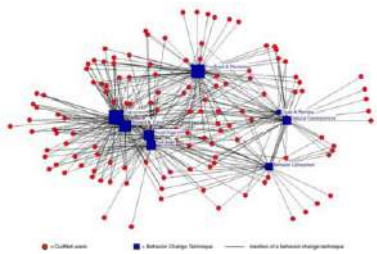

Figure 2. The network structure of mentions of behavior change techniques among 126 members of QuitNet as a 2-mode cessation technique affiliation network: 2014 and 2015.

Exponential Random Graph Model (ERGM)

Results of the two-mode ERGM are shown in Table 3. Reported in this table are parameter estimates, standard errors, and t-ratios, which reveal parameter convergence (t<0.1). The maximum likelihood (ML) estimate for a parameter indicates the direction of its propensity above what would be expected by chance alone. The significance is achieved when the ML estimate is greater than twice the SE.

Table 3. Exponential Random Graph Model of 2-Mode QuitNet User Affiliation Network with Behavior Change Techniques with Gender Modeled as Covariates

Parameter	ML Estimate	Standard Error(SE)	t-ratio
2-mode structure			
Edge density	-0.26	1.01	-0.01
Alternating k-star	-0.3	0.6	-0.02
User attribute-based edges			
Gender edge density	-1.23*	0.6	-0.02
Age edge density	0.004	0.01	-0.02
Gender based expansiveness	-0.09	0.2	-0.04
Gender homophily	0.10*	0.01	0.01
Age based expansiveness	0.0001	0.003	-0.04

Two-Mode Structural Effects

Here, the model estimates the effects of two structural or non-attribute parameters, which represent local structural patterns in the QuitNet user affiliation network. The required Edge parameter is negative, indicating that QuitNet users are less likely than expected to affiliate with behavior change techniques (ML Estimate=-0.26, SE=1.01). This reinforces the low density of the user affiliation network and suggests that adopting behavior change techniques is not random or haphazard. The negative estimate of alternating K-star parameter suggests that the likelihood of a user affiliating with multiple techniques is less likely than expected by chance (ML=-0.30, SE=-0.59).

Attribute - Based Edge Effects

The first attribute-based parameter, Gender density, is negative and significant (ML Estimate=-1.23, SE=0.60) indicating that men are less likely to adopt a behavior change technique than expected by chance. The attribute-based edge parameter for users' age (ML Estimate=0.004, SE=0.01) is positive indicating that older people are likely to adopt behavior change techniques. However, the effect is not significant. The gender-based expansiveness parameter estimate is not significant (ML Estimate=-0.09, SE=0.20), suggesting that men are no more or less likely than expected by chance to adopt multiple behavior change techniques. The gender homophily parameter estimate is positive and significant (ML Estimate=0.10, SE=0.02), indicating that men are more likely than expected by chance to adopt the same techniques. Finally, age-based expansiveness, which represents the likelihood that older QuitNet users are more likely to adopt multiple techniques is not significant (ML Estimate=0.0001, SE=0.003).

Discussion

Given that people increasingly turn to online social environments to find community and support, an opportunity arises to employ these platforms in health behavior interventions. Adopting a two-mode network analytic approach, we used a class of stochastic models called exponential random graph models (ERGMs) to determine the ways in which attributes of community users structure their communicative interactions about behavior change. Descriptively, we found that users more often discussed techniques that fell into the *Comparison of Outcomes*, *Feedback & Monitoring*, and *Reward & Threat* categories of behavior change. This finding can inform future interventions the need for a more adaptive and personalized, technology driven interventions such as a mobile app that includes effective quit plans, use of novel machine learning algorithms based on feature selection to obtain high classification rates to predict relapse (for e.g., smoking urges) and population-level interventions focusing on health effects of tobacco use.

A strength of this study lies in its analytic approach. Standard regression models are designed for data where independence among observations can be assumed. However, in a networked and open online forum like QuitNet, where users observe and respond to what others are posting about, we cannot assume that observation of what one user communicates about is independent of what others are talking about in those spaces. As such, an approach was needed that could account for those dependencies. To this end, we drew on the exponential random graph model (ERGM), which allows us to see how characteristics of QuitNet users condition their interactions and communication about behavior change techniques. The utility of automated text analysis approaches has allowed us to bridge two threads of socio-behavioral science driven by theoretical constructs and network models. Findings from our analysis provide insights about the underlying social dynamics of behavioral choices (e.g., adopting a behavior change technique) that would otherwise go undetected using standard regression models. These insights provide health researchers and interventionists with new directions for designing network based behavioral interventions [28] that target the social dynamics of behaviors like abstinence from tobacco use.

Our study has several limitations. Firstly, because these data are cross-sectional, inferences about cause and effect cannot be made. Secondly, our sample is limited to only those users who are highly engaged during 2014-2015. Moving forward, we should adopt the proposed techniques to identify patterns of relapse and quit sustenance. In addition, the accuracy of the automated system can further be improved through the use of advanced word representations [29, 30].

Conclusion

Tobacco use causes seven million deaths around the world each year. New modes of nicotine intake (JUULS, e-cigs) are now considered safer than traditional cigarettes and misinformation

is quite prevalent regarding these topics. In this new media environment, adaptive social interventions to help people abstain from tobacco use is a high-priority task. The major contribution of this study is its employment of integrative analytical framework to elucidate the structural dependencies between community users and their communication attributes. Insights from this work allow implementation of targeted, recommendation engines to promote meaningful affiliations with content and social ties based on user characteristics. Such translation can set the stage for scalable network-based interventions that can enable individuals and communities to engage in positive health behaviors.

Abstract

In a data driven environment, healthcare has seen ongoing digital transformation to meet both clinical and business needs. But, have the educational and functional requirements of the health informatics and information management (HIIM) workforce also adapted? This study examined the current employment opportunities in HIIM globally. Using 11 keywords generated from a literature review, postings on the job advertisement website Indeed™ for all available countries were analyzed. The results show that job postings tend to fall within 4 discrete categories: 1) health information technology; 2) health research; 3) health leadership and project management; and 4) health compliance. Data indicated a higher prevalence for certain areas by country. The findings from this study can inform HIIM educational providers about future skill requirements.

Keywords:

Career Choice, Medical Informatics, Cluster Analysis

Introduction

One of the primary reasons to seek higher education is to prepare for a career with interesting work that pays a living wage. In an attempt to determine which skills and competencies are currently most desired by employers, a group of health informatics and information management (HIIM) educators undertook a qualitative analysis of health information management and health informatics-related job postings from Indeed.com.

In health informatics, many of the educational competencies required for training programs have been determined primarily by educators or professionals who have been in the field for years. While these stakeholders certainly have experience and a role to play, they may not be the main employers. Worse, these people are often not aware of emerging trends or knowledgeable about all of the new skills needed by the workforce. This is more of a concern for fields such as health informatics and information management, where significant technical change is occurring, as well as for any current job where machine learning has the potential to be employed at less expense than the human workers.

The purpose of this study is to describe the characteristics of careers related to health informatics and information management, as well as explain the geographical commonalities and differences in the skills and knowledge required for employment using international job posting data.

Background

With the growth of Information Technology (IT) and the advent of big data, the healthcare industry is dynamically adapting to the current need to harness big data for improving healthcare performance and decision-making [1]. The adoption of electronic health records (EHRs), has been a central focus in United States in the past few years with providers all around the world continuing to adapt to technology at a rapid pace. Several studies from Canada, Iran, Nigeria and Saudi Arabia have identified obstacles in IT implementation relating to a health information management workforce shortage [2-4]. A specific study by the Canadian Health Information Management Association in 2014 identified workers needed in the areas of standards, data quality and management, information governance, change and project management [5].

Globally, EHR adoption rates have been influenced by the availability of funding, governance, standardization, interoperability, and communication [6]. Recently, Black Book Research conducted a poll surveying 7,459 physicians, health administrators, technology managers and clinical leaders in both inpatient and ambulatory settings across 23 countries to identify gaps, challenges and successes in healthcare IT adoption and connectivity. Included in those surveyed were five countries with evidence of nearly 100% EHR adoption rates: Norway, Netherlands, United Kingdom, New Zealand, and Australia, as well as five countries with nearly 75% provider adoption rates: Germany, France, Canada, Switzerland, and Singapore. Regions from Europe, Middle East, and South Asia showed a drift from siloed EHRs to more integrated healthcare IT systems. With the increased adoption and use of the digital technology, new roles have emerged in e-health to support the implementation and the administration of the operations and maintenance of the technological infrastructure [7]. To augment these roles there is a need for enhancing the skillset to strengthen the health informatics and information management workforce. The International Federation of Health Information Management (IFHIMA) documented the Global Health Information Curricula Competencies in their comprehensive 2015 report for Health Informatics, Health Information Management and Health Information and Communication Technologies. The premise was that even though universities strive to provide relevant curricula to students, it may not represent the actual needs of a career-ready graduate.

Furthermore, with the adaptation of new technology, growing consumer engagement and changes in legislation and regulatory requirements there are changes to the healthcare workforce [8]. The workforce has seen a trend of new career opportunities emerging in the areas of data analytics, data governance, privacy and security and interoperability. Our objective through this study is to highlight trends in health informatics and information management careers that are most

prevalent globally and examine if there are differences across countries using data acquired from the job site Indeed.com.

Methods

Keyword Derivation

The research team generated a list of 11 categories to search for online job postings based on recent literature, suggesting trends of increased growth in these areas: Information Technology, Classification and Clinical Documentation Improvement, Consumer Engagement, Leadership, Research, Information Governance, Project Management, Health Informatics, Information Technology, Compliance, and Health Data Analysis. These categories were used as the keywords when searching for job postings.

Query of International Job Postings

In September 2018, job postings from 64 countries were queried from Indeed.com. Queries were generated for the 11 job categories described earlier. In addition to the job titles, the word "health" was used as a qualifier to exclude job postings not related to healthcare. The job title, date of posting, location, company, and a URL to the full job description was obtained using the Indeed.com API. The job description and requirements were derived from the text located on the URL from each job posting. Using the *urllib.request* python library only valid URLs were included in the analysis, as determined by an HTTP status code of 200 (i.e., indicating a successfully working URL). The *BeautifulSoup* Python library was used to query the contents of the HTML files. All of the content located on the specified URL landing page was used as the original resource text. The HTML files were then prepared to remove duplicate records and aberrant text.

Analysis of Text

The job posting URL landing page text was prepared using the R statistical software package. The *tm* R package was used to tokenize the text which was transformed to lowercase, punctuation was removed, the resulting white space was stripped, common English words (i.e., stopwords) were removed from the text, and word stems were discarded. The text corpus was normalized using Term Frequency-Inverse Document Frequency (TF-IDF) to emphasize terms that appear multiple times in a single job posting while decreasing the importance of terms that appear many times across all job postings. Sparse terms amongst the jobs posted were also removed.

The corpus of text was evaluated to cluster similar job postings with K-Means clustering using Euclidean distances. Cluster tags were generated based on the cluster centers to determine which postings belonged to particular clusters. The optimal number of clusters was determined using the average silhouette approach to obtain the number of clusters that yields the highest quality of separation. The clusters were characterized by the terms at cluster centers that had the highest and lowest means to better understand the differentiating features of the clusters.

To compare the frequency of job posting categories by country, a heatmap was used to compare the frequency of postings across all countries and the 11 job categories. Additionally, the relative differences of needed skills and knowledge emphasized across job categories in each country was depicted in a stacked bar plot based on the proportion of job postings in each country for a particular cluster across each of the 11 job categories.

Results

The results show that by using an automated method of clustering, job postings tend to fall within 4 discrete categories. Additionally, there are differences in the frequency of job postings related to the 11 key categories when comparing countries.

Table 1 - Characteristics of Clusters

Cluster	WSS*	Size	Key Terms
1	83.1	7350	data, engine, software, test, analyst, design, security, system, technology, solution
2	63.3	4894	clinic, patient, medic, care, hospitals, research, studies, healthcare, staff, site
3	194.7	18695	sale, market, custom, research, client, business, project, account, service, product
4	87.2	7039	safety, engine, site, maintenance, equip, project, regulatory, environment, manufacturer, compliance

*WSS= Within-Sum Squares

In Table 1, the clusters are distinguished by key characteristics. The total within-cluster sum of squares (WSS) was 428.3 and the between-cluster sum of squares was 20.1 resulting in an internal cohesion of 0.045. This demonstrates that there was a large variance of job postings within clusters and moderate to small separation of job postings between clusters (Figure 1). Cluster 1 is the 2nd largest and is distinguished by containing jobs postings related to more technical skills and knowledge related to data, software, design, and technology. Custer 2 was the smallest in size and the job postings within the cluster were the most highly related. Job postings in Cluster 2 were more clinically focused, as shown by the prevalence of terms related to clinic, patient, medicine, and care. Cluster 3 had the largest number of job postings and the highest degree of variation. The most common terms to occur in job postings in Cluster 3 included sale, market, research, client, business, and terms more related to healthcare sales, marketing, and project management. Lastly, job postings in Cluster 4 included terms related to compliance such as safety, regulatory, and maintenance.

The number of job postings in each cluster across the 11 categories shows that the majority of the jobs in Cluster 1 are related to health information technology; in Cluster 2 to health research; in Cluster 3 to health leadership and health project management, and in Cluster 4 to health compliance (Figure 2).

When comparing the job postings by country, the proportion of postings are predominantly assigned to Cluster 3 (Figure 3). When comparing the frequency of job postings by category for each country (Figure 4), the most common category is Health Project Management followed by Health Leadership, Health Information Technology, and Health Research. The least common categories include Health Informatics, Health Consumer Engagement, and Clinical Documentation Improvement. Interestingly, there are categories in the United States which occur frequently that do not occur often in other countries. These include Health Consumer Engagement, and Clinical Documentation Improvement. Additionally, Health Data Analysis is frequent in the United Kingdom, Canada, Australia, and India, but is less frequent in the United States.

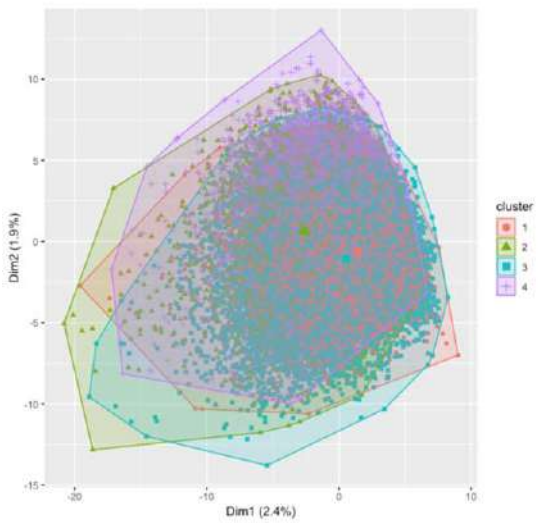

Figure 1 - K-Means Clustering of Job Postings

Discussion

This study demonstrated that jobs in health informatics and information management can be distinguished by key characteristics and there are differences across countries in the prevalence of jobs postings by these characteristics. In general, this study showed that job listings can be categorized into 4 distinct groups based on required skills and knowledge: technology focused; clinically focused; compliance focused; and sales/marketing/management focused. This approach is different than previously published initiatives to define needed competencies for the health informatics and information management workforce by the International Medical Informatics Association (IMIA), the Health Information Management and Systems Society (HIMSS) in cooperation with the European Union, the U.S., Australia, and Canada [5, 9-14]. The mapping of these can be found in Table 2.

	1	2	3	4
Clinical Documentation Improvement	100	627	236	138
Health Compliance	442	541	2249	2220
Health Consumer Engagement	110	64	763	30
Health Data Analysis	1119	184	1291	344
Health Informatics	249	268	155	11
Health Information Governance	325	232	674	135
Health Information Technology	2064	606	2651	460
Health Leadership	737	786	3941	1432
Health Project Management	1281	357	3538	1869
Health Research	923	1229	3197	400

Figure 2 - Heatmap of Job Postings Within Each Cluster Across Job Categories

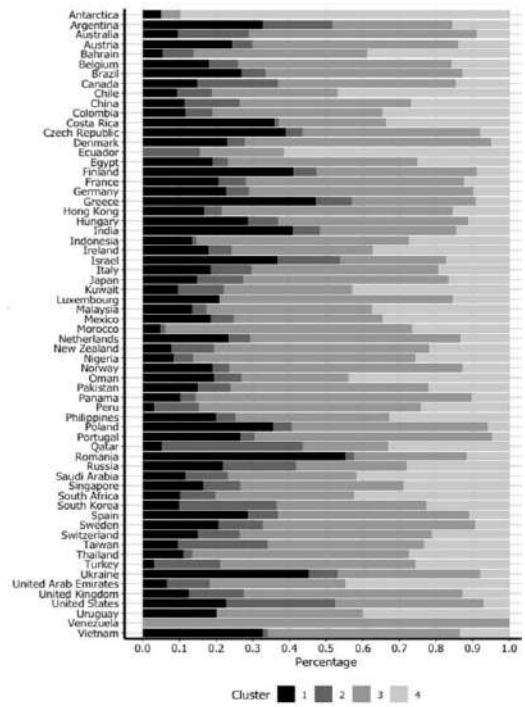

Figure 3 - Proportion of Job Postings in Each Cluster for Each Country

Global Comparison

In 2010, IMIA made recommendations for biomedical and health informatics education [9]. Interestingly, the IMIA domain area of informatics/computer science, mathematics, and biometry is closely related to technology cluster of this study, with the domain of medicine, health and biosciences, and health system organization related to clinical cluster. The third domain of the IMIA recommendations relates to foundational informatics knowledge and skills.

There has also been a cooperative effort between the EU and the U.S. to develop a comprehensive list of Health Information Technology Competencies (HITComp) [10]. There are 1,025 detailed competencies in the HITComp set, mapped to 15 domains. These 15 domains have 4 general categories of Administration, Direct Patient Care, Informatics, and Research/Biomedicine. This is consistent with the study's technology, clinical, and compliance clusters.

Table 2 – Mapping of Clusters to Competencies

Cluster & Focus	IMIA	HIT-Comp	CHIA	COACH	AMIA
1 – technology	XX	XX	XX	XX	XX
2 – clinical	XX	XX	XX	XX	XX
3 – business			x	x	
4 – compliance		XX	XX	XX	

Australasia

The Health Information Management Association of Australia (HIMAA) HIM Competency Standards (3rd edition) has three competency levels, from graduate entry through advanced practitioner [11]. The competencies are set within 9 domains, including clinical, management, terminologies and classifications, compliance, and technology. The Certified Health Informatician Australasia (CHIA) released the first edition of their Certified Health Informatics Competencies Framework in 2013 [12]. The CHIA framework is consistent with the technology, clinical, and compliance clusters, though CHIA includes project management in their management science domain, which is found in the business cluster of this analysis.

Canada

Canada's Health Informatics Association, COACH, has 7 categories of competencies [13]. As with the previous organizations, it includes content relevant to the technology, clinical, and compliance clusters. Consistent with the HIMAA and CHIA frameworks, it includes project management from the business cluster.

United States

The American Medical Informatics Association (AMIA) released a new set of core competencies in 2017 [14]. Very broadly drawn to include a variety of focus areas, the knowledge, skills, and abilities (KSAs) map most clearly to the technology and clinical clusters.
The American Health Information Management Association (AHIMA) also revised their core competencies as part of their HIM Reimagined strategy. The 2018 draft competencies expand capabilities across the areas of data analytics, auditing, and information governance [15].

Conclusions

Overall, the competencies currently articulated for educational programs by IMIA, the HITComp project, and associations in several countries, covers a majority of the terms found in job descriptions; however, sales and marketing are noticeably missing. Health informatics jobs are generally low, possibly due to a lack of standardized job titles in the informatics field.

When looking at the job categories, the majority of jobs are focused on project management, health leadership, and health information technology with fewest on health informatics, health consumer engagement, and clinical documentation improvement. The UK, Canada, Australia, and India have a greater prevalence of data analysis jobs compared with the U.S., which has a high number of consumer engagement, clinical documentation improvement, and information governance jobs. The findings from this study can inform HIIM educational providers about future skill requirements.

User -Centered Design of a Patient Medication Reconciliation Module in an Integrated Personal Health Record

Santiago Márquez Fosser[a], Janine Sommer[a], Mariana Simón[a], Liliana Giraldo[a], Fernando Plazzotta[a], Daniel Luna[a]

[a] *Department of Health Informatics, Hospital Italiano de Buenos Aires, Ciudad de Buenos Aires, Argentina.*

Abstract

With the adoption of Personal Health Records (PHRs) integrated with Electronic Health Records (EHRs) and the increase of accessibility to data, institutions have the possibility of exchanging medical information with their patients. Involving the patient reported data has the potential to improve the quality of care and safety and create a feedback loop between patients and health professionals. The objective of this study is to describe a user-centered design of a module for medication list with reconciliation functionalities managed by the patients themselves, and connected to their EHR for supervision and medical validation. We conducted 42 interviews (31 patients and 11 general practitioners). From the interviews, we performed qualitative analysis and extracted the main findings from comments in both groups. Correctitude rate was 57 to 100%, and satisfaction of use (SUS) maximum was 96% and 92%. These findings may be relevant to patients, health care providers, and policymakers.

Keywords:

Electronic Health Record, Medication Reconciliation, Personal Health Record

Introduction

The medication reconciliation is the process of obtaining the best, complete, and accurate list of each patient's current home medications including name, dosage, frequency, and route of administration, and comparing admission, transfer, and/or discharge medication orders to that list. The reconciliation is done to avoid medication errors.

The patient's medication list represents one of the most important components in the Electronic Health Record (EHR). It describes the pharmacological and non-pharmacological indications that the doctor prescribes medications to the patient, and provides the best list of medical indications that the patient has at that time. In the EHR, this list serves as a record, for the same prescribing physician, and his colleagues. The data are used to conduct research studies, indicate electronic prescriptions, and evaluate the quality of patient care and support decision-making.

The literature reports the existence of more than 50% of a discrepancy between the medication that patients take and their medical record [1–3]. Patients can discontinue their medications, change regimens when their symptoms improve or when they suffer an adverse effect, and do not report these changes to their doctors [4–6]. Moreover, medical specialists prescribe new medications or change previous regimens without notifying the attending physician [5,6]. The existence of discrepancies between the list of ambulatory medications recorded in the EHR and what the patient takes is a source of potential problems in health care, which may induce inadequate decisions by the treating team, generate side effects reactions, and exacerbations of comorbidities.

The international organizations such as the Joint Commission make accreditation and certification and are recognized as a symbol of quality and commitment to meeting performance standards. The organizations recommend that: "*Find out what medicines the patient is taking. Compare those medicines to new medicines given to the patient. Make sure the patient knows which medicines to take when they are at home. Tell the patient, it is important to bring their up-to-date list of medicines every time they visit a doctor*" [7].

New strategies should be considered to mitigate this situation. The reconciliation of medication is the process by which the best list of a patient's usual medication is elaborated to use that information in different areas of care, and provide the appropriate treatment. If a patient changes the scope of care, for example at home without requiring assistance or in the outpatient setting, and consults the ward for an acute event, it is critical to establish the reconciliation of the medication. Reconciling the last record taken from the list of habitual medications with what the patient or the relatives confirm through a series of questions, generate the best possible list. In this model, the patient or family members play a passive role in which the healthcare team asks them and compiles the list.

There are experiences with different strategies that reduce discrepancies, especially during the admission interview at the hospital [2,8,9]. One of them is involving pharmacists at the admission of patients. Pharmacists have a lower error rate in the registration of the list of drugs in the EHR, compared with doctors and nurses. Another strategy is incorporating a permanent education to those who make the prescriptions [2]. Researchers investigated the usage of patient-reported data in which patients are asked to review their medications, corrected them [5]. Afterward, a general practitioner validates this information and updates the data in the EHR [5].

The objective of this study is to describe a user-centered design (UCD) of a medication reconciliation module managed by patients, connected to their EHR for supervision and medical validation managed by physicians.

Methods

We carried out this descriptive study, which is a UCD of a medication reconciliation framework involving patients and doctors, in Hospital Italiano de Buenos Aires. For the UCD, we conducted iterative cycles of designing and testing with patients

on the reconciliation functionalities in the Personal Health Portal and to doctors for the EHR functionalities.

Setting

Hospital Italiano de Buenos Aires (HIBA) is a non-profit organization with 165 years of history in Argentina. Its healthcare network includes a university hospital of high complexity that covers health care for outpatients, inpatients, emergencies, critical care, home care, chronic care, and medical and surgical specialties. It has its medical insurance service (health maintenance organization), with more than 160,000 affiliates, and provides health services to 1,500,000 people with other health insurances. Annually, more than 45,000 patients are admitted to their hospitals, and 45,000 surgical procedures and 3,000,000 outpatient visits take place.

Since 1998, the HIBA has its own health information system (in-house) that includes the management of clinical and administrative information. Its EHR is an integrated, modular, problem-oriented, and patient-centered system, and is used in the different clinical scenarios (ambulatory, hospitalization, emergency center, and home care) [10,11]. As part of the information system, an integrated Personal Health Records (PHR) called POPES is available to all outpatients since 2007. The PHR allows patients to receive medical care in the hospital network, to access and verify clinical and administrative information, and to interact with the health system. Among its main functionalities, the PHR allows users to update their personal information, share information, manage scheduled appointments, view test results, check, order and buy prescribed medication, and the possibility to consult with the healthcare team through Telemedicine tools. Moreover, it has a messaging service for communication with the general practitioner" At present, POPES has approximately 400,000 registered users [12].

Medication reconciliation by patient

PHR currently has a module for patient medications that display prescribed drugs, generic and brand name, dosage, and prescribing physician. It also allows the patient to ask to deliver medication to their homes (purchasing). The number of patients who used this module from January 1, 2018 to November 9, was 90,977, and the number of medications purchased in the same period was 145,188. In this context, the redesign of the software incorporated new features.

We built the patient's medication reconciliation in the drug module in the PHR and integrated it with the prescription order entry of the EHR. This functionality consists of a new list of actions that is self-management by the patient in the system (load, modify posology, or eliminate medications on the list). After generating the patient-provided list, doctors viewed it in the EHR and validated or rejected it. A UCD methodology was used for the development of new functionalities in the medication module for both, the PHR (patient reconciliation) and the EHR (doctor validation).

User Centered Design

Health professionals and patients value health care software, but they demand better products that satisfy their clinical information needs [3]. According to reviews, many of the issues that prevent adoption and satisfactory use are related to poor design and low usability [1, 2, 8]. Usability is a measure of efficacy, efficiency, and user satisfaction [9]. Usability has been established as a key factor for applications that provide the needed support while focusing on their tasks [6]. Usable applications are easy to learn, efficient to use, easy to remember, not prone to errors, and subjectively pleasing to use [5]. UCD is an approach to achieve usable products introduced by Norman and Draper [4]. UCD has evolved from the human-computer interaction field, with the contribution of cognitive psychology, software engineering, sociology, and other disciplines that influenced it and developed methodologies that embody their points of view [6]. Usability engineering presents an iterative cycle of design and evaluation until the fulfillment of established quantitative goals measured on lab tests [5]. The contextual design includes ethnographic methods for user research while participatory design involves users by setting goals and exploring design solutions, instead of just taking part in evaluation [6]. UCD has been applied successfully to enhance the adoption and success of products [13].

However, these applications presented usability challenges described in the literature mentioned above. While the users valued the availability of online health records and tools for administrative tasks, they also noted the lack of desired functionality and difficulties to learn and use the tools. Therefore, the department implemented UCD in 2011, applying usability engineering, participatory design, contextual design, and a user-centered framework for redesigning health care software [14].

Prototype development

The design consists of different stages, which we will describe in this section. We start the prototype development from the design of the already existing medication module. To achieve an efficient design, with lower error rate and greater value for the user, we divided the design into 4 phases: *initial prototype design, initial usability tests* (for both, patients and doctors), *modifications in the prototype* (2nd iteration), and *final usability tests.* We tested the prototypes, in different iterations, through similar clinical scenarios, for a total of 31 patients (7 on paper and 24 digital) and 11 doctors digitally.

Phase 1: Initial prototype design

We designed the prototype using Adobe Fireworks, Illustrator and Balsamiq.

Phase 2: Initial usability tests

We displayed the prototype to 5 users (patients and GP), aimed to detect usability problems [15]. The objectives were identifying the user's level of understanding about the complete process of each task and measuring the ease of use. For both, patients and doctors, we used a desktop version.

Patient's usability tasks were:

1. Identify the module of medications in the home page
2. Add a new medication (e.g., Levothyroxine)
3. Modify the dose of recently added medication (e.g., Esomeprazole)
4. Remove an existing medication from the list (e.g., Amoxicillin)
5. Request a prescription renewal (e.g., Ibuprofen)

All of them divided into different hypothetical scenarios for better understanding. We provided the doctors with clinical cases specially designed for the test.

GP usability tasks:

1. Validate new medication (Levothyroxine) and generate a prescription with new credits.
2. Validate the elimination of a drug (Amoxicillin)

3. Validate the modification of dose for an already existing drug (Esomeprazole)
4. Reject Clonazepam suggested by the patient and justify it.
5. Reject Tramadol suggested by the patient and justify it. Replace it with another medication (Ibuprofen).

The test is an exercise for practice use. The user must read the task aloud and try to solve it. At the same time, they were requested, as the test went forward, to express what happens and comment on its interpretation. The session included 3 participants: the user, the observer who paid attention to the user and registered on paper, and the facilitator who moderated the test. Finally, at the end of the test, we conducted a final System Usability Scale (SUS) questionnaire to evaluate the satisfaction of use. During the interviews, we consented the users orally and recorded notes and audio their voices. We also recorded the video of the screen with MORAE software. In this way, we could record their interaction with the application while performing the assigned tasks.

Phase 3. Prototypes' modifications

Based on the tests, we modified the prototypes with the detected errors and created an updated design.

Phase 4. Final usability tests

After thorough preparation of the scenarios scripts for the new test, between August 2017 and May 2018, we individually contacted patients in the waiting room of the Health Plan of the HIBA and invited them to participate in the test. They were performed in an empty room, which physician usually use to see patients.

Between February and May of 2018, we individually invite GP from the Family Medicine Department to participate. The tests were performed on a laboratory version, with interactive PDF and were registered in Morae.

Results

The first version (Figure 1) proposed an update of the drug labels with the new features. It contained the "Add Medication" button, and the actions to modify, delete each medication previously prescribed by the physician.

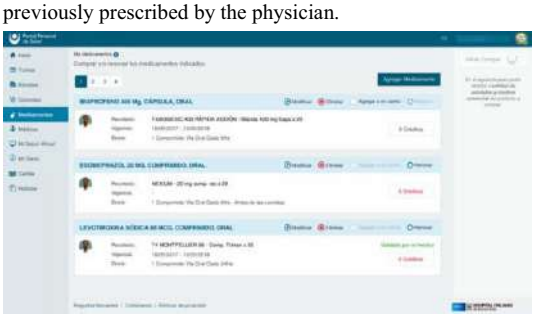

Figure 1– Initial prototype in the PHR

On the side of the GP, a new update prototype was displayed with different color under the title "Loaded by the patient", that was located at the top of the pre-existing prescribed medication list in the EHR. A "Validate" button was added to each new suggestion where the doctor had to enter it to decide what steps should be performed in each case (Figure 2).

Qualitative analysis

We performed a qualitative analysis for the registered notes and audio recordings from 31 patients and 11 physicians (end users). Characteristics of users tested are shown in Table 1.

Figure 2– Initial prototype in the EHR

Table 1– Characteristics of users tested

Variable	Value
Patients	31
Age average (years old)	52
Female	87%
Technology level*	77/100
General Practitioners	11
Age average (years old)	28
Female	
Specialty	72%
Technology level*	Family doctors (GP) 81/100
Total users	42

**Technology level was self-reported using a Likert scale.*

The main findings and comments during the testing were:

Patients:

- "It can be difficult for old people"
- "I find it useful but more for the doctor who does the control, not for me"
- "I do not know how long it will take the doctor to validate it, it should be automatically"
- "I think that could be of helpful, I would use it"
- "I do not know if I would use it, I'm not going to medicate myself"
- "I come from a different healthcare institution where everything is paper, this is wonderful"

Doctors:

- "Is going to add work to us"
- "There are doctors who do not want to prescribe medications indicated by another doctor"
- "It's good that they write it, it's easier and faster. That speeds up a lot"
- "I think it's good for patients to be able to promote autonomy, and contact more quickly with us"
- "It is useful. It saves the patient and the doctor time "

- "As a negative, you may lose the opportunity to explain to the patient why you would not indicate such medication that he suggests. e.g. He suggest clonazepam and I want to indicate something else"
- "I find it useful. It is good that there is a record of what the patient takes"
- "The change is very positive. Now, these things notify me by messages. In this way I have everything ordered"

The following findings were taken into account to make modifications on the initial prototypes:

- PHR: we included a medication search field and a print drug list button. We incorporated the possibility of uploading the medication photo for better identification. The main actions of the patient reconciliation functionality happened to have greater hierarchy, from being labels to buttons.

The fields of the medication identification were improved. We added brand name, dose, frequency, and prescribing physician. Moreover, we modified the main button of "add medication" by loading new medication. (Figure 3 and Figure 4). Table 2 presents the first 3 tests carried out with patients.

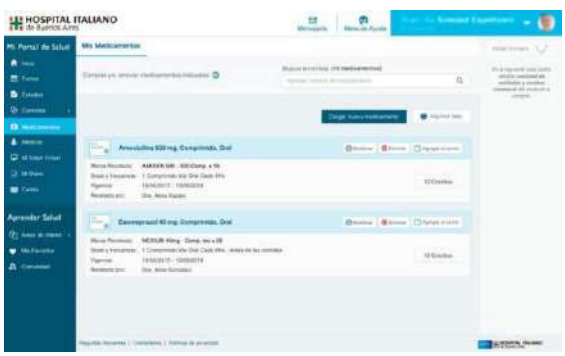

Figure 3– Final medication list. Patient view in the PHR

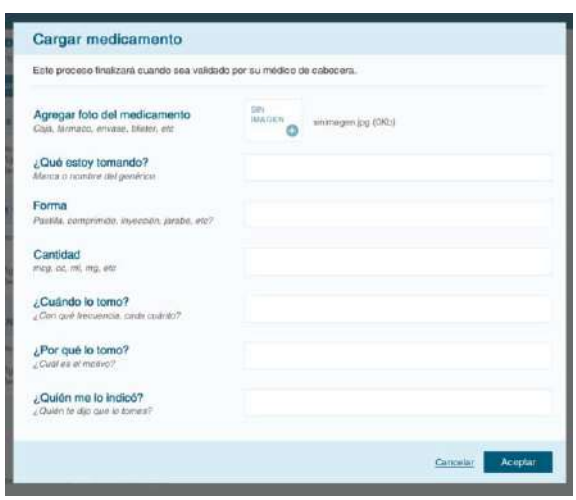

Figure 4– Patient view in the PHR (Recording a new medication):Patient should write the drug's generic or brand name, dosage, reason for prescription and prescribing physician (based on a FDA patient form to charge of a new medication) [16,17]

Discussion

Several articles have been carried out where patients were asked to review their medication list. Findings demonstrate that patients agree to correct their medication and review it effectively. Other studies concluded that the inclusion of a module with the medication list in PHRs improves the patient's medication list.

Figure 5– Prescription order entry on the EHR. In blue are listed the medication previously charged by the patient in the PHR and displayed here. Physicians have the ability to validate or dismiss changes

Table 2– Effectiveness of the exercise tasks

Task	Test 1 Correct %	Test 2 Correct%	Test 3 Correct%
Identify the module of Medications in the home page.	85%	88%	100%
Add a new medication.	71%	100%	100%
Modify the dose of recently added medication.	71%	88%	100%
Remove an existing medication from the list.	71%	100%	100%
Request a prescription renewal.	57%	100%	100%

The results of the SUS measurement of the medical and patients tests are shown in Table 3. For the first iteration, cycle we did not perform a satisfaction of use assessment.

Table 3– Patients and general practitioners satisfaction of use. Results of SUS

Number of iteration	Users	Number of users	SUS
1st	Patients	8	85%
2nd	Patients	3	93%
3rd	Patients	4	96%
4th	Patients	5	89%
1nd	Doctors	5	87%
2nd	Doctors	6	92%

Patients send an alert to updated medication prescription, but the doctors do not update the list. This problem could occur due to cultural, organizational, or relational problems, since professionals may have doubts when modifying the medications prescribed by another professional, or doubt about the information provided by patients [4,5].

In recent years, it has been proposed, as a strategy to improve the list of medication, that the patients themselves refine the list [5] since they know the medications they took in the past and the current medications. This model, with a vision of empowering patient in their care added to the correct use of the information systems, has a practical impact for the generation or modification of current computerized systems involving the active participation of patients in the medication list generation. The participation of the patient (or caregiver) is proposed as a fundamental element in the preparation of the best medication list.

We presented a user-centered design of a module of medication list with reconciliation functionalities and managed by the patients, connected to their EHR for supervision and medical validation. It is important to establish guidelines on these key activities to support the implementation in a hospital environment [18]. Our findings of SUS satisfaction of use in the final iteration (89% at 4th cycle, while 96% previously) demonstrate that we need to identify the probable cause and new modifications that will be necessary with re-testing of the final version.

Conclusions

This paper identifies the importance of involving primary care patients by integrating them into care processes and strengthening the doctor-patient relationship. A common issue on medication management arises when a patient is discharged from hospital. The study suggests possible modifications to the established models for medication reconciliation. The findings may be relevant to health care providers and policymakers who have an interest in encouraging patients to use PHR. This type of study could be replicated and extended in other settings to better understanding how to make the technology more useful for patients in their own health care.

Designing New Buildings to Accommodate Current Technologies

Ryan McNew[a], Elizabeth Weiner[a], Jeffry Gordon[a]

[a] *Frist Nursing Informatics Center, Vanderbilt University School of Nursing Nashville, TN, USA*

Abstract

Growing higher educational programs are always interested in adding physical facilities to their campus. Many times the initial plans do not include all the technology details needed for either a standard or a cutting-edge program. This paper describes planning and implementation efforts at the Vanderbilt University School of Nursing, which has resulted in a new 29,947-square-foot facility addition. The new space includes a complete floor designated as simulation laboratory space, an interactive classroom with five screens suitable for small group interaction, and a virtual classroom for cutting-edge multimedia production and transmission. Additional floors house both technology rich seminar meeting rooms as well as collaborative offices. All spaces are integrated using the innovative Crestron control system, including a multitude of their solutions that help to make this a smarter workplace that is both secure, smart, and worthy of completing educational goals.

Keywords:

Educational technology, distance education, organization and administration.

Introduction

Adding an additional facility into a school with a rich history brings challenges which are not always conceived in the early planning and design phases of the project. The Vanderbilt University School of Nursing (VUSN) has been providing quality education for nursing students since 1908 and distance education for over twenty years. The addition of a new building to the current facility brings the challenge of creating state-of-the-art spaces that not only provide a rich educational experience to our local students but also to our distance students. What we have found is that it is vital to have an informatics representative involved starting in the early planning stages and attend not only the Owners but also the sub-contractor's meetings. This representative needs to provide insight into what technologies (hardware, software, and networking) will need to be implemented into the new space as well as the requirements to make them function properly.

Prior to construction, VUSN consisted of three buildings, which were built at different times and housed all of the classrooms, simulation laboratory, conference rooms as well as faculty and staff offices. The total square footage for VUSN, prior to construction, was 79,304 square feet. The new building adds an additional 29,947 square feet for a grand total of 109,251 square feet. This presentation describes the lessons that we learned from not having an informatics representative involved from the beginning of the project, but also how we were able to ultimately achieve our goal of providing an educational experience, which utilizes the state-of-the-art technologies in the curriculum.

Throughout the years as technology changed so did the needs of our students, which meant that our educational spaces required upgrades. Technologies used in the everyday life of a student are expected to be used within the higher education environment to aid the student with developing their skills [1]. A major hindrance we discovered in bringing that technology is that due to the physical limits of the buildings, we were not always capable of implementing the latest technologies without significant costs. The new building was designed so that all of the buildings would connect, thus providing us with a means of upgrading several technologies used within the school.

Methods

Our biggest challenge was designing these new spaces without having any input into the architectural design of the facility. The informatics team at VUSN, led by Senior Associate Dean for Informatics Dr. Betsy Weiner, consists of twenty-eight individuals. Positions include classroom support, computer lab coordinator, network manager, web developer, graphic artists, general IT support, instructional designers, program coordinator, videographers, materials coordinator, videographers, media services, programmers, simulation staff, and informatics faculty. Due to the size of the informatics team, and because they are housed in Frist Hall, the name Frist Nursing Informatics Center has been given to them.

The first interaction with the new building was after months of designing and development had already taken place by the Owners and architects. There was zero input during the initial design phase from anyone within the Informatics Department. Our department received the completed floor plans and was given the directive to "make it work." When asked why our group was late to the planning, the leadership team responded that they didn't want "too many opinions at once." Unfortunately, that also meant that original budgets for fund raising purposes was not adequate for meeting the IT and simulation infrastructure needs.

Simulation Laboratory

The simulation laboratory, originally housed in a 1,290-square-foot space and located within Godchaux Hall, was to be relocated into a space within the new building which occupies an entire floor. The new space is over three times (3,932 square feet) the square footage of the original location. The original laboratory made use of a single, medium sized " L" shaped laboratory using rudimentary means with a large amount of imagination to run a simulation and zero control rooms in which the simulation is guided. Another classroom down the hall from the laboratory was being used for pre and post briefing sessions. During the post brief, the faculty could

only discuss the simulation using their recollection of events as well as that of students. Occasionally videotaped sessions were directed there so that group critique could take place, but there was no effective method to capture feedback for individual students.

The new simulation lab takes up an entire floor and consists of thirteen bed bays. Each bed has its own assigned control booth with direct line of sight to the bed. There is a large storage and prep room located in the center of the lab along with a complete computer setup allowing the simulation technicians to monitor the simulations in real time as well as aid faculty in the event they are needed. The facility looks like any hospital floor, complete with headwalls, hospital beds, simulated gasses, and computer monitors. Additional equipments can be rolled in from the storage room as required by the simulation. Curtains to block the sounds of the control rooms were also deemed important.

A barrier, which we encountered early on in the project, was that there was zero input from educators or technologists that would use or support the simulation laboratory. Another was that some of our floor space was taken up with main support structure for the building and could not be moved, providing some space constraints that we could not physically avoid. Our first priority was to ensure that it not only met the needs of the students, faculty, and staff, but also fit within in the confines of the new space we were given. After the initial design phase was complete, the informatics team was given the plans and tasked with developing a technology plan for a 13-bed simulation lab each with its own control room as well as two pre and post briefing rooms.

We quickly identified key members of the needed planning team. Participants included the Informatics Department (including the simulation staff who run the lab on a daily basis), and other faculty who are skilled in using advanced simulation within the Medical Center environment called the Center for Learning and Experiential Assessment (CELA). Initial discussion centered on revising the floor plan to better suit the running of complex simulations, complete with control rooms and simulation management software (B-Line Medical®). Additional considerations were noted so that faculty could best take advantage of all the factors the new facility would bring. Suggested revisions prompted several larger meetings with the Dean, architects and a smaller subset of the task force to discuss why the plans would not work as well as give our suggestions of change. This process repeated four times until we had a floor plan that would work for all parties involved. There was some initial resistance to taking this time due to the established opening date for the new facility, but the importance of a well-planned facility that met our needs was finally understood. Once the plans were finalized, we were able to focus on making the lab function properly.

The simulation lab utilizes a product from B-Line Medical®, called SimCapture which seamlessly captures audio and high quality video during the simulation encounter, streams live to faculty and students watching the simulation in real time, as well as records it for playback during the debrief and assessment sessions [2]. Students being recorded during their simulation experience then watched their experiences post-simulation and helped students learn by using active and contextual aspects from within the meaningful learning model [3]. Under optimal conditions, the equipment required to run the system should be on the same floor as the lab itself. Our simulation lab "server room," however, is located on the floor below the lab. Working closely with the audio/video (AV) integrator as well as the architects we designed the cable paths to run throughout the lab ceiling and then follow a conduit down into the "server room" below.

Each bed bay is equipped with a Stryker bed and over the bed table, two Axis cameras, two microphones, a functioning Amico headwall with simulated med gasses, vitals monitor, a computer with monitor and a B-Line SimCapture Node. Both monitors bedside are ELO Touch mounted to the headwall with custom Amico monitor arms. We installed a camera at the head of the bed facing the feet and another camera placed at the foot of the bed facing the head so that the entire simulation bed can be covered. The two ceiling mounted microphones use a cardioid polar pattern to pick up the audio bedside while helping to reduce the amount of ambient noise from other areas outside of the bed bay. Every bed has a functioning Amico headwall with simulated med gasses.

Figure 1- Bed bay

Each control room is equipped with one-way glass so that the simulation controller can operate the simulation while having a direct line of sight into the bed bay, a computer with dual monitors (with space permitting), headphones and speaker and a voice changer allowing the controller to alter his or her voice to fit the simulation happening bedside. For instance, a male faculty member could use the voice changer to sound like a female.

Figure 2 - Control room

We decided that it would be beneficial to build in redundancy. In order to ensure a simulation takes place, we designed the system so that any control station has the ability to operate any bed bay. For example, control room one could have a technical issue preventing the scheduled simulation from being performed; we now have the ability to utilize any unoccupied control room to monitor the simulation happening in bay one. The only downside is that the controller would lose direct line of sight.

In order to make this happen, we needed custom programming and additional equipment to ensure that the video and audio streams are routed from beds to control rooms. We contracted with a local integrator, Tristar Digital Connections, LLC, to provide all the equipment and programming. Each night at midnight, the system reboots and resets all of the streams to their default locations. In our "server room," we have the master controls for audio and video routing. The programming allows us to reroute the audio and video signals from any bed to any control room should a control room go down. The display uses a Crestron 10" panel and allows us to drag any bed from the top bank to any control room in the bottom bank. We also have the ability to reset all of the connections manually as a failsafe.

Figure 3- Server room

Wachtmeister Interactive Classroom

This classroom is unlike any classroom we have ever had as it flips the traditional classroom. A typical classroom has a lectern with a computer, feeding into a projector, which then projects the image, typically a PowerPoint presentation, onto a screen located behind the instructor. Students sit in rows of chairs normally bolted to the floor, they then take notes and watch the presentation. We chose to do none of that in this classroom in an effort to promote better student interactivity.

This classroom is equipped with five interactive ViewSonic, 4K displays each containing a blade PC, a PanaCast 2 panoramic-4K camera mounted on a fully articulating Triad-Orbit mount and a Crestron AirMedia 200; however, there is not a display located at the front of the classroom with the lectern. The Crestron AirMedia 200 allows our students to wirelessly present content from any of their devices such as laptops, tablets, and even cellphones [4]. The use of technology is what enables our students to become active learners and as such our nursing educators must also integrate technology into their curriculum [5]. Our main goal of using this technology was to embrace the interactive learning model by finding ways to have the faculty interact with the students and provide engaging content to the learning model.

During the design phase of this room, we developed multiple scenarios of potential use cases. The sole intent of this space was to develop learning environment where the faculty and students interact not only with the faculty, content but also amongst their peers during the class.

One such scenario developed was that this classroom would operate with the faculty starting class at the lectern by loading the lessons content onto the PC located within the lectern or onto a Microsoft Surface Pro. Using the controls located within the lectern touch panel control station or using a mirrored set of control on the Surface Pro, they are capable of sending the information to all 5 displays. The students can then cluster around any of the five displays and engage in the content with the instructor interacting with the student clusters.

Another scenario describes where up to five topics of discussion are identified. Students are divided into small breakout groups to discuss their specific topics and then to present their findings to the class during the class period.

Figure 4- 3 of the 5 displays in the Interactive classroom

For this scenario to work, we met with our integrator and discussed how we wanted the room to function: (1) each of the displays must be able to display the content from the lectern; (2) each display must be capable of displaying its own content; (3) we must be able to matrix the displays so that, as an example two of the five displays must have the same content, and the other three be able to have their own content; (4) students must be allowed to connect their devices to the display; (5) the faculty must be able to take any display and make it display onto any number of the displays. Our integrator came back with a solution that entailed over 60,000 lines of code to make the matrixing function using our guidelines. With the addition of the Crestron AirMedia we can allow our students to connect any device wirelessly to the display. Each display has a Crestron TouchPanel adjacent to the display; with a simple touch of a button the input for the display can easily be changed. The faculty have a master control, which allows them to control the input for each display, along with changing the matrixing.

Virtual Classroom

The concept behind the Virtual Classroom is for it to be more of a production studio than a typical classroom. We have found that there has been a growing demand for various types of recordings from faculty and students. The process to make a single recording happen was extremely labor intensive in regard to setup and tear down. Our team had no place to setup cameras, teleprompters as well as lights and leave the setup in place for any length of time due to the fact that we had to reserve classroom space for these recordings.

The space is a large corner room with windows facing both the street outside as well as the large open-air atrium on the right of the room. Our primary concerns were sound and light filtering into the space and causing detrimental effects on the production quality. Our first attempt to mitigate the effects was to request that the windows be blanked out (filled in). Our request was promptly declined due to it throwing off the aesthetics of the entire building. Our second attempt was to request blackout shades installed over every window that would be lowered while filming, that request was approved.

Due to being a LEED®- and WELL-certified building™, we were required to have regular offices lights in the space [6]. These lights do not provide satisfactory results for producing videos. We were able to discuss it with the architects and have the minimal amount of required lights as well as the ability to control them manually. Lighting was still problematic. Our solution was to remove the ceiling and paint it black at 9' above the finished floor (AFF). This exposed the deck and allowed us to install a grid system with electrical boxes located in numerous places around the grid to support the numerous LED lights for video production. This allows us to hang them in any configuration required for the video shoot. We also made the decision to hang the required office lights higher than the light grid to avoid the possibility of casting shadows.

Secondly, we were tasked with how to dampen the sound during recordings since all the walls were hard and flat causing sound waves to bounce off them. In discussing the situation with our AV vendor, we came up with the plan to add acoustic tiles around the peripheral of the room. These panels will help to absorb sound providing with the desired audio effect.

Thirdly, we had the possibility of having noisy equipment, such as light or sound boards, in the space during recording. Our solution to this issue was moving our Media Producer/Director's office adjacent to the classroom with a large pass-through conduit running from his office into the classroom. This solves the noisy board issue by having the equipment run from inside his office then passing the cables through the conduit into the classroom to the actual devices. The Media Producers office has one-way glass allowing him to see into the room but not distract the filming.

We also mounted a ViewSonic 4K Interactive display with blade PC on an articulating arm allowing us to angle the display to best suit the application. We also included a Crestron AirMedia 200 which allows any device to wirelessly connect to and display content.

This space can now be used for various scenarios; however, there will not be an audience in most cases. The question was how to get the content to our student population? We devised two different scenarios. Our first is that we would record and edit the video for dispersal at a later point in time, such as video on demand. Our second case was for doctoral defenses, which we could stream to larger classrooms. For this we used Crestron NVX, which provides streaming audio and video with no latency over a 1-Gigabit network connection to another NVX device located in another one of our classrooms [7].

Crestron NVX allows us to remove costly, large profile processors and adopt a more cost-effective means of sending and receiving data throughout the school. With one NVX node set to send and the other set to receive, we are able to send data HD (high definition) content across the network without latency; all while providing a large cost savings. Without NVX, we would have had to incur more costs by upgrading our switcher as well as a lot more AV wiring. To make use of the NVX environment, the user must give formal permissions for the content to be viewable by another group; our AV team then uses the NVX Director to establish a connection between the two or more rooms.

Seminar Meeting Rooms and Collaborative Offices

Both the Simulation lab and Interactive Classroom are technology laden and thus require some training in order to make full use of the space. We chose a unified and simplistic approach to the seminar spaces and collaborative offices. Each space makes use of the same ViewSonic 4K Interactive displays as well as the Crestron AirMedia 200 used within the Interactive Classroom. Each one of these rooms is also equipped with a Crestron NVX node allowing us to stream any of these rooms to any other NVX equipped room within the School of Nursing. Our objective was to create spaces using the latest technology while designing the space for ease of use to diminish the amount of tech support calls.

We accomplished this task by designing the spaces using the same technology in all collaborative spaces. This allows anyone within the Vanderbilt University School of Nursing to walk into any collaborative space and immediately feel comfortable knowing that the user will be able to operate the room as intended. Following the same layout design as the Interactive Classroom, we mounted one to two interactive displays, located next to each display is a Crestron TouchPanel controlling the inputs as well as a Crestron AirMedia 200 allowing the user the ability to connect wirelessly any device to share content. Numerous factors were taken into account to determine the number of displays required for a space as well as screen size and resolution. Factors considered were: size of room and content displayed (content such as detailed images maintains requirements much greater than that of a Word or Excel document). When two displays were required, we made the decision to install a Crestron AirMedia 200 with each display allowing both displays to show the same content or depending on the use case each display could be showing separate content.

Results

The various spaces discussed within this paper will be open for use early January 2019. The various, unforseen, delays during construction moved our opening from August 2018 until Janurary 2019. A short video will be shown during this presentation showing the Simulation Lab and Wachtmeister Interactive Classroom fucntioning and performing the tasks described within this paper, along with photos to show other spaces.

Evaluations will be given to both faculty and students in regards to ease of use and overall functionality of the systems and spaces. Results will be presented.

Discussion

It is anticipated that the results of the surveys will be positive from both the faculty and students. During the design phase we had input from many faculty within the VUSON, adjustments were made to the designs based off of their feedback. Our instructional designers were brought into the classroom space and asked to provide feedback on the design as well as to start the process of helping faculty to design course material utilizing the interactive of the space.

Feeback was taken into consideration and adjustments made based off of the feedback from all parties. There are numerous possibilities for altering how synchronous learning is administered within the school with a bleed over into asynchronous as well.

Conclusions

Technology is used to instruct our students; technology is constantly changing and so should the way the our learners are taught. Technology use, such as mobile technology, in education shows that it impacts the students learning objectives positively [8]. Interactive learning is happening on a daily basis, when parents hand their child a cellphone or tablet to play a game or watch an educational video, that child is learning using technology. We should not be satisfied with a learning model decades old and our students should not be either.

Nurses are known for their abilty to get things done when responding to situations, thinking quickly to find solutions to problems that are presented; technology can only enhance the abilily of nurses by provinding access to real-time data [9]. Why should we not use the latest technology to enhance the skillset of our students? In order to produce the highest quality students, they need to be exposed to as many different scenarios as possible. This is accomplished by bringing innovative ways to teach our students and expose them to scenarios not typically available.

We learned that administrators need to understand the detailed planning needed for both technology and simulation laboratory infrastructure early on. This message needs to start before initial plans are made, not after. Simulation laboratories are not well understood by those outside of healthcare (particularly the complicated networking plans) and cannot be stressed enough times to the installers. LEED® and WELL™ certified buildings are additional challenges that create need for compromise. Lighting and sound accomodations can be made that meet those requirements. In conculsion, while there are many details to be considered, a knowledgeable team of technnology professionals can help to add to the cutting-edge-facility in such a way that everyone is satisfied with state-of-the-art technologies that are innovative and useful.

Acknowledgements

The authors wish to thank DF Chase, Inc. Construction for their willingness to working with my team and accept our countless change orders on our first ever construction project. The Tristar Digital connections, LLC team without your expertise this project would not have gone as smoothly as it did. As well as all the Vanderbilt University faculty and staff that provided input into the project. While faculty and staff as of this writing occupy offices within the building none of the other spaces are yet open, they will be open in January 2019.

Abstract

Low-back pain (LBP) is a leading cause of disability globally. It is complex and multifactorial, with a miriad of factors interwining and interacting to burden healthcare and individuals. Self-management support is central as part of best-practice to improve outcomes. In recent years, informatics has increasingly been considered to support care; however, due to its complex nature, several factors need to be unpacked in order to consider how technologies might support LBP. The present study utilised semi-structured interviews involving N=20 participants (n=10 practicing clinicains and n=10 indidivuals living with chronic LBP (cLBP)) to collect user-centered perceptions and considerations for key factors central to technology succeeding in supporting cLBP. Six themes were identified: tracking, alterts, user-experience, communication, feedback, and content. Findings lay groundwork for future research aimed at developing technologies that can encourage shared-decision making in supporting cLBP management in a particpatory health paradigm.

Keywords:

Low Back Pain; Informatics; Self-Management

Introduction

Low-back pain (LBP) continues to be listed as the leading cause of disability according to the Global Burden of Disease study by the World Health Organization (WHO) [1,2]. This can be observed via years lived with disability, ballooning costs, opioid analgesic abuse, increasing service demand, poorer quality of life, and inability to work [3,4,5]. Fear-avoidance of movement and poor adherence to self-management are major challenges at the heart of clinical patient management and individuals' self-management of chronic LBP (cLBP). This condition continues to plague health professionals and individuals within a participatory health and shared-decision making paradigm to achieve good outcomes, due to its complex and multifactorial etiology, with significant physical and psychosocial effects underpinning its presentation [4,6,7,8].

With greater self-management support for those living with cLBP, there is an increased likelihood that [9,10]: return to work outcomes will improve; overprescribing of opioids will decrease; unnecessary referrals to public chronic pain services from primary care will be reduced, thus unburdening the public healthcare system; better treatment options and health outcomes can be provided to individuals in rural and remote communities with difficulty accessing services; private health insurance claims may decrease, allowing opportunity for premiums to be reassessed.

Informatics technologies have been considered in its management. User-centered and participatory health enabling mobile health technologies have previously been reported to have a positive impact on motivation, behavior change, adherence to interventions, and pain outcomes in this context [11,12,13,14].

Clinicians, researchers, and informaticians continue to consider digital self-management support technologies for a variety of presentations of LBP; for example, this includes wearable monitoring device for movement and posture detection, and motivation and adherence tracking applications. These have the potential to transform current practices by improving health literacy, thus promoting greater self-management and improved outcomes [15,16,17,18].

However, before further developments in the digital monitoring and support space for cLBP can be achieved, more research is prudent to ascertain key evidence-based, user-centered considerations, in order to gather value specifications and user requirements for technology from both clinicians who treat cLBP and individuals living with cLBP. The present study forms part of a larger project, whose ultimate aim is to develop digital technology to support outcomes for LBP. The present study reports on data collected from individuals regarding perceptions concerning what underpins safe, effective and empowering mobile and/or digital monitoring technologies for this cohort. In other words, what will be required for participatory health enabling technologies for them to have a significant effect on cLBP management?

Methods

The present study recruited clinical health care professionals (HCP) with expertise in managing cLBP and individuals living with cLBP to participate in exploratory telephone-based semi-structured interviews (SSIs) to discuss the complex needs of living with and/or managing cLBP, as well as perceptions around the use and utility of informatics technologies to support care.

The University's Human Research Ethics Committee has approved this project (ID: 2018/135).

Recruitment

Participants were recruited through various avenues, inlcuding: word of mouth, study recruitment posters in clinical settings, and the study investigators' clinical networks spanning public primary health care settings, tertiary multidisciplinary pain services, and private primary care clinics

Once individuals registered interest in participating in the study, they were directed to an online form that included the study plain language statement and screening questions, which then directed them to the informed consent form. The questionnaire screened particpants against study inclusion criteria (which, for eligible participants from the cohort living with cLBP, included completing the Oswetry Disability Index to confirm a self-reported diagnosis of at least moderate LBP), and collected baseline demographics for descriptive statistical purposes (e.g. age range, gender, employment status, clinical speciality, years living with cLBP, etc.).

Data Collection

Data was collected and recorded using SSIs. Interviews took on average 22.7 minutes to complete.

The broader research project is methodologically sound and underpinned in informatics methodologies central to the robust and successful design and development of technologies for digital health interventions. This includes underpinning the research in the rigorous and academically validated roadmap for developing technology in health, the "Centre for eHealth Research Roadmap (CeHRES)", which has been used in a sample of chronic pain patients [19,20,21] http://www.ehealthresearchcenter.org/wiki/index.php/Main_Page . The present study is part of the 'value-specification' stage of CeHRES.

Furthermore, Greenhalgh et al. [22] recently published a robust review proposing a novel informatics model to ensure that future interventions in digital health do not fail the nonadoption, abandonment, scale-up, spread, and sustainability framework (NASSS). The framework consists of seven inter-related domains that should be considered when developing technology for health to support success.

Using NASSS as the methodological underpinning for data collection, the present research is the first (to the investigators' knowledge) to appropriate NASSS into a qualitative data collection instrument to conduct interviews as part of the value specification per CeHRES [20,22]. Hence, this study's data collection tool is a unique offering in itself to the informatics knowledgement management community as well.

Data Analysis

Once conducted, interviews were transcribed verbatim. Inductive thematic content analysis (TCA) was employed to identify themes latent within the data [23]. This was because the primary goal of the present study was to explore and examine user-centered consideration for technology that supportted management of LBP. Thematic analysis aims to identify themes in a set of qualitative data in an attempt to give meaning to the common voices of collective participants [23]. As described, basic descriptive statistics were also collected to quantify simple closed questions, such as demographics and condition-related data.

Three investigators (MM, CM, and AP) analysed the first interviews to be transcribed to create a preliminary coding schema and MM then used this framework to analyse the data.

Results

Recruitment and Participants

The present study successfully recruited and interviewed a total of N=20 participants. This included an even cohort of n=10 clinical health professionals with expertise in managing cLBP, and n=10 individuals living with cLBP. A full prospective co-hort of N=27 were originally screened; however, after applying inclusion/exclusion criteria, five clinical health professionals were excluded due to lack of follow-up after pre-registering. Two prospective LBP patients were excluded for the reasons of lack of follow-up post registration of interest, and non-chronic LBP as per the Oswestry.

Participant demographics of those included can be seen in Table 1. As can be observed, health professionals came from a mixed background, were predominately male, between the ages of 30-39, with a wide range of clinical years of experience (3-25 years post-graduation), and skewed towards practicing in the hospital setting. Of participating patients living with cLBP, age range was also skewed towards 30-39, with an average Oswestry dis-ability score of 39.1 (range = 31.1-51.1).

Table 1 - Participant Demographics

	HCP (n=10)	Individuals with cLBP (n=10)
Gender		
Male	8	5

Age Range		
30-39	8	5
40-59	2	3
60-69	-	2
Level of Education		
High School or Less	-	4
College/University Completed	2	3
Post-Graduate Degree Completed	8	3

Thematic Content Analysis

A total of seven hours and 35 mintues of interview data was coded. Following the first round of coding, a total of n=52 codes were identified. This was broken down into n=31 individual codes from the health professional interview data, and n=21 codes from the cLBP cohort. This preliminary coding schema was conferred by the investigators and after a second round of coding, refined to group like codes into a resultant categorisation of n=6 themes common across both cohorts pertaining to digital technology for supporting cLBP. Of the n=6 resultant themes, these were broken down into sub-categories: N=19 identified by the clinical health professional cohort, and n=12 identified by people living with cLBP. Themes and sub-categories can be observed in Table 2.

Tracking

Participants from both cohorts idenitified the utility of any technological solutions to be able to track several metrics. For example, these may inlcude: activity tracking, other physiological metrics (i.e. inflammation, heart rate, etc.), posture, sleep, regimen adherence, and pain levels.

"I'd sort of think of something like that, where it feeds back and says oh, you're in this posture or you're in that posture, those sorts of things" (PRT05)

Alerts

Similarly, participants identified that a useful feature of digital technology to support cLBP would be to include alert/reminder features. This might include reminders to move or complete prescribed exercises, or further provide physical prompts and/or

motivating prompts to breath, move, and reinforce good behaviours. Of note, as opposed to the health professional cohort, patients suggested haptic prompts, such as vibrations or prods, which might reinforce positive behaviours or postures.

"..almost like a, you know when the Apple watches, they give you a little buzz if you've been sitting down for too long, that kind of stuff I would be really, I'd find that really useful" (PRT04)

User-experience

User-experience of prospective digital solutions was also featured in the identified themes. This referred to both the platform of any physical platform (which was overwhelmingly suggested to be app and smartphone based), as well as reference to more aesthetic and subjective features. Feedback included suggestions for any technology to be small, portable, wireless, visually appealing, insightful, lightweight, and durable.

Communication

Clinicians were more vocal around their desire for digital solutions that support LBP management to include robust communication features. Whilst individuals living with LBP also indicated that SMS or text messaging features would be useful, clinical health professionals were more direct in their suggestions, recommending secure messaging features, email capabilities, and even social networking features for patients to connect with one another.

Feedback

Feedback was another theme commonly idenitfied. Quite similar to the 'alerts' theme, at the heart of providing feedback, participants indicated that they believed any digital technology designed for this context would be valuable and useful if it were intuitive to positively reinforce positive behaviours. This might include providing insights and reinforcement around good posture, regimen adherence, and gains/improvements.

"I can imagine if you had a wearable device that was, like, you've been standing for X number of minutes and we know that your tolerance is four minutes and you've been standing for three and a half, you need to go and sit down.." (PRT05)

Content

Finally, but perhaps the most strongly represented theme, several codes described key content or, functionality that the technology should include. For example, the most obvious inclusion according to both health professionals and individuals with cLBP, was the provision of education resources that educated individuals about cLBP, its causes, progress, and management. Furthermore, health professionals indicated certain complimentary features, such as, the inclusion of educative (or demonstrative) videos, the ability to prescribe and view exercises from within an app, gamification features to enhance motivation and/or adherence, mental health components (i.e. coping strategies, pacing and mindfulness training), as well as one suggestion to be able to collect pre-screening patient data before they arrive for an appointment. Patients on the other hand, also indicated that teleconsultation features, such as video-based consultation ability with their practitioner might be desirable.

"If there was some application component around what chronicity does to pain, and how that changes how pain is perceived in your brain..that woud be beneficial" (HCP02)

Discussion

The data collected from the present study provides prelminary insights into the user-centered needs for informatics technologies that have the potential to support cLBP management. Findings indicate that both health professionals who manage cLBP, as well as individuals living with it, consider a range of factors when envisioning where and how informatics technologies might support management of the condition**, such as** being able to track progress, communicate, provide or receive feedback and reminders, and source educational content. Similar themes have been reported in a previous study [24]. The range of diverse themes identified (n=6) pertaining to techology to support cLBP further highlights the complexity of managing a condition like cLBP, with its mulifactorial nature [4,7,10].

Whilst both cohorts of participants (clinicians and individuals living with cLBP) provided data on the **six** themes, there was a slight difference in their individual perceptions or motivations underpinning these. For example, language pertaining to patient perceptions towards technologies surrounded their desire for technology to support active participation in self-management. Descriptive langauge used by participants pertaining to the sub-categories presented in Table 2 was quite 'active' in that it promoted active engagement in self-management (e.g. move, enter, log, reinforce, motivate, remind me). This supports literature in the participatory health domain, indicating that patients living with complex chronic conditions wish to be empowered shared-decision makers in their rehabilitative journey [14,16]. **Likewise, this** was also evident to some extent in comments from clinicians in describing their desire for technology to include robust communication features to enhance patient-practitioner communication, which has previously been reported to be beneficial [25]. Furthermore, patient comments commonly referenced their desire for technology that supports LBP management to focus on providing them motivation, feedback**,** and reinforcement to perform their exercises and rehabiltiation regimens. This was also broached by one clinician, who suggested gamification may be useful. These comments align to literature promoting best practice for LBP management, indicating that one of the primary factors in supporting the course of cLBP is to enhance

motivation, decrease fear avoidance, and thus improve adherence in order to generate positive outcomes [11,12].

Conversely, descriptive language regarding the same **six** themes as described by health professionals, depicts language that is skewed towards data presentation and key indices of disease-specific progress (e.g. physical activity, measure, monitor, angles, habits, questionnaires, insight, and pre-screening), which has also been previously reported [24]. Whilst this is not suggestive of a disconnect, it does suggest that clinicians and patients do have differing needs and perceptions regarding the utilitiy of informatics in supporting outcomes. Hence, it is recommended that these subtle nuances are taken into consideration when considering technology to support care.

Study Limitations

As seen in the demographics of study participants, the insights generated in this study represent opinions from a range of clinical health professionals. **Eighty percent** of data represents a cohort aged between 30-39, which suggests that data is not to be generalised to a broader age range. This is similarly cautioned regarding the sample size, as well as themes generated not being an exhaustive list**; h**owever, several methodological approaches were included in study design to support and control for these biases. For example, a) the study's clinical cohort represented clincians working in a variety of settings, with a range of years of experience, working in several speciality areas (i.e. pain management, general medicine, physiothera**p**y, occupational therapy, psychology, etc). b) individuals living with cLBP were screened for inclusion using the widely used and validated Oswestry Disability Index, in order to be more confident participants lived with a moderate degree of LBP [26]. c) The entire scoping of this research project **was** guided and underpinned by the validated and published informatics roadmap for digital health development, the CeHRES Roadmap [20]. Finally, d) To the investigators' knowledge, this is one of the first studies to utilise, adapt**,** and appropriate the recently published rigorous informatics methodology published by Greenhalgh et al**.,** NASSS [22]. The authors believe that by considering the 7 domains of NASSS, the relevant insights obtained from the data are in depth and well considered.

Conclusions

This work adds to the informatics community in several ways. A) It provides unique insights into person-centered considerations for developing technology to support LBP, b) it offers a novel appropriation of the well-regarded NASSS framework, and c) suggests that multiple facets of informatics can come together under a single model to conduct research that has the potential to improve healthcare: i.e. user-centered design, evidence-based practice, patient-reported outcomes, and informatics research methods.

The present study provides preliminary evidence of what clinicians and patients perceive to be central considerations for developing digital technology to support LBP. Whilst the study cautions against wider generalizability outside of the present conditions, its findings are underpinned by well-regarded and validated informatics methodologies and offers a novel approach to considering technologies to improve patient-reported outcomes in a participatory health paradigm.

Future research is planned and will progress to a larger project aimed at designing and prototyping technology in this domain.

Acknowledgements

The authors duly acknowledge participants who provided data, and Kieser Australia for supporting recruitment of particpants.

Abstract

Among American women, the rate of breast cancer is only second to lung cancer. An estimated 12.4% women will develop breast cancer over the course of their lifetime. The widespread use of social media across the socio-economic spectrum offers unparalleled ways to facilitate information sharing, in particular as it pertains to health. Social media is also used by many healthcare stakeholders, ranging from government agencies to healthcare industry, to disseminate health information and to engage patients. The purpose of this study is to investigate people's perceptions and attitudes related to breast cancer, especially those that are related to physical activities, on Twitter. To achieve this, we first identified and collected tweets related to breast cancer; and then used topic modeling and sentiment analysis techniques to understand discussion themes and quantify Twitter users' perceptions and emotions with respect tobreast cancer to answer 5 research questions.

Keywords:

Analysis, Breast Cancer, Social Media

Introduction

A report from the National Cancer Institute (NCI) indicates that one in eight women will develop breast cancer during the course of her lifetime [1]. An estimated 266,120 new cases of invasive breast cancers, and 63,960 non invasive breast cancers will be diagnosed in 2018 in the U.S. Among American women, breast cancer remains the second most diagnosed cancer, just behind lung cancer [2]. Nevertheless, a recent study shows that physically active women have a lower risk of breast cancer than inactive women [3]. Furthermore, for breast cancer surivivors, physical activities (PAs) have benefits on their mental health, physical conditions, and movement, which ultimatedly improve patients' quality of life [4].

Access to care, access to adequate health information, and health literacy largely remain to be significant issues especially in disenfranchised populations and minorities [5], despite improvements following the implementation of the Affordable Care Act (ACA). However, the widespread availability and uptake of Internet technologies across the socio-economic spectrum has the potential to facilitate health information sharing. Specifically, nearly 9 in 10 Americans have access to high-speed Internet and 7 in 10 use at least one social media platform [6]. Not only are private citizens widely using social media resources, but the various healthcare stakeholders, e.g. industry, governmental agencies, healthcare professionals, have been increasingly using these online platforms to disseminate health information, engage patients, and recruit for clinical trials. Social media platforms provide unique sources of essentially, an endless data stream, voluntarily shared by their users. These user-generated data provide unique insights into public health; and if mined appropriately, these data are invaluable for understanding various social and health issues.

Twitter is a particularly relevant and effective data source to understand how users' perceptions and attitudes towards health-related issues change over time. In our previous work, we used Lynch syndrome as a case study to show that Twitter can be used effectively to explore discussion topics, and how promotional information can impact laypeople's discussions [7]. In this paper, we describe our Twitter analysis pipeline, as it pertains to users' general perceptions and attitudes towards breast cancer and more specifically whether and how PAs were discussed in these breast cancer-related tweets. We specifically addressed the following five research questions (RQs):

- RQ1: How do people's attitudes (i.e., emotions) towards breast cancer change over time?
- RQ2: How do people's attitudes towards breast cancer differ across geospatial regions?
- RQ3: Can we identify latent topics/themes and topic trends in breast cancer-related tweets?
- RQ4: How does promotional information impact laypeople discussion themes over time?
- RQ5: How physical activities were discussed in laypeople's breast cancer-related tweets?

Methods

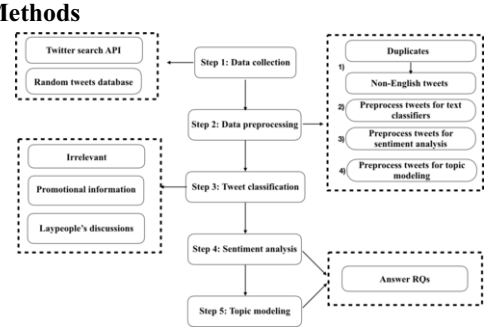

Figure 1. The Workflow of Our Twitter Analysis Pipeline

Our approach started with collecting tweets that are relevant to breast cancer discussions. We then classified these tweets into three groups (i.e., irrelevant, promotional information, and laypeople's discussions), assessed laypeople's attitudes (i.e., emotional states) using sentiment analysis, and explored latent themes using a topic modeling approach on both promotional and laypeople's tweets. Finally, based on the sentiment analysis and topic modeling results, we addressed the 5 RQs. Figure 1 illustrates our analysis workflow in 5 steps.

Step 1: Data collection. The data used in this study were from two different sources: 1) we collected breast cancer tweets from May 27, 2018 to October 13, 2018 (139 days) using a Twitter crawler based on a set of keywords related to breast cancer (e.g., "*breast cancer*" and "*#BreastCancerFighter*"). The keywords were generated through a snowball sampling process, where we started with seed keywords (e.g., "*#BreastScreening*" and "*#lumpectomy*"), then searched on Twitter with these keywords to retrieve a sample of tweets, evaluated the relevance of each tweet, and identified new relevant keywords. We did this process iterately unitl no new keywords were found; and 2) we used the keywords developed above to identify related tweets on a database of public random tweets, which we collected using the Twitter steaming application programming interface (API) from January 1, 2013 to December 30, 2017.

Step 2: Data Preprocessing. We preprocessed the collected data to eliminate tweets that were 1) duplicates across the two sources, or 2) not in English.

To develop tweet classification models (see Step 3), we preprocessed the tweets following the steps used by Glove [8]: 1) replaced hyperlinks (e.g., "http://t.co/xQgeMny5") with "<url>", 2) replaced mentions (e.g., @Channel9") with "<user>", 3) replaced hashtags (e.g.,"#breastcancer") with "<hastag>", and 4) all emojis were replaced with "<emojies>".

For sentiment analysis, we preprocessed the data with the following steps: 1) removed hyperlinks, 2) removed mentions, 3) converted hashtags into original English words (e.g., converted "#breastcancer" to "breastcancer"), 3) removed all emojies, and 4) geocoded each tweets with a geocoding tool we developed previously [9]. For topic modeling, we lemmatized each word and removed stop words (e.g., "this" and "is").

Step 3: Tweet Classification. Even though a tweet contains keywords related to breast cancer, the tweet may not be relevant to the breast cancer discussion (e.g., "*I am going to write #fiction about a 40+ year old mom with #oneboob who finds love and life's meanings who wants to read*"). Thus, we developed a two-step process with two classification models to categorize the massive amount of tweets into 3 groups (i.e., irrelevant, promotional, and laypeople's discussions).

We first annotated 1,774 tweets randomly selected from the overall dataset to create a training set. We then experimented with two different deep learning algorithms: convolutional neural networks (CNN) and long short-term memory (LSTM). We implemented both the CNN- and LSTM-based models in Keras on top of the Tensorflow framework.

A common strategy for building deep learning sentence classifiers is to use word embeddings to transform raw texts into vectors of real numbers as features. Thus, we initialized the embedding layer with a pretrained Twitter word embeddings (i.e., 100 dimension) from GloVe. The same feature matrics were used in the two-step classification process: one that categorized tweets into relevant vs. irrelevant, and another one that further categorized the relevant tweets into promotional information vs. laypeople's discussions. Models whith the best performance were adopted to classify the rest of the tweets.

Step 4: Sentiment analysis. The Linguistic Inquiry and Word Count (LIWC) is a text analysis tool, which can assess indivdiuals' attitudes through counting the percentage of emotional words used in a given text. LIWC has been used widely and its validity and reliability were validated [10]. We used LIWC on all laypeople's discussions to assess their attitudes/emotions in 5 aspects (i.e., positive emotion, negative emotion, anxiety, anger, and sadness).

Step 5: Topic modeling. Topic modeling is a statistical, unsupervised approach that can discover abstract themes in a collection of documents. We used the Biterm algorithm to find the main topics in all relevant tweets (i.e., combined both promotional information and laypeople's discussions). Different from conventional topic modeling approaches (e.g., latent Dirichlet allocation) that are based on word-document co-occurrences, Biterm learns topics by modeling word-word co-occurrences patterns, which performs better on short texts [11]. Although topic modeling is a unsupervised method, the number of topics is a parameter that needs to be determined *a priori*. Based on our previous work [7], to capture as many topics as possible, we set the number of topics as 100, visualized the topics in wordclouds, and then manually evaluated each topic's quality and merged topics with similar themes.

To answer our RQs, we also need to know the topic of each tweet. The Biterm model can infer the topic of a given tweet and return a list of topics and associated topic probabilities. We extracted the topic with the highest probability for each tweet.

Results

Data Collection

Our data came from two different sources as shown in Table 1. First, we collected 1,672,178 tweets using 32 breast cancer-related keywords and the Twitter search API from May 27, 2018 to October 13, 2018. After filtering out duplicates and non-English tweets, 1,467,783 tweets were left. Second, we used the same list of keywords to identify relevant tweets from a database of random public tweets we collected from January 1, 2013 to December 30, 2017. We found 257,045 tweets from this database, within which 167,205 tweets were written in English. Due to the different mechanisms behind the two Twitter APIs (i.e., streaming vs. search), the volume of the tweets from the two data sources were significantly different. For Twitter search API, users can retrieve almost all public tweets related to the provided keywords within 10 to 14 days (i.e., the exact time range is not published by Twitter); while the Twitter streaming API returns a random sample (i.e., roughly 1% to 20% varying acros the years) of all public tweets at the time and covers a wide range of topics. The number of tweets related to breast cancer in the random sample database was expected to be low. We plot the trends of the tweet volumes for the two sources separately as shown in Figure 2.

Table 1. Descriptive Statistics of the Two Data Sources

Data source	Data time range	# of tweets before pre-processing	# of English tweets	# of geotagged tweets
Twitter search API	05/27/2018-10/13/2018	1,672,178	1,467,783	428,041
Random public tweets	01/01/2013-12/30/2017	257,045	167,205	61,273

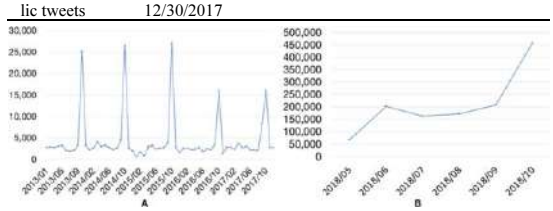

Figure 2. Breast Cancer Tweet Volume Distributions Across Time (A: random public tweets; and B: Twitter search API).

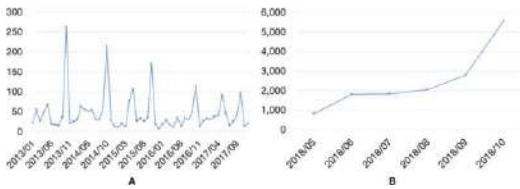

Figure 3. The Volume Trends of Tweets Related to Physical Activity in Laypeople's Breast Cancer Discussions (A: random public tweets; B: Twitter search API)

After integrating and eliminating duplicates and non-English tweets from the two sources, there were 1,634,988 unique tweets, in which 489,314 tweets can be geotagged to a US state.

To identify tweets related to PA from breast cancer tweets, a list of PA keywords (n=133) were developed through a snowball sampling process. Figure 3 shows the volume trends of tweets related to PA in laypeople's breast cancer discussions.

Text Classification

We explored two deep learning classifiers to category the tweets. Both CNN and LSTM have been wildly used in text classifications and achieved state-of-the-art performance. Table 2 shows the performance of the different classifiers and tasks. We used 80% of the annotated data for training and the performance was measured on the remaining 20% as an independent test data. As shown in Table 2, the CNN models outperformed the LSTM models in both tasks (i.e., 1) relevant vs. irrelevant; and 2) promotional information vs. laypeople's discussions). Thus, we adopted the CNN models as the final classifier.

Table 2. A Comparison of Classifier Performance

Classifier	Precision	Recall	F-score
Task 1: Relevant vs. Irrelevant			
CNN	0.886	0.851	0.865
LSTM	0.847	0.797	0.814
Task 2: Promotional information vs. Laypeople's discussions			
CNN	0.943	0.937	0.941
LSTM	0.914	0.898	0.903

The CNN models identified 1,466,292 relevant tweets (out of 1,634,988 breast cancer related tweets). Out of the 1,466,292 relevant tweets, 961,110 are tweets with promotional information and 505,182 tweets are laypeople's discussions.

Sentiment analysis

To answer RQ1 (i.e., "*How do people's emotions towards breast cancer change over time?*"), we assessed 5 emotion aspects (i.e., positive emotion, negative emotion, anxiety, anger, and sadness) of laypeople's breast cancer discussion tweets using LIWC. We visualized the changes of their emotion scores across time as shown in Figure 4. The Y-axis is the emotion scores generated by the LIWC. Even though there were fluctuations, the overall trends of negative emotion, anxiety, anger, and sadness have been decreasing since 2013 with significant Mann-Kendall test scores ($P_{trend} < .05$) as shown in Table 3.

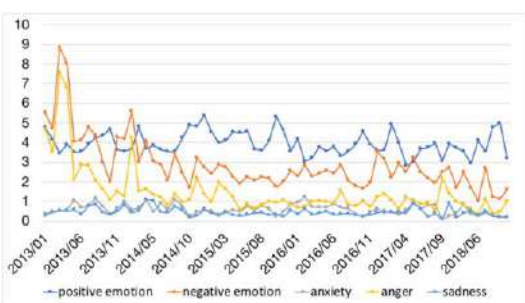

Figure 4. Laypeople's Emotion Changes by Time

Table 3. Mann-Kendall Tests of Laypeople's Emotion Changes

Emotion	P-value	Test-score	Trend
positive emotion	0.17	-1.37	not significant
negative emotion	<0.01	-5.45	decreasing
anxiety	0.01	-2.53	decreasing
anger	<0.01	-5.44	decreasing
sadness	0.01	-2.59	decreasing

We also compared the emotion scores of laypeople's breast cancer discussions across states, as heatmaps in Figure 5. The warmer the color, the higher the emotion score. People in Mississippi had the highest negative emotion and anger when they discussed breast cancer on Twitter. Delaware had the highest positive emotion. Hawaii had the highest sadness. Washington D.C. had the highest anxiety.

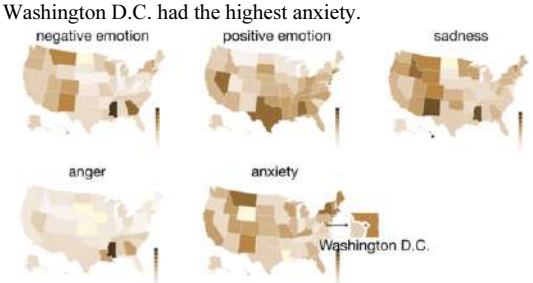

Figure 5. Comparsion of Laypeople's Emotions Towards Breast Cancer Issues Across States

We also analyzed laypeople's emotion changes over time by state. California (n=30,404) and Florida (n=17,983) had the highest number of breast cancer-related laypeople discussions, which gave us sufficient sample sizes to detect the trends. The trends of laypeople's emotion changes for these two states were decreasing as shown in Figure 6 and Table 4.

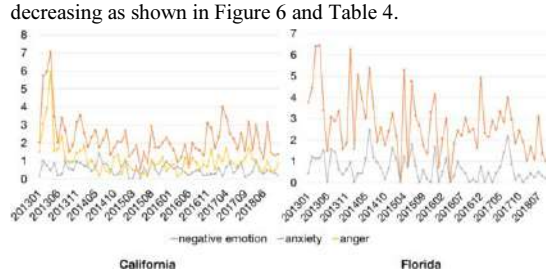

Figure 6. Laypeople's Emotion Changes by Time.

Table 4. Mann-Kendall Test o Laypeople's Discussions from California and Florida

State	Emotion	P-value	Test-score	Trend
California	negative emotion	0.01	-2.47	decreasing
	anxiety	0.02	-2.30	decreasing
	anger	0.03	-2.16	decreasing
Florida	negative emotion	<0.01	-3.09	decreasing
	anxiety	0.01	-2.60	decreasing

Topic modeling

To answer RQ 2-4, we used Biterm to discover the latent topics in our data. Based on experience from our previous work [7], we first set the number of topics to 100 to extract as many topics as possible. We then manually reviewed the 100 topics and a sample of associated tweets to assess topic quality and merge topics with similar themes. We summarized the 100 topics into 12 topics. The results are visualized as wordclouds in Figure 7.

The topic distributions of laypeople's discussions and promotional information are shown in Figure 8. Laypeople discussed more on the topics of "*family*", "*friend*", "*diagnosis*", "*food*", and "*treatment*"; while they talked less about "*risk*" and "*mortality*" compared with topics in promotional information.

Figure 7. 12 Topics Summarized from the 100 Topics Learned with a Biterm Topic Model.

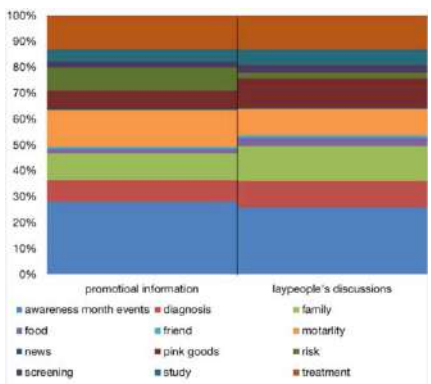

Figure 8. Topic Distributions by Tweet Type (promotional information vs. laypeople's discussions)

To exam the relations between promotional information and laypeople's discussions by topic, we used the random tweet dataset (spanning from 2013 to 2017) and calculated the Pearson correlation coefficient between the two (promotional vs laypeople) based on their monthly tweet volumes for each topic. As shown in Table 5, laypeople's discussions had strong correlations with promotional information on "*awareness month events*", "*risk*", and "*treatment*" and moderate correlations on "*diagnosis*", "*family*", "*friend*", "*news*", "*pink goods*", "*screening*", and "*study*". The monthly trends from 2013 to 2017 for these topics are shown in Figure 9.

Table 5. Correlations Between Promotional Information and Laypeople's Discussions Based on Tweet Volumes by Topic.

Topic	Correlation coefficient	P-value
awareness month events	0.711	<0.001
diagnosis	0.635	<0.001
family	0.682	<0.001
friend	0.526	<0.001
news	0.642	<0.001
pink goods	0.557	<0.001
risk	0.767	<0.001
screening	0.690	<0.001
study	0.683	<0.001
treatment	0.788	<0.001

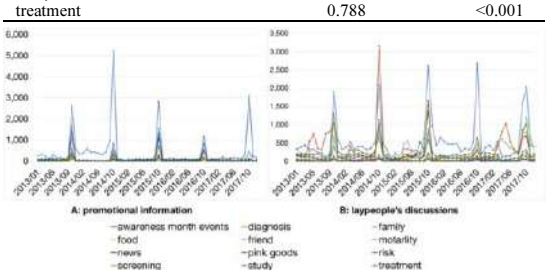

Figure 9. Selected Topic Trends from 2013 to 2017 with Significant Correlations Between Promotional Information and Laypeople's Discussions.

To answer RQ5, we first extracted all laypeople's breast cancer discussions that were aslo related to physical activites (PAs, i.e., discussions that contain PA-related keywords). We then extracted 100 topics using the Biterm method on these PA-related dicssuions. Similar topics were merged into one; and two themes emerged: give support (i.e., give support to breast cancer awareness through sporting events) and reduce risk (i.e., raise awareness that PAs can reduce breast cancer risks). The wordclouds of the two themes are shown in Figure 10; and a few example tweets for each theme are shown in Table 5.

Figure 10. Two Main Themes in Laypeople Tweets Related to Both Breast Cancer and Physical Activities

Table 5. Example of Physical Activity Related Tweets by Theme

Themes	Example tweets
A: give support to breast cancer awareness through sporting events	• *"I don't understand why it happened to me, but hope because I got cancer I can help bring about change." #BreastCancer survivor Shannon O'Fallon supports research with #Obliteride's 5K walk & urges others to help #curecancerfaster."* • *"On May 14th of this year I lost my older sister Ashley to breast cancer. On August 11th my family will walk in her honor"*
B: physical activities can reduce the risk of breast cancer	• *"Important to think about HOW we #exercise, #breastcancer incidence and relapse risk can be reduced by physical activity https://t.co/ajfew2wY5D"* • *"@RepDavidYoung I ran 91 miles in June. One of the reasons I run is bc it reduces my risk of recurrence of my breast cancer. O"*

Discussion and Conclusions

The goals of our study were to examine breast cancer-related discussions on Twitter and to understand people's percetions and attitudes towards breast cancer through their Twitter posts. We were also interested in assessing how promotional information impacts laypeople's discussions on Twitter. Thus, we used well-established text analysis approaches (i.e., sentiment analysis and topic modeling) on breast cancer-related tweets to answer our five RQs.

As shown in our results (Figure 4), laypeople's attitudes towards breast cancer changed from time to time. The overall trends of negative affects (i.e., negative emotion, anger, anxiety, and sadness) have been decreasing since 2013. There have been some controversial issues being discussed on public news outlets related to breast cancer prevention and treatments, which might lead people to think negatively. Taking the discussions on mammography as an example, mammography is a common way to screen for breast cancer as an early detection method. However, many people on Twitter questioned the effectiveness of mammography and raised concerns that it might bring overdiagnoses and overtreatments to patients. Nevertheless, as the negative attitudes are decreasing, it might indicate that stakeholders such as health organizations and agencies are doing a better job educating the public.

We also found that emotions in laypeople's breast cancer discussions on Twitter differ across the states. As shown in Figure 5, people in Mississippi had significantly higher negative emotion and anger when they discussed breast cancer-related issues on Twitter. Neverthless, further investigations are needed to find the reasons behind these state differences. For example, people's attitudes towards breast cancer maybe a reflection of breast cancer screening rates. Mississippi is one of the states with the lowest breast cancer screening rate possibly due to barriers for people to access screening programs. These barriers may lead to negative emotions

expressed in tweets (e.g., "*To cure a patient's disease at the cost of financial ruin falls short of our duty as physicians to serve*").

Laypeople's discussions were correlated with promotional information on a number of topics as shown in Table 5. These strong correlations might, from another perspective, indicate that breast cancer-related promotion strategies to raise public awareness have been rather successful in the past few years. Further, as observed in Figure 9, both promotional information and laypeople's discussions surged in October (i.e., breast cancer awareness month) every year, which suggested that promotional events in media (including social media) are effective ways to gain participants and raise public's awareness. Such raises in awareness would ultimately lead to improved health outcomes. For example, in early 1987, when the American Cancer Society started to focused on raising breast cancer awareness and before breast cancer became an official National Health Observances (NHO) event, only 26% of women in the U.S. had undergone a mammogram in the previous 12 months; while by October of the same year, the proportion had raised to 38% [12].

Over half of the women diagnosed with breast cancer gained weight during treatment with multiple reasons [13]. Chemotherapy often leads to fluid retention, reduced PA levels (due to pain and fatigue), decreased metabolism, and food cravings (that can reduce nausea). Nevertheless, breast cancer survivors should engage in a weight management program focusing on dietary intake and PA even during treatment, if manageable. There is clear evidence that weight management including PAs have a positive impact on mental health during and after cancer treatment [14]. As shown in Figure 10, we obtained two general themes from laypeople's breast cancer discussions that are also related to PAs: 1) people like to give support (to breast cancer awareness through sporting events), and 2) people are aware of the benefits of PAs that can reduce breast cancer risks. When we looked into these tweets in more details, we also found tweets from breast cancer survivors (e.g., "*@raceforlife Fully intended to do this (for the 5th year running; pardon the pun!!) but breast cancer diagnosis and treatment have run off with my fitness. Next year though!*"), which provides evidence data that social media might be a good source of information to study behavioral factors such as PAs related to improving surviorships including their quality of life (QoS). For example, we can further understand the barriers to adopting an exercise program among breast cancer survivors in our future work using social media data sources.

In sum, our study demonstrated that 1) social media such as Twitter are invaluable sources to provide insights into public and consumer health; and 2) natural language processing combined with machine learning are effective tools and methods to assess laypeople's attitudes changes in their health-related tweets, discover laypeople's perceptions towards specific health topics, and understand how promotional informaiton has an impact on laypeople's discussions.

Abstract

Medical information, such as physicians' descriptions, nursing records, and various examination reports, is stored separately in the subsystems of an electronic medical record (EMR). To provide efficient treatment, health professionals require a universal viewer that collectively organizes and visualizes this distributed information at each clinical phase (i.e., first outpatient visit, treatment, follow-up observation, etc.). This research investigates a method to enable physicians to easily browse relevant information at each clinical phase, and to reflect and verify information in a universal viewer. We analyzed the patterns of picture archiving and communication system (PACS) reference logs and EMR performed orders to identify relevant information. We found that by considering the locations of display terminals in addition to disease types (clinical departments) and clinical phases, more relevant information could be identified, and the contents displayed on a universal viewer were improved accordingly.

Computer-Assisted Therapy, Information Technology, Neoplasms

Introduction

Our institution is a specialized hospital for treatment of malignant tumors with 597 beds, approximately 2,500 outpatients per day, and 10,000 new patients per year. Physicians specialize by organ, such as head and neck, lung, gastrointestinal, urinary, breast, and so on, in addition to the divisions of internal medicine, surgery, psychiatry, and palliative care. Our hospital information system (HIS) consists of an electronic medical record (EMR) system and approximately 60 departmental systems, such as radiation, biochemical testing, physiological testing, medicine, surgery information systems, and so on.

To fully understand a patient's situation, physicians must display a plurality of screens, such as the EMR description, a record of the first visit, biochemical test results, images from a picture archiving and communication system (PACS), and a pathology report. Information must be manually organized and displayed before each instance of medical care for patients. This complicated task takes significant time away from the medical care that should be prioritized.

Therefore, we have been investigating methods to enable physicians to browse the relevant information (i.e., medical records, nursing records, examination reports, etc.) necessary for clinical practice [1-4]. Morgan showed that integrated information visualization can improve radiologists' use of clinical decision support tools [5]. Jorritsma investigated the usability of PACS by analyzing logs based on pattern mining [6]. De-Arteaga and Zeng showed the possibility of improving retrieved information by analyzing image queries [7,8]. Vest showed a difference in access frequency of radiology reports between outpatient and inpatient users [9]. Our previous research identified that clinical departments (disease types) and clinical phases (i.e., first visit, treatment, follow-up observation, etc.) are important parameters distinguishing the relevant information that should be displayed in a universal viewer [10]. This research investigates whether the information on location of display terminals (i.e., inpatient ward and outpatient clinic) from PACS logs can aid in identifying relevant content for physicians.

It was determined by the ethics committee (institutional review board: IRB) of our institution that a formal review by the IRB was not required for this research.

Methods

Data Set

PACS reference logs from April 1-30, 2018, in respiratory medicine, colorectal surgery, and breast surgery departments were analyzed. The PACS reference logs included the operating physicians' information and referred image information. The operating physicians' information included physician ID, reference date and time, physician department, and terminal IP address and location. Referred image information included patient ID, imaging date and time, modality, and region of images. Modalities included computed radiography (CR), computed tomography (CT), endoscopy (ES), mammography (MG), magnetic resonance (MR), nuclear medicine (NM), positron emission tomography (PT), radio fluoroscopy (RF), x-ray angiography (XA), and others (OT). Image regions included the chest, pelvis, abdomen, head, and breast.

Pattern Analysis of Image References

The number of image references were counted for each clinical department, clinical phase, location of image references, imaging modality, and region of images.

Clinical Phase of Image References

The clinical phases of each image reference were determined by the time of the references. Major clinical events (e.g., first visit, hospitalization, surgery, discharge) and their time were extracted from EMR performed order information. The interval between two consecutive clinical events was defined as a clinical phase (e.g., hospitalization – surgery) [10]. The clinical phase of each image reference was determined by comparing

the time of the image reference and the time of the patient's clinical phases. This research focused on the clinical phases of first visit, before hospitalization, during hospitalization, and after discharge.

Location of Image References

The location of each image reference was determined by the IP address of the display terminal. Locations were categorized into three types: outpatient clinic, inpatient ward, and others. This research compared image reference patterns in outpatient clinics and inpatient wards.

Frequency of Image References

To quantify the frequency patterns of image references by physicians, we counted the frequency of references to each image or combination of images referred to at the same time. A sequence of image references for the same patient within 30 minutes by a single physician on a single terminal was defined as *one reference*. The number of image references was then counted based on this definition.

Days Elapsed from Imaging

To investigate the time distribution of the images referred to by physicians, we measured the number of days elapsed between the imaging date and the reference date. Elapsed days were categorized as shown in Table 1. The range for each category was determined so that reference counts for each category were distributed nearly equally, and so that categories would be weekly or monthly. Figure 1 shows the number of image references in each category.

Table 1 - Categorization of elapsed days

Category	Range of elapsed days	Note
0	0	Same date
1	1 – 3	1 to 3 days ago
2	4 – 7	3 days to 1 week ago
3	8 – 14	1 to 2 weeks ago
4	15 – 21	2 to 3 weeks ago
5	22 – 30	3 weeks to 1 month ago
6	31 – 40	1 month to 40 days ago
7	41 – 60	40 days to 2 months ago
8	61 – 150	2 to 5 months ago
9	151 +	More than 5 months ago

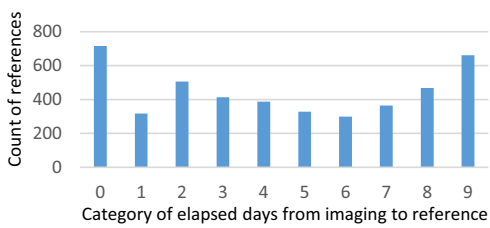

Figure 1 - Image reference counts in each category for days elapsed between imaging and reference

Combination Pattern of Referred Images

To analyze which images were referred to in combination, we analyzed combinations of images in one reference (defined above). The following three combination types were considered.

Type 1: Combination of elapsed days categories
Type 2: Combination of elapsed days categories and modalities
Type 3: Combination of elapsed days categories, modalities, and imaging regions

For example, when a physician referred to an abdomen MRI image from that same day (Category 0) and a chest CT image from more than 5 months ago (Category 9), Type 1 generated the combination (0,9), type 2 generated the combination (0_MRI, 9_CT), and type 3 generated the combination (0_MRI_ABDOMEN, 9_CT_CHEST). If only one image from the same day was referred to, Type 1 would generate (0), for example.

Comparison of Image Reference Patterns

The frequency of combination patterns of referred images was counted and compared among clinical departments, display terminal locations (outpatient clinic, inpatient ward), and clinical phases (first visit, before hospitalization, during hospitalization, after discharge). The relative frequency (ratio), as defined below, was compared.

Relative frequency (ratio) = number of image references for each combination / total number of image references

Analysis Environment

Python 3.7 was used on a computer running Windows 10 64-bit OS with 16 GB of memory.

Display of Relevant Information on a Universal Viewer

The combinations of frequently referred images were considered to be relevant information in each clinical phase and location. We developed a prototype universal viewer [11] that displays the frequent combinations of referred images at each clinical phase and location. The universal viewer displays modality images, reports, laboratory tests, image measurements, clinicians' descriptions, nursing records, and so on, switching the displayed contents to show those that are relevant at each clinical phase (Figure 2). The configuration of displayed content at each clinical phase and location was determined by the above method. The universal viewer runs on a web browser and can flexibly adjust to various sizes/resolutions of displays including multiple displays and tablet displays.

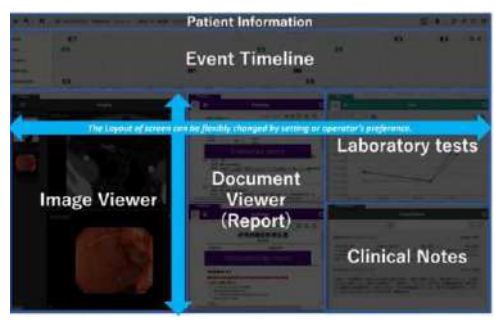

Figure 2 – Screen configuration of a universal viewer

Results

The total number of PACS image reference logs was 24,966. The total number of terminals with log records of usage was 234 (outpatient clinic 19, inpatient ward 121, others 94). Thirty-eight physicians used PACS (14 in respiratory medicine, 11 in colorectal surgery, 13 in breast surgery). The total number of

image references as defined in the Methods section was 3,331 (1,066 in respiratory medicine, 939 in colorectal surgery, 1,316 in breast surgery).

The results of pattern analysis of image references are illustrated in Figures 3-15.

At outpatient terminals, there were many cases of reference to an image from within one week alone, and to combinations of current and several months old images (Figure 3). At inpatient ward terminals, same-day images alone were most referred to (Figure 4).

Analysis of the reference information at outpatient and ward terminals with consideration of clinical phase showed the following tendency. At outpatient terminals upon first visit, there were many cases of references to images from within one week or from several months previous alone (Figure 5). At outpatient terminals after discharge, combinations of same-day images and images from 2 to 5 months ago were referred to (Figure 6). At ward terminals, the number of references was greater before hospitalization than during hospitalization. The reference pattern included images from various periods, particularly images from immediately before hospitalization (Figure 7). At ward terminals during hospitalization, same-day images alone were most referred to (Figure 8).

Adding clinical department as a parameter showed the following tendency. At outpatient terminals in respiratory medicine, same-day images alone or combinations of same-day images and images from 2 to 5 months ago were referred to most, regardless of clinical phase (Figure 9). However, images from a relatively long period were referred to equally at ward terminals (Figure 10). In colorectal surgery, recent images were referred to at outpatient terminals (Figure 11). At ward terminals, references differed before hospitalization (Figure 12) and during hospitalization (Figure 13). During hospitalization, same-day images were referred to. In breast surgery, images (mammography) from one or two weeks previous were primarily referred to at outpatient terminals upon first visit (Figure 14). Same-day images (nuclear medicine) were referred to during hospitalization (Figure 15).

Considering these results, the information display on a universal viewer was configured for each terminal location and clinical phase. Figure 16 shows a display for breast surgery at outpatient terminals upon first visit (left) and a display forward terminal before hospitalization (right). Figure 17 shows the difference in screen configuration between breast surgery (left) and colorectal surgery (right) during treatment.

Discussion

In previous research, physicians' behavior was analyzed by PACS operation logs or retrieval queries mainly to improve usability of PACS or image retrieval systems [5-9]. However, this research analyzed the PACS operation logs to investigate the method to display relevant information at each clinical phase. Specifically, this research showed that identification of the clinical scene (clinical department, clinical phase and the location of display terminals) and pattern analysis of physicians' image references (imaging date and time, modality, and regions of the images) at the clinical scene allow the universal viewer to display relevant information, which is effective for clinical decision support for diagnosis and treatment.

In our hospital, almost all patients are referrals from other hospitals. Cases in which a physician refers to an image from several months before the first outpatient visit are presumed to be references to the initial examinations at the patient's original hospital to verify the patient's status at the time of the initial diagnosis.

Images from before hospitalization are referred to at inpatient wards for conferencing and consideration of treatment policy. Images are referred to during hospitalization to confirm the treatment situation and conduct necessary immediate examinations. The results of this study's analysis reflect the clinical workflow in practice.

The finding that reference tendencies differ among clinical departments also reflects differences in the requirements of each department. The treatment period is longer in respiratory medicine, and confirmation of status during the course of treatment is important. Colorectal surgery and breast surgery require examinations for recurrence and confirmation of metastasis.

References to mammography images before hospitalization and to nuclear medicine images during hospitalization in breast surgery also reflect clinical practice, considering the burden of mammography on patients and the necessity of metastasis examination.

The limitation of this research is that PACS reference logs are available at the study level, but not the series level. Display of axial images of specific series, sagittal images, and fusion images according to disease condition and reference purpose warrants further investigation

Conclusions

This research showed that the location of display terminals (outpatient clinic, inpatient ward) in combination with clinical phase and disease type (hospital department) can potentially identify relevant contents for display on a universal viewer. The results warrant further investigation for the application of the proposed method to other clinical departments, clinical scenes, and diseases, given that a universal viewer is expected to improve the efficiency of medical treatment for various diseases, not only for specific diseases such as cancer.

The Handover from Intensive Care Unit to General Ward: Baseline Performance and Participatory Design of an Electronic Follow-Up Plan

Kija Lin Østergaard[a], Jesper Simonsen[a], Morten Hertzum[b]

[a] Department of People and Technology, Roskilde University, Roskilde, Denmark,
[b] Department of Information Studies, University of Copenhagen, Copenhagen, Denmark

Abstract

The transfer of patients from intensive care unit (ICU) to general ward involves risk to patient health. To mitigate this risk the present study investigates the current use of follow-up plans in the handover from ICU to general ward and proposes a novel design of follow-up plans. On the basis of a record audit we find that follow-up plans exist for only 16% of the audited transfers, that these plans are rarely used, and that 25% of the patients with a plan die within 24 hours of their transfer. In a subsequent series of participatory-design workshops with ICU and ward nurses we devised an electronic follow-up plan that consists of an attend-to list rather than a checklist. The attend-to list specifies the issues of concern but leaves the process of attaining them for the general-ward nurses to decide, thereby acknowledging and utilizing their expertise.

Keywords:
Patient transfer, Patient handoff, Electronic health records.

Introduction

Patients are habitually transferred from one clinical setting to another, such as from ambulance care to emergency department [1], from one ward to another ward within a hospital [2], and from hospital care to primary care [3]. These transfers involve risks of information loss [4], discontinuity of care [3], and adverse events [5]. To mitigate these risks, patient transfers are accompanied by handovers during which information about the patient is transferred to the receiving staff. In the present study we focus on the handover from intensive care unit (ICU) to general ward. This handover warrants attention because the patients arriving from the ICU will be among the weakest patients at the general wards and because the general wards have far fewer resources for monitoring and treating patients than the ICU.

ICUs cater to patients with severe, life-threatening conditions that require constant monitoring, advanced equipment, and specialist medication to sustain normal bodily functions [6]. As a consequence, the mortality rate is high for ICU patients. Table 1 shows the mortality rate for ICU patients in Denmark, the country in which this study is conducted. Not only do many patients die in the ICU, there are also many patients who die shortly after ICU discharge, and this pattern has been stable over the past several years. In the year July 2016 - June 2017 the 4% deaths within 48 hours of ICU discharge correspond to 986 patients. Temporally these deaths coincide closely with the transfer of the patient from ICU to general ward.

At the studied hospital the handover from ICU to general ward was facilitated by a follow-up plan made for the individual patient by the ICU nurses. The follow-up plan covered the initial 24 hours after transfer and consisted of a prioritized list of tasks for the nurses at the general ward, such as that the patient needed supplementary oxygen. For each task it was indicated when the task should be performed and whether there were special issues to consider. The day after the transfer the ICU nurse would visit the general ward to check up on whether the patient was treated according to the follow-up plan. In spite of the follow-up plans 4% of the patients died within 48 hours of their transfer, see Table 2. In addition, patient mortality within 30 days of ICU discharge was substantially above the national average (Table 1 vs. Table 2) and, thereby, called for scrutinizing follow-up practices.

Table 1 – Mortality of ICU Patients at Danish Hospitals

Mortality measure	2012-13 [a]	2016-17 [a]
In-ICU mortality	13%	11% (2958)
Within 48 hours of ICU discharge	4%	4% (986)
Within 30 days of ICU discharge	21%	21% (5966)

Table 2 – Mortality of ICU Patients at the Studied Hospital

Mortality measure	2012-13 [a]	2016-17 [a]
In-ICU mortality	15%	14% (91)
Within 48 hours of ICU discharge	4%	4% (23)
Within 30 days of ICU discharge	27%	27% (167)

[a] The12-month period July 1 - June 30. Sources: [7], [8].

In December 2012 the studied hospital installed electronic whiteboards at all wards to support interdepartmental communication and coordination. After the whiteboard had been installed the local clinicians were encouraged to configure it for their needs [9]. The whiteboard provided an opportunity to rethink follow-up procedures and introduce electronic follow-up plans instead of the existing paper-based plans. By using the whiteboard for coordinating patient transfers the follow-up plans would become more visible and interactive.

In this paper we report from our yearlong collaboration with the hospital to investigate existing follow-up practices and design electronic follow-up plans. While the former was achieved through a record audit, the latter involved a process of participatory design. We specifically ask:

- To what extent are follow-up plans made and used when ICU patients are transferred to a general ward?

- What should an electronic follow-up plan look like to support the transfer better than the current paper plan?

Systematic reviews of handover effectiveness recommend the use of electronic tools and of forms that systematize the information to be transferred, but they also report limited effects on patient mortality [4; 10]. In addition, studies of the nursing of former ICU patients show that general wards tend to feel overwhelmed by unrealistic demands [11; 12].

Methods

This study was conducted at a hospital in Region Zealand, one of the five healthcare regions in Denmark. The hospital had 250 beds and about 35,000 annual admissions. Before the study started it was approved by hospital management. The participants individually consented to take part.

Record Audit

To determine the extent to which follow-up plans were made and used we audited the records of all patients admitted to the ICU in 2012. First, hospital records were consulted to extract the patients who met our inclusion criteria, then local ICU records were consulted to obtain these patients' follow-up information. The inclusion criteria mirrored the criteria at the ICU for when follow-up should be performed. Follow-up could be initiated for additional patients at the ICU nurses' discretion, but we restricted our study to the patients who met the general criteria for follow-up. That is, we applied these five *inclusion criteria*:

- Patients >18 years of age, because people under the age of 18 were transferred to other hospitals if they needed intensive-care treatment.
- Mechanically ventilated >24 hours (invasively or non-invasively), because the complications associated with ventilation necessitated close monitoring of the patient after ICU discharge.
- ICU admission >72 hours, because the complications following ICU admission increased with its length.
- Unplanned transfers to a general ward in the evening or night (16:00-07:00), because the general wards had fewer staff resources during evenings and nights and, therefore, reduced capacity for unplanned tasks.
- Transfers to a general ward at the hospital, because follow-up was restricted to the hospital and, thus, did not cover patients transferred to other hospitals.

To avoid skewing the results of the audit we *excluded* patients transferred to the general ward for palliative care, because these patients had a high mortality rate irrespective of whether they were transferred from the ICU or from another ward. On the basis of these inclusion and exclusion criteria a total of 304 of the 946 patients admitted to the ICU in 2012 were included in the audit. The included patients were transferred from the ICU to three general wards: the medical ward for pulmonary diseases, the orthopedic ward, and the surgical ward. For each of the 304 included patients we inspected the records for information about whether a follow-up plan existed, whether it had been read at the general ward, whether ICU staff had made a follow-up visit to the general ward, whether the follow-up plan had been completed, and whether the patient died within 24 hours of the transfer to the general ward.

Participatory-Design Workshops

We applied a participatory-design approach [13] to investigate how an electronic follow-up plan could be designed to support the patient transfers. Following this approach, we aimed at engaging the nurses from the involved departments in mutual learning processes to investigate the realities and challenges of the transfer situation. By iteratively articulating their needs and discussing how these needs might be supported the nurses arrived at a design proposal for a follow-up plan integrated in the electronic whiteboard.

The participatory-design process involved the ICU and the three same general wards as in the record audit: the medical ward for pulmonary diseases, the orthopedic ward, and the surgical ward. To ensure the representation of all nursing staff from these four wards, 24 participatory-design workshops were conducted, each lasting 1-1.5 hours. The workshops were conducted by the first author and spread across day, evening, and night shifts. Each workshop was attended by 1-8 nurses, who were at the same time on call in case the busy clinical environment demanded their attention. Eight workshops were held at the ICU, six at the medical ward, four at the orthopedic ward, and six at the surgical ward. The workshops sought to identify the processes and challenges in the current paper-based ICU follow-up and to discuss ideas for how to address the challenges through an electronic version of the follow-up plan.

On the basis of the 24 workshops a preliminary design proposal was made. This proposal was presented and discussed at two subsequent 3-hour workshops attended by eight representatives, two from each of the four wards. The representatives included four managing nurses, that is head nurse, head nurse assistant, or clinical development nurse. At these two workshops the design proposal was thoroughly discussed and revised into a final design of an electronic follow-up plan [14].

Results

We first report the results of the record audit and then those of the participatory-design workshops.

Baseline Performance

Follow-up plans existed for only 48 (16%) of the 304 eligible patients. That is, follow-up plans were absent for 84% of the patients for whom such plans should have been present. In addition, Table 3 shows that the majority of the plans that did exist were not accompanied by a follow-up visit by an ICU nurse, not read by the staff at the general ward, and not carried through to completion. Because our exclusion criterion eliminated transfers to palliative care the 48 patients with a follow-up plan were expected to survive. However, 12 (25%) of them died within 24 hours of their transfer to the general ward.

Table 3 – Baseline Performance

Category	Number	Percent
Follow-up plan made by ICU	48	100
Follow-up visit performed by ICU	10	21
Follow-up plan read at general ward	20	42
Follow-up plan completed	15	31
Death within 24 hours of transfer	12	25

For all 12 patients who died the follow-up plans prescribed supplementary oxygen and lung therapy. Nevertheless, the cause of death for two of them was hypoxic heart failure (i.e., insufficient oxygen or lack of supplementary oxygen). For four of

the 12 patients the follow-up plans also prescribed physiotherapy in relation to dysphagia (difficulties swallowing; a common complication after invasive mechanical ventilation). However, the cause of death for two of these four patients was aspiration failure (i.e., food or fluids going down the windpipe). These findings suggest that a redesign of the follow-up plans might improve the handover from ICU to general ward and save lives.

Design of Electronic Follow-Up Plans

The participatory-design workshops revealed that follow-up plans were poorly implemented in the transfer of ICU patients to the general wards. The idea of facilitating the transfer with a follow-up plan was initiated by an ICU nurse who studied such plans as part of her continuing education four years prior to this study. The ICU managing nurse appreciated the idea of a written follow-up plan, asked the nurse to make a template, and arranged with the general wards to start using follow-up plans. The follow-up plan was introduced at the involved wards in 2008, but since then no systematic evaluation had been made. The follow-up plan was seen as an extra service provided by the ICU; no resources were specifically allocated to producing the plans.

The nurses, especially the ICU nurses, were astonished when they realized the poor baseline performance indicated in Table 3. The workshops uncovered that the follow-up plans were not integrated in ICU routines: Remarkably few were made and even fewer were followed up by visits at the general wards. The ICU nurses mentioned busyness and lack of management attention as primary causes, along with the experience that many of the follow-up plans they did make were not read at the general wards. At the general wards the situation surrounding the follow-up plans was also characterized by poor integration into work routines, busyness, and lack of management attention. In addition, plans were often displaced or not discovered by general-ward nurses. And the plans were generally considered confusing, overly detailed, and unrealistic. The main source of the perceived lack of realism was that the prescriptions in the plans did not fit the conditions and practices of the general wards, especially their staffing (up to 20 patients per nurse). Therefore, the participating nurses from all wards welcomed the initiative to redesign the follow-up plan and its integration into their work practices.

The workshops investigated two different paths for the redesign of the electronic follow-up plan: the checklist and the attend-to list. The checklist reflected an attempt to turn the paper-based follow-up plan into an electronic substitute with similar features. The initial 24 workshops followed this path. At the two final workshops the checklist design was challenged and revised into the attend-to list.

The paper-based follow-up plan was a checklist that contained evidence-based tasks for the general-ward nurses to perform. As such the paper-based plan followed an approach that originated from aviation and formed the traditional way of handling patient safety issues in healthcare, especially in relation to surgery [15]. A checklist is a cognitive aid that supports memory recall during high-stress situations. It seeks to regulate and standardize processes in order to comply with best practices and reduce errors [16]. A checklist-based follow-up plan functions as an aide-mémoire with a list of specific actions to perform and boxes for ticking off each action when completed.

In designing the electronic follow-up plan the ICU nurses established a base list of all the tasks it could potentially be relevant to include in a specific follow-up plan. This base list was largely adopted from the work leading to the paper-based plan. To create a specific follow-up, plan the ICU nurse would walk through the base list and select the tasks relevant to the patient in question. The proposed design of the electronic follow-up plan included a facility on the electronic whiteboard in the ICU for creating the plan from the base list. When the patient was transferred the follow-up plan would become available on the electronic whiteboard in the general ward. The general-ward nurse responsible for the patient would then follow the plan and indicate the completion of its tasks by signing them off on the whiteboard. This way the administered care would be registered, and it would be made visible how far care had progressed toward completion of the plan. For example, the provision of lung therapy through continuous positive airway pressure (CPAP) would be specified as a task to be performed at 06:00, 10:00, 14:00, 18:00, 22:00 and 02:00 for at least 5 minutes, with a box to tick off the completion of each CPAP instance.

At the two final workshops the general-ward nurses raised concerns about the checklist-based design proposal. They felt that their professional integrity was compromised, and their competences questioned. The rigid checklist format was perceived as the ICU nurses stating in detail how the follow-up process should be performed, as if the general-ward nurses were novices. Furthermore, the checklist prescribed actions to be done according to ICU routines. The general-ward nurses were responsible for performing the tasks on the checklist, but they were not able to do it according to the detailed instructions in the proposed follow-up plan. The prescribed follow-up process did not align with the staffing and routines of the general wards. As an example of misalignment with general-ward routines, the ICU and the general wards calculated the patients' fluid balance at different times during the day. Thus, when a patient was transferred either the ICU or the general ward had to recalculate the patient's fluid balance. The times at which fluid balances were calculated depended on the time at which the nurses in each ward started their shifts, on their workload, and on the need to align their activities with those of other clinicians, such as the physicians' medical rounds. The differences in work contexts and the associated difficulties for the general-ward nurses to comply with the detailed task prescriptions in the follow-up plan were considered main reasons for the non-use of the paper-based plans. The general-ward nurses were compelled to perform only those tasks that were practicable under general-ward conditions and leave the rest of the follow-up plan undone. This problem was not addressed in the checklist-based proposal for an electronic follow-up plan. Rather, it was aggravated by timestamping the general-ward nurses' activities and, potentially, giving the impression of non-compliance and low quality.

To resolve the problems with the checklist-based plans the participants at the two final workshops redesigned the electronic follow-up plan into an attend-to list. This list itemized the issues that required the general-ward nurses' attention. While the list specified the issues of concern, it left it to the general-ward nurses to decide how best to attend to these issues within the constraints of the general ward. That is, the attend-to list described the pursued goals and left the process required to meet these goals for situated specification by local actors, see Table 4. For example, balancing a patient's fluids could be described as maintaining a fluid balance that was positive by 1000 ml. As another example the avoidance of aspiration could be described as regaining the patient's swallowing function or mobilizing mucus, rather than by prescribing when and how to perform CPAP. The workshop participants felt that the attend-to list supported the general-ward nurses' memory and optimized the communication between ICU and general ward, thereby preserving the positive features of the checklist. The ICU nurses were to select the issues of concern from a base list. This approach would make the selection quick for the ICU nurses and

safeguard against accidental omissions. The final design included a base list of 39 issues – seven of which with links to standard clinical guidelines – arranged under five overall tasks.

Table 4 – The Checklist Compared to the Attend-to List

The checklist	The attend-to list
Process-oriented	Goal-oriented
• Prescribes the process of a task but not necessarily its goal	• Describes the goal (issue of concern) without prescribing the process
Controlled processes	Contextual processes
• Processes are standardized to bolster quality and safeguard against errors	• Process decisions are left to the nurse's discretion in the given context
Novice-oriented	Expertise-oriented
• Relies on instruction to tell the general-ward nurse how to care for the patient	• Relies on the general-ward nurse's competence to decide how best to proceed

Discussion

Our results (a) document the risk associated with the handover from ICU to general ward at the studied hospital, (b) reveal a handover reality that is quite different from how it was perceived by, especially, the ICU nurses, and (c) provide a novel design of electronic follow-up plans that consist of an attend-to list rather than a checklist. A follow-up plan existed for only 16% of the audited patient transfers. Furthermore, as much as 25% of the patients with a follow-up plan died within 24 hours of their transfer; in several of these cases the cause of death suggested that the general-ward nurses had remained inattentive to information specified in the follow-up plan. Thus, it is evident that improved handover practices are needed in the ICU, which is responsible for making the follow-up plans, as well as in the general wards, which are responsible for the patients after their transfer.

The present study highlights that handover procedures such as follow-up plans must cater to the differences between the ICU and the general wards. This finding echoes previous studies. For example Kauppi et al. [12] observe that the "gap between how care is structured and practiced in a general ward in comparison with an ICU requires adaptation of care in order to ensure a smooth transition", point to the need for "the best possible preparation and collaboration between the nurses at the ICU and the nurses in the general wards", and suggest to "improve the reporting and documentation prior to the ICU discharge." Similarly, Enger and Andershed [11] emphasize the importance of a good handover report and observe that the general-ward nurses "often found reports to be suboptimal, without a clear caring plan for the patient, or too long, containing too much information about the procedures and medications given in the ICU." The present study shows that failing to heed these insights may have fatal consequences for the transferred patients.

The participatory-design workshops with nurses from the ICU and three general wards constitute an extensive collaborative effort to reflect on the transfer situation and propose ways of improving it. The importance of a collaborative approach has previously been stressed by Enger and Andershed [11], who "encourage an interdisciplinary dialogue" by observing that the general-ward nurses "lacked a greater understanding of the work in the ICU", whereas the "ICU nurses did not understand how much work they had to do on the general ward."

The main result of the participatory-design workshops was the realization that checklist-based follow-up plans were suboptimal, and the design of an alternative based on attend-to lists. A checklist-based follow-up plan imposes a specified process on the general ward. The general-ward nurses perceive this approach as being treated like novices when they struggle to apply the prescriptions from the ICU. As Bosk et al. [17] note they "come to feel that checklists undermine their claims to expertise." The limitations of the checklist-based approach are consistent with how Markus [18] characterizes the knowledge reuse situation of the expertise-seeking novice. The contextual differences between the ICU and the general wards result in a follow-up plan with de-contextualized prescriptions that could easily be re-contextualized back into the ICU but were near impossible for the general-ward nurses to re-contextualize into their work.

Instead of the checklist-based plan the workshop participants propose an electronic follow-up plan based on attend-to lists. This alternative acknowledges the differences between the ICU and the general wards by avoiding detailed process prescription. At the same time the attend-to list enables the ICU nurses to convey their expert knowledge about the patient to the general ward in terms of specified issues of concern. The attend-to list specifies the goals (e.g., maintaining a fluid balance that is positive by 1000 ml) but leaves the process of attaining and sustaining them for the general-ward nurses to decide. Thereby, the attend-to list also acknowledges and utilizes the general-ward nurses' expertise.

The checklist and attend-to list represent two very different strategies for supporting the handover. Checklists subscribe to the same line of thinking as accreditation, a quality-improvement strategy that has dominated the healthcare sector in Denmark for more than a decade [19]. That is, checklists value behavior control [20] and aim to improve quality by standardizing work processes [21]. Conversely, the attend-to list corresponds to outcome control [20] and aims to ensure quality by leaving the decisions about how to conduct work in the hands of trained and skilled individuals [21]. The former is effective when the work can be planned in detail, while the latter is effective when the work is characterized by frequent exceptions and the need for situated adjustments. The attend-to list acknowledges the reality of a "gap between how care is structured and practiced" [12]. This gap limits the possibilities for pre-planning the patient transfer from ICU to general ward. Instead, the proposal to base follow-up plans on attend-to lists leaves the process of deciding how to handle the issues of concern to the discretion – and expertise – of the nurses at the receiving ward.

In interpreting the results of this study, it is important to remember its limitations. First of all, the attend-to list has been devised but its use has not been evaluated in clinical practice. Such evaluation is important future work. The present study provides a baseline against which to compare the results of introducing follow-up plans that consist of attend-to lists. A second limitation is that this study is restricted to one hospital. While its above average patient mortality within 30 days of ICU discharge calls for improving handover practices, it may also indicate differences in the composition of the patient population compared to other parts of Denmark. Such differences may, in turn, influence the work in the ICU and general wards. The handovers at the studied hospital are, however, complicated by issues similar to those discussed in previous studies.

Conclusions

Discharge from the ICU involves risk to patient health. At the studied hospital 25% of the patients for whom the ICU has made a follow-up plan die within 24 hours of their transfer to a

general ward. Part of the reason for these deaths is that the follow-up plans fail to consider the staffing and other practical realities at the general wards and, therefore, mostly remain unread or uncompleted. An alternative design of the follow-up plans was devised in collaboration with ICU and general-ward nurses. This design made use of the electronic whiteboard already in use across the hospital and consisted of an attend-to list rather than a checklist. The attend-to list specifies the issues of concern and leaves it for the general-ward nurses to heed these issues in the way they deem right on the basis of their situated understanding of general-ward work.

Acknowledgements

This study was co-funded by Region Zealand and the studied hospital. In the interest of full disclosure, we declare that prior to the study the first author has worked as an ICU nurse at the studied hospital. Special thanks are due to the workshop participants.

Abstract

Improving visualizations in clinical quality reports and dashboards may improve the visualization influence on clinical practice. Tailored displays could accommodate individual and situational differences, but these diplays introduce complex requirements across healthcare professionals and teams. We applied user stories, a method for managing complex software requirements, to a user-centered design process for tailored visual displays about postpartum contraception care. We mapped user stories to tailored displays to identify the quantity of displays that were supported by each user story. We developed 9 tailored displays and 11 user stories. Displays varied in their mappings to user stories (mean 5, max 9, min 0), revealing differences in healthcare professionals and teams preferences and information needs. User stories and user-centered design may be useful for healthcare organizations to manage complex requirements of tailored displays in clinical practice feedback.

Keywords:

Feedback, quality improvement, software design.

Introduction

Clinical quality reports and dashboards are widely used to communicate about clinical performance to healthcare professionals and teams [1,2]. Visual displays, such as charts, graphs, and tables, are a central component of dashboards and performance reports because of the ability to reduce the cognitive burden required to understand performance data [3,4]. However, evidence about the use of these reporting tools as feedback interventions to change practice shows a wide range of results [5], suggesting that ideal conditions may exist under which performance feedback is highly influential on clinical practice.

An approach that may achieve ideal conditions is the tailoring of feedback reports where population-level practice feedback could deliver prioritized, actionable information [6]. Tailoring information has been demonstrated to improve cognitive processing of messages and the effects on motivation in the field of health promotion and communication [7]. Tailored feedback could accommodate provider differences such as numeracy and graph literacy, which can vary among healthcare professionals [8,9], and to accommodate changing priorities based on evolving gaps and trends in quality measures. Tailoring feedback requires representations of individual and situational difference characteristics that may change over time across healthcare professionals and teams.

User stories are a method for managing software requirements in complex and dynamic environments from the agile software methodology [10]. A key feature of user stories is that they associate a specific software function (what) with a specific user (who) and a rationale (why). User stories have been applied in an agile approach to clinical decision support [11] and quality dashboard development [12], but to our knowledge have not been applied to the development of feedback reports for the purpose of tailored messaging.

User-centered design is increasingly used in healthcare to develop information resources, including performance feedback reports [13]. We applied user-centered design methods to develop prototype clinical quality feedback reports for healthcare professionals and teams in a department of obstetrics and gynecology at an academic medical center. The focus of this work was to support the implementation of a new practice of offering immediate postpartum long-acting reversible contraception (IPLARC) to patients. The objective of this study was to explore how user-centered design and user stories could support complex requirements management for tailored displays of clinical performance.

Methods

Setting and Participants

This work was done in an academic department of obstetrics and gynecology that provides clinical quality feedback to approximately 40 providers in a regional health system with 8 clinics in the midwestern United States. Healthcare professionals in the department include nurses, midwives, resident physicians, and attending physicians. The department routinely measures the quality of care using EHR and administrative data. Reports are routinely produced in a clinical quality dashboard. A single report is also sent monthly via email about appropriate screening for vaccination. We recruited participants for the user-centered design activities via email. They were not financially compensated. We focused on the measurement of performance for postpartum contraceptive counselling. The study was determined to be not regulated as human subjects research by the University of Michigan Medical School IRB (HUM00140107).

Design Process

We designed tailored displays and user stories in iterative and multi-stage process (Figure 1). The process of tailoring prototype displays involved a qualitative component that served to

generate themes for both the display design process and for user story development. At the conclusion of the design process we mapped tailored displays and user stories to understand the comprehensiveness of the displays in addressing individual and situational difference characteristics described in user stories.

Tailored Prototype Display Development

Prototype design displays for feedback reports in the following steps: 1) iterative low-fidelity prototyping with contextual interviews and usability testing, 2) affinity diagramming, and 3) high-fidelity prototype development.

Iterative Low-Fidelity Prototyping

We conducted 30-minute contextual interviews with healthcare professionals from each provider role in the department (midwife, nurse, resident, attending physician). We audio-recorded interviews and took field notes to identify the existing feedback reports that participants use, the channels through which feedback reports were delivered, and the contexts in which reports were viewed. We also asked open-ended questions about the goals and preferences of healthcare professionals with respect to receiving, understanding and acting on feedback reports.

We collected examples of feedback reports in the OB/GYN department and designs from published examples in the literature to inform the creation of low-fidelity prototypes. We held 4 design meetings to generate a wide range of initial display possibilities in sketches on paper. We prioritized a group of displays from an initial set of sketches for testing and we created initial prototypes for testing with synthetic performance data.

We tested the usability of the prototypes using think-aloud technique, asking each provider to verbalize their thoughts as they viewed each prototype. We also tested the comprehensibility of prototypes by asking participants questions like "what is your clinic's performance this month?". After displays had been tested, we asked participants to compare and express their preferences for the prototypes. We recorded audio and took notes in usability testing sessions.

Affinity Diagramming

We created an affinity diagram to identify themes from interviews and usability testing [14]. We used post-it notes to write down interview quotes, facts, and observations. Similar notes were grouped together and new groups were formed when notes did not fit in an existing cluster. Each cluster of post-it notes addressed one theme or idea. We looked for similarities and differences between different professional groups in terms of preferences to identify requirements for tailoring feedback.

High-Fidelity Prototype Development

After iterating through the display designs, we eliminated displays that proved to be inappropriate, unanimously unpopular, or difficult to comprehend. We created high-fidelity prototypes using Sketch (Hague, NL) design toolkit based on our tested low-fidelity prototype displays.

User Story Development

We wrote user stories based on the themes from affinity diagramming [Table 1]. One member of the study team drafted the stories, and a second team member proposed revisions to create the set of stories for analysis. These user stories followed the three-part format of:

*As a*_____

I want to receive performance feedback _____

So that I can _____.

Mapping User Stories and Prototype Displays

To map user stories with prototype displays, two members of the study team independently selected the prototype displays that appeared to be compatible with each user story. Selections were recorded in a shared spreadsheet. One team member identified differences in selections and then both team members met to resolve differences through discussion.

Results

Prototype Design

Design activities took place over a period of 5 months between June and October in 2018.

Iterative Low-Fidelity Prototyping

We conducted 3 cycles of contextual interviews, low-fidelity prototyping, and usability testing. We interviewed 10 healthcare professionals, including 2 attending physicians, 2 nurses, 4 midwives and 2 residents.

We developed 13 low-fidelity prototype designs for testing.

We conducted 4 usability testing sessions with attending physicians to test the usability of the displays.

As we iteratively developed low-fidelity prototypes, we gained insights that lead us to focus on specific user groups and to refine elements of the low-fidelity prototypes. We learned that the performance measures focusing on IPLARC were not directly actionable for nursing staff, therefore we did not seek to test the usability of prototypes with nurse participants. We learned that resident physician's goals and preferences were focused on immediate feedback about skill

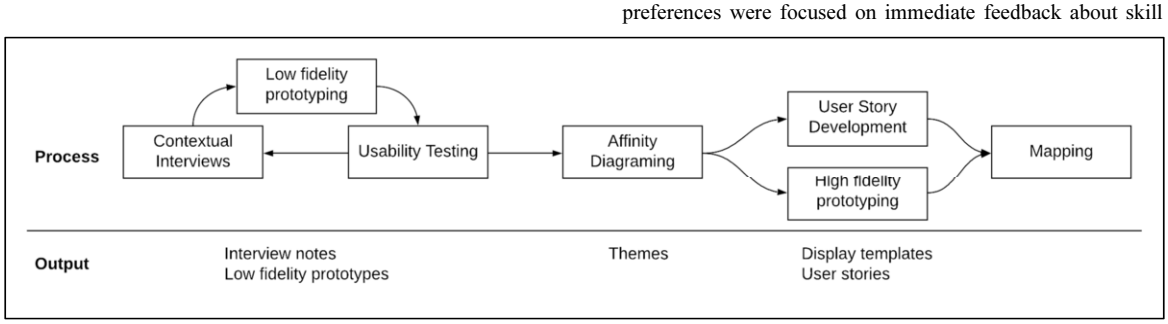

Figure 1– User-Centered Design Process for Tailored Displays of Clinical Performance

Table 1— User Story Development

Quotes	Theme	User Story
"I like seeing c-section rates and the trends" - *Midwife 2* "It's nice to see the trend" - *Midwife 4* "Trend is helpful... what is the reason behind this trend for the clinic?" - *Attending Physician 1*	Providers like seeing trends in the report	**As a** provider, **I want to** receive performance feedback reports that shows trends **So that** I can see how my clinic's performance changes over time.
"I like seeing the comparison of how you're doing in relation to other clinics" - *Attending Physician 4* "I'm competitive, it's nice to see I'm the best...I like comparison" - *Attending Physician 6*	Attending physicians want to see names and performance of other clinics	**As an** attending physician, **I want to** receive performance feedback with data from other clinics **So that** I can compare my clinic's performance to others.

acquisition to the extent that summary performance feedback about individual management of patient and especially for clinic-level performance was perceived to be largely not actionable. We also learned that midwives in the department used a separate performance measurement and feedback process that was distinct from physician-focused quality improvement reporting. Given the available resources for the project we focused our scope on attending physician feedback, who voiced the most support for the utility and actionability of the feedback reports in contextual interviews.

High-Fidelity Prototyping and User Stories Mapping

We identified 11 themes in an affinity diagram. We identified themes about display features and report delivery. We iteratively developed display designs in 3 cycles. We created 9 high fidelity prototype displays for our collection. Each display contains one graph or table with synthetic performance data. We created 11 user stories based on these themes. Each user story corresponded to a single theme from the affinity diagram [Table 2].

The mapping process helped us to identify 2 user stories that were not supported (8 and 9) and two user stories that were each addressed by only a single display (10 and 11). We also identified four user stories(1, 3, 5 and 6) that were supported by all 9 displays. Prototype displays were mapped to an average of 6 user stories (min 5, max 7). User stories were were mapped to an average of 5 prototype displays (min 0, max 9).

Table 2— User Stories

	User Story		
Story ID	**As a...**	**I want to...**	**So that...**
1	provider	receive performance feedback reports regularly	I can check them routinely
2	provider	see a target or goal value in the performance feedback reports	I can track and compare my performance
3	provider	see both percentages and raw data in the performance feedback reports	I can better understand the reports
4	provider	receive performance feedback reports that shows trends	I can see how my performance changes over time
5	attending physician	receive a performance feedback report about counselling, placement and outcomes of IPLARC	I can evaluate my performance holistically
6	attending physician	receive a performance feedback report within the body of an email	I can spend less time opening attachments
7	attending physician	receive performance data from other clinics	I can see how well my clinic is doing compared to others
8	provider	know how my performance data is collected	I can better understand the performance feedback reports
9	resident	receive feedback about my performance immediately	I can improve my skills and techniques
10	attending physician	receive a congratulations message when my clinic performance is consistently high for 4 months	I can recognize our achievements
11	attending physician	receive a "fun" feedback report	I am more likely to look at the report when I receive it

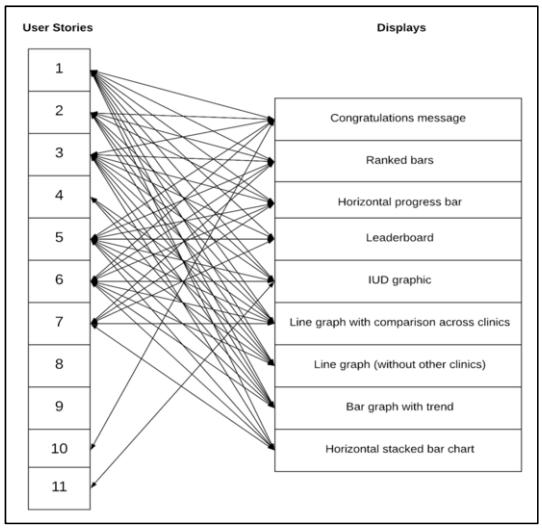

Figure 2– Mapping between User Stories and Display Prototypes. User story numbers correspond with numbers in table 2

Discussion

User stories are a promising approach for representing complex requirements to tailor clinical practice feedback displays to healthcare professionals and teams. Our preliminary experience with a user-centered design method for tailored feedback suggests that user stories may enable improved design, evaluation, and maintenance of tailored feedback interventions. We applied this process to support performance measurement and feedback about IPLARC to healthcare professionals and teams. Incorporating user stories into the design process enabled us to represent contextual factors and preferences of participants that have potential to improve the effectiveness of feedback reports about the quality of clinical practice by supporting the delivery of tailored feedback.

Mapping user stories to displays gave us insight into the ability of a collection of displays to support variable requirements that represent a critical first step toward the delivery of tailored feedback. The mappings served as a preliminary validation of the collection of displays, indicating that each display supported a minimum of 5 user stories. Mapping also revealed the stories that were not supported by any displays. For example, an absence of mappings to Story 9 confirmed what we had learned in contextual interviews about the preferences of residents for receiving performance feedback that was not compatible with the current types of performance measurement that our project supported [Table 2]. Similarly, an absence of mappings to Story 8 revealed a preference that was beyond the scope of this project to address but represented an important next step in the the report design process.

User stories require the story developer to provide a rationale for the user's desire to have a specific function in the information resource. Including a rationale can support the maintenance of tailored reports as user context evolves but also enables feedback report developers to identify stories with rationales that are no longer justified and then to identify the displays that they are supported by for revision or removal from an active collection of tailored displays.

A promising aspect of this approach is the potential to use user stories to develop metadata for tailored displays and to automate the delivery based on user roles and personal profiles. We also anticipate that user stories could be used to improve the user-centered design process if used in a participatory approach [15].

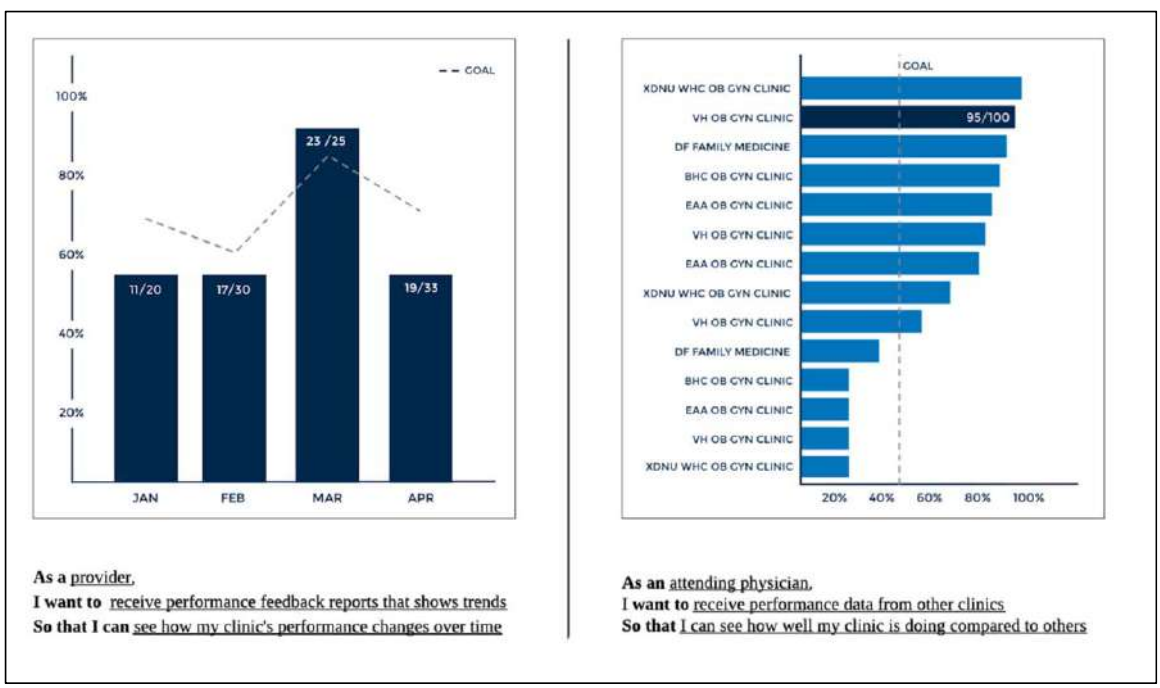

Figure 3– User Story - Display Mapping. Each display is mapped with the user story below it and is incompatible with the other user story.

A limitation we encountered with the user story structure was that it is not appropriate for expressing negative themes. Representation of negative themes is not necessary for general characteristics of reports, but may be necessary to express requirements that differ between users within a context or professional role.

A limitation for this exploratory study is the preliminary nature of the analysis. In some cases, we did not elicit a specific rationale for the report characteristics that participants expressed preferences, leaving a gap for writing the user story rationales. In these cases, we created the rationale based on our interpretation of the general goals and motivations of participants. We plan to conduct follow-up interviews to check our stories and to continue to iteratively improve the requirements for tailored feedback reports. We anticipate that healthcare organizations may apply a similarly iterative approach to refine and adapt user stories.

Conclusions

We have explored the application of a user-centered design methods with user stories to develop tailored displays for clinical performance feedback. We found that these methods enabled the representation of complex requirements across healthcare professional roles. We anticipate that healthcare organizations could use this method to improve the design of visual displays in clinical quality dashboards and reports. We plan to develop these methods to incorporate participatory design approaches and metadata generation to support automated tailoring of clinical performance feedback.

Abstract

To prevent cardiovascular diseases, eHealth solutions may be used as tools, involving health care consumers in the set-up of their prevention plan, a fundamental condition for improving their long-term adherence to the plan. This paper presents the first step in a web platform design aiming to support the co-elaboration by health care consumers and clinicians of personalized prevention plans. Applying a user driven innovation approach, first, a questionnaire and semi-structured interviews were combined to identify clinicians' needs. Then, three focus group sessions with consumers and clinicians were organized to identify their needs, creating the system workflows, its graphical user interface, and its navigation paths, with the best ideas shaped by paper mockups. An interactive mockup was designed including 30 screens (ex. user dashboards, desk for co-elaborating plan). This user driven approach enabled to design not only the technology and its graphical user interface, but also a prevention plan design process.

Ergonomics; Research Design; Primary Prevention

Introduction

The number of deaths related to preventable risk factors keeps on increasing. High blood pressure is at the top of the list of preventable risks, contributing to more than 10 million deaths worldwide [1]. Tobacco ranks second before obesity and diabetes. When combined, these risk factors are responsible for cardiovascular diseases (CVD), leading to death. Thereby, health prevention actions against those risk factors are essential.

Despite many initiatives, setting up a prevention plan is not easy for health care consumers and clinicians [2]. Prevention is the active and empowered management by a person of his or her health capital. Clinicians mostly initiate prevention actions and require the active involvement of the person. However, from a clinician's perspective, initiating prevention actions is time-consuming while the consultation time is limited, and available tools are unhelpful to support this task [3,4]. As for the health care consumers, they must be highly motivated to be involved in prevention actions [2]. Besides, while healthy people are the main target of prevention actions, prevention is not their priority.

eHealth solutions may be used as tools to modernize prevention practices and get healthcare consumers involved in their prevention plan. Connected devices and web platforms, such as forums and/or social networks, may help health care consumers join health programs (e.g. weight loss or smoking cessation in groups). Nonetheless, so far, the impact of those solutions is limited [5-7]. To be adopted by health care consumers and be used efficiently, those solutions must be well-integrated into clinicians' work environment and must not increase their workload [8]. Behavior change techniques must be embedded in those solutions to help health care consumers get involved in their prevention plan [10]. Finally, the solutions must appropriately support the codesign of a personalized prevention plan by health care consumers and their clinicians [10,11] to increase the likelihood that health care consumers adhere to their prevention plan: finding a consensus between a consumer's preferences, abilities and habits, and his or her clinician's recommendations is essential. [12,13]

This paper presents the PEPS project that aims to design a collaborative clinician-health care consumer web solution for cardiovascular diseases prevention. The project is ambitious in terms of involving end users (i.e. health care consumers, clinicians) into a codesign approach to ensure that the future solution (i) is usable and (ii) encourages and supports the co-elaboration of personalized prevention plans (PPP) by the clinician and the consumer. A user-driven innovation approach was adopted to tap users' explicit and tacit knowledge and develop innovative solutions. The process systematically and actively involved users to get a sound understanding of their actual needs and practices [14:]. With this goal in mind, in addition to researchers in ergonomics and decision support systems and to electronic health record companies, the project board also included the French College of General Medicine (FCGM) and an association of patient associations (Inter-Associative Collective on Health). The FCGM and the association ensured the involvement of primary care clinicians (general practitioners (GPs) - and nurses) and of persons at risk of CVD at all stages of the design and evaluation process. In this paper, we present the first step in the design process, i.e. the application of codesign proven methods to analyze end users' needs and to get mockups and design specifications codesigned by health care consumers and clinicians.

Methods

The methodology proceeded in three steps.

Preliminary Questionnaire and Interviews

An on-line questionnaire was developed to identify current needs of the GPs. It identified: the technology currently used to prevent CVD, appreciated and criticized features, GPs' expectations, and the behavior change techniques they use to prevent CVD. The questionnaire was sent electronically to members of the FCGM.

Semi-structured interviews were performed to get deeper qualitative insights into the results of the questionnaire. They addressed the same questions plus clinicians' CVD prevention practices, their difficulties, their ideas and proposals to improve their practices, and the perceived pros and cons of PPP. Respondents to the questionnaire who were interested were contacted. The FCGM completed the recruitment with some of their members and nurses.

Focus Groups

Three sessions of focus groups were organized successively. They aimed (i) to validate nurses and GP's needs identified through the questionnaire and interviews, (ii) to support the ideation about how the PEPS solution should work with its graphical user interface and its navigation paths, and (iii) to shape the best ideas with paper mockups.

The three focus groups sessions complemented each other: they addressed different parts of the PEPS solution (see Figure 1).

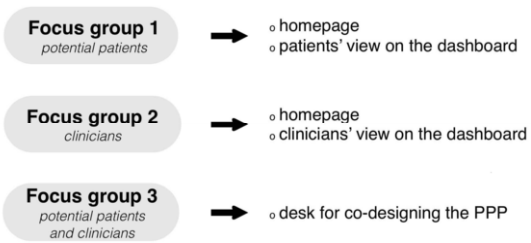

Figure 1– Schematic Representation of the Aims of Each Focus Group Session.

The "studio design" method [15] was the inspiration for the design of the focus groups. This method is a creative problem-solving process to quickly generate ideas and to compare them and achieve a consensus on an agreed-upon solution. It consists in asking participants to sketch mockups in response to a problem. Mockups must be minimal and must enable one to understand the screen's arrangement and content. Several steps of sketching, first individual, then collective, stimulate the creativity and the codesign of a consensual solution that may satisfy the needs of all participants.

Two experts in ergonomics organized and hosted each focus group session.

Focus Group One: Health Care Consumers

This session aimed to get insights regarding the PEPS homepage (accessible without login) and the PEPS prevention dashboard as it appears once logged in with a consumer's account. Participants at risk of CVD (according to their results to the French Federation of Cardiology questionnaire[1]) and healthy participants were recruited.

First, the PEPS project, its aims, and the basics of CVD prevention and of prototyping were introduced. Then, participants were confronted with the following problem: how to engage consumers in CVD prevention? To answer it, participants were divided up into two mixed groups, including both at risk and healthy participants. They had to go through four steps:

1. Brainstorming: they were asked to list techniques and information that may be useful to prevent CVD.
2. Individual prototyping: each participant was asked to sketch how those techniques and information could be displayed and arranged on the PEPS solution.
3. Group prototyping: participants had to explain their own mockup to their group and how their solution answered the initial problem. Then, the group had to combine the best ideas and design elements to create the group's mockup.
4. Inter-groups consensus: then, groups were gathered together. They had to present their own mockup before deciding by consensus on the best ideas and combining them into one new mockup.

At the end of the session, participants had to present their mockup to the experts in ergonomics and to explain how it answered the initial problem.

Focus Group Two: Nurses and GPs

This session aimed to get insights regarding the PEPS homepage and the PEPS prevention dashboard as it appears once logged in with a clinician's account. GPs and nurses were recruited by the FCGM. The problem asked was: how a web solution could help prevent CVD?

This focus group was structured like focus group one except on the first step. After an introduction to the PEPS project, instead of brainstorming, participants had to read the list of needs identified through the questionnaire and interviews and the description of four personas of consumers (see Figure 2). A persona is a fictional character created to represent a person that may use a solution [16]. Then participants were divided in two groups including both nurses and physicians and steps two, three and four occurred like in focus group one. At the end of the session, participants had to present their mockup to the experts in ergonomics.

Focus Group Three: Health Care Consumers, Nurses and GPs

This session aimed to describe precisely the PPP co-elaboration process involving health care consumers and clinicians and to create the screens and the arrangement of information that may support it efficiently. Consumers at risk for CVD, nurses, and GPs who did not take part in the first sessions were recruited. After the introduction to the PEPS project and to the goals of the focus group, participants were split into three mixed groups.

Participants had to answer the following problem: how a website could make easier the co-elaboration of a PPP for CVD? This session proceeded in two steps:

1. Group prototyping: paper cards illustrating the features and the information that may support the PPP elaboration identified through the questionnaire, and the interviews were distributed to both groups. Participants could create new cards if needed. At this step, participants were asked to arrange the cards to follow the PPP design process and to create mockups of the related screens. At the end, the groups were gathered together.
2. Inter-group consensus: each group had to present its process and associated screens' mockups. Together, participants had to decide on the best ideas and to combine them into one new mockup of the solution.

Participants had to present their mockup to the experts in ergonomics and to explain how it answerd the initial problem.

Figure 2 – Instance of Persona Used to Support the Discussion.

Ergonomics Specifications for the Solution

The experts reworked on the paper mockup of the solution with Sketch® to turn it interactive. Then, the computerized mockup was put online with InVision®.To ensure the final mockup was true to the results of the focus groups and met end users' needs, the link to the mockup was sent to 46 former participants/respondents to the three focus groups and to the questionnaire and interviews. This step enabled to get feedback on the designed mockup. Participants could either make comments through the mockup's link or send their comments by email.

Results

Questionnaire and Interviews

A total of 145 GPs replied to the questionnaire; six GPs and three nurses were interviewed. Five main themes arose. First, clinicians need synthesized, unambiguous, updated information, and advice on the prevention of CVD (e.g. under the form of practical memo) along with a synthesized overview of the PPP. The advice must be adapted to the profile of their patient. In addition, clinicians need information about religious and cultural elements they should consider when designing the PPP (e.g. specific diet).

Second, clinicians highlighted a need for interaction through the PEPS website. They need to share the PPP with their patients, and their experiences with colleagues. They need multimedia supports (e.g. video, comics) along with translated supports to communicate with patients who do not understand French fluently. They also need to set the prevention goals and to modify them if needed. Notifications about patients who did not log on for a long time would also be useful.

Third, clinicians insisted on the ergonomics characteristics of the PEPS website: entering and managing data must be easy and quick. The information displayed must always be easy to understand and reusable to save time. Fourth, the PPP should be integrated into their patient electronic record. In this case, the website could be fully interoperable with this record to avoid duplicate data entries. Fifth, clinicians insisted that their patients must be enabled to communicate together (e.g. through social network) to share their experiences and their tricks to achieve prevention goals. Patient must also access an address book of experts.

Focus Groups

Focus Group One: Health Care Consumers

A total of 8 consumers took part to the first focus group: 5 at risk and 3 healthy. Participants expressed that prevention information must be easily accessible through the homepage without being connected nor creating an account. Synthesized medical information on CVD, links to related social network, adapted balanced recipes etc. must be easy to find.

Concerning their account, participants highlighted that it must include "a zone displaying a summary of the statistics on calorie burn and food intake, defined prevention goals, and a way to enter daily those data thanks to a slider, for instance (…) I would need also a calendar to enter the number of cigarettes smoked per day and notes about breathlessness during exercise etc. There would be a kind of side menu displaying my profile, my action plan with its main milestones, my progress, and, if goals were not achieved, a way to change them (…) The GP must also have access to the information".

Finally, health care consumers insisted that the data and the advice must be reliable.

Focus Group Two: Nurses and GPs

Three GPs and four nurses took part in the second focus group.

Clinicians expressed that they should not access the same information as consumers. Once connected, clinicians should see which patients are in a prevention program and, for each patient, charts with statistics to rapidly identify each patient's room for improvement. The website must not be a copy of the patient's electronic record: to avoid double data entry, the website must automatically update data from the patient's electronic record (e.g. automatic retrieval of new lab results). Furthermore, clinicians must be able to access prevention programs and tools and be able to network with colleagues to ask them questions regarding their patients.

As for the health care consumers' accounts, clinicians think that "one should find: the solution must display the PPP with the patient's objective and the level of achievement per week (e.g. under the form of percentage) for each objective (e.g. exercise, level of cholesterol, food intake). The patient must also find

features to enter data such as weight, intakes, amount of exercise, contact details, along with links to recipes and social networks."

Finally, clinicians insisted on the credibility of the information displayed: "sources and scientific references must be displayed".

Focus Group Three: Health Care Consumers, Nurses, and GPs

Two GPs, two nurses, and three consumers took part in the third focus group.

The co-elaboration of the PPP must start with the patients completing a questionnaire about their lifestyle, their medical history, their current risks, and data, such as weight, size etc. Then, each GP will "complete those data with other clinical data gathered during an appointment in such a way as to make a diagnosis". Based on the data entered in the PEPS solution and / or retrieved automatically from the patient electronic record, the solution must propose prevention objectives and associated deadlines. The GP and the healthcare consumer will discuss together the proposed objectives, the ways to achieve them (e.g. exercise, monitoring of intakes) and their implementation into daily life.

To advise consumers and help them make informed decisions, GPs need a toolbox gathering persuasive information (e.g. patient's gain if an objective is achieved). The information must be proposed clearly and be easy to understand. As for the consumers, they must access rapidly a summary of their objectives and actions to take. They should be able to change the objectives if they are too high.

When entering the PPP agreed-upon in the PEPS website, each GP must be able to order tests to check regularly the progress of their patients. Finally, "once the actions to achieve the goals have been chosen with the patients and entered, one must get a summary of the actions decided, and an appointment must be arranged to check how the PPP is followed."

Ergonomics Specifications for the Solution

An interactive mockup of the proposed PEPS solution was designed including 30 screens (e.g. homepage, dashboard for consumers, dashboard for clinicians, desk for the codesign of the PPP, see Figure 3). Navigation paths were represented using flowcharts.

Five former participants provided feedback on the mockup. Overall, respondents appreciated the mockup. Their main concerns were:

- The phrasing of the initial questionnaire: some questions require explanations or should be gender-specific. Scientific references should be added to improve the credibility of the questionnaire.
- Despite its usefulness, the "practical information" screen is too cumbersome. The information density should be reduced.
- Links to other relevant websites should be added.

Discussion

The main objective of the PEPS project was to design a usable tool supporting the co-elaboration of PPP for CVD. The design approach adopted in the project relied on a user driven innovation process to empower end users and give them an active role in the design of the web solution. The "studio design" method involved GPs, nurses, and health care consumers at risk for CVD. As a result, these end users produced mockups of the solution. Even if participants were not used nor trained to graphical user interface techniques, they proved to be able to draw relevant basic mockups, with the information organized within an arrangement. Working on problems they could face during the co-elaboration of PPP helped the participants imagine and design solutions that could help them.

The user driven innovation strategy places the users at the core of the innovation process in a systematic way and facilitates the integration of their knowledge into the increasingly complex design process [17]. Participants' profiles noticeably impacted the design process and its results. Focus group one involved health care consumers, a very heterogeneous population in terms of technology and health literacy, background, needs etc. They proceeded mostly (i) by listing and accumulating different needed information and features and then (ii) by prioritizing those elements to achieve a consensus on the relevant elements the web solution should include. Clinicians who took part in focus group two proceeded differenty. Since they are a quite homogenous group (more than health care consumers even if it represented both GPs and nurses), they expressed similar needs and did not have to reach a consensus on the information and features to display. Consequently, all along the mockups refining process, they questioned in detail how the mockups they produced would actually work *in situ*; they identified blocking elements and found solutions to fix them. Finally, involving both health care consumers and clincians in focus group three enabled them to discuss the PPP design process and to exhange on their respective needs and constraints. The common thinking participants had on the co-elaboration of the PPP allowed them to go deeper than designing the graphical user interfaces of the web solution. Adopting a user driven design process enabled them to design not only a technology but, to a larger extend, a socio-technical system [18].

Comments we get about the online interactive mockup were considered to improve it; an improved version was presented with related specifications to developers. The PEPS web solution is now under development. Once available, its usefulness and its usability will be evaluated with representative end users other than the ones involved in the design process. Then, the solution will be deployed in pilot sites to evaluate its medium and long-term usage. To ensure the PEPS platform is well-accepted and therefore may support the long term prevention of CVD, attention will be paid to acceptability factors by exploring how well the platform is integrated into daily life, how it contributes to transform clinicians' and health care consumers' activities, and to what extent the solution fits end users' personal and social values. [19]

Conclusions

The PEPS project aims to develop a web solution that supports the co-elaboration of the PPP by health care consumers and clinicians. The applied user driven innovation approach enabled to design an interactive mockup of the proposed PEPS solution including 30 screens. This mockup supports the process of co-elaboration of PPP. Ultimately, it must help increase the likelihood that health care consumers adhere in the long run to PPP for cardiovascular diseases.

b Department of Internal Medicine, Vanderbilt University Medical Center, Nashville, Tennessee, USA

Abstract

In 2017, a US academic medical center switched to a commerical EHR system using the "specialist training the specialist" model, which combines peer-to-peer training, class-room based training, and web-based training. We conducted semi-structured interviews with physicians at multiple training levels to investigate the impact of this EHR switch and to explore the training experience of physicians and their perception of the training quality pre and post Go-Live. Our team used Grounded Theory methodology to classify the interview information. Themes that emerged from the interviews included stress and anxiety, the desire for more realistic training environments tailored to specialty needs, and concerns about the duration of time between training and implementation. In future implementations, we recommend more data-rich test patients and the demonstration of real-world workflows during training.

Keywords:

Electronic Health Record, Physician

Introduction

Physicians worldwide are concerned about the complexity of today's electronic health record (EHR) systems even though the technology has been available and evolving for more than 50 years. [1] Organizations use multiple techniques to prepare and train clinicians for an impending electronic health record implementation from remote phone training, class-room training, role-based training, web-based training, [2] and the "*specialist training the specialis*t" training model. A 2015 study showed that interns, who had a physician led, skills based EHR curriculum focusing on case-based simulation and skills rather than in-class or even online lectures during on-boarding, performed better on an EHR skills test and rated their training as more useful. [3] A critical question for health care facilities around the world is how to train physicians effectively to use new electronic health record systems.

Our health care system (Vanderbilt University Medical Center (VUMC)) in Nashville, Tennessee, USA selected a replacement system for the existing EHR. This change provided an excellent opportunity for a pre and post implementation study of physicians' perspective of the selected training method.

To judge the success of the implementation, our research effort focused on the perception of physicians regarding their training before and after implementation of the new electronic health record system. VUMC elected to use the "*specialist training the specialis*t" model for implementation. This model combines peer-to-peer training, class-room based training, and web-based training. Due to a paucity of research focused specifically on physician training, we chose to focus the research on the physician's perception of training effectiveness, the effect of new electronic health record system on physicians, and the perceptions of the similarities and differences of the legacy home-grown EHR with the new commercial electronic health record system before and after the implementation.

Methods

In the context of switching to a new electronic health record system, the research goal was to explore physician perception of the training experience and of the training quality pre and post Go-Live. Our sampling goal was to recruit a balanced cohort of residents, fellows, and attendings with the intent to interview 40 participants in each data collection phase. We also collected demographic data for the physicians including medical specialty, gender, age, and training level.

The research process consisted of a written survey and structured interviews with a cross section (senior physician, fellows and residents) of physicians. The pre and post Go-Live surveys/interviews consisted of five topics:

- The physician's expectation for using the new system with patients.
- Use of alternatives to the training to prepare for the new system, and if so, which alternatives were used?
- Anticipations of advantages using the new system with patients.
- Anticipations of disadvantages using the new system with patients.
- Expectations about how the technology might affect the physician on a personal basis.

The actual pre and post Go-Live questions used during the semi-structured interviews are presented in **Figure 1**.

The pre Go-Live interviews occurred in October 2017 (one month prior to the EHR Go-Live) and the post Go-Live interviews occurred in February 2018 and continued into March of 2018 (approximately three to four months post EHR implementation). The selection of physician participants was based on a convenience sampling, and the direct interview process was conducted with the same set of physicians. The data collected from the interviews were classified according to the Grounded Theory methodology.[4]

The Grounded Theory methodology allows respondent answers to be coded by one author and validated by a second (RR and

CP). The codes were then evaluated for central themes. Questions about perception of the training and overall implementation were identified as being amenable for more quantitative analysis.

We focused on physician perception of training pre and post Go-Live and how technology affected the physician personally. We also focused on advantages and disadvantages of the EHR compared to the previously used proprietary system. We also collected the thoughts about training that could have improved their post-implementation work-flow.

Results

During the pre Go-Live phase, we interviewed 37 physicians. This cohort consisted of 21 residents, 3 fellows, and 13 attending physicians from a variety of specialty disciplines. Internal Medicine provided the majority of respondents with 21 physicians. Other specialties included Pulmonary and Critical Care with 5 respondents, Emergency Medicine with 4, Internal Medicine and Pediatrics with 2, Cardiology with 2, Pediatric Emergency Medicine with 2, and Pediatrics with 2 physicians. Our respondents' age range varied, however most of our cohort fell into the 26-30 category with 20 physicians recording their age in this range which accounted for 54 percent of our cohort and a median age range of 26-30. Other categories consisted of 10 physicians in the 31-35 category, 1 in the 36-40 category, 3 in the 41-45 category, 1 in the 56-60 category, 1 in the 61-65 category, and 1 in the 66-70 category.

During the post Go-Live phase, the cohort included 27 physicians: 18 residents, 0 fellows, and 9 attending physicians. The research goal was to interview the same people pre and post implementation. However, 10 physicians were not interviewed in the post Go-Live phase of the study secondary to issues such as schedule conflicts and the inability to speak with us for an extended period of time. Therefore, we were unable to connect with everyone who was originally interviewed. Internal Medicine provided the majority of the cohort with 19 respondents. Other specialties included Cardiology (2), Pediatric Emergency Medicine (2), Pediatrics(1), Pulmonary Critical Care, Internal Medicine-Pediatrics dual appointment, and adult Emergency Medicine all with 1 each.

The respondents' age range also varied in the post Go-Live interviews, however most of our respondents fell into the 26-30 category with 16 physicians recording their age in this range which accounted for 59 percent of our cohort and a median age range of 26-30. Other categories consisted of 7 physicians in the 31-35 category, 1 in the 36-40 category, 1 in the 41-45 category, 1 in the 61-65 category, and 1 in the 66-70 category. (See **Table 1** for a detailed list of respondents).

For the extensive open-ended grounded theory analysis, the codes generated and the number of times they were applied are provided in the ***Figures and Graphs*** section. **Figure 2** shows that the physicians' perception of the training received turned from an overall positive opinion prior to Go-Live to a decidedly negative opinion in the post Go-Live period. The initial opinion began at 54% positive prior to Go-Live, declining to 19% post Go-Live. **Figure 3** shows that the perception of the impact of the EHR technology change turned from a more negative perception before to a more neutral after Go-live with 73% negative opinion declining to 50%.

To illustrate how perceptions of training and EHR experience changed by individual, **Tables 2** and **Tables 3** compare the quantitatively post Go-Live perception to the pre Go-Live response. Perception of training shifted markedly towards the negative for respondents, who had been neutral and positive pre Go Live with 63% and 57% of respondents switching from positive or neutral to native responses. However, the perception of the technology change generally improved with 35% of respondents who had a negative initial response switching to a positive response.

End-User Perceptions of the Technology Change

Based on training experience, 85% of clinicians were positive or neutral prior to Go-Live. We heard comments such as: "That [Epic] is an EMR that I will now be using; Pretty neutral as far as my opinion on that...I'm sure it will be better in some ways and worse in others."

After implementation, there were 65% of respondents who felt negatively regards to the training received. They tended to focus on concerns about better tailoring the training to the actual needs of the clinician. "The training I did with e-Star covered a lot of different Epic functions but not many of them that I use in my clinical practice. It was a broad training but not tailored [to what] I do in my daily work. Currently [I use] stuff [that] I learned in the weeks post, not [in] the training […] beforehand...Having a very broad training applicable to clinicians did not apply very specifically to my work flow in the ICU."

A significant concern related to the need for more practical, on the job training especially immediately after implementation was expressed as: "It seemed like we needed [to do] actual work … to feel out what was necessary. I wish there were more knowledgeable people after Go-Live. Too many people with only half of the right answer."

Desired Training Alternatives

The most common concern regarding training before and after implementation was the lack of verisimilitude of the training. The training provided to all clinicians included a walk-though of a general medicine inpatient, outpatient, and emergency department encounters. Physicians identified gaps in training as compared to their regular activities. One respondent commented, "I do wish they had a class where they would have us admit a patient from step 1 in the playground environment. I felt like 'talking about it and half-way doing it' was not enough."

The need for better personalization of the vendor's system was another major concern. One respondent stated: "It would have been nice to have set up notes, order sets, etc. We did have personalization[,] but I felt like I was left on my own and did not really get the help I needed and had to try and figure things out for myself."

Benefits of New System

Except for two physicians, all respondents described some benefits of the new EHR usually focusing on improved clinical and coding efficiencies. There was little change in perception over time. About half of providers cited increased clinical efficiency as a benefit and the remainder focused on a variety of benefits including improved communication, mobile interface, and billing. However, 15% of clinicians felt there were no benefits to the new system after implementation: " that's a good question...I cannot think of anything...there is literally nothing."

Disadvantages of New System

Prior to implementation, the majority of physicians felt the most pressing disadvantage was the cost associated with changing/transitioning systems: "I think the transition will be rough, […] but in there will be probably some changes to the workflow but overall I think it will be better." After the transition, the physicians' focus was mostly on work-flow

disruption and an increased burden of documentation and the resulting increased time spent interfaced with the EHR. "Too many clicks. Especially in outpatient. When you are trying to write a note, you click on a problem, then assessment, and plan...just let me click on one thing."

Personal Impact of Technology Change

Most clinicians felt they were significantly affected by the technology change, both before and after implementation. Before implementation, anxiety and concern about the transition itself were prominent: “It has caused some anxiety over if it will slow me down in the ER and make it more difficult for me to see patients efficiently.” These nonspecific concerns became more focused on a variety of ways that the system had altered healthcare delivery making processes more and less difficult. Even several months post implementation, many clinicians still expressed stress from the transition: "I finally empathize with all the headlines from 10 years ago with all of the doctors who were 60 years old who thought that it was just too much of a lift and retired."

An especially concerning sentiment was a loss of confidence in the clinician’s ability to deliver reliably high-quality care: "I think in the first couple of months, it was slowing down note writing and chart reviewing although that has gotten better. Ordering is slower and messaging is much more difficult… I don't have confidence that what I am ordering is actually happening."

Discussion

Interviews with physicians before and after implementation were conducted to explore possible opportunities to improve the experience of implementation of a new EHR prior and after the implementation. The physicians interviewed expressed significant concerns in the pre implementation period on how the new EHR would affect productivity and work-flow. While concern is natural given the significant role of the EHR in the modern medical environment, it was notable that there were more concerns prior to implementation than afterwards suggesting that the fear of change was worse than the change itself.

As physician expectations for the new system were low after training and before implementation, an opportunity for improvement may include better communication of the benefits of the new system prior implementation. The importance of robust change management strategies has previously been identified in the implementation of an EHR from paper, but our results indicated its continued importance even when transitioning between EHRs.[5, 6]

Part of the EHR implementation challenge is that user experience varies widely, which can make a workflow solution for one physician disruptive to another. Further, the differing perspectives and priorities of different specialties and provider types challenge any communication effort and make it difficult to train a large array of specialties prior to the implementation. As a result, many work flow solutions had to be discovered by providers once the system was operational.

The nature of the training emerged as a primary concern for our physicians. One limiting factor for the training process included the fact that the system was not completely built while physicians underwent training thus omitting important workflows or features that were finally available when the system went live. This issue created physician frustration with functionality not having been discussed or experienced in training, functionality not working as described in training, or tools not performing appropriately at Go-Live. Further, many users expressed a desire for more realistic simulations of their work-flow during training to allow them expectation setting for Go-Live. This concern was described previously with physician training[7] and emerged in our interviews as one of the most substantial challenges for physicians.

Ideal training would walk physicians accurately through a day in their life in a data-rich practice with complex patients. In our training, the lack of integration of specifically tailored workflows in a specialty clinic or an intensive care unit provided physicians with only a very generalized simulation of the clinical environment lacking verisimilitude to clinical reality and omitting critical details important to efficiently discharge their documentation, ordering, and other duties. While increased training specificity would have further magnified the logistical challenge of training, its lack was found to be frustrating and likely reduced the impact on physician preparedness for clinical workflow optimization and documentation.

The final major themes were the proximity of the training to Go-Live. Many physicians expressed that the long period of time between training and Go-Live resulted in a reduced retention of learned and practiced content by the time implementation took place. Unfortunately, in a large organization, the logistical challenge may be insurmountable to train every end user immediately prior to Go-Live, but physicians suggested an abbreviated refresher course the week prior to Go-Live. While those with a negative opinion of their training prior to Go-Live continued to feel that way after, it is notable that there was a significant shift in perception among physicians, who felt positive pre Go-Live, to negative afterwards.

Conclusions

In conclusion, many physicians felt passionate about the training they received and the EHR technology transition. Training needs to reflect the experience of physicians in their day to day lives and must be in a narrow time window to implementation to be recalled and be impactful. The more practical and tailored to clinical reality the training can be, the more it is appreciated by physicians. Otherwise, as was experienced in this implementation, physicians will experience significant frustration with the quality of training and may develop resentment towards the technology change.

Study Limitations

Our study was limited to the implementation of one large vendor system at a large academic medical center. Because in-person interviews require a substantial amount of time and resources, we had to limit the number of participants in the study and had difficulty scheduling interviews with the same individuals post-implementation. We also were not able to fully represent all specialties in our research sample (e.g. surgical specialties), which may have provided additional perspectives on training. Online surveys may be helpful in broadening the reach of this type of research, although the in-person interviews helped with gaining a deeper understanding of physician experiences and perceptions.

Figures and Tables

Research Questions for Physicians e-Star Implementation – Pre Go-Live

1. After your training and receiving information about e-Star, what is your perception about using e-Star with patients?
2. What other options do you wish you would have experimented with to prepare for the implementation of e-Star?
3. If you had one wish of how e-Star could improve throughput/workflow post implementation, what would it be?
4. What are your expectations of the advantages with using e-Star with patients? What are your expectations of the disadvantages with using e-Star with patients?
5. Tell me a little more about how this implementation and technology change is affecting you.

Research Questions for Physicians e-Star Implementation – Post Go-Live

1. After using e-Star for a little over a month now, what is your perception of your training and preparation for the implantation?
2. Are there any other avenues you wish you would have experimented with to prepare for the e-Star implantation?
3. After using e-Star over the past few weeks (or months), what would you have changed about your training to improve your post-implementation work-flow?
4. What are the advantages or disadvantages you noted when using e-Star with patients over the past few weeks (or months)? How does this compare with StarPanel or is it similar to StarPanel?
5. Tell me a little more about how this implementation and technology change is affecting you.

The Barriers and Facilitators for Nurse Educators Using Telehealth for Education

Maria Prendergast[a], Michelle Honey[b]

[a] *Nurse Educator, Thames Hospital, Waikato District Health Board, Waikato, New Zealand*
[b] *School of Nursing, University of Auckland, Auckland, New Zealand*

Abstract

Telehealth is available world-wide and in addition to clinical uses, it can also be used to provide education for health professionals, supporting e-Networking. However, within New Zealand the uptake and widespread use of telehealth remains low, and why telehealth is not used more is not understood. This study describes nurse educators use of telehealth for education and identifies barriers and facilitators to increase the uptake of telehealth amongst nurse educators. An on-line survey administered using Survey Monkey had a response rate of 57% (n=19). Equipment that was not user friendly and a lack of initial training were recognised as barriers to their uptake of telehealth. Telehealth training and support, and local champions were identified facilitators to increase the uptake of telehealth. Recommendations include the need for early adopting nurse educators to be recognised and encouraged, to role model good practice in telehealth, and mentor and support others.

Keywords:

Surveys and Questionnaires; Telemedicine; Faulty, Nursing

Introduction

Telehealth and telemedicine are terms often used interchangeably to describe health services provided across distance to both healthcare providers and their clients [1]. Telehealth is available world-wide to support long distance health care and education to both patients' and health professionals [2] but internationally, the uptake and use of telehealth remains disappointing [3]. Within the European Union the expectations of both policy makers and stakeholders fall short [4], whilst in Norway the use of their telehealth system and services is much lower compared to face-to-face options [5]. In Canada, however, telehealth is rapidly increasing in quality, accessibility and popularity [6]. Within New Zealand (NZ), the introduction of ultra-fast broadband is expected to increase the accessibility of telehealth for New Zealanders [7]. To maximise the true potential for telehealth, it is necessary to understand the barriers and facilitators that will lead to an increase in telehealth uptake, not just for service delivery, but also for health professional education.

Background

Internationally, there remains a preference for face-to-face education when compared to providing education via videoconferencing [8]. The term video-conferencing describes real-time, synchronous, two way transmission of digitalised audio and video images between two or more locations [9]. The use of telehealth for education has not developed at the pace and scale expected [10]. The traditional method of gathering as one central group for education does not meet the needs of rural health professionals [11], hence the growth in popularity in the use of telehealth to support their ongoing education. Barriers to the uptake of telehealth include funding, time, infrastructure, skills and preference for the traditional face-to-face approach for education and service [12]. Santos [13] recognises the lack of managerial support, lack of access to and relevance of education sessions, and also workplace culture can be barriers to nurses accessing education via telehealth.

Within NZ, the Ministry of Health has introduced both the NZ Health Strategy and the Health Information Strategy to guide the regional District Health Boards (DHBs) in their introduction and use of telehealth. Despite 17 of the country's 20 DHBs actively using telehealth, a national stocktake in 2014 found the momentum did not reflect the true potential available [14]. This stocktake also recognised the most used telehealth equipment was videoconferencing, which can be used as an adjunct to support health professional education [14]. Yet issues about the use of telehealth, and specifically videoconferencing for educational use, within the DHBs have not been explored. This study will investigate such issues, and form recommendations for future use.

Methods

To explore barriers and facilitators for nurse educators using videoconferencing, a mixed methods approach was selected as it can provide descriptive data including demographics, attitudes and behaviour from a selected group [15]. The participants, employed within one District Health Board in New Zealand, were using videoconferencing as part of their education role. With a population of over 400,000 people, this District Health Board represents the fourth largest region in New Zealand, but over 60% of the people live outside the main city, hence there are a number of small satellite rural hospitals. The nursing staff in these rural hospitals can be disadvanatged by being unable to access continuing nursing education.

For data collection, a questionnaire was created with 13 questions developed, drawing on the available literature. The questions were piloted by three colleagues who did not participate in the survey, and their feedback was used to refine and clarify the questions, finalise the order of questions and also to determine the time needed to complete the survey.

Ethical approval was gained from the University Ethics Committee (Ref. 018105) and the associated DHB (RD: 016114) before the questionnaire was distributed on-line in late 2016, using a commercial survey tool, Survey Monkey.

Survey Monkey was selected for the on-line survey because it was easy to use and familiar to respondents. An email with the link to the survey was sent to all 33 nurse educators who work within one DHB. One reminder email was also sent.

Collation of the responses occurred automatically. Analysis of the numerical data was completed using an Excel spreadsheet, with graphs to present the data. The responses to the open-ended question "Please add any further feedback you would like to share" were thematically analysed based on the process described by Braun and Clarke [16]. The results presented below report the demographics, nurse educators' experience of telehealth, and factors that impact on their engagement with telehealth.

Results

In total, 19 out of 33 nurse educators completed the survey, giving a response rate of 57%.

Demographics

The nurse educators ranged from 31 to over 50 years of age, and the majority (74%) had more than 15 years nursing experience (Table 1).

Table 1- Nurse educator demographics (n = 19)

Demographic	n	%
Age		
< 30 years	0	0
31-40 years	5	26
41-50 years	10	53
>51 years	4	21
Experience as a nurse		
< 5 years	0	0
6-10 years	1	5
11-15 years	4	21
>16 years	14	74

Experience of telehealth

The majority, (90%, n=17) of the nurse educators had not experienced telehealth during their initial nursing education. When asked about their current use of telehealth in their role, nearly two-thirds (63%, n=12) of the nurse educators responded that they were not using telehealth and 31% (n=6) responded that they were using telehealth to some degree; and one respondent (5%) was uncertain. However, nearly 80% (n=13) of the nurse educators felt telehealth was "somewhat important" or "important" for their role (Figure 1).

Of the 19 respondents, 42% (n=8) reported having had "a little" experience with telehealth. Although 31% (n=6) of the nurse educators had either "some" or "quite a lot" of experience, there was still 26% (n=5) of the group who had not experienced telehealth at all. When asked to rate their understanding of telehealth, the majority of respondents (n=13, 68%) reported being "knowledgeable" or "somewhat knowledgeable". There is however, 32% (n=6) of the group who considered themselves "not knowledgeable" at all in the use of telehealth. Furthermore, when asked about the importance of gaining competence in using telehealth, two thirds (67%) believed gaining competence is either "important" or "very important".

Although no respondents felt gaining competence was not important at all, there was still nearly one-third (33%, n=6) of the group who see gaining competence as only "somewhat

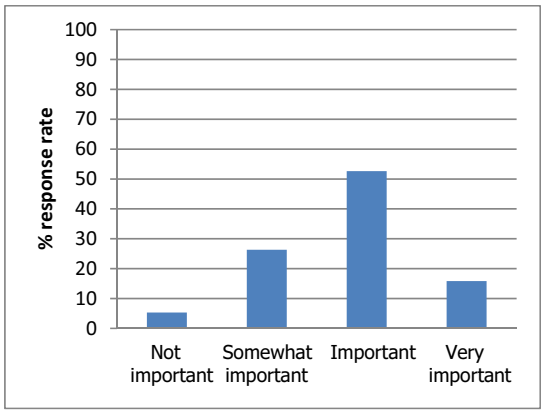

Figure 1- Importance of telehealth for nurse educator role

important."

Respondents were also asked to rate their skill when engaging in telehealth as either novice, competent, proficient or expert, based on the scale of Benner's terms [17]. Approximately two thirds (68%, n=13) of the nurse educators viewed themselves at novice level; 21% (n=4) as competent, and 11% (n=2) rated themselves as proficient. No one considered they are practicing telehealth at an expert level.

Factors for engaging with telehealth

A list of factors that influence staff engagement with telehealth was compiled from the relevant literature, and respondents were asked to identify any factors that applied to them. There was only one statement that all respondents indicated and this was for telehealth equipment to be easy-to-use and reliable (Figure 2). The second most important factor was the need for training and support, with strong leadership and the need to recruit local champions being viewed as third most important. The least important factors identified by the respondents were negative impact on service change and negative impact on staff.

Themes from further comments

Only seven (37%) respondents made further comments in the free text question: "Please add any further feedback you would like to share". To analyse these comments, words with the same or similar meaning were bracketed, then grouped, and from this three themes emerged. These were: engagement in telehealth, the importance of telehealth, and technology.

Engagement in telehealth was the most common theme to emerge in the comments, such as "*Will need to engage in order to be effective*" and, "*I will engage more and more over time*". The importance of telehealth was another theme, with statements such as: "*Telehealth use is very important*". The third theme indicated feelingsabout the importance of telehealth technology, with comments such as, "*vital technology*" and "*equipment and technology is a positive change*".

The positive comments saw telehealth as "*the way of the future*", "*will achieve bang for our educational buck*" and "*likely to improve patient outcomes*". However, the challenges identified by the respondents included the need to "*grow in confidence*" and "*it will take time and support to make it work*".

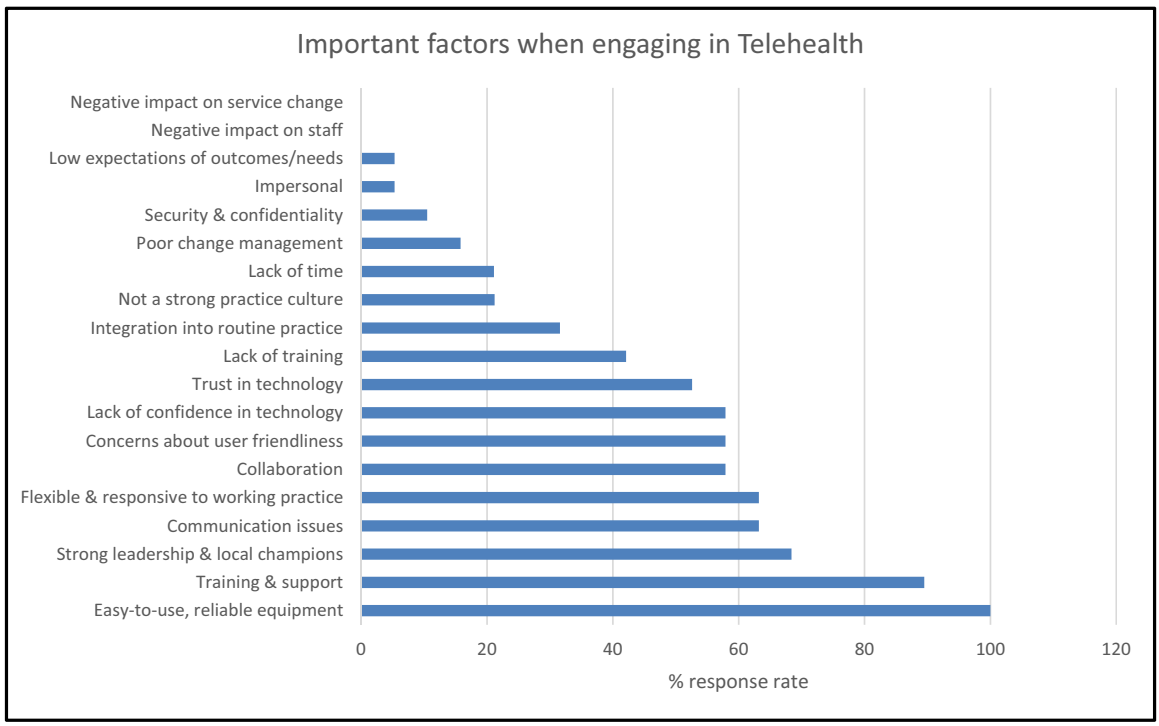

Figure 2: Important factors when engaging in telehealth

Discussion

The results of this survey provide insight into nurse educators' use of telehealth within one DHB. Overall, the results reflect results found in the literature concerning the lack of telehealth uptake, but there is evidence that some of the nurse educators are keen to engage and use telehealth within their role. Telehealth will never remain static, rather it is becoming an increasingly essential element of healthcare [18], so it is important for the nurse educators to become further involved as it provides another format for the provision of education to nurses. Additionally, telehealth has been shown to improve access to educational opportunities for rural and isolated health professionals [11,12].

Using telehealth

Telehealth equipment which is reliable and easy-to-use was recognised as the most important factor in this study, and this is similar to literature that found it to be instrumental in staff acceptance of telehealth [10,19]. Possible issues, echoed in the results of this survey and reflected in the literature, which prevent staff from engaging in telehealth include a lack of adequate equipment [20], and lack of appropriate training [21]. Sligo, Gauld, Roberts, and Villa [22] however, believe there should be a good fit between the technology and the users from the beginning, and the technology should be intuitive so that little staff training is required. Training and support was identified in this study as an important factor for successful implementation of telehealth, both initially and in the longer term. To improve the uptake and sustainability of telehealth use, training should be held in the workplace with staff trained to troubleshoot technical issues [21]. There also needs to be dedicated technical support during the implementation phase [19], as well as later, to consolidate staff knowledge and technological skills [23]. Additionally, providing training and support has been shown to improve staff confidence and engagement in the usage of telehealth [19]. In this study, the nurse educators were not very experienced telehealth users. However, it is essential to acknowledge staff who have more experience as they could be recognised as innovators and possible clinical champions in the future [24].

Leadership and local champions

Successful implementation of telehealth also requires strong leadership and local champions, a finding from this survey and supported by the literature, where champions contribute to the successful implementation [25]. These individuals can be facilitators for the adoption of telehealth [10].

Success of telehealth depends on the competency of the nursing staff [26]. From this survey, nearly two-thirds of the nurse educators felt it was important or very important to gain competence in telehealth, but with a similar proportion rating themselves as a telehealth novice. Based on these findings, further education needs to be planned and implemented. The use of telehealth competencies, including topics such as communication, use of the technology, ethics and coaching skills may be helpful to increase users' skills [27]. Grading the competencies into novice, competent, proficient and expert levels may allow the nurse educators to develop their technical skills in a manner that grows their confidence and competence in a timely manner [28].

Limitations and areas for further research

Although a good response rate for this survey was achieved, there are still nearly half of the nurse educators who did not respond and their perceptions on telehealth remain unknown. The results presented here indicate the experience and perceptions of the nurse educators in one region of New Zealand, therefore repeating this study across a wider area is

warranted. Additionally, further research is needed to explore nurse educators' perceptions as this may indicate strategies that would improve telehealth use for education. A qualitative approach, perhaps using focus group interviews, is recommended which may provide the depth that this study could not.

Conclusions

This study provides insight into the current barriers and facilitators for telehealth use in education from the perspective of nurse educators from one region in New Zealand. Despite low usage and skills with telehealth, this study identifies that most nurse educators are ready to use telehealth to provide health professional education.

The recognition of champions who can act as leaders and assist in the implementation of telehealth is vital to assist in engagement and acceptance by staff. There is also a need to seek early adopters within a health professional group who can role model good practices for telehealth, as well as encourage others to accept telehealth within their daily work. There is a need for educators to have the necessary skills in using telehealth to be able to provide education via this medium.

Abstract

Detection of difficult for understanding words is a crucial task for ensuring the proper understanding of medical texts such as diagnoses and drug instructions. We propose to combine supervised machine learning algorithms using various features with word embeddings which contain context information of words. Data in French are manually cross-annotated by seven annotators. On the basis of these data, we propose cross-validation scenarios in order to test the generalization ability of models to detect the difficulty of medical words. On data provided by seven annotators, we show that the models are generalizable from one annotator to another.

Keywords:

Natural Language Processing; Terminology; Health Information Systems

Introduction

Specialized areas, such as medical area, convey and use technical words, or terms, which are typically related to knowledge developed within these areas. In the medical area, this specific knowledge often corresponds to fundamental medical notions related to disorders, procedures, treatments, human anatomy, etc. For instance, technical terms like *blepharospasm* (abnormal contraction or twitch of the eyelid), *alexithymia* (inability to identify and describe emotions in the self), *appendicectomy* (surgical removal of the vermiform appendix from intestine), or *lombalgia* (low back pain) are frequently used in the medical area texts. Patients and their relatives usually have some difficulties in the understanding and using of such terms: they show indeed poor health literacy. Some existing studies stressed the difficulty in understanding medical notions and terms by non-expert users, and its impact on a successful healthcare process [1,2]. Yet, it is not uncommon that patients and their relatives must face very technical health documents and information. Examples of this kind are frequent and usually the non-expert users are at loss in such situations: understanding of information on drug intake [3,4], of clinical documents [5], of clinical brochures or informed consents [6], of information provided for patients by different websites [7,8], and communication between patients and medical staff [9,10]. These observations provide the motivation to our work: we address the needs of non-specialized users facing health information and propose to predict the readability of medical words.

In what follows, we first present some related work and introduce the material used as well as the proposed method. We then present and discuss the results. Finally, we conclude with some directions for future work.

Related Work

For studying the readability of medical documents, researchers usually exploit readability measures. Among these measures, it is possible to distinguish classical and computational readability measures [11]. Classical measures usually rely on number of letters and/or of syllables a word contains and on linear regression models [12,13], while computational readability measures may involve vector models and a great variability of features, among which the following have been used for processing the biomedical documents: combination of classical readability formulas with medical terminologies [14]; n-grams of characters [15], stylistic [16] or discursive [17] features, lexicon [18], morphological features [19], combinations of different features [5].

At a more fine-grained level, the readability of words has been addressed much less frequently. In the general language, some research actions are often performed as part of the NLP challenges, such as the SemEval NLP (*www.cs.york.ac.uk/semeval-2012*) challenge held in 2012. This challenge proposed the following task: for a short text and a target word, several possible substitutions satisfying the context have also been proposed. The objective was to rate and to order the substitutions according to their degree of simplicity [20]. The participants applied rule-based and/or machine learning systems. Combinations of various features, designed to detect the simplicity of words, have been used, such as: lexicon from spoken corpus and from Wikipedia, Google n-grams, WordNet [21]; word length, number of syllables, latent semantic analysis, mutual information and word frequency[22]; Wikipedia frequency, word length, n-grams of characters and of words, random indexing and syntactic complexity of documents [23]; n-grams and frequency from Wikipedia, Google n-grams [24]; WordNet and word frequency [25]. The best systems reached up to 0.60 Top-rank and 0.575 Recall. Another work has been done on scholar texts in French written for children with the purpose to differentiate between the texts from various scholar levels and to test various features suitable for that [26]. This system reached up to 0.62 classification accuracy.

In the medical area, we can mention three experiments: manual rating of medical words [27], automatic rating of medical words on the basis of their presence in different vocabularies [28], and exploitation of machine learning approach with various features

[29]. This last experiment achieved up to 0.85 F-measure on individual annotations.

Another issue is to know what are the most suitable data for the analysis of text readability. These data have indeed crucial impact on models created and on their usability. Several approaches have been proposed:

- exploitation of expert judgment, who have an idea on needs of population aimed in the study [30]. The main limitation is that experts may have difficulties to figure out what are the real needs of population;
- exploitation of text books created for population according to their readability levels, such as school books [26]. The main limitation is that such books are usually created by experts using theoretical basis and observations;
- exploitation of crowdsourcing involving large population [30]. The main limitation is that the population involved is uncontrolled and unknown;
- exploitation of eye-tracking methods for a more finegrained analysis of reading difficulties [31,32]. The main limitation is that only short text spans can be used;
- manual annotation by human annotators [33]. In this case, the annotators represent the population, they are part of the controlled population, they can perform more complicated tasks than in case of crowdsourcing, although they are usually less many than in crowdsourcing experiments.

Related to this issue is the question on generalizability of data and of models generated from these data. For instance, it has been observed that data from experts are difficult to generalize over the population [30].

We propose to study the generalizability of the automatic categorization models for a stronger distinction of readability of medical words and distinction of words which may present understanding difficulties to non-experts users. The medical data processed are in French. Seven human annotators participated in creation of the reference data.

Material

The source terms are obtained from Snomed Int [34], which is the most extensive terminology in French, such as available from the ASIP SANTE website (*esante.gouv.fr/services/referentiels/referentiels-d-interoperabilite/snomed-35vf*). Snomed contains 151,104 medical terms organized in eleven axes such as disorders, procedures, chemical products, living organisms, anatomy, social status. For our purpose, we use five axes: disorders, abnormalities, procedures, functions, and anatomy. The assumption is that studying the understanding of these terms is important because they are related to main medical notions and laymen must face then frequently. The 104,649 selected terms are lemmatized and tokenized into words resulting in 29,641 unique words.

The set of 29,641 unique words was annotated by seven French speakers, 25 to 65-year-old, without medical training and without specific medical problems. The annotators are expected to represent the average knowledge of medical words among the population as a whole. The annotators are presented with the list of terms and asked to assign each term to one of the three categories:

- *I can understand the word;*
- *I am not sure about the meaning of the word;*
- *I cannot understand the word.*

The assumption is that terms, which are not understandable by the annotators, are also difficult to understand by patients. The annotators were asked not to use dictionaries during the annotation process. Further to the annotation process, the most frequent category is I cannot understand the word, which gathers between 65 to 70% of terms.

Methods

We propose to tackle the problem through the supervised categorization: the purpose is to categorize terms according to whether they can be understood or not by lay people. The manual annotations provide the reference data. The categorization pipeline is the following: categorization features are computed, they are used for training the classifiers, and the results are evaluated using the cross-validation.

We exploit 11 types of automatically computed features:

- *Syntactic categories*. Syntactic categories and lemmas are computed by *TreeTagger* [35] and then checked by *Flemm* [36]. The syntactic categories are assigned to words within the context of their terms. If a given word receives more than one category, the most frequent one is kept as feature. Among the main categories we find for instance nouns, adjectives, proper names, verbs and abbreviations.
- *Presence of words in reference lexica*. We exploit two reference lexica of the French language: TLFi (*www.atilf.fr/*) and lexique.org (*www.lexique.org/*). TLFi is a dictionary of the French language covering XIX and XX centuries. It contains almost 100,000 entries. lexique.org is a lexicon created for psycholinguistic experiments. It contains over 135,000 entries, among which inflectional forms of verbs, adjectives and nouns. It contains almost 35,000 lemmas.
- *Frequency of words through a non specialized search engine*. For each word, we query the Google search engine in order to know its frequency attested on the web.
- *Frequency of words in the medical terminology*. We also compute the frequency of words in the medical terminology Snomed International.
- *Number and types of semantic categories associated to words*. We exploit the information on the semantic categories of Snomed International.
- *Length of words in number of their characters and syllables*. For each word, we compute the number of its characters and syllables.
- *Number of bases and affixes*. Each lemma is analyzed by the morphological analyzer *Dérif* [37], adapted to the treatment of medical words. It performs the decomposition of lemmas into bases and affixes known in its database and it provides also semantic explanation of the analyzed lexemes. We exploit the morphological decomposition information (number of affixes and bases).

- *Initial and final substrings of the words*. We compute the initial and final substrings of different length, from three to five characters.
- *Number and percentage of consonants, vowels and other characters*. We compute the number and the percentage of consonants, vowels and other characters (i.e., hyphen, apostrophe, comas).
- *Classical readability scores*. We apply two classical readability measures: Flesch [12] and its variant FleschKincaid [38]. Such measures are typically used for evaluating the difficulty level of a text. They exploit surface characteristics of words (number of characters and/or syllables) and normalize these values with specifically designed coefficients.
- *FastText word embeddings* [39] pre-trained on French Wikipedia corpus, which cover up to 56% of the words from our dataset. Tthe embeddings cluster together words that share common contexts and semantics, and can help in generalizing other features over contextually and semantically close words.

The ten first types of features, linguistic and non-linguistic, are called *standard features*, while the embeddings stand for themselves.

The supervised categorization is performed with decision tree (DT) classifier from the scikit-learn library (*scikit-learn.org*).

In the proposed experiments, we learn the model from all the annotations of a given annotator and then test the model on annotations provided by other annotators. In this way, we can measure the ability of the classifier to generalize on all known words, but for unknown annotators. This scenario is realistic to a real-world situation: the reference annotations can be obtained only from a couple of users, presumably representing the overall population, but not from all the possible users. Yet, it is necessary to predict the familiarity of medical words for all the potential users even if they did not participate in the annotations. Hence, the generalizability of models occupies the central position in these experiments.

Results and Discussion

The results obtained are presented in Table 1. The first two columns indicate the annotators. Data provided by each annotator are used for training the classifier (first column). The model generated is then tested on data from all the annotators including the reference annotator (second column). Three sets of such experiments are performed, depending on features exploited: standard features, word embeddings, and combination of all the features available. Each experiment is evaluated with several measures: *P* Precision, *R* Recall, *F* F-measure to evaluate the efficiency in prediction which medical words are understandable or not understandable for a given annotator: the darker background, the better the results.

We can do several observations on these results. Features used show an impact on the results. Thus, standard features usually show better results than embeddings. One explanation is that standard features include 24 individual features covering different aspects of linguistic and non-linguistic description of words, while word embeddings rely only on distribution of words and their similarity. Yet, combination of all the features (standard and embeddings) usually improves overall results, sometimes going to up to 2.9 improvement of F-measure. Our hypothesis is that there exists a robust nonlinear dependency between some subsets of standard features and subword-level components of word embeddings. Testing this hypothesis is the topic of our further research.

Recall values are always higher than Precision values. In each set of experiments, the best results are not obtained when the model of a given annotator is applied to own data. For instance, the *O1* model provides better results when tested on data from annotators *O2, O3* and *A8*. Similarly, the *A7* model shows better results when applied to data from annotators *O1*, *O2*, *O3* and *A8*. This is an important issue because it shows that the models acquired from one annotator can be successfully generalized over other annotators.

Besides, it seems that the annotators form two clusters according to the classification of difficult medical words: one cluster with four annotators (*O1, O2, O3, A8*) and one cluster with three annotators (*A1, A2, A7*). This issue may be related to the health literacy of annotators. This may indicate that the annotation models can be shared by people with similar skills and knowledge. Yet, to confirm this hypothesis, it is necessary to define the level of health literacy of annotators. This task is rather difficult because there is no existing tests created for computing the health literacy level for French-speaking healthy people. Another hypothesis is that some models may be better generalizable than other models. This hypothesis must also be verified with additional experiments.

Another important point is that, while the annotations go forward, the annotators usually show learning progress in decoding the morphological structure of terms and their understanding [40]. This progress is not taken into account in the current models.

Conclusions and Future Work

We proposed to address the detection of medical words which understanding may be difficult for non-specialized users of the medical area. We exploit for this machine learning algorithms, reference data from seven annotators, and several sets of NLP features: standard features (syntactic information, reference lexica, frequency, etc.), distributional features (word embeddings), and their combination. Our results provide several indications. Hence, the combination of all features is the most efficient. Concerning the generalization, we propose to learn model on a given annotator and then to apply it to data obtained from other annotators. This set of experiments indicates that models provide better results when tested on data from other annotators. We consider this to be a positive issue because it is important to be able to generalize annotations provided by a set of users on the whole population. Yet, these results may point out that the users should be apprehended through their health literacy, while currently there is no available tests for measuring it in French-language healthy people.

We have several directions for future work. For instance, we will train our own word embeddings specific to medical data in French, so that they suit better our data. We also plan to implement and test other deep learning/neural networks/NLP methods which use the morphological information of words, such as character-level recurrent neural networks and character embeddings together with 1D convolutions. In addition to the readability of medical words, we will also work on measuring health literacy of French-speaking people.

Acknowledgements

This work was partly funded by the French National Agency for Research (ANR) as part of the *CLEAR* project (*Communication, Literacy, Education, Accessibility, Readability*), ANR-17-CE19-0016-01. Also, we thank again the annotators who participated in preparing the reference data.

Abstract

Clinical paper searching is a major task for clinical researchers to collect authoritative and up-to-date evidences to support their research works and clinical practices. Currently, this task needs huge amount of labor work. Researchers usually spend a lot of time searching on the online repository and iterating many times to get the final paper list. Systematic review is a special case, in which the paper searching process is a critical step. To address this challenge, this paper introduces a method to streamline the iterative paper searching process. It automatically selects the most probably matched papers, and then generates new search strategy. All the intermediate results are visualized based on the paper citation graph. It assembles technologies such as PageRank and Topic-based clustering to accelerate the paper searching tasks. The precision, recall, and execution time of the proposed method are then evaluated by comparing with published systematic reviews.

Keywords:

Paper, Bibliometrics, Literature Based Discovery

Introduction

Clinical paper searching is a major task for clinical researchers to collect authoritative and up-to-date evidences to support their research works and clinical practices. Clinicians/writers of clinical reviews and clinical guidelines also spend a lot of time on clinical paper searching. Starting from a research problem or a research topic, the goal of the searching process is to find clinical papers that mostly depict the corresponding topic. Search strategy is carefully constructed to reveal the research topic, which usually contains at least a set of keywords as search terms, other objects such as fields, in which, part the keywords will be searched in clinical papers, and search logic operators to organize the keywords [1]. Then it is used to do queries via online clinical databases. By further reading and filtering the retrieved papers, clinical researchers can get a comprehensive view about the research topic from the final paper set. A special case is systematic review [2], which aims to collect secondary data from published clinical papers to offer a complete, exhaustive summary for the research question [3].

There are many challenges during the paper searching process from search strategy construction to final paper set confirmation, which include the following:

- In order to include most matched clinical papers, the search strategy is set to relatively broad. That often leads to huge amounts of irrelevant papers being retrieved (precision as low as 0.3% [4]).
- Expert searchers usually use iterative refinement of search queries to improve the precision of paper searching. Nevertheless, this kind of iterative process has not been well automated yet [5].
- There are lack of visualization tools to monitor the searching process, especially when the searchings are iterated for many times, which increase the burden of searchers for capturing the intermediate results.

To use web tools, information retrieval, and machine learning methods to help the clinical paper searching process is a sustained topic since the online literature databases such as PubMed were built up [5,6,7]. AskMEDLINE [8] handles user queries in the form of free-text questions. It can automatically complete the patient, intervention, comparison, outcome (PICO [9]) form by parsing the clinical questions. RefMed [10] retrieves search results based on user queries, learns a ranking function based on the user feedback information, and then applies the ranking function to the retrieved results in the next iteration. Another work named MedlineRanker [11] automatically learns a list of most discriminative words from a set of documents to represent certain topic. Then the learned words are used to score and rank newly published papers on the topic. Chen et. al. [12] used a PageRank based algorithm to assess the relative importance of all publications to find some exceptional papers that are universally familiar to physicists.

This paper introduces a method to streamline the iterative paper searching process. It automatically selects the most probably matched papers, and then generates a new search strategy. All the intermediate results are visualized based on the paper citation graph. It assembles technologies such as PageRank [13] and topic-based clustering [14] to accelerate the paper searching tasks. The contributions of the paper include the following:

- It provides a generalized mechanism to streamline the iterative clinical paper searching process to get most probably matched papers, which is independent of specific research topics.
- A visualization based on paper citation graph is produced to show intermediate results, which can provide evidence and provenance about how the papers are collected and selected during the iterative searching process.
- The precision, recall, and execution time of the proposed method, which assembles technologies such as PageRank [13] and topic-based clustering [14], is evaluated by comparing with published systematic reviews.

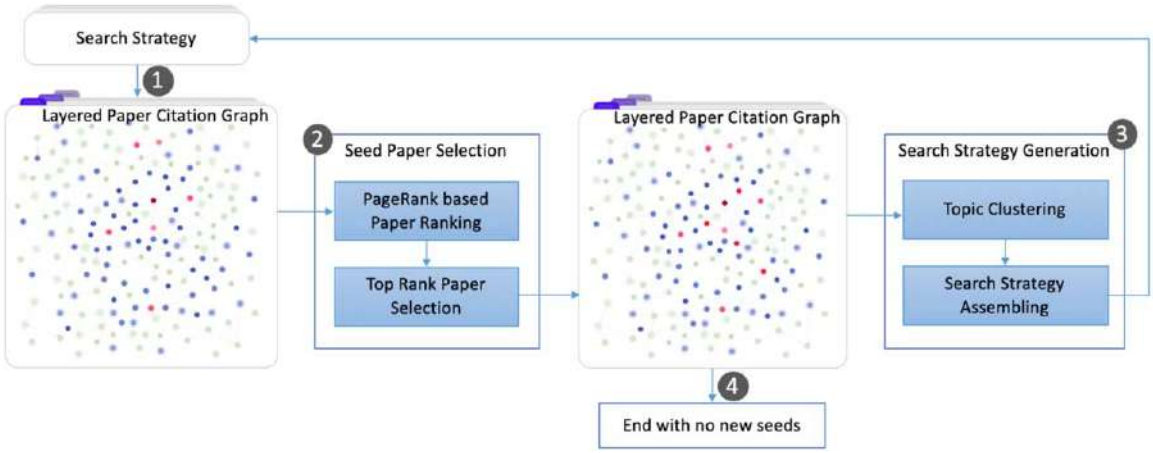

Figure 1– Illustration of the proposed method. (1) When the search strategy is generated, paper querying is performed to retrieve a set of papers, which are then represented into the layered paper citation. (2) Based on the current paper set, papers are ranked by PageRank algorithm, and finally select the top-n papers as seed papers, which are the most probably matched papers. (3) Given the seed papers, a topic-based clustering algorithm is performed to extract key topics and terms from different fields and then assemble them to form a search strategy. (4) The process will be ended until there is no new seed selected.

Methods

The proposed method is illustrated in Figure 1. Starting from a primary search strategy and several papers as seeds, the paper searching process can be iterated automatically until there is no new seed paper selected. A seed paper is a paper identified as a most probably matched paper with the research topic. It is used to generate search strategy for the next iteration, and the overall set of seed papers will be output as the final inclusion set. In spite of the seed paper list, the final results of our method also include a list of search strategies and a list of all retrieved papers. The layered paper citation graph will keep all the intermediate results as provenance. Next we will introduce the main components respectively.

Layered Paper Citation Graph

A Layered Paper Citation Graph (LPCGraph) is a graph representing the intermediate results from different iterations during the searching process (Figure 2). Each node represents a retrieved paper. Edges between the nodes represent the direction of citation relationship. For example, if there is an edge from node A to node B, that means the clinical paper B is cited by paper A. To capture the intermediate results in each iteration, LPCGraph is specifically equipped with the following features, which can provide evidence and provenance about how the papers are collected and selected.

- Layers. Due to the huge number of papers retrieved, it's important to reveal in which iteration a paper is retrieved, and how many times the paper is queried in different iterations. The layer feature in LPCGraph represents the corresponding iteration. Nodes in different layer have different transparency, and nodes with more overlap times will have darker colors.
- Role of nodes. A node in the LPCGraph has multiple roles, which capture different characteristics of a retrieved paper. The layer feature, as mentioned above, represent the iteration in which the paper is retrieved, as well as the overlap times of a paper in different iterations. Another setting is when the corresponding paper is selected as a seed paper, it is represented in red colors. If it is retrieved for multiple times, the red color will be even darker.

For example, in Figure 2(a) and 2(b), node with id *17548730* is a seed paper in the current iteration and it is retrieved multiple times. It is highlighted by deep red color. Its title is *Randomized trial of acupuncture to lower blood pressure*, and the published date is *2007/6/6*.

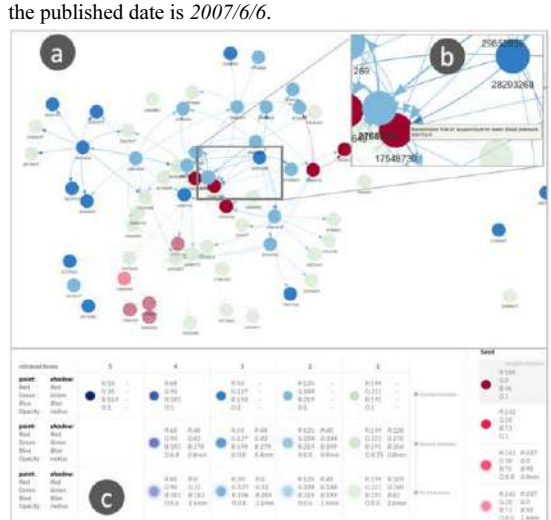

Figure 2– Illustration of the LPCGraph. (a) Overall view of the graph during certain paper searching iteration. (b) Zoom in view of the framed subgraph. (c) Legend of node views for different roles and layers.

Seed Paper Selection

The goal of the paper searching process is to form an inclusion paper set, which could relate back to the research topic. Within our method, the papers are retrieved iteratively, which means that in each iteration, there will be new seed papers selected and included into the set.

Consider the task of seed paper selection in an iteration. Without regard to other information, every paper retrieved by the given search strategy would have the same chance to be selected as a seed paper. If we consider the citation relationships among these papers, the ones with more citations stand out more likely as exceptional because their contents are more influential. Given the hypothesis that the retrieved papers are probably related to the research topic, which is represented by the search strategy, the most cited papers have higher probabilities to match the topic than other less cited ones. The importance level based on citations can be measured by PageRank algorithm [12]. The PageRank algorithm [13] is depicted as following:

$$PR(u) = \frac{1-d}{N} + d\sum_{v\in B(u)}\frac{PR(v)}{L(v)} \quad (1)$$

Where u and v represents a web page respectively. *PR(u)* and *PR(v)* are rank scores of page u and v. d is a dampening factor, which is usually set to 0.85. N is the total number of pages. *B(u)* is the set of pages that point to u. *L(v)* denotes the number of outgoing links of page v.

Search Strategy Generation

If there are new seed papers selected in an iteration, new search strategy should be generated to cover information from these newly included ones and launch the next iteration to further retrieve papers. We apply the idea of topic-based clustering to extract common concepts from different fields of the seed papers and properly assemble them together in the format of search strategy. Topic-based clustering is an unsupervised approach for automatic keyphrase extraction from documents [14]. Instead of extracting words as candidate keyphrases directly, it groups the candidate keyphrases into topics, such that each topic is composed of only those candidate keyphrases that are related to that topic.

The design of search strategy for clinical paper searching follows some guidelines [19]. Checking the common structure of a search strategy in Figure 3, it mainly contains a set of keyphrase candidates as search terms and fields align with the search term that will be searched in clinical papers. Keyphrase candidates which belong to the same topic will be jointly connected by "OR", and "AND" is used to connect bunches of keyphrase candidates belonging to different topics.

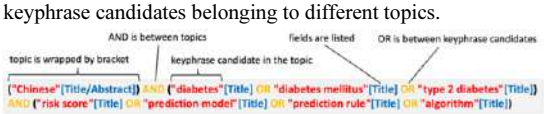

Figure 3– A sample search strategy

In order to generate such search strategy, we apply the idea of graph-based topic ranking for keyphrase extraction [15]. In this work, a graph is built-in, which, vertices are topics represented as clusters of lexically similar keyphrase candidates and all topics are ranked according to their significance. Naturally, the top-n ranked topics and corresponding keyphrases extracted from seed papers could be assembled to form a search strategy, which will represent the main topic of these papers.

$$dist(c_i, c_j) = \sum_{p_i\in pos(c_i)}\sum_{p_j\in pos(c_j)}\frac{1}{|p_i - p_j|} \quad (2)$$

Where $dist(c_i, c_j)$ refers to the reciprocal distances between the offset positions of the candidate keyphrase c_i and c_j in the paper. $pos(c_i)$ represents all the offset positions of the candidate keyphrase c_i.

Results

The selection of benchmark systematic reviews followed some criteria, e.g., whether the full text of the review can be retrieved, whether it reports the search strategy and lists all inclusion papers, and whether its search results can be reproduced on PubMed. Given the research interest of '*treatment of hypertension*' and corresponding search strategy *'treatment of hypertension AND Review[ptyp] AND free full text[sb]'*, the first eligible systematic review [18] was selected from the search results on PubMed. Then the proposed method was applied to mimic the paper searching process in this review for evaluation. The method used PubMed as the literature search service, and did the paper querying via the Entrez search interface [16]. Note that the proposed method is not restricted to specific databases such as PubMed. The method was implemented in Python and the LPCGraph was visualized via visNetwork [17]. The systematic review totally includes 23 papers about RCTs involving acupuncture as a therapeutic intervention for treating hypertension, in which nine papers are retrieved by searching from PubMed. We name the list of nine included papers as *ground_truth_paper_list*.

The experiment started from retrieving papers via the Entrez search interface by using the search strategy from the systematic review (Figure 6(a)). Several papers in the *ground_truth_paper_list* were marked as seed papers manually in the first iteration to guide the clustering of topics. The searching method was run iteratively until there is no new seed selected. All the seed papers were collected together for output, named as *seed_paper_list*. The experiment was executed multiple times with different number of seed papers selected (*number_of_seeds*). All the paper queries were done online via the Entrez search interface to retrieve the newest results. We also use cache mechanism to reduce the time of network connecting. The execution date of the experiment was Nov 23, 2018.

Figure 4 shows the precision and recall of the experiment with different *number_of_seeds*. The calculations of precision and recall are as follows.

$$precision = \frac{|\{x|x\in seed\_paper\_list \& \ x\in ground\_truth\_paper\_list\}|}{|\{x|x\in seed\_paper\_list\}|} \quad (3)$$

$$recall = \frac{|\{x|x\in seed\_paper\_list \& \ x\in ground\_truth\_paper\_list\}|}{|\{x|x\in ground\_truth\_paper\_list\}|} \quad (4)$$

The recall increases when more papers in the *ground_truth_paper_list* are selected as seeds by our method. And the precision decreases because when the *number_of_seeds* becomes larger, more papers are selected into the *seed_paper_list*. It is worth mentioning that when the *number_of_seeds* was set to five, precision and recall together get a balanced value, namely 0.7 and 0.7778, respectively. It indicates that by carefully setting the value of *number_of_seeds*, our method could reach an acceptable and balanced performance, as well as the execution efficiency corresponding to the execution time shown in Figure 5. The results can be further verified by Figure 6. Figure 6(a) is the search strategy copied from the systematic review paper, which contains three topics: acupuncture, hypertension, and randomized trial. Figure 6(b) is the final search strategy automatically generated by our method with *number_of_seeds* as five, which indicates five topics including acupuncture, blood pressure, hypertension, treatment, and group. It is visible that our method kept the original topics, and also expanded the topic of hypertension to blood pressure, which is meaningful.

Figure 2 shows the generated LPCGraph with *number_of_seeds* as five. Totally 135 papers were retrieved and represented in the graph. Ten paper nodes colored with red were selected as seed paper and input into the *seed_paper_list*, among which the five ones with no transparency were automatically selected in the latest iteration

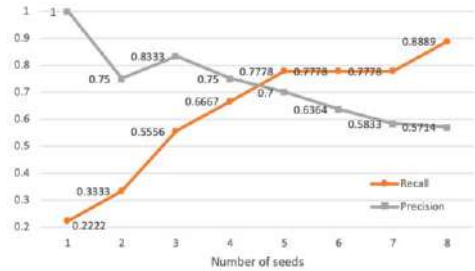

Figure 4– Precision and recall when selecting different number of seeds

by our method. In spite of the LPCGraph, Table 1 also shows the comparison between the *ground_truth_paper_list* and the *seed_paper_list*. There are two papers in *ground_truth_paper_list* but not in *seed_paper_list*. The paper with id *16541853* can be searched in PubMed by id, but can not be retrieved by the original search strategy in the

Figure 6– (a) The search strategy in the first iteration from the systematic review paper. (b) The search strategy in the final iteration generated by the proposed method

systematic review, which leads to an exclusion to our overall paper list. The paper with id *10352369* was retrieved by our method, but due to the lack of citation information, its rank is low and not ever selected as a seed. Another list in Table 1 is the papers in *seed_paper_list* but not in *ground_truth_paper_list*. Considering the content of title and abstract, these papers are highly related to the research topic. But further confirmation need to be done by clinical researchers.

Table 1– Comparison between ground_truth_paper_list and seed_paper_list

Papers in *ground_truth_paper_list* but not in *seed_paper_list*	
16541853	Observation on therapeutic effect of "reducing south and reinforcing north" needling method on hypertension of type of yang-hyperactivity due to yin-deficiency
10352369	Effect of a standardized acupuncture treatment on complains, blood pressure and serum lipids of hypertensive, postmenopausal women. A randomized, controlled clinical study
Papers in *seed_paper_list* but not in *ground_truth_paper_list*	
17359649	Acupuncture, a promising adjunctive therapy for essential hypertension: a double-blind, randomized, controlled trial.
2052631	Effect of acupuncture-point stimulation on diastolic blood pressure in hypertensive subjects: a preliminary study.
16990216	Acupuncture reduces experimental renovascular hypertension through mechanisms involving nitric oxide synthases.

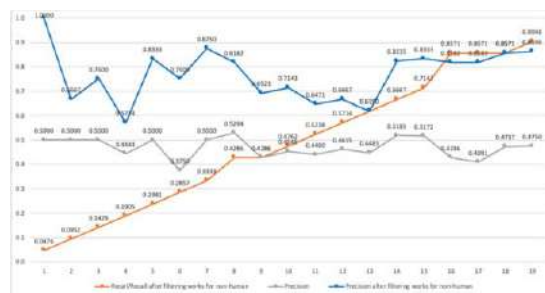

Figure 7– Precision and recall when selecting different number of seeds, and after filtering works for non-humans

Evaluation was performed on another systematic review [20] given the research interest of '*risk of diabetic nephropathy*'. Due to space limitations, we only show the precision and recall in Figure 7. As the *seed_paper_list* contain works for non-human, we also list the adjusted results after filtering the non-human works.

Discussion

The method introduced in this paper provides a generalized mechanism to automate the clinical paper searching task. The implementation of the method is independent of topic specific restrictions. Precision and recall in Figure 4 indicate that by carefully setting the value of *number_of_seeds*, our method could reach an acceptable and balanced performance. Comparing to manual searching, we also demonstrate the concrete execution efficiency of our method via the execution time in Figure 5. In the results of the second experiment, we observed that works for non-human were included as seeds. According to the statement of the review [20], we filtered those works and calculated the adjusted precision and recall in Figure 7. The adjusted results show consistent performance with the first experiment. The reason why the precision before adjustment is relatively low is that the review manually rejects all the works for non-human, but this information is not well

catched by the search strategy. Such kind of 'exclusion' will lead to the use of NOT in the search strategy, which is beyond the scope of the current implementation.

The use of PageRank for ranking and selecting seed papers is intuitive, especially when the original search strategy is not arbitrarily defined by clinical researchers. Given the hypothesis that the retrieved papers are probably related to the research topic, the most cited papers have higher probabilities to match the topic than other less cited ones. When the original search strategy from the review paper is somewhat ambiguous, the seed papers selected by the PageRank algorithm subsequently have more change to deviate from the research topic. As in the second experiment, the original search strategy didn't explicitly depict the exclusion of works for non-human. So the generated LPCGraph have two separated centroids: one relates to works for human and the other relates to works for non-human (mice). As a result, as the PageRank algorithm ranks seed papers from both of them, it leads to lower precision when comparing to the original systematic review. In the future, we will try to address the problem of ambiguous original search strategy, e.g., by comparing seed candidates with the original selected ones.

The topic-based clustering algorithm is applied to generate keyphrases and further cluster them into topics, which are assembled to form a sophisticated search strategy. The main structure of the search strategy follows guidance from Lu [7] and Kitchenham[19]. As discussed above, we will try to include NOT as a connector into the structure of the search strategy in future works.

A main limitation of this method is that it depends on the availability of search interfaces of different online databases. According to our observation during the survey of systematic reviews, most of the reviews search papers from multiple databases such as PubMed, Embase, and Cochrane etc. Lack of access to certain databases will lead to bias of clinical paper selection.

Conclusions

In this paper we proposed an iterative clinical paper searching method to capture the three aspects of the searching process, namely seed paper selection, search strategy generation, and layered paper citation graph visualization. We showed a detailed implementation of the method by leveraging PageRank algorithm, topic-based clustering, and paper citation graph based visualization. We applied the method to mimic the paper searching process in published systematic review, and the results show that our method can be used to accelerate the paper searching process as well as keeping the intermediate results as provenance in a quick and effective way.

Abstract

Juvenile Idiopathic Arthritis (JIA) is the most common chronic rheumatic disease of childhood, with outcomes including pain, prolonged dependence on medications, and disability. Parents of children with JIA report being overwhelmed by the volume of information in the patient education materials that are available to them. This paper addresses this educational gap by applying an artificial intelligence method, based on an extended model of argument, to design and implement a dialogue system that allows users get the educational material they need, when they need it. In the developed system, the studied model of argument was leveraged as part of the system's dialogue manager. A qualitative evaluation of the system, using cognitive walkthroughs and semi-structured interviews with JIA domain experts, suggests that these methods show great promise for providing quality information to families of children with JIA when they need it.

Keywords:

Patient Education, Artificial Intelligence, Semantic Web

Introduction

Juvenile Idiopathic Arthritis (JIA) is a chronic rheumatic disease with clear physical and social burdens for those with the condition—and is also known to cause an "emotional rollercoaster" for affected families [1]. Appropriate patient education has been shown to reduce some of these burdens and improve quality of life [2]. Nevertheless, caregivers of children with JIA in Canada have expressed being overwhelmed from the myriad of information sources available to them [3]. Indeed, best practices in patient education call for giving caregivers control over what content they view [4]. Moreover, there seems to exist a strong preference towards education information from trusted sources, such as healthcare providers or the Arthritis Society [3]. Thus, there is a clear need to provide *trusted* patient educational content to (families of) children with JIA, which is not overwhelming and delivers content control and access to the information outside of clinic.

Dialogue systems are automated efforts to imitate a person-to-person communication style to make the interaction with a computer system more intuitive for the user [5]. Unlike traditional verbal and printed patient education mediums, dialogue systems are accessible via computers or mobile phones at the user's convenience. The key feature of dialogue systems is the flexibility of access to the educational content, as the user controls the subject of inquiry. This is unlike paper-based Patient Education Materials (PEM) or static websites, where the information is prepackaged. While dialogue systems have been only sparingly used for patient education, it has been reported that this educational medium results in a significant improvement in knowledge [6] and self-management [7]. Two types of dialogue are relevant to patient education—i.e., information seeking dialogue, where the aim is to provide information to answer a user's question; and inquiry dialogue, where users seek to explore and verify evidence [8].

An AI-based argument theory, based on the Toulmin model of argument, provides a useful model to represent educational content for a dialogue system. Argument theory offers a set of information representational constructs to represent the central elements of any dialogue, such as the dialogue's claim, the evidence backing the authenticity of the claim, the data used to derive the evidence, certain exceptions to the claim and so on. Toulmin's argument model, therefore, supprts the functions of language that are used to justify a claim in terms of a narrative structure that mimics a dialogue [9]. Therefore, there is a case for using argument theory to develop dialogue systems for patient education, as not only are dialogue systems more friendly and intuitive for educational purposes, but they also provide information that is backed up by evidence and can be further investigated for alternative options and/or additional details. Toulmin's model has been used by patient education tools, albeit for question-answering as opposed to a dialogue that manifests a series of follow-up questions [10].

Our objective is to investigate the use of argument theory to model the JIA educational content so it can be delivered via a dialogue system—with the goal of addressing the educational needs of families of children with JIA. Given the requirements of the JIA patient education materials, we leverage the *Extended Model of Argument* (EMA) [11] since it encompasses the diversity of topics and forms of information found in JIA PEM. Using the EMA, we developed an interactive dialogue based JIA patient education system—i.e., the Juvenile idiopathic Arthritis Dialogue-based Education (JADE) system (see Figure 1). In this paper, we present our knowledge management approach to develop JADE [12]. We discuss (**i**) the formulation of an ontology-based EMA knowledge model to formally represent the concepts and relationships underlying (extended) argument theory, resulting in the *JADE Ontology* (JO); (**ii**) the abstraction of relevant education themes from the available PEM, using thematic coding; and (**iii**) computerizing the PEM content, alongside the identified themes, using the JO. JADE has been developed and it contains 32 PEM covering 16 topics, in terms of 931 arguments. We developed semantic web-based reasoning methods to reason over the PEM content, represented using the JO, to formulate an interactive dialogue where the user can ask an initial question, as well as a series of

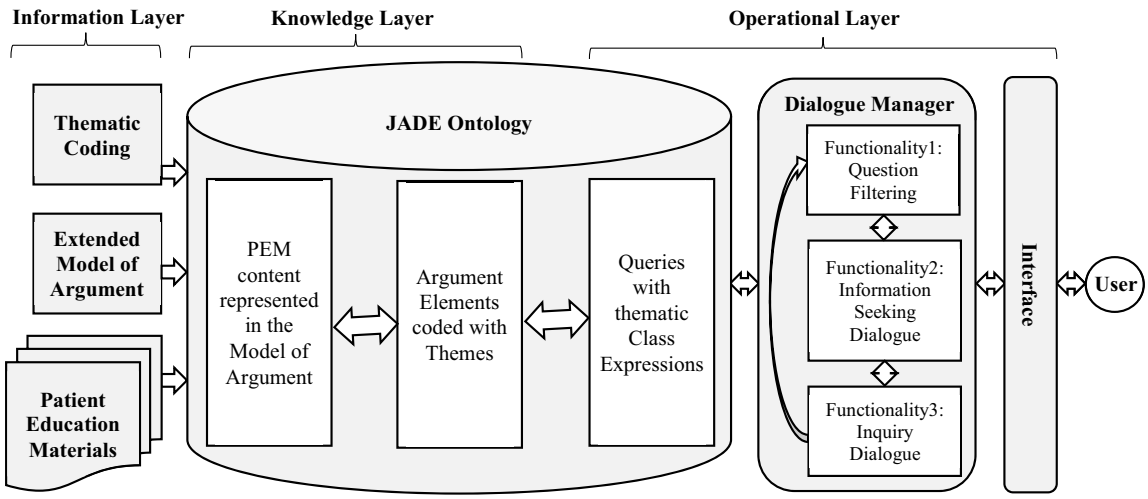

Figure 1– Architecture of the JADE system

follow-up questions. In this way, JADE provides families of children with JIA access to trusted PEM content approved by their healthcare providers—in a way that gives users control over the educational content that they are presented. JADE has been evaluated for content completeness, relevance, and utility.

The novel aspect of our patient education approach is the provision of a dialogue that is dynamically generated (in response to a variety of user queries) by selecting relevant arguments encoded in the JO and chaining a series of arguments using reasoning. According to the literature, one other dialogue system has used the Toulmin model of argument [10], however it is clinician facing and can only respond to a single question with content from a single argument.

JADE Architecture

Figure 1 depicts the 3 layers of the JADE system's design:

1. The information layer contains the EMA, thematic codes, and PEM content described previously [11]. This layer provids the knowledge model which is used to represent the PEM content in the JO.
2. The knowledge layer is comprised of the PEM content, coded to the EMA and thematic coding, represented in an ontology. This layer creates a computerized structure which the operational layer can draw on to provide an interactive dialogue. Thematic coding links individual EMA elements to an initial user question and the relationships between EMA elements, and individual arguments, allow for follow up questions about the content of the initial response.
3. The operational layer is made up of potential user questions encoded in the ontology, the dialogue manager, and the user interface. The dialogue manager receives the user's input through the interface and interacts with the ontology to formulate and deliver responses. It allows the user to find and select questions that are of interest to them, to have an information seeking dialogue by asking and receiving answers to their questions, and to participate in an inquiry dialogue. The latter uses question prompts based on the EMA and the chaining of arguments to help the user navigate through the PEM content.

Methods

The EMA serves as the knowledge model for integrating PEM content into the JADE system and is used to structure the inquiry dialogue it provides. Based on the Toulmin model, which contains 6 constructs: the claim, qualifier, data, warrant, backing, and rebuttal (renamed exception) [9], the EMA's 7 elements represent the parts used to justify a statement [11]:

1. The Claim is the statement being justified.
2. The Qualifier denotes the strength of the claim.
3. The Data represents situations where the claim is true.
4. Warrants, either explicit or implicit, explains how the data relates to the claim.
5. Exceptions are situations where the claim is not true.
6. Elaborations give more information about another element, for example a definition.
7. The Backing is the source of the information.

Thus, the following argument from the pamphlet: 'Using Ice and Heat at Home' (backing) can be coded to this model as follows: 'Some pinking of the skin is normal (exception), however, ice should be removed (claim) if the skin becomes pale and/or pain is felt (data) as this is a sign that skin damage due to cold is beginning (explicit warrant). As well, periodic skin checks are recommended (elaboration to the claim).' This knowledge model was formalized as the JO using Protégé 5.0.0 (Stanford University, 2016). Since the strengths of ontologies include reusability and extendibility, we have based the JO on Vitali and Peroni's Argument Model Ontology [13].

PEM Topic Identification

Thematic coding of the PEM content was used by the JADE system to filter questions, so users can ask about what interests them, and to locate relevant PEM content in the ontology in response to a user's question. Themes were generated inductively from the PEM content using grounded theory [14]. For example, the element 'periodic skin checks are recommended' was coded as *Periodic* and *Skin checks* during open coding. Selective coding merged *Skin checks* with similar codes into the *Monitor* code. *Monitor* and codes such as *Use treatment* were then grouped under the theme *Recommendation* during axial coding.

Knowledge Formalization

The JADE system requires a structured repository of domain specific content, so that it can be accessed by the dialogue manager to formulate responses to user's questions. For this purpose, the PEM content and linked thematic codes were computerized using the JO. The ontology has 4 top-level classes depicted in Figure 2 and described in detail below.

Individual arguments are represented as instances of **the 'ArgumentAsRepresentedByImplicitWarrant' (ARIW) class**. Since two or more arguments could share the same data element, i.e. have the same situation for which a claim is true, such as taking a certain medication, the data element was not unique. Neither was the claim element, as two or more arguments could share the same conclusion, for example, the recommendation to use a treatment. The implicit warrant, usually expressed as 'If Data, then Claim', was unique for all arguments.

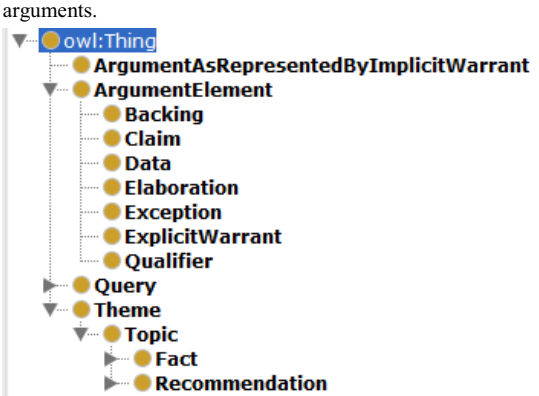

Figure 2– Top-level classes of the JADE ontology

The ArgumentElement class represents the 7 elements of the EMA, which are encoded individually as subclasses. PEM content, coded to the argument elements, was represented as instances of the coded element. For example, the argument: *If using heat and your child's skin turns red* (data)*, although some pinking of the skin is normal* (exception)*, then remove the heat source* (claim) from the pamphlet 'Using Ice and Heat at Home' (backing) was represented in the ontology as five instances: one each of the claim, data, exception, backing, and ARIW classes. Relationships between elements were encoded using object properties as shown in Table 1. Arguments were theoretically chained together when the claim of one argument contained the same content as an element of another argument. For example, the exception in: *There is no cure for JIA* (claim) *although there are medications that can reduce the inflammation and relieve the pain and swelling* (exception), is a claim in another argument: *If you have* JIA (data) *there are medications that can reduce the inflammation and relieve the pain and swelling* (claim). These links needed to be represented in the ontology, so we reused the 'sameAs' object property to link two elements of different arguments that contain the same content.

The Query class represents the questions users of the JADE system require to enter the network of PEM content encoded in the ontology. Individual questions were represented as subclasses of the Query class and were generated inductively from the PEM content. For example, PEM content describing the side effects of methotrexate, a medication used to treat JIA, induced the question: 'What are the side effects of methotrexate?'.

Each Query subclass has a class expression which attempts to translate the English question into a syntax the ontology reasoner can understand. For instance, the question above was expressed as the class expression:

(HasTheme some 'Side effects') and (IsElementOf some (HasElement some (HasTheme value Methotrexate))).

This tells the reasoner to find an argument element instance that has an instance of the 'Side effect' theme and is part of an argument in which an argument element has the theme 'Methotrexate'. The class expressions were written in the format of looking for one topic theme, or class of themes, that describes the subject of the query and one or more themes, or classes of themes, present in the argument describe its context. In the previous example, the topic theme was 'Side effects' and the context theme was 'Methotrexate'.

Table 1– The domain and range of the ontology object properties with inverse properties in brackets

Domain	Object Property	Range
Theme	DefinesThematically (HasTheme)	Argument-Element
Argument-Element	IsElementOf (HasElement)	ARIW
Backing	Backs (HasBacking)	ARIW
Elaboration	Elaborates (HasElaboration)	ExplicitWarrant, Data, Claim, Exception, Elaboration
Exception	Excepts (HasException)	Claim, Data, ExplicitWarrant, Elaboration
Qualifier	Qualifies (HasQualification)	Claim
Explicit-Warrant	Requires (HasRequirement)	Data
Data	Supports (HasSupport)	Claim
Explicit-Warrant	Warrants (HasWarrant)	Claim
Explicit-Warrant	HasAdditionalWarrant	ExplicitWarrant
Claim	sameAs	Argument-Element

The Theme class represents the thematic coding of the PEM. The codes are represented with a hierarchy of subclasses with the leaf codes as instances. For instance, the theme 'Liver damage' is an instance of the class 'Side effects' which is a subclass of the class 'Fact' that represents the context of a user's situation. The object property 'DefinesThematically' linked the instances to the argument elements they were coded to.

To date, 351 arguments extracted from the PEM have been instantiated as argument elements in the ontology. These arguments were prioritized as they were directly relevant or adjacent to topics covered in the scenarios used in the evaluation, which will be described further below. They represented most of the structures i.e. journal articles and pamphlets, topics i.e. treatments and etiology, and formats i.e. lists and images. Thus, this was a representative sample of the arguments extracted from the JIA PEM.

JADE Functionalities

The JADE system was designed with 3 functionalities:

1. A question filtering system offers a way to choose interesting questions that fit their situation.
2. An information seeking dialogue provides quality information from PEM in response to user's questions.

3. An inquiry dialogue allows users to explore the PEM content to determine whether the information provided was trustworthy and relevant to their situation.

Functionality 1: There are currently 163 questions encoded in the ontology. This functionality uses the thematic codes and class expression format to allow users to screen these options for the questions they want to ask. A user selects from a list of themes to find questions looking for: 'Recommendations about Methotrexate and DrinkingAlcohol', yielding 1, namely: 'Can I drink alcohol while taking methotrexate?'.

Functionality 2: By choosing a question, the user engages the information seeking dialogue functionality. This functionality uses the thematic coding represented in the ontology to deliver relevant content from PEM in response to user questions. Each question represents a query subclass and its class expression. The reasoner locates argument elements from the ontology that fit the class expression. In our example, the claim: 'it is best to avoid alcohol' is located because its themes are 'Drinking alcohol' and an instance of the Recommendation class and its data HasTheme 'Methotrexate'.

Question prompts for the inquiry dialogue functionality are also generated here according to the object properties present in the argument of the located element. In our example both HasWarrant and HasBacking properties are present in the located claim's argument. Thus, the full dialogue system response as per our example is:

If taking methotrexate, then it is best to avoid alcohol.

Want to know the reason for this?

Want to know the source of this?

Functionality 3: By choosing a question prompt the user can engage in an inquiry dialogue and explore the PEM content surrounding the answer to their question. The inquiry dialogue functionality leverages the object properties between argument elements, derived from the EMA, to create question prompts the user could use to explore and verify information from the PEM. To continue our example, the user chooses the first prompt: 'Want to know more about this?'. In response, the dialogue system locates the relevant argument element(s) in the range of the object property associated with this prompt, i.e. HasWarrant. This locates the explicit warrant: 'Taking methotrexate and drinking alcohol could harm your liver'. As in functionality 2 question prompts are generated. Although, in this functionality only object properties for the argument element in question, not the entire argument, will be used. The entire response as viewed by the user is:

Taking methotrexate and drinking alcohol could harm your liver.

Want to know the reason for this?

From here the user can use the home button to return to the question filtering of functionality 1, or the back button to return to the information seeking dialogue of functionality 2, or a question prompt to continue with functionality 3.

Evaluation Study

The JADE system was qualitatively evaluated to determine whether its responses were complete, relevant, accurate, and understandable. We aimed to recruit 5-8 healthcare providers from the IWK Pediatric Rheumatology Division for their expert domain knowledge of JIA and familiarity with the PEM content used in the dialogue system. Participants completed a cognitive walkthrough of the dialogue system followed by a semi-structured interview. Cognitive walkthroughs involved the participants verbalizing their thoughts as they interacted with the dialogue system, guided by a scenario and set of tasks [15]. The interview questions were based on the content portion of the O'Grady framework for evaluating interactive applications [16]. Screen capture and audio recordings of the evaluations were analyzed qualitatively using directed content analysis, with the O'Grady framework used as predetermined codes [17]. Approval for this study was given by the IWK Research Ethics Board (approval #1023261).

Results

6 clinicians have participated in the evaluation study: 4 nurses and allied health professionals and 2 pediatric rheumatologists. Two had less than 5 years of experience working in the pediatric rheumatology division, 3 had between 11 and 20 years of experience, and one had more than 20 years of experience. Three claimed to be very comfortable with computers, 1 was moderately comfortable, while two were moderately uncomfortable. Three reported that more than 75% of their clinical encounters involved using PEM, while 3 reported less than 40%.

Eight major themes were identified during analysis. Themes were determined to be major if 40% or more of participants had responses categorized under that code. Saturation was achieved, as evidenced by the fact that no new codes were added after the third evaluation. The major themes are listed below with examples of quotes from participants.

1. Positive responses to the JADE system.

   Participant 6: Having that data…available like this is really exciting!

2. Content was largely accurate outside of some inaccuracies in the PEM.

   Participant 4: [There was] nothing that was incorrect.

   Participant 3: [This PEM is from] 2011, yikes, that'll be from before some of these kids were born.

3. Content was credible but could be improved through better presentation.

   Participant 1: [Having links to the sources] is going to be really helpful.

   Participant 4: For instance, if you have a [hospital] logo… that tends to increase folk's credibility.

4. Content was mostly relevant, with a few exceptions.

   Participant 4: I think it's really relevant to what the patients and families are experiencing.

   Participant 5: Interesting, because I clicked on [a question about] 'ice' and then it starts talking about 'heat' [when I click on a question prompt].

5. Content was mostly complete, with a few exceptions.

   Participant 5: As you continued to 'want to know more about it' I think you did get all the information.

   Participant 3: Is there something about not getting live virus vaccines [while taking methotrexate]? One of your issues is going to be how are all the links set up, because they aren't a single linear link, its lots of things that end up being a complicated Gordian knot.

6. Individual responses were clear and consise, but a broader organization of the content was lacking.

   Participant 2: I think that's simple, to the point, uncomplicated.

   Participant 3: You have things that follow each other that are totally unrelated…with a big long list, people read the first two or three things and then they get bored and miss stuff.

7. Awkward wording occasionally made the information unclear.

Participant 5: 'What does that describe?' ... It's a bit awkward.

8. Accessibility issues to the JADE system.

   Participant 4: This is very much geared towards users that have the ability to be able to navigate it physically. Are there any parameters for folks who have limitations in terms of audio or visual?

Discussion

The results of the evaluation study show that the application of the AI-based argument theory method for delivering patient education dialogue was largely successful. The PEM content was fully integrated and formalized into the JO using the EMA and domain experts found the resulting dialogue content to have utility, outside of a few exceptions. The reasons for the few irrelevant, incomplete, and difficult to understand responses found during the evaluation are discussed here.

The majority of irrelevant or incomplete responses were due to gaps in the existing PEM. The remainder were caused by two issues with how the thematic coding and chaining between arguments were represented in the JO. First there was no representation in the JO of the causation of a side effect by a drug opposed to merely appearing in the same argument as the drug. Second, the sameAs property caused the reasoner to conflate the themes from two chained arguments, which should be separate, leading to irrelevant elements being selected during information seeking dialogue. Future work will address this by using alternate methods of representation.

The 6th theme of the evaluation shows the limits of the EMA, which does not contain constructs to model knowledge beyond the level of individual arguments. Thus, while the EMA and thematic coding have successfully represented a large portion of the knowledge contained in the PEM, another layer of representation is required. The relative importance and overall subject of each argument need to be modelled to organize the elements, relative to each other, in the system's responses. Future work will identify such a model and implement it.

We believe the remaining issues highlighted in the evaluation study, i.e awkward wording, accessibility issues, and credible presentation, can be best addressed in co-design with JIA stakeholders. Future work will therefore seek to engage families of children with JIA and their healthcare providers.

Limitations

The participants recruited for the evaluation study were from a single site and while their familiarity with the PEM used in the system was beneficial to the study it potentially limits the breadth of viewpoints a broader inclusion strategy could have offered. Similarly, the analysis of the results was performed by a single coder which increases the potential for bias.

While the methods used in this work are generalizable to patient education for other conditions, the substantial time and knowledge required, limits their applicability. The coder(s) must have a good working knowledge of the EMA as well as grounded theory for the thematic coding. They must also understand the condition described by the PEM and be able to represent the resulting codes in an ontology. The time needed to do this is an additional barrier to these methods being used.

Conclusions

This work describes a novel method of using a model of argument to create a patient education dialogue system for healthcare users. The evaluation of the JADE system showed that it provided responses that were mostly relevant, understandable, and complete, thus demonstrating its potential to address some of the current gaps in patient education experienced by families of children with JIA.

Student Nurse Attitudes and Behaviours when Using Social Network Sites

Roseanne Sadd

Department of Nursing, Toi Ohomai Institute of Technology, Tauranga, New Zealand.

Abstract

The purpose of this study is to describe the effect of education in professional boundaries on the use and management of social media by using quantitative survey methods to ask "What are the social networking behaviours of student nurses following education in professional boundaries?

Findings from this research indicate that student nurses are active SNS users, primarily for personal engagement. Facebook is overwhelmingly the most popular SNS, with snapchat and Instagram also commonly used. While students primarily used SNS for personal reasons, many reported SNS use for educational / professional purposes as well, including to discuss academic related topics. Most students responded that they were aware of privacy settings on SNS, however there is a discrepancy between awareness of privacy settings and the number of students implementing the privacy features.

Keywords:

Privacy, Professionalism

Introduction

Social network sites (SNS) are a form of social media that allow immediate, real-time interaction, utilising Web 2.0 applications to create, share, and interact with, information. In New Zealand, two-thirds of Internet users engage in regular social network use including sites such as Facebook, Twitter, blogs and forums [1]. SNS have become a common form of communication and interaction in our personal and professional lives [2,3]. Nurses too, are increasingly using SNS, both as part of their professional role, and in their private lives [4].

While there is increasing literature regarding student use of SNS, there is a little research that specifically examines students from the health professions despite the risk of breaching the privacy of those the health professionals care for [5]. Few studies involving health professionals (student or otherwise) discuss professionalism when using SNS. Content analysis of the SNS Facebook by Levati, [2] found differences in the use and access of SNS by United Kingdom and Italian nurses. However, both groups had posted personal information and potentially unprofessional information. Hall, Hanna & Huey [6] reported that despite awareness of privacy settings and requirements when using SNS, pharmacy students blurred the lines between personal and professional online behaviours. Similarly, student nurses in South Africa lacked understanding of the risk of posting personal content, many reporting having postings that potentially breached patient privacy [7].

In New Zealand, nurses are educated within a Bachelor of Nursing or similar baccalaureate degree governed by the Nursing Council of New Zealand (NCNZ) under the Health Practitioners Competence Assurance Act 2003. It is the responsibility of educational institutions providing these programmes to ensure student nurses achieve competency to practice, including ethical, legal and professional competency. Although students do not fall directly under the jurisdiction of the nursing council, student nurses must comply with the standards of their educational institution and maintain the same professional conduct as a Registered Nurse. Nursing education needs to keep abreast of changes to develop graduate nurses who are confident and competent to practice within the healthcare environment. Educational institutions have a responsibility to ensure nursing students are aware of the risks of social network use and have strategies to ensure their on-line presence remains professional [8,9]. Currently there is no published research on the use of SNS by nurses or student nurses in the New Zealand context.

In year one of a Bachelor of Nursing programme students complete a course on professional practice with the aim of introducing students to the "professional, ethical and legislative requirements of nursing practice". The question that arises is whether students integrate this learning into their own use of social network; in simple terms, does theory integrate into practice?

The central question asked by this study is "What are the social network site attitudes and behaviours of student nurses following education in professional boundaries".

The scope of this research is the self-reporting attitudes and behaviours of students nurses currently enrolled in a Bachelor of Nursing course. This research is not expected to measure the effectiveness of professional boundary education, but, rather investigate and describe student social network attitudes behaviour to the maintenance of professional boundaries online – have students have put theory into practice when using social network sites?

Methods

This research is a descriptive survey using quantitative methods to provide a snapshot of student nurse attitudes and behaviours regarding the use of SNS, ascertaining frequency and purpose as well as describing the measures taken by student nurses to maintain professionalism.

The objective of this research is to investigate the use and management of social network sites by Bachelor of Nursing students, questioning how students use SNS, how they protect privacy on SNS, and, what their attitudes are to maintaining professionalism when engaging with SNS. Do students recognise the risks involved with social networking? What measures do students take to protect their own information, and

the information of patients they care for, in order to maintain their professional boundaries?

Ethics approval was granted by the Faculty of Business, Information Technology, and Creative Arts, Research Committee of Waiariki Institute of Technology (now Toi Ohomai Institute of Technology).

Sampling

The target population was Bachelor of Nursing students at one tertiary institute who had successfully completed a course in professional boundaries. A face to face information session for potential participants was followed up by an email outlining the research project as their rights as a research participant. Interested participants were emailed a link to the online survey giving assurance of confidentiality, informed consent, and voluntary participation. Consent was gained by participants agreeing (consent) online prior to the survey commencing. Subsequently eligible students were sent an email with an individual participant web-link directing them to the survey. Students were emailed a reminder at one week and before the survey closed using their online learning platform. Once the survey had closed, results were exported from Survey Monkey and prepared for importing into statistical processing software.

Data collection

Data were collected by way of an online self-reporting questionnaire using the web-based format of 'Survey Monkey', (http://www.surveymonkey.com), adapted from that of Hall, Hanna and Huey [6]. The adapted questionnaire was reviewed for face validity by two senior colleagues and content validity by an experienced researcher from another institution. Participants were asked to self-report behaviors and attitudes when engaging with SNS.

Participants were asked to self-report behaviors and attitudes when engaging with SNS. The questionnaire is presented in four sections.

- Use of social networking
- Online profile and privacy
- Professionalism and social networking
- Demographics

The questionnaire asked a series of closed - ended questions answered by yes or no, or, questions to determine responses using a Likert scale ranging from strongly agree to strongly disagree.

Due to the population (BN students within one specific program), no gender or ethnicity data was collected as this information could potentially identify participants. The only demographic data collected was age group <25years or > 25years. This age selection relates to the concept of digital natives (<25 years age) who have grown up with online technology and digital immigrants (>25 years age) who have had to adapt to the technology [10]

Once the survey had closed, results were exported from Survey Monkey and prepared for importing into statistical processing software.

Data analysis

Responses were coded and entered into IBM's Statistical Package for Social Sciences (SPSS) version 24. Data were analyzed using descriptive and inferential statistics providing a description of student nurse behaviours and attitudes when using SNS. Based on the preliminary analyses, it was determined that the research data was primarily categorical and ordinal in nature and non-normally distributed therefore relationships between use, privacy and professionalism were identified using non - parametric tests. An a priori level of less than .05 ($p<.05$) was set as significant. Missing data were not estimated or used in analyses.

Results

228 year one and year two Bachelor of Nursing students were invited to participate in an online survey via an email link to the Survey Monkey website. 102 valid responses were received.

Table 1: Sample population / respondents

Age Group	Total Population	Respondents (valid)	% valid respondents to population
18-25	112	47	42%
26+	116	55	48%
Total	228	102	45%

"How do student nurses use SNS?"

Respondents were asked to select which SNS sites they use. Over 90% reported using Facebook with Snapchat and Instagram being the next most common SNS' reported (Figure 1). 'Other' included sites such as Youtube (*n*=4), Tumblr (*n*=1), and WhatsApp (*n*=1).

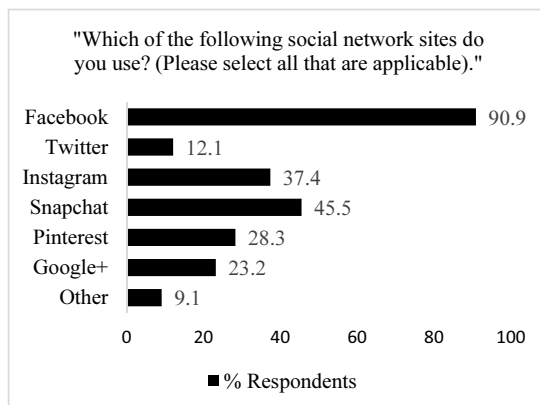

Figure 1: SNS accessed by students

Almost half of the students (49.5%) used three or more SNS while over 70% of students spent between 0.5 – 2 hrs accessing SNS daily. Students access SNS primarily for personal reasons (94.5%), with over half of the respondents reporting that they use SNS for both personal and education purposes (53.5%).

Students reinforced their use of SNS for educational purposes with 65.7% strongly agreeing or agreeing to the question to the questions that they "I *have used social network sites to discuss academic related problems*". However, just under one fifth of students (19.1%) disagreed with this statement. Most students

(92.9%) strongly agreed or agreed that they had "*been made sufficiently aware of the professional behaviour that is expected of me when using social network sites*".

The relationship between number of SNS used and purpose for using SNS showed there was a small positive relationship between the two variables with the higher the number of SNS used, the higher the number of reasons for using SNS, rho = .226, n = 99, p < .05. This relationship was stronger in the 18-25 year age group rho = .311, n = 45, p <.05.

A Mann-Whitney U Test was used to test for difference between the two age groups (18-25, 26+) and responses to the statement "I have used social network sites to discuss academic-related problems". A significant difference was found ranking the 18-25 year age group (Md = 1, n = 45) higher than the 26+ age group (Md = 1, n = 54), U = 965000, z = -2.09, p = .04, r = .21. indicating the 18-25 age group are more likely to use SNS for academic discussion.

"Do students protect privacy when using SNS?"

The first two questions in this section referred to student awareness and use of SNS privacy settings. Although most students were "*aware of the privacy features available on social network sites limiting the amount of information available to the public"*, only three quarters (76.8%) of students reported using these privacy features (Figure 2).

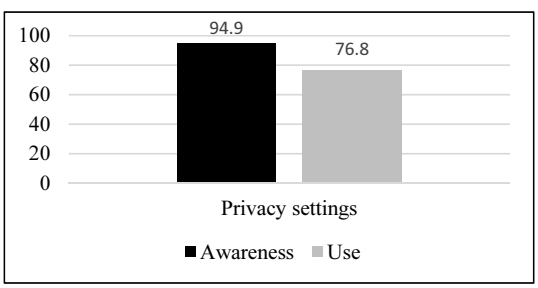

Figure 2: Awareness & use of privacy settings

Over half of the respondents reported that they agreed with the statement "*The profile and activity I present on social network sites websites is an accurate representation of my character*", however, less that one quarter 'strongly agreed' (22.2%), and over a quarter neither agreed or disagreed with the statement When asked about the concern "*that others could post information or photos"* students had a varied response. Just over half agreed (40.4%) or strongly agreed (13.1%) that this concerned them; a further 27.3% neither agreed nor disagreed When asked whether it was "*acceptable to publish whatever I like"* if privacy settings were in place, again the response was varied, 69.7% reporting they 'disagree' or 'Strongly disagree" with the statement, and 30.2% of respondents selecting 'neither agree nor disagree' or 'agree'.

There was also a relationship between the use of SNS privacy settings and the unacceptability of publishing "*whatever I like on social network sites*". The relationship is weak but suggests awareness of maintaining privacy when publishing on SNS, *rho* = .235, $n = 99$, $p < .05$.

There was no significant difference between age groups and awareness of privacy settings. Similarly, there was no significant association between age group and use of privacy settings, χ^2 (1, n=99) – 0, p = 1.0, *phi =0.22*

Do students maintain professional boundaries when using SNS?

The final section of the questionnaire asked questions about students' attitudes to professionalism when using SNS (Table 2). Most students (79.8%), 'agreed' or 'strongly agreed' that they maintain the same professional standards whether using SNS or on clinical placements and 96% of students took responsibility for all information they have posted on SNS including comments.

Table 2: Responsibility for own postings

Strongly agree	67.7%
Agree	28.3%
Neither agree nor disagree	2%
Disagree	2%

A portion of students reported having posted information they would not want either academic staff or an employer to see (Figure 3).

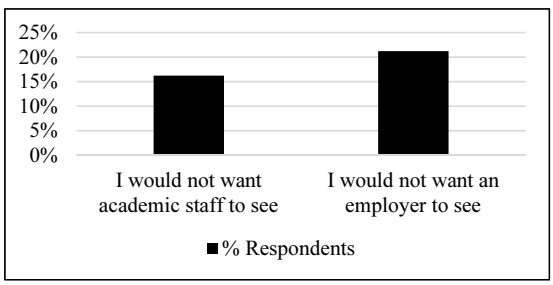

Figure 3: Information posted seen by academic staff / employer

When asked whether it was fair that employers use information from social network sites there was no clear response given, similarly, responses were mixed for the question about whether students were concerned that their professionalism could be judged by their SNS use (Table 3). Just over 50% of respondents reported that viewing of the SNS activities of student nurses by the public could affect their reputation. When qualified or seeking employment 69.7% of respondents said when they would not change SNS behaviours, while 30.3% stated they would change their SNS behaviour when qualified.

Table 3: Judging professionalism by SNS use

Strongly agree	9.1%
Agree	41.4%
Neither agree nor disagree	23.2%
Disagree	23.2%
Strongly disagree	3.0%

The majority of respondents (94%) 'Disagreed' or 'Strongly disagreed' that it was acceptable to comment about patients. While it is encouraging that there was a clear understanding of the importance of respecting patient privacy, it is a concern that this question was not answered with 100% disaffirmation.

Kruskal -Wallis Tests did not reveal any significant difference in either total privacy or profile (composite variable), or total professionalism (composite variable) across the different number of SNS used by students (p<0.5).

Discussion

There are approximately 48000 Registered Nurses in New Zealand [10], but no detail on when, if, or how, they engage with social network sites. Nurses hold a privileged position where patients may share personal information and insights into a patient's life. Nurses are often privy to very personal and sometimes delicate information; therefore have a legal, and ethical, responsibility to protect this information and maintain patient privacy [11]. Inappropriate on-line behaviour by nurses can result in damage to their relationships with patients, colleagues and the profession as a whole. Registered Nurses' use of SNS has the potential to breach professional boundaries, breach privacy and damage trust the public have in the nursing profession.

The aim of this study was to determine if student nurses maintain professional boundaries when engaging on social network sites. While the overall response rate to the online questionnaire was only 45%, the respondent age groups were similar to that of the student nurse population. It is possible that potential participants who did not use SNS most likely did not respond, therefore the analysis of SNS use focused on "how" and "what" SNS do students use.

Findings indicated that students are active SNS users, primarily for personal engagement, in line with other studies [6,12]. Facebook is overwhelmingly the most popular SNS, reflecting general population trends [13]. Student nurses of both age groups in the study, (digital natives, 18-25 year age group, and digital immigrants, 26+ age group) are engaging with SNS, primarily Facebook, with snapchat and Instagram also commonly used.

The similarity in use for the two age groups in the study reflect StrauB and Nentwich's [14] assertion that SNS has become relevant to all ages. While students primarily used SNS for personal reasons, many reported SNS use for educational / professional purposes as well, including to discuss academic related topics. Hall et al. [6] identified a pattern of increasing use of SNS for academic purpose as students entered professional study. It is possible that students who use SNS for education and personal reasons, use multiple SNS sites for different purposes, although the digital natives in the study are more likely to use SNS for academic purposes. Having grown up with online technology, may predispose the digital natives to see SNS as an immediate source of assistance.

Most students responded that they were aware of privacy settings on SNS, however there is a discrepancy between awareness of privacy settings and the number of students implementing the privacy features despite strong recommendations in professional nursing guidelines [9]. This is in contrast to findings by Hall et al., [6], and Kitsis et al. [12] which reported high levels of privacy setting by health profession students.

Students in the study appear to be aware of how they may be judged by their online profile. Despite this, while not evident in this research it is possible that students who did do not use privacy settings are more likely to have inappropriate postings viewed by others, especially as some students reported concern about what others may post about them.

SNS such as snapchat and Instagram (the second and third most popular SNS used by respondents) are mainly used to share images and photos, a format which can inadvertently expose identifiable information by capturing an organisation or emblem in an image, or people in the background of a photo. Students who do not utilise privacy settings may feel their privacy settings are sufficient to protect them, avoid photos or have friends and acquaintances who rarely use post on SNS. Some of the most common posts which portray nurses in potentially unprofessional situations are photos [2].

Professional boundaries need to be maintained not just when dealing with patients or clients. Dual relationships can also develop between a nurse and colleague, employer or other health professionals. Blurring of boundaries results when information gleaned from the professional environment is brought into the personal environment such as discussing the workplace in a social setting. This is exacerbated when in the online SNS setting as information is more able to be inadvertently shared, or, misinterpreted.

The image portrayed by nurses on SNS has an impact on the image of the nursing profession as a whole [16]. Over half of the students in the study reported general concerns with how the nursing profession reputation would be portrayed if student nurse SNS were viewed by public, yet the majority of student nurses in the study took responsibility for content on their SNS and reported maintaining the same professional standards whether on SNS or on a clinical placement suggesting understanding of the importance of professional behaviour. Some students reported they would change their SNS behaviour when becoming qualified (registered), questioning whether students consider themselves as part of the nursing profession while completing their qualification.

Students reported understanding of the importance of maintaining privacy and professional behaviours, yet response were varied when considering how others may view their SNS use, possibly relating to the ethical aspects of others viewing an individual's SNS. Whether it be a potential employer viewing an applicant's SNS or someone judging a nurse's professionalism based on their personal SNS postings, answers could be reflective of whether it is right to use SNS in this way rather than reflective of students postings.

From this research, and other previous research, it is unclear whether students do understand the importance of protecting their personal persona on SNS for today and for the future? Similar findings from the United Kingdom concluded that while nurses are aware of the risks of SNS use, a significant number only partially protected their privacy online [2]. Kitsis et al. [12] acknowledges that medical students can struggle to develop a professional identity separate from their personal persona online, while Hall et al. [6] and Nyangeni et al. [7] reinforce the need for ongoing education in professional behaviour. Findings from this research indicate that student nurses who have completed education in professional boundaries in the first year of their degree are aware of privacy and the need for care when posting on SNS, but it cannot conclude that student do indeed maintain boundaries without further research.

Limitations

Limitations to the research findings result from the small sample size and self-reporting format used for the survey. Non-response bias cannot be eliminated, however the proportion of respondents did reflect the population makeup. A written questionnaire format may have delivered more responses, but could also have pressured potential participants to take part.

Findings could be further explored through a larger study, by interview or by analysis of actual SNS sites in the future. Findings may not offer a specific revelation, but provide a description of student nurse attitudes and behaviours when using SNS within the New Zealand context.

Conclusion

The Nursing Council of New Zealand (NCNZ) have demonstrated the importance of nurses maintaining their professionalism when online through the Code of Conduct and guidelines for social media [11,15]. Despite guidelines from NCNZ, and education in the first year of the Bachelor of Nursing degree, organisational policies are required to set standards of acceptable online behaviour when engaging with SNS. Education must be ongoing throughout the degree, not only in the regard to use of SNS, but in all areas where there is blurring of the personal and professional boundaries of student nurses and the potential to breach professional conduct.

With a respondent's rate of 45% for this research, it is not possible to make conclusions about the wider student nurse population. However, data from the general population and from other studies reporting health professional student use of SNS suggest it is likely that the majority of students are engaging with SNS.

While we know what SNS sites student nurses are using, little is known about the type of content being posted. If students are using SNS more frequently for educational purposes, what type of academic questions are being asked, and where is the information coming from. Content analysis of SNS used by student nurses would validate the self-reported findings and perhaps help explain what nurses consider as acceptable postings on SNS, which would build on this study in an attempt to answer many of the questions raised by the research findings.

Acknowledgements

This research was undertaken in partial fulfillment of Master of Management (Health). The author acknowledges all Bachelor of Nursing students who completed the survey.

Multi-Modal Methodology for Adapting Digital Health Tools to New Populations: Adaptation of the Video Information Provider (VIP) for Persons Living with HIV with HIV-Associated Non-AIDS (HANA) Conditions

Abstract

The goal of this study was to illustrate the translation of our extant eHealth intervention (VIP) into an mHealth app for persons living with HIV (PLWH) with HIV-Associated non-AIDS (HANA) conditions, a new clinical problem. We integrated different quantitative and qualitative methodologies from different disciplines to accomplish the task of adapting an eHealth system for a new set of clinical problems. Building off of our past development of the VIP website, we used a multi-modal, iterative user-centered design process to develop the VIP-HANA app. Our process was used to better understand the needs of a national sample of PLWH recruited online. Findings from the usability evaluation demonstrate a potentially useful and easy to use app. Integration of multi-modal methodologies from different fields to accomplish the tasks of adaptation and evaluation of a mobile app is an appealing, rigorous and useful approach.

Keywords:
HIV, Mobile Applications, Symptoms

Introduction

Psychological theories often provide the guiding framework for eHealth interventions, yet the actual development process often relies on developer clairvoyance and the serendipity of the researcher in successfully communicating his/her goals to the software developer. This oftentimes arbitrary process is less than scientific and not ideally suited for efficient, rigorous and reproducible intervention development. The instantiation of behavioral health interventions delivered via technology and the expanded need for translating eHealth tools to a new clinical problem are the impetus for clearly outlining the development process of consumer health informatics tools. The goal of this paper is to illustrate the integration of multi-modal methodologies for adapting an extant intervention for new or growing clinical problems. Our multi-modal iterative development process was comprised of an online web-based survey, expert review, software development, and usability evaluation with experts and end users.

Background

HIV has evolved from an acute to a chronic illness largely due to advances in antiretroviral therapy (ART) [1]. As a result, persons living with HIV (PLWH) are living longer and about 50% of PLWH in the US are currently over 50 years old [2]. As PLWH age,they are developing chronic illnesses and co-morbid conditions at a younger age than individuals who are HIV negative [3, 4]. Fifty to sixty percent of deaths in PLWH occur from HIV associated non-AIDS (HANA) conditions (e.g., cardiovascular disease, liver disease, diabetes, and asthma) and people suffering from these conditions are more likely to be affected by adverse symptoms [5]. An individual's ability to identify and self-manage symptoms of HIV has been shown to improve patient outcomes and quality of life [6-8].. Consequently, a team of researchers at UCSF School of Nursing developed a paper-based symptom management manual with self-care strategies for 21 common HIV/AIDS symptoms. The efficacy of this manual for improving symptoms was established in a 775-person randomized clinical trial (RCT) over three months at 12 sites [9].

To enhance uptake of these strategies by PLWH, we developed and pilot-tested the Video Information Provider (VIP), a web application (app) that delivered HIV-related symptom self-care strategies for PLWH (P30NR010677-03S1). Results from our 3-month pilot study (N=42) overwhelmingly demonstrated the feasibility of the system. Participants reported a decrease in HIV-related symptom frequency and intensity after using the VIP system for 12 weeks [10]. However, the UCSF symptom management manual and VIP were not developed for managing symptoms related to HANA conditions. Little is known about the symptom experience or self-care strategies used by PLWH with HANA conditions. Based on the existing evidence and our previous work, we sought to adapt the VIP system to include tailored self-care strategies to ameliorate HANA condition-related symptoms. Strategies are tailored based on the following characteristics: symptom, sex, race/ethnicity and HANA condition. Following our identification of the most useful self-care strategies for PLWH with HANA conditions, we sought to incorporate these strategies into a user-centered consumer health informatics app (VIP-HANA) to improve health outcomes.

Anonymous Online Survey

Methods

To assess the frequency and severity of HANA symptoms, we distributed an anonymous online survey. Details on the methods and findings for the online survey have been published elsewhere [11]. In short, we posted banner advertisements on CraigsList, POZ.com, BGCLive.com, and Facebook.com to

recruit 769 PLWH living in the US to participate. Those who clicked on the banner ad were directed to a study landing page hosted by Qualtrics software that allowed them to complete a screener to determine if they qualified for study participation. Inclusion criteria included: a) 18 years or older, b) having a HIV diagnosis, c) current US residence, d) a diagnosis of one of the following HANA conditions: arthritis, asthma, cardiovascular disease, chronic obstructive pulmonary disease (COPD), diabetes, liver disease, osteoporosis and renal failure, e) not being pregnant or breastfeeding, f) able to read and understand Spanish or English, and g) having at least one of 28 HANA symptoms. Those who qualified completed the consent form through a clickable link preceding the Qualtrics survey.

The survey assessed the frequency and bothersomeness of 28 symptoms: 1) anxiety, 2) change in appetite, 3) clumsiness, difficulty with balance, 4) difficulty concentrating, 5) constipation, gas, bloating, 6) cough, 7) depression, 8) decreased sex drive, 9) diarrhea, 10) difficulty remembering, 11) lightheadedness/ dizziness, 12) dry eyes, 13) thirst/ dry mouth, 14) difficulty falling asleep, 15) low energy/ fatigue, 16) fever, night sweats or chills, 17) heartburn, 18) problems achieving or maintaining an erection (males only), 19) muscle aches or pain, 20) neuropathy, 21) pain or discomfort during sex, 22) ringing in ears/ noise intolerance, 23) shortness of breath, 24) speech difficulties, 25) difficulty staying asleep, 26) difficulty with urination, 27) nausea/ vomiting, and 28) unplanned weight change. We included open-ended questions for participants to report self-care strategies used to ameliorate each symptom experienced, rate its degree of helpfulness and identify the information source for the strategy.

Results

Survey results yielded a total of 4,036 self-care strategies across the 28 symptoms. These survey findings provided additional information on the usefulness of each strategy as well as the information source for the strategy, which are reported elsewhere [11].

Coding and Analysis of the Self-Care Strategies

Methods

We used multiple steps to rank self-care strategies (very helpful, only a little helpful, etc.) that could then be used to tailor recommendations based on individual characteristics (using branching logic) to be integrated into the app. A qualitative data analytic approach was used to code and organize the 4,036 self-care strategies obtained in the anonymous online surveys. Open-ended responses were categorized into an overall heading. For example, open-ended survey responses included "take a nap," "rest," "rest in the afternoon," and these were all categorized as "take a nap." We then removed the self-care strategies that were rated as only a little helpful or not helpful at all. We also had a group of expert clinicians, HIV researchers, and nurses review each of the strategies to ensure their safety and legality. The purpose of this work was to identify helpful self-care strategies for future use by PLWH with HANA conditions and therefore we did not include strategies which were not helpful, not clinically advised (e.g., do nothing for a depressed patient), or potentially harmful (e.g., using illegal substances or gambling).

After consolidating initial codes of strategies on the basis of conceptual similarities and clinical significance, and after removing unhelpful, illegal and unsafe strategies, we had a final dataset of 728 self-care strategies. We then ranked the self-care strategies based on how frequently study participants rated the self-care strategy as being helpful and completing the review of all of the self-care strategies. Chi-square analysis was performed to test the association between the self-care strategies and each of the following dichotomized variables, which include race/ethnicity (white versus non-white), sex (male versus female), and status (Yes versus No) of each of the nine HANA conditions (Asthma, bronchitis, cardiovascular disease, COPD, diabetes, liver disease, osteoporosis, renal failure, and arthritis). Variables with p-value less than 0.05 were considered to be significantly associated with the frequencies of self-care strategies. If there were more than one single significant variables, then a second-step Chi-square analysis ensued: we first split the data into each category of variable with the lowest p-value from the firsts-step Chi-square, and then further Chi-square analysis was performed between the remaining significant variables and self-care strategies. We then ranked the strategies from the highest to lowest frequency stratified by significant variables identified from each step of Chi-square analysis. We repeated the procedures for each symptom. For example, for the self-care strategies of decreased sex drive, we first identified sex and race as variables significantly associated with this strategy and sex had the lowest p-value. We then split the data into male and female and performed a second-step Chi-square analysis between race and self-care strategies of this symptom by male and female separately. Race was still significant for female participants, but not significant for male participants. Thus, we ranked the self-care strategies of this symptom from the highest to lowest frequency by three separate groups: male, female white, and female non-white. Strategies were further categorized when relevant by sex, race and HANA condition.

Results

Branching logic was developed based on this analysis and provided the knowledge base for the delivery of the self-care strategies to users. Most symptoms had branching logic associated with sex, race and HANA condition. Speech difficulties and pain/ discomfort during sex were the only symptoms with no branching logic. All participants would receive the same ranking and listing of self-care strategies. All other symptoms were tailored by at least one of the three characteristics (sex, race, or HANA condition). Examples of the branching logic are illustrated in Table 1.

Development of the VIP-HANA system

Methods

Once the self-care strategies were finalized, we used Powtoons software to create animated videos (see sample screenshot of video in Figure 1) to illustrate each strategy which would later be integrated into the self-care strategy database. Ruby on Rails, an open source software framework that provides standardized structures for building was used to develop the web-app.

Results

The final VIP-HANA app included the following components: (1) a user profile which collects information at baseline on sex, race, and HANA condition of the user (Figure 2a), (2) reminder system to use the app weekly, (3) weekly symptom assessment (Figure 2c), (4) avatar selection (Figure 2d), (5) an overview report of the recommended strategies (Figure 2e), (6) symptom reports (figure 2f) and (7) a back-end database that provides tailored strategies based on the user profile and their symptom assessment. Videos were hosted on Vimeo software and participants received a video illustrating the self-care strategy every time they used the app and reported a symptom.

Table 1. Sample Self-Care Strategies for Anxiety, Sleep and Sex Drive Symptoms Tailored by HANA Condition, Sex, and Race

Top 3 Ranked Self-Care Strategies for Symptoms of Anxiety tailored by HANA conditions		
HANA Condition	Ranking	Self-Care strategy
Arthritis	1	Try breathing exercises to help with anxiety. An example would be taking a deep inhaled breath into your belly.
	2	Try relaxation or stress-reducing activities, such as meditation, personal "quiet time," or prayer.
	3	Try spending some time alone in a relaxed and calm environment.
No Arthritis	1	Try relaxation or stress-reducing activities, such as meditation, personal "quiet time," or prayer.
	2	Try to prioritize more sleep if possible. A good night's sleep is important.
	3	Try to live an active lifestyle and stay busy. Physical activity has been shown to reduce anxiety.
Top 3 Ranked Self-Care Strategies for Symptoms of Difficulty Staying Asleep tailored by HANA conditions		
HANA Condition	Ranking	Self-Care strategy
Renal Failure	1	Try making time for activities that you personally enjoy.
	2	Don't give up and keep trying different strategies to help you stay asleep.
	3	Some people who have dealt with this have found that taking time to wait while staying calm.
No Renal Failure	1	Try a sleeping aid if you are having trouble falling or staying asleep.
	2	Try to practice good sleep hygiene and relaxation techniques to improve your quality of sleep.
	3	Try making time for activities that you personally enjoy.
Top 3 Ranked Self- Care Strategies for Decreased Sex Drive Tailored by Sex and Race		
Sex/ Race	Ranking	Self-Care strategy
Female/ White	1	Try adding more physical activity to your life. Physical activity can increase blood flow and can help increase your sex drive.
	2	Have an open and honest conversation with your partner about your symptoms and talk about strategies you can use together.
	3	Don't give up and keep trying different strategies that may help you increase your sex drive.
Female/ non-white	1	Some people who have dealt with this have found that taking time to wait or sleeping can help.
	2	Try having sex when you are in different moods. Some people find sex more enjoyable after they've argued, while others find this more distracting.
	3	Try adding more physical activity to your life. Physical activity can increase blood flow.
Male	1	Try using porn to increase your sex drive and increase your sexual desire.
	2	Some people who have dealt with this have found that taking time to wait or sleeping can help.
	3	Try masturbating more often, which can boost your sex drive.

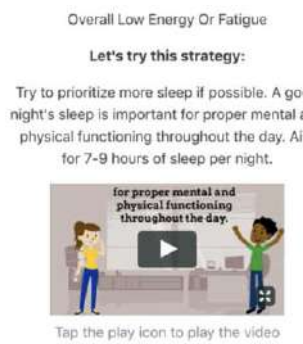

Figure 1. Self-Care Strategy Animated Video

Usability Evaluation of the VIP-HANA system

Methods

The final component of our development process was a laboratory usability evaluation with experts in human computer interaction and PLWH with at least 1 HANA condition. Full details of the usability evaluation are published elsewhere [12]. In brief, participants were provided with a Beta version of the app and asked to use the app to complete a use-case scenario created by the research team. Participants were asked to think aloud as they used the app and Morae screen capture software was used to record the session.

Results

Informatics experts (N=5) and end-users (N=20) rated the VIP-HANA app as a highly usable system. Yet they did make useful recommendations which we incorporated into the system as part of the app development and prior to our trial. End-users had difficulty completing advanced app functions, such as changing their avatar, emailing symptom reports, setting weekly reminders and enlarging videos. Experts and end-users agreed that the app needed to provide more instructions. Experts suggested that this be accomplished through a help button and end-users recommended including in-app instructions with straightforward and simple language. End-users also wanted to see features in big, bright, and bold text with a clear font.

VIP-HANA Trial

Following the implementation of the recommended changes from the usability testing, the software development company updated the app in preparation for a systematic evaluation. Currently, we are conducting a randomized trial with 100 PLWH with HANA conditions living in New York City. The goal of the trial will be to examine the effect of the VIP-HANA app on symptom burden, quality of life and frailty over a 6-month period (NCT03182738).

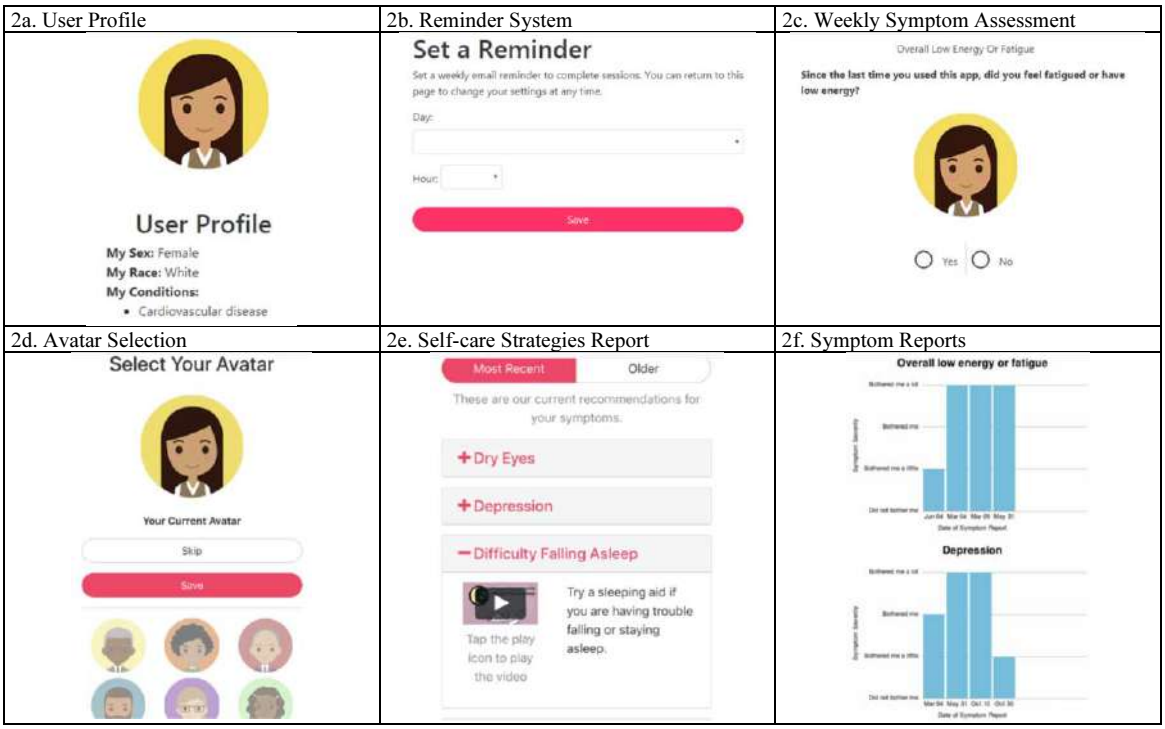

Figure 2. Screenshots of App Component

Discussion

This study demonstrated the ability to successfully translate our extant eHealth intervention for a growing clinical problem, HANA conditions. We incorporated quantitative and qualitative methods to better understand the needs of our target population and then successfully integrated these findings into our VIP eHealth platform, conducted usability testing and then conducted an RCT. Notably, our study population of PLWH with HANA conditions have unmet needs and we had the opportunity to advance our VIP intervention for a new set of users. With the proliferation of eHealth interventions, the aging of the US population and the reduction of healthcare services, there will likely be an increasing need for this translating and adapting eHealth interventions. Our study population is unique in that they are comprised of PLWH who are predominately low-income racial ethnic minorities, suffer from a chronic illness and also an infectious disease. Given the high needs of our study population in terms of social, physical and psychological support and their low socioeconomic status, development of informatics tools that can be used in these persons' everyday settings have the potential to dramatically improve clinical outcomes and quality of life, while also providing savings to our over-burdened healthcare system.

Building on our past approaches to developing mobile technology using end-user feedback and an iterative approach [13-16], this paper presents the integration of innovative methods for the creation of consumer health informatics tools. Notably, our approach included a large national US survey, clinican and expert review of the content, translation of survey data into a database which is the knowledge system of a patient-facing tool and a rigorous usability evaluation. Moreover, our study methods paid close attention to the needs of our study population by developing videos to maintain consumer engagement in the app.

Further, development of consumer health informatics tools can be complicated because of the need to integrate patient preferences, user-centered design principles, the limitations of software tools and the safety and potential efficacy from clinician experts. Given the complex integration of sources, there is a strong need for the development and dissemination of iterative development processes which integrate multiple stakeholders and result in usable and useful health information technology [17]. Finally, this paper illustrates the development of a practical and useful tool with immediate application that enables improvement in population-level quality of life. There is promising potential for integration of these tools to wider popular platforms.

Conclusions

This paper illustrates the development of a consumer health informatics app for ameliorating symptoms in PLWH with HANA conditions. We successfully completed a multi-modal development process incorporating the critical elements of user-centered design to build our app. Findings from the usability evaluation demonstrate a potentially useful and easy to use app. Integration of different quantitative and qualitative methods from different disciplines to accomplish the task of adaptation and evaluation of a mobile app is an appealing, rigorous and useful approach.

[a]*Department of Health Informatics, Hospital Italiano de Buenos Aires, Argentina*

Abstract

Health organizations aim to identify patients with high fall risk in the different attention scenarios in order to provide safety and quality care. In order to address this issue, we designed an assessment tool that surveys fall risk through three questions in self-service terminals in the outpatient setting. Our objectives in this article are to describe the implementation process. A cross sectional design was used for the pilot (between October and November 2018). The issued tickets rate with high fall risk (defined as ⅔ positive responses) was 34.3%. Some adjustments needed to be done because some patients did not have true risk criteria due to self-report. We conclude that this tool will allow quicker identification of patients with true high risk. Effective prevention strategies will be necessary to improve safety after risk fall identification.

Information systems; Risk assessment; Self-management,

Introduction

Health professionals and decision makers in health organizations are aware of the need to provide quality and safe care. Patient safety is usually an institutional policy and is considered part of healthcare quality. Unwanted side effects in healthcare represent a considerable cause of morbidity and mortality in health systems.

The American Geriatrics Society and the British Geriatrics Society have published a clinical practice guideline on detection, evaluation and management of fall risk where it is recommended to annually evaluate all adults over 65 years of fall risk. This test involves asking patients if they have fallen two or more times in the past year, received medical attention for a fall, or experienced unsteadiness or loss of balance when standing or walking. It has been shown that patients who respond positively to any of these questions have an increased risk of falls and should receive an additional evaluation [1].

Patient assessment and identification of characteristics that can increase the probability of falls are fundamental for planning effective prevention strategies [2]. Using a specific tool to identify patients with greater susceptibility to fall can assist in preventing injuries [3]. There are investigations related to falls in different areas [4,5], which have provided insights into fall incidence related to the ambulatory care setting and evaluation of fall risk through validated instruments [6].

Nurses in primary care use the Morse scale for assessing the risk of falling but may not be transferrable to an outpatient setting. For that, evidence-based tools that define the risk of falls in non-hospitalized patients are promising [7].

If the fall rates are not reduced in an immediate future, it is projected that the number of injuries caused by falls will double by 2030 [8]. In our institution fall risk prevention for non-hospitalized patients is part of the 6th objective of the Joint Commission International (JCI), warning that fall risk methods should be appropriate for patient, taking into account risk differences (diversity of populations: pregnant, post-surgical or elderly) [9].To date, we have found no reports related to falls in outpatient settings, or assessments of preventive fall interventions.

The assessment of the Fall Risk Scale is normally performed at the time of the medical consultation or nursing intervention. However, there are no early identification of the risk until admission to the institution. This does not ensure patients receive preventive intervention and are informed about safe practices for patients at fall risk. Thus, the objectives of our paper is to describe the design of an assessment tool for fall risk through self-service terminals in the outpatient setting and to report the results of use in the pilot test.

Methods

Setting

Hospital Italiano de Buenos Aires (HIBA) is a non-profit organization with 165 years of history in Argentina. Its healthcare network includes a university hospital of high complexity that covers health care for outpatient, inpatients, emergencies, critical care, home care, chronic care and medical and surgical specialties. It has its own medical insurance service (health maintenance organization), with more than 160,000 affiliates, and provides health services to 1,500,000 people with other health insurances. Annually, more than 45,000 patients are admitted to HIBA hospitals, and 45,000 surgical procedures and 3,000,000 outpatient visits occur. Since 1998, the HIBA has its own health information system (in-house) that includes the management of clinical and administrative information. Its electronic health record (EHR) is an integrated, modular, problem-oriented and patient-centered system, used in the different clinical scenarios (ambulatory, hospitalization, emergency center and home care) [10,11].

Since 2009, self-service terminals have been implemented into the HIBA, and are currently distributed in all ambulatory care areas. It is a standing self-service touch screen cabinet (Fig 1), with multiple features, developed and manufactured in Argentina. The main features of this tool are: appointment scheduling, ticket printing, as well as data recording. The main function for the outpatient is self-reception when attending a

scheduled appointment. It has a modern and ergonomic design, with great versatility and robustness. The self-service terminals are recommended for high-concurrency spaces, to support smooth to flow of outpatients in our hospital.

Figure 1: Self-service Terminal

Design

In order to assess fall risk fall and identify of patients at risk in the ambulatory area, we decided to incorporate a new functionality in the pre-existing self-service terminal in the ambulatory area at the Hospital. We used a cross-sectional analysis to analyze and report the assessment tool use during the pilot test performed during the period between October 18 and November 7, 2018 at Hospital Italiano de Buenos Aires.

Relative and absolute frequencies included were:

- All patients with potential risk of falls (defined as those requiring priority attention by self-report: pregnant, reduced mobility and / or disability);
- Rate of tickets issued (defined as those patients with high risk: at least 2 out of 3 affirmative responses);
- Number of patients attended and intervened by nursing.

Phase 1: Situation Diagnosis

The 6th version of the JCI Manual recommends having a tool to identify risk of fall in the ambulatory area from the moment patients enter the institution, which allows them to be correctly identified and to establish a secure circuit. The scope is to detect patients at risk of falling, as well as identify risk factors. The educational intervention carried out by the nursing staff must be recorded in the EHR.

Phase 2: Development of the Prototype

This stage is based on the already implemented features design of the self-service terminals (see Figure 2), which includes the incorporation of the fall risk assessment.

Figure 2: Self-service Terminal - Initial Screen Translation: Welcome to the self-service terminal. Which transaction do you wish to perform? Confirm I'm Present (I already have an appointment). Book an appointment. Register (It's my first time at Hospital Italiano). Other tasks.

In the prototype, three questions of assessment are aligned to the left and the possible answers (YES / NO) on the right side of the screen (See Figure 3).

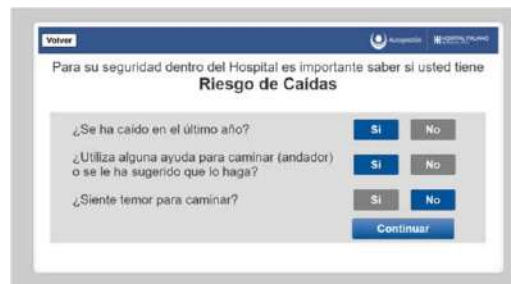

Figure 3: Self-service Terminal - Risk Fall Assessment Screen Translation: For your safety at Hospital Italiano it is important to know your falling risk. Have you fallen the last year? (Yes/No). Do you use any walking assistance, or have you been suggested to do so? (Yes/No). Are you afraid when walking? (Yes/No).

Listed below the questions, is a ' CONTINUE' option that the patient should select and is disabled until the three questions mentioned above are answered. In order to ensure completeness of the scale, all three data fields are mandatory.

For those patients with high risk (defined as two of three affirmative answers), a ticket is printed with the letter C as shown in Figure 4.

Figure 4: Emisión de ticket con Riesgo de caída. Translation: Please take your printed ticket and wait to be attended, thank you.

For the development of the software, we decided to build a web application. Java™ language was used to program all the functionalities of the back-end, with HTML and JavaScript for the front-end. The final set of the application was deployed on web servers and accessed using a Chrome™ browser installed in each self-service terminal, under Windows 7™ or Windows 10™, configured to be used from a touch screen. Eventually the application will also be able to run under Linux™ (Red Hat™, Ubuntu™, Debian™, etc.).

Phase 3: Implementation

The pilot test of the printing ticket feature and process was implemented during the month of October. The care circuit for patients with potential risk fall was established. The administrative staff and nurses were involved in the process. The process begins with the printing of a ticket identify with the letter C (possible patient with risk fall detected), which is generated by answering affirmatively two of the questions, in the self-service terminal. Once the ticket has been issued, the patient waits for his call by the administrative staff, then the patient is identified with a green bracelet in the wrist and is oriented towards a safe place. The nursing staff is informed to locate the patient in a safe place. In addition, the nurse performs Morse scale assessment of falls risk, provides educational materia, and records the intervention in the EHR.

Results

Based on the prototype, the following modifications were made: the size of the letter was increased, and the color was improved and adapted to improve user experience of older adults. The necessary adjustments were made until arriving at the final version, which is currently being used in a pilot test (See Figure 5).

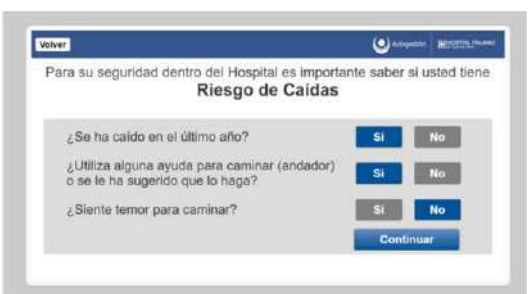

Figure 5: Self-service Terminal - Risk Fall Assessment Screen Adapted from the Original Ddesign.
Translation: For your safety at Hospital Italiano it is important to know your falling risk. Have you fallen the last year? (Yes/No). Do you use any walking assistance, or have you been suggested to do so? (Yes/No). Are you afraid when walking? (Yes/No).

During the study period, there were a total of 1784 patients with potential risk of falls who responded to the assessment, of which the rate of issued tickets was 34.3% (95% CI 32.10-36.56).Figure 6 shows the frequency distribution of patients that carried out the survey and the generation of ticket with fall risk according to the dates. The red line indicates completed surveys that did not generate a ticket, and the blue line indicates the surveys completed that resulted in generation of a ticket.

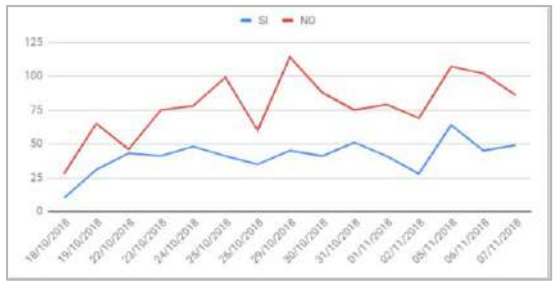

Figure 6: Frequency Distribution of Patients who Completed the Survey that Resulted in Generation of a Fall Risk Ticket

The number of patients who received nursing care each day of the pilot is shown in Figure 7.

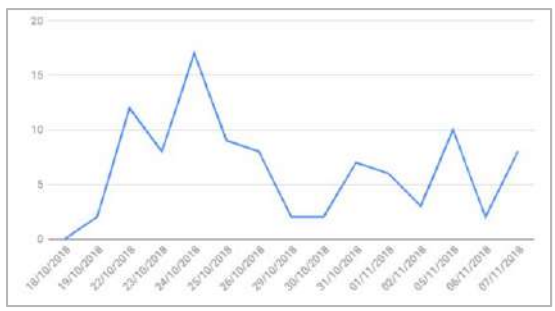

Figure 7: Total Patients Attended by Nursing

An important finding in the validation of patient conditions with potential falling risk was that many of them did not meet a true risk criterion. Table 1 shows the details of this findings.

Table 1: Patients without True Criteria for Falling Risk

Other reasons for consultation (not related to programmed ambulatory appointments)	• Registration application • Request for laboratory printing • Appointment scheduling • Others arrangements
Technical failures in communication	• Patient who wanted priority attention

Discussion

The design of this tool aimed at assessing and detect patients who were at high fall risk within the outpatient setting, in order to plan effective prevention strategies. This process could improve the waiting conditions, adapt specific needs of high fall risk populations, improve patient safety, and potentially reduce the risk of falls within the institution. The rate of tickets issued was 34.3%, higher than expected, due to the logistics and necessary resources required for the implementation of effective prevention strategies, and the coordination of all the actors involved. However, this rate could be overestimated, given that patients reported untrue data, and thus further validation is required. We believe that the step of validation is important, because many patients reported having high risk to avoid the system waiting times, in order to be treated with priority. The process of self-report generates the need to validate the true positive cases of

patients with a high risk of falling, and in some cases the answer of the generated ticket.

The full patient population may also not have been represented, as there were a small number of terminals in which the survey was implemented (not enough for the number of patients), connectivity issues (which sometimes prevented the use of the terminal), and difficulties with the touch screen.

This is our first experience of implementing a technological tool to improve the quality and safety of patients in the outpatient setting. Although, it is a novel tool with great potential and in consistency with JCI priority lines, diffusion, institutional communication and training are needed. For this, it requires more communication and teamwork (security, administrative, nursing, among others).

Furthermore, standard strategies for continuity of care are needed, focused on addressing the diversity of patients with potential risk fall, integrating all the necessary staff of the process with a single objective. At the same time, it highlights the importance of indicators.

As future pending lines of work, we propose: re-design to overcome some of the aforementioned technical difficulties, improving usability and adapting new functionalities to the user needs (incorporation of patient identification through QR or through Personal Health Record).

Conclusions

The design of this tool will allow the rapid identification of patient with true positive high risk of fall in the outpatient setting, and effective prevention strategies will be necessary to guarantee a safe course of action for patients. This could support improving waiting conditions, adapting to the specific needs of the population at high risk, and potentially decreasing the risk of falls within the institution.

Acknowledgements

This study was carried out under the Residency Program in Health Informatics and the Area of Information Technology Oriented to the Community of the HIBA. We want to thank the entire interdisciplinary team (doctors, nurses, designers, developers) for the work you have done.

Abstract

Although e-health is an area recognized as essential in the rapid development of healthcare systems in low resource contexts, many challenges prevent the emergence of an effective e-health ecosystem. Lack in capacity around health informatics is one of the main challenges. Based on a longitudinal case study gathering data pertaining to a master's program in biomedical informatics in Sri Lanka designed for doctors, in this paper we demonstrate that creating 'hybrid doctors' may be the way forward. We illustrate how hybrid doctors conversant in healthcare and information and communication technology (ICT) are able to facilitate the creation of an e-health ecosystem in a way that it would contribute significantly to the ICT driven healthcare reforms. Through this case study we highlight the importance of multidisciplinarity, participatory design, strategic investments, learning that aligns with developmental needs, networking, gaining legitimacy and re-packaging perspectives on 'health informatics capacity development'.

Keywords:

Health Information Systems; Education, Medical; Medical Informatics,

Introduction

Capacity development around health informatics remains a considerable challenge in low resource settings [1]. In the absence of adequate capacity, many countries lag in incorporating e-health solutions to elevate their healthcare systems and gain better health outcomes [2]. With the recognition that technology could be a main driver in achieving sustainable developmental goals in 2030 [3], identifying ways and means of incorporating technology in healthcare has gained considerable interest.

Developing health informatics capacity among doctors or healthcare professionals has been a focus of attention for a considerable period [4]. The International Medical Informatics Association's (IMIA) initiatives in developing programs to improve health informatics capacity among healthcare professionals have been well received. However, in low resource contexts, capacity development in health informatics remains in the hands of non-governmental organizations or local universities supported by donor agencies [2,5]. Although such programs have contributed to the development of local capacity in health informatics to various degree, there is limited evidence on the impact of these programs in the wider e-health ecosystem of a country.

In 2008, the Postgraduate Institute of Medicine (PGIM), University of Colombo, Sri Lanka in collaboration with the Department of Informatics of the University of Oslo, Norway and the Health Informatics Society of Sri Lanka embarked on an ambitious program in the creation of 'hybrid doctors'. Funded by the NORAD program for Master Studies (NOMA), the program aimed to develop health informatics capacity among doctors in Sri Lanka by developing, implementing and scaling up frugal health information systems without having to depend on imported health informatics expertise. Currently at ten years after implementation, the Master's program in Biomedical Informatics in Sri Lanka at the PGIM has trained more than 150 medical doctors, and the e-health ecosystem in Sri Lanka has been disrupted towards one of the most dynamic in the region. The program has not only generated capacity, but it has also had a high impact on national level health information systems, health informatics policy, innovations, networking, publications and South-South knowledge translation, and expertise sharing. We have been unable to find similar examples of programs in other low/middle income countries that have paved the way towards a standalone specialty in health informatics for doctors.

In this paper, we summarize a decade of work around this capacity development initiative in health informatics in a systematic manner in view of identifying the key factors that contributed to the success of this program. We also discuss how the capacity development effort disrupted the e-health ecosystem in Sri Lanka, a low and middle income country, in a relatively short period of time. In doing so, we address one of the burning questions in health informatics, how to successfully innovate and sustain health information systems in low resource contexts.

Methods

Drawing from data gathered from 2008 to 2018, allowed us to observe the changes taking place within the e-health system that consisted of people, organizations and the environment. In line with Pettigrew's illustration on longitudinal field research [6] and case study research as described by Yin [7], we adopted a longitudinal case study method. The authors of this paper have been involved in this project as principle investigators, project managers, researcher cum educators and as trainees. This has allowed different authors to bring in different perspectives in the interpretation of study data. Using multiple methods, which included semi-structured interviews, focus groups, document analysis, online discussion forums and e-mail communications; we gathered qualitative data pertaining to different yet seemingly overlapping phases of program evolution. Based on our understanding of key developments that took place since the inception of the master's program, these phases were classified as 1) initiation 2) legitimation and institutionalization 3) impact generation and 4) scaling and sustainability phases –

Additional reports have been published on the evaluations of program outcomes as reported by students and the PGIM. Thematic analysis was conducted on the data, where all authors of this paper participated in collectively building themes emerging from the systematically coded data. This approach to data analysis enabled us to overcome the researcher bias that generally plagues information system research [8,9].

Results

In presenting the results, we will provide an overview of each of the phases in general, followed by presentation of the key themes that were developed.

Initiation

The initiation phase consisted of the first two years following signing the memorandum of understanding between the PGIM and the University of Oslo. This phase was highlighted by the creation of a multidisciplinary board comprising of academics and practitioners from various academic disciplines, the Ministry of Health (MoH), professional organizations such as the Health Informatics Society of Sri Lanka (HISSL) and the private sector. The Northern partner, the University of Oslo, provided technical support, but did hold a position on the board. The board had the power to decide how the program should be run in accordance with the university regulations in collaboration with the partners such as the MoH, other universities, professional organizations and private sector enterprises. The key tasks performed by the multidisciplinary board were to develop the curriculum, identifying the training strategy, create learning opportunities for the trainees, negotiate with the stakeholders on the implementation of the program and manage NORAD in the development and implementation of the master's program.

The initiation phase was characterized by a proactive effort towards facilitating multidisciplinarity and participatory design, largely through the creation of a multidisciplinary board. This phase was also characterized by the decisions made on strategic investments in training unit development, trainer training and network building, which contributed to the emergence of a conducive learning environment for teaching and learning. In particular, effective utilization of donor funds to student projects aimed at improving service delivery in various state health institutions . The health institutions in this case benefited in two ways. First, the student projects helped solve issues related to service delivery in a training unit. Second, the fulfilment in establishing a basic infrastructure for these projects facilitated implementation and sustainment of these projects. Given that students were involved in frugal innovations and the scope of the master's projects were limited, the cost incurred for each project was minimal. This enabled the board to support multiple projects across the health care system.

Legitimizing and institutionalizing

The legitimizing and institutionalizing phase of the program represented the first three to four years of the program where the first two batches of graduates became part of the MoH workforce as Medical Officers in Medical Informatics (MOMI). The creation of the post, a unique position for a medical officer within the health sector of a low resource context, was one of the key characteristics identified during this phase. The acceptance of the graduates of the program by the MoH as an integral part of its master-plan for e-health was another critical component during this phase. We identified that this recognition was gained through advocacy and demonstration of competency by the newly graduated doctors and champions of the program. In this phase, roles that were previously filled by experts from other fields (e.g. ICT, engineering) who limited healthcare background transitioned to being within the MoH and were replaced with the MOMIs. In addition, the data collected during this phase illustrated how placement of students cum doctors in various healthcare institutions and programs were solicited by the stakeholders for the master's program. We identified the integration between the academic program and practice as an important theme during this phase.

Other themes recognized during this phase included: South-South collaborations between the program and the regional partners paving way towards sharing of expertise and knowledge regionally. At the same time, recognition of the qualification by the MoH as a means of promotion for the doctors generated renewed interest among potential candidates for the program. This essentially meant that all doctors who qualified this program would be funded by the MoH and would receive full pay after two years. We found this to be a key contributor towards the sustainment of the program beyond the funding period from NOMA.

Impact Generation

The impact generation phase began in from the fourth year and continued to the present. At the beginning of this phase some of the students' projects started attracting the attention of the MoH as proposing potential systems that could be scaled island wide to facilitate national health information flow. This recognition was encouraged by placement of students in strategic locations where there was a need for health information system development or upgrading of existing systems. Additionally, adopting open source software tools made students' projects attractive to the stakeholders.

The phase was also highlighted by the involvement of the graduates of the program in the development and implementation of health information systems, e-health policy and guidelines, consultations with various stakeholders (including donor agencies) and scientific publications presented at various national and international forums. Table 1 highlights some of these impacts.

As highlighted in Table 1, this phase also demonstrated the entrepreneurship potential of the graduates working with various international and private sector organizations on various health informatics projects. The tendency of the private sector and other organizations to seek expertise of the graduates of the program was perceived by us as an indication of further legitimization of the program and development of competencies of the graduates, and facilitation of building an ecosystem across organizational boundaries.

The involvement of the graduates within various aspects of the e-health ecosystem was also facilitated by the HISSL, which became the main representative body of health informaticians of the country. Many of the opportunities gained by the students and graduates to network with the industry, foreign and local experts, as well as donor agencies were facilitated through HISSL.

Table 1 – Impacts of the Biomedical Informatics Master's program (2008 – 2018)

Areas of Impact	Indicators of high Impact
Practical HIS development	National/program wide HISs developed and implemented – more than 12 Institution focused HIS – more than 20
Research papers published	Journal papers – 37; Conference presentations – 88 (up to 2017)
Networking opportunities: International conferences attended	More than 7 regional and international conferences attended (e.g. APAMI, APMEC, e-Health Asia, AEHIN etc.) by students and faculty of the health informatics program.
Networking opportunities: International conferences hosted (organized by HISSL)	e-Health Sri Lanka 2010 and 2014. IFIP 9.4 conference 2014 eHealth Asia 2015 Commonwealth Digital Health Conference 2016, 2017, 2018 APAMI conference 2018 AeHIN conference 2018
Networking and advocacy	Networks established through educational program and supporting activities Linking with organizations such as Health Information Systems Program/DHIS2, OpenMRS, AeHIN, IMIA, Commonwealth Medical Association Active contribution within national bodies such as National eHealth Steering Committee, National Foundation for Open Source Health Software Drafting of National eHealth Policy, National eHealth Standards and Guidelines Pioneering work around Health Identification Number.
Program evolution and sustainability	Eight batches since 2008 Introduction of the MD program - two batches in training (38 students). Gradually increasing demand for the master's program since the introduction of the MD with board certification in Health Informatics Government investment of approximately 40 to 50 million LKR on trainee scholarships since 2008 (up to 2017) Investment set to increase by approximately 100 million LKR each year to support a one-year foreign placement for each MD trainee to gain foreign exposure.
Entrepreneurs hip contributed through capacity development	HISP Sri Lanka was established Multiple e-health companies were engaged with dealing with personal medical records, e-learning, social media, etc. Individual consultations carried out for international development partners such as UNICEF, WHO, USAID, Vital Strategies (VS) and the private sector.

Scaling and Sustainability

This phase was recognized with the renewed interest generated among the potential candidates for the capacity development program following the \approval of the MD program in health informatics. With the creation of this program, those who have successfully completed the master's program would be able to specialize in health informatics similar to any other specialty in medicine. The acceptance of the MD program as a specialist qualification by the MoH further highlighted the ongoing institutionalization process. The return of doctoral level qualified resource personnel in health informatics from their overseas training also demarcated this phase, as it facilitated a path for higher level capacity development directly in Sri Lanka. The creation of a pool of resource personnel from graduated doctors also characterized this phase as an important contributor towards the scaling and sustainability of the program, as it fulfilled the need for trainers with experience in systems development and implementation from the local context.

Discussion

The creation of hybrid doctors who are conversant in healthcare and ICT have enabled Sri Lankan e-health ecosystem to benefit in multiple ways. Firstly, the case study illustrates how government investment in training medical professionals as health informaticians enables them to drive innovations, which are frugal, scalable, sustainable and context sensitive. Secondly, the case study also illustrates the effective use of development funds aimed at capacity development and healthcare system strengthening. In this case, the funds enabled not only training of doctors, but also in creating the learning environments that facilitated innovation, collaboration and sharing of knowledge both within and outside the local context.

However, a capacity development program particularly in low- and middle-income countries cannot exist in isolation without being linked with the development efforts within the healthcare system –[5]. This was clear from the Sri Lankan experience as one of the key factors contributing to the success of the program was its alignment with the national health sector development initiatives. This was achieved through the multidisciplinary multi-stakeholder governing body, the board, and the early exposure of the trainees to problem solving in real life e-health projects. The stakeholders were equal partners in the training similar to the status of the academic institution hosting and running the program and the funding agency providing technical support. The participatory design approach [10, 11] adopted in developing the program ensured that local needs are embedded in the training and that student learning was context oriented, rather than a mere transfer of knowledge from North to South. Networking, therefore, became a key competency for the doctors undergoing training in health informatics, as the knowledge that they were expected to harness was not always transferable but was also tacit in nature [12].

Traditionally, health informatics capacity development in low resource contexts is dependent on donor funding [13,14] and is dominated by academic institutions [15]. These are oth uni-disciplinary and do not necessarily partner with the development efforts in a country. Traditional capacity development programs for health informatics also tend to target people who are competent in ICT [5], which may be partly due to the lack of interest among doctors in becoming health informaticians. From a socio-cultural point of view, a doctor is perceived in many contexts as a person who would treat a person wearing a stethoscope. Even the doctors in these contexts may not pursue their interests as they become confined to the acceptable societal perception of a doctor [16]. In the case

of Sri Lanka, the barriers towards creating hybrid-doctors were broken through multiple means: clear and progressive career paths, guarantee of employment, community of doctors who are also health informaticians, network opportunities with likeminded people both within and outside their own context, and legitimation gained by professionals within their work settings. The perceived change however was not achieved overnight, particularly when it came to change underlying perceptions and beliefs. The case study demonstrated the need to evolve with the changing socio-cultural-political environment for capacity development effort that can be sustained and impactful [17].

As mentioned earlier, one of the key aims of this program was to create an entity who could be the bridge between the domains of ICT and healthcare. In other words, the entity being trained needed to be recognized by the stakeholders of e-health – the MoH, the ICT industry, the development partners, doctors, other healthcare and non-healthcare professionals, academia, etc. Recognition of a doctor as an integral part of the healthcare sector [18] appears to have helped them perform their expected role in bridging the domains of healthcare and ICT. While their role of being doctors enabled them to decode the complexities existing among healthcare professionals in accepting and complying with technology implementations, their expertise in health informatics enabled them to explain the needs of the healthcare system to ICT professionals. During system implementation and scaling up, the doctors had the power to make decisions, negotiate with other professionals, gather and analyze data and intervene in problem resolution. More importantly, they garnered trust among stakeholders of health informatics paving the way for the bridging their dual roles.

While the hybrid-doctors had impact through active participation in the design, development, implementation and scaling up of health information systems, the e-health ecosystem appears to have evolved in several directions. The direct involvement of the doctors in e-health projects within the MoH triggered many more departments and campaigns to identify technology needs and engage in frugal HIS developments. Additionally, the private sector identified the potential of these doctors in serving as idea generators and consultants, which further encouraged private sector involvement in the e-health ecosystem of the country. The development agencies also recognized the potential of hybrid-doctors, which enhanced development support and collaborations. Beyond the local contexts, the e-health ecosystem started to link up with international networks through the connections made by hybrid-doctors, and enabled sharing of knowledge and expertise that extended across different countries. Such networking has long been advocated in the development of health information systems in low resource contexts [19]. The path of evolution however may not always be clear-cut and controllable [20], thus highlighting the need to continuously look at capacity development as part of the evolving e-health ecosystem, rather than as a narrowly focused educational effort. In other words, the creation of hybrid doctors and facilitating the cultivation of an e-health ecosystem reminded us of the Aristotelian quote, 'the whole is greater than the sum of its parts'.

Conclusions

In this paper we illustrated how a capacity development program in health informatics for doctors disrupted the e-health ecosystem in Sri Lanka and achieved high impacts. We attribute the program's success to the multidisciplinary and participatory design approach and integration with ongoing development efforts within the healthcare system . We also highlighted the importance of motivating the students by creating a conducive learning environment, ensuring career pathways and changing the traditional perspective about doctors. Hybrid-doctors was at the core of the emerging e-health ecosystem in Sri Lanka in performing the important role of bridging ICT and healthcare domains.

The nature of the training, which was context sensitive and action oriented, promoted the idea of frugal innovation by linking academia and practice at a very early stage. Not only did the students have to solve real life problems, but they also had the opportunity to contextualize their learning. The learning in this case was not an isolated academic exercise, but a graduated process of integrating health informatics expertise within the healthcare system.

Acknowledgements

We would like to thank the support extended by the NORAD program for Master Studies, which funded the initial phase of this program. We would also like to acknowledge the support extended by the Postgraduate Institute of Medicine of the University of Colombo, the Department of Informatics, Faculty of Mathematics and Natural Sciences of the University of Oslo and the Health Informatics Society of Sri Lanka.

Abstract

Little is known about data sharing preferences for care and research of behavioral health patients. Eighty-six behavioral health patients (n =37 Latinos; n = 32 with serious mental illness) completed questionnaires, in either English or Spanish, with items assessing their views on privacy and sensitivity of health record information. Most patients (82.5%) considered mental health information as sensitive. In general, there was a direct correspondence between perceived sensitivity of information and willingness to share with all or some providers. A main motivation for sharing data with providers was improving the patient's own care (77.8%). Most participants (96.5%) indicated they would be extremely to somewhat willing to share their data for research with their care facilities and universities. Follow-up patient interviews are being conducted to further elucidate these findings.

Keywords:
Privacy, Electronic Health Records, Surveys

Introduction

Behavioral health problems include substance use disorders, serious psychological distress, suicide, and mental disorders [1]. In the U.S., behavioral health conditions affect over 44 million (18.3%) adults, including 10.4 million (4.2%) adults who have a serious mental illness (SMI) such as major depression [2]. On average, SMI patients have 3.5 times higher emergency room visits, 4 times higher primary care visits, and 5 times higher specialist visits than the general population [3]. It is estimated that 17.8% of the U.S. population is Latino or Hispanic [4]. Of those, 15.6% (over 8.9 million) had a diagnosable mental illness in the past year. The rate of illicit drug use for Hispanic individuals ages 12 and up was 8.9%, while the national average was 10.2% [5].

The growth of health information exchanges (HIEs) and healthcare technologies have stimulated interest in integrated care and data sharing. Behavioral health patients often visit multiple health care providers when receiving behavioral and physical health treatments, and care coordination among those providers could be advantageous [3]. While data sharing among care providers may improve care, it may also impact patient privacy [6,7]. Privacy concerns may lead patients to avoid discussing their problems with providers, delay care and withhold information from providers [8–10]. Additionally, patients with behavioral health conditions frequently experience social stigma, employment and insurance discrimination, legal concerns, and worry regarding disclosing information to others [11,12].

The Office for the National Coordinator for Health Information Technology (ONC) recommends giving patients more granular level control over how and with whom their health record information is shared [13]. Granular control could include giving patients more authority over with which providers, under which circumstances, and for which purposes their data are shared. For example, ability to make decisions over whether or not to share alcohol abuse-related information with a physical health provider. Studies indicate that patients desire more control over their health data for care and research [11,14,15]. A recent study of 394 patients indicated that they were reluctant to share clinical data with for-profit research organizations, and that 32% of them expressed a desire for choices regarding the data sharing category (for example, mental health, substance abuse history, etc.) and data recipient when sharing medical records for care [14]. Understanding the level of granularity that individuals desire is still an open question.

Little is known about data sharing preferences for care and research of behavioral health patients. Grando et al. surveyed 50 English speaking behavioral health patients with no SMI concerning their data sharing preferences [11]. The study showed that behavioral patients may wish granularity over who can access their personal health data for care and research. Understanding patients' data sharing preferences and perceptions may improve education and consent processes that influence their decisions to release or withhold health information.

The purpose of this study was to survey English and Spanish speaking behavioral health patients, including those with SMIs, on their perceptions regarding data sensitivity, willingness to share health data for care and research and related motivations.

Methods

Study Sites

Study site 1 is a community clinic in Arizona providing general mental health (GMH) treatment and social services to adults of all ages. Site 2, also in Arizona, offers case management services to adult patients with SMI.

Survey

We found validated English surveys, such as [16], developed to assess patients' data sharing choices. But there was a lack of bilingual (English and Spanish) data sharing questionnaires validated with behavioral health patients.

Our survey was based on [11]. Demographic information was categorized based on U.S. Census Bureau classifications, except diagnoses, which were adapted per National Institute of Mental Health categorization [17,18]. The sensitive categories used in our instrument to ask questions related to sensitive data were based on those used by the National Committee on Vital and Health Statistics [19]. The resulting survey was translated to Spanish and back-translated to English by native Spanish speakers.

Survey Reliability Testing

Reliabilities of questionnaire items were examined using a test-retest approach with 31 Spanish and English-speaking adult behavioral health patients from study sites 1 and 2. Participants completed the questionnaire, in either English or Spanish, on two occasions, 14-21 days apart. Questionnaire items were revised based on the outcomes of the reliability analyses. The revised questionnaire was used in the current study.

Study Participants

Participants for the study described here were recruited from the same study sites where the reliability study was conducted. Potential participants were identified by study site staff members during routine clinical visits and referred to the recruiters. After the recruiter met with the prospective participant at the facility and explained the study to him/her (in either English or Spanish), the recruiter assessed the participant's decision-making capability (using the UBACC test)[20]. We excluded participants with low consent comprehension (i.e., with UBACC scores < 15). Adult patients (21 years old or older) diagnosed with GMH or SMI who agreed to complete the questionnaire in English or Spanish and were deemed capable of giving informed consent were considered eligible to participate.

Study Design

After initial screening and consenting of eligible participant, the recruiter offered the participant the option of completing the questionnaire either in English or Spanish, and either electronically or on paper. The recruiter was present to help the participant with any questions or technical difficulties. Participants were compensated for their time.

Data Analysis

We used univariate statistics (e.g., frequencies, means, standard deviations, percentages) and plots to summarize the data. Parametric inferential statistical methods were used to analyze perceptions of data sensitivity and willingness to share data among English and Spanish-speaking, Latino and non-Latino participants from GMH and SMI populations.

Results

Demographics

Of the 88 participants recruited, 2 were excluded because of inability to understand and follow the study protocol, as measured by the UBACC test. Table 1 shows the demographics of participants included in the sample. The majority (n = 54; 62.8%) of patients had a GMH condition, while the rest were patients with SMI diagnoses. Most participants (n = 71; 82.5%) opted to have the questionnaire administered in English; the remainder opted for Spanish.

Table 1: Demographic of participants

** As participants may have more than one diagnosis, the percentages are not reported.*

Data Sharing for Care

We asked questions to understand participants' desire for granular data sharing control based on type of information, information recipient and purpose of data usage. We asked participants how likely they were to share their behavioral

health data with different behavioral and non-behavioral providers (Figure 1). Participants were most willing to always or sometimes share their health information with the behavioral providers at the study sites, followed by emergency providers, other non-behavioral providers at the study sites (e.g., primary and specialty care providers, pharmacists), behavioral providers outside the sites, and lastly with other non-behavioral providers outside the study sites. No significant differences in responses were seen in comparisons of English vs. Spanish speakers (χ^2=1.27, p=0.866), Latino vs. non-Latino participants (χ^2=0.78, p=0.941), or GMH vs. SMI patients (χ^2=0.12, p=0.998).

In assessing participants' perceptions about how sensitive different types of health information are, we provided them with eight health information categories: mental health, psychotherapy notes, sexual and reproductive health, domestic violence and abuse information, information on sexually transmitted diseases, drug or substance abuse, alcohol abuse, and genetic data. Most participants considered mental health information the most sensitive, followed by psychotherapy notes (Figure 2). For several categories, the most common single response was '*It does not apply to me'*. Unfortunately, we did not collect with the survey information that could be used to check if the participant did not have certain types of sensitive medical records.

Participants were then asked about the likelihood of sharing sensitive health information with providers outside the study sites (Figure 3). We computed the mean percentage of patients who wanted choices regarding sharing their data with different types of providers. On average, when self-reporting having sensitive information in their medical records (the option *'It does not apply for me'* was not selected), many participants (64.15%) wanted to restrict those records from some or all health care providers.

In general, we observed a direct correspondence between perceived sensitivity of information and willingness to share. The main exception was genetic data. While participants considered genetic data the eighth most sensitive type of information, they ranked it as the third most sharable. However, with the exception of sexually transmitted diseases ($p<.05$, Fisher's exact test), none of the associations between willingness to share a particular category of information and perceived sensitivity of the information).

We asked participants about providers' access to health information when prescribing a new medication. Most participants (78.0%) responded that the providers should have access to all their health data, 12.0% thought that providers should see only
the data to which a patient provides the access, and 10.0% indicated that the providers should see all the health data only when the new medication may have any harmful interactions or effects.

Similarly, we asked patients about emergency providers' access to data in a life-threatening situation. Most of the participants (70.0%), reported that providers should have access to all their data, 19.0% endorsed giving emergency providers access only to data shared by the patients, and 11.0% indicated that providers should have access to all health data only when the emergency may be life threatening.

Participants endorsed sharing their data when it can benefit their own care and treatment (77.8%) or if/when their providers asked them to share their data (61.1%). Large majorities of participants trusted the providers at the study sites overall (87.8%) and trusted them to share only the health data that they consented to share (93.3%).

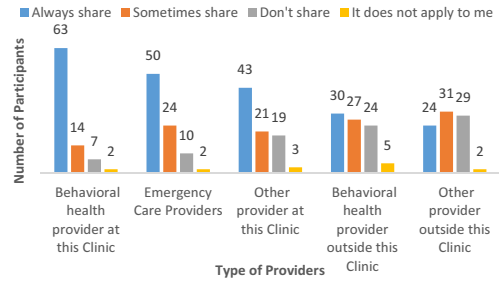

Figure 1: Behavioral health data sharing preferences, based on the type of medical provider

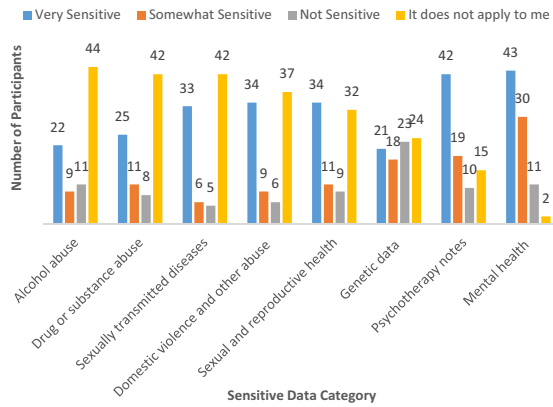

Figure 2: Health categories classification as sensitive information

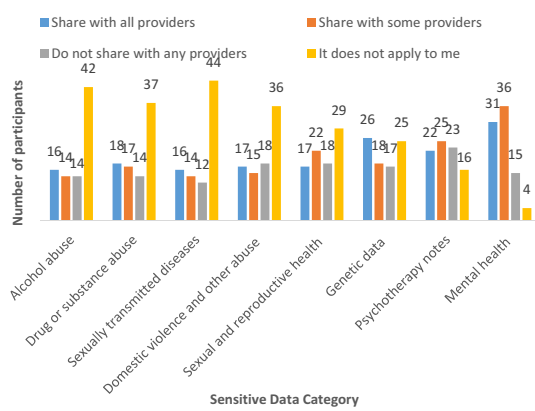

Figure 3: Willingness to share sensitive health data with providers outside study sites

Large majorities also reported that they would be upset if their providers shared their health data without asking them (83.3%) and that they might react by leaving such providers (65.6%). Only 30% of the participants reported worrying about providers knowing that they receive mental health treatment.

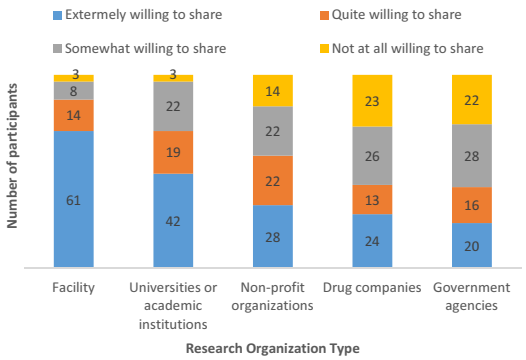

Figure 4: Willingness to share data for research with different types of organizations.

Data sharing for Research

Participants were generally willing to share health information with researchers when their own care (91.1%) or care for others (78.9%) could be improved. About half (51.1%) of participants, indicated they would always share their data for research, while 35.6% indicated that they would share their data for research if they were paid for it. Finally, we asked participants how likely they would be to share their health information with researchers (Figure 4). Participants indicated they would be extremely to somewhat willing to share their data for research purposes with their care facilities (96.5%). Participants appeared less willing to share their health information with drug development companies and government agencies. For each participant, we looked at whether their willingness level varied between different types of organizations. For example; varying willingness to share data with care facility compared to drug companies. Most (78.9%) participants desired control over how they want to share data with different research organizations.

There were no significant differences in data sharing preferences between English vs. Spanish speakers (χ^2=0.29, p=0.990), Latino vs. non-Latino participants (χ^2=0.59, p=0.964), or GMH vs. SMI patients (χ^2=0.25, p=0.993).

Discussion

Consistent with previous studies on behavioral health patients, participants wanted control over how to share sensitive health data with health providers [11]. In general, there was a direct correspondence between perceived sensitivity of information and willingness to share with all or some providers. When we contrast our results to studies from patients without behavioral conditions, it has been reported that patients with and without sensitive information prefer to restrict the sharing of sensitive versus less sensitive EHR information [14,15]. As reported in the literature, most of the participants appeared to be motivated to share health data unconditionally to avoid medical emergencies or drug-drug interactions [15,21,22]. As in previous studies, our participants trusted their providers at the study sites and trust in providers was an important motivation for sharing health information [11,16,23,24]. Additionally, improvement in a patient's own care and treatment was an important motivating factor for sharing health data with providers.

As in previous studies [11,14], patients wanted control over how to share health data with researchers. Consistent with literature, willingness to share data decreases when the recipient is a for-profit research organization and important motivations to share health information for research were benefiting own care or improving care for others [11,25].

The '*It does not apply to me'* response was frequently used when asked to assess the sensitivity of health data and willingness to share sensitive data with providers (34.4% for all types of data, and 29.7% for mental health, psychotherapy notes, drug or substance abuse and alcohol abuse). Participants' lack of understanding of the meaning of certain sensitive data categories, inability to form opinions regarding sensitive categories, or stigma related to disclosing this information could be potential explanations for this response. For some categories, like sexually transmitted disease or substance abuse, it is highly probable that the question did not apply to the participants. For other categories, such as genetic data, the recruiters received frequent requests from participants for clarifications. These results highlight the need for better on-demand education material to address patients' varying data sharing preferences and levels of health literacy.

A limitation of our study is that study participants were sampled from only two outpatient clinics in similar geographic areas with similar social demographics. Additional studies should be conducted on a larger sample of the population to capture more diverse views.

The outcomes of this survey and previous formative studies will guide follow-up card sorting interviews [11,25]. Thirty-six survey participants have given access to their health medical records available through the HIE. In the upcoming interviews, data privacy questions will be asked while study participants have access to a subset of their medical records.

Outcomes from that study will influence the design of an e-consent tool based on the Consent2Share software developed by the Substance Abuse and Mental Health Services Administration (SAMHSA) [26]. The My Data Choices tool will support patient-driven data access based on data sharing interoperability standards. Patient data will be shared in compliance with federal and state confidentiality laws, including protection of confidentiality of substance use disorder (42 CFR Part 2) [27]. On-demand multimedia patient education material will be embedded in the tool to illustrate risks and benefits of cross-organizational data sharing. We aim to pilot test the tool with 270 behavioral health patients in a prospective study.

Conclusions

A better understanding of behavioral health patients' attitudes towards data sharing is needed. The outcomes of this survey indicate consistency between the perspectives on data sharing and privacy of behavioral health patients and other previously surveyed populations of patients with or without sensitive medical records.

In future work, we plan to apply lessons learned from the completed survey to conduct follow-up interviews with a subset of the surveyed patients. The knowledge gained from the interviews will be used for the development of an e-consent tool that will support patient-driven data sharing control and on-demand educational resources to better inform data sharing choices.

Networking of Young Researchers in the European Area: Relevance, Requirements and Realization Possibilities

Bianca Steiner[a] and Birgit Saalfeld[b]

[a] *Peter L. Reichertz Institute for Medical Informatics of TU Braunschweig and Hannover Medical School, Braunschweig, Germany*
[b] *Peter L. Reichertz Institute for Medical Informatics of TU Braunschweig and Hannover Medical School, Hannover, Germany*

Abstract

Networking is a key competence, especially for young researchers in the field of medical informatics. Therefore, it is encouraged in organizations like AMIA. Since, in Europe no such networking possibility is known, concepts and ideas for the implementation shall be established and assessed with regard to their appropriateness. Demands, suggestions and attitudes of the community were collected in an online survey. Based on this, a workshop with international participants was conducted at Medical Informatics Europe 2018 in Gothenburg, Sweden. Following topics were addressed: i) communication channels, ii) activities to be carried out, iii) organizational structures and iv) acquisition of participants. The results show the relevance of such a networking platform. Furthermore, numerous requirements and realization possibilities, but also challenges were identified and assessed during the workshop. Altogether, essential ideas for the implementation of an European Young Researcher Network (EYouRNet) were collected, which can serve as a basis for the realization.

Keywords:

Social Networking; Students; Medical Informatics

Introduction

During the doctoral studies students need not only to exchange with senior professionals, but also within their peer group in order to share their knowledge and experiences. Furthermore, discussing approaches and problems with other young scientists can encourage the tackling of their own topic with new ideas and enthusiasm. Especially in the field of medical informatics, as a highly cross-sectional discipline [1], this interchange is particularly important to learn from one another.

In the international area, various associations provide support for the networking of young scientists through an organizational framework. The "Young European Associated Researchers Network" (YEAR), for example, offers young researchers from all scientific fields the opportunity for training, networking and consulting. However, membership is only possible for young scientists working in an organization that is a member of the European Association of Research and Technology Organisations [2]. Due to this fact, it is rather difficult for individuals to participate in such a network. Apart from this, there is a multitude of other discipline-specific networks, such as the EMES in the area of social enterprise [3]. A special forum for young medical informatics researchers is offered by the American Medical Informatics Association (AMIA) with the "Student Working Group" where (doctoral) students "*[...] can share their educational experiences and viewpoints, as well as information about career and educational opportunities*" [4]. In Germany, once a year a doctoral symposium is held funded by the German Association for Medical Informatics, Biometry and Epidemiology (GMDS). Thereby, the aim is to offer doctoral students from the field of medical informatics the opportunity for networking, and sharing information and experiences [5].

For the interchange of doctoral students within the European area, there is no such networking possibility known. Therefore, as a first step, it is important to clarify to what extent an European network is really needed. In addition, if there is a need, a framework must be created with regard to how such a networking platform should exist, what requirements it should meet and what topics it should deal with.

For this purpose, the idea of the European Young Researcher Network (EYouRNet) as a starting point for a possible realization of such networking platform, was created. Young scientists should have the opportunity to share their experiences, answer questions and get inspired by the work of others. Furthermore, a logo (as seen in Figure 1) was developed beforehand for the recognition value of the EYouRNet-project.

Figure 1 – EyouRNet Logo

Methods

An online survey was used to determine to what extend such a networking platform is considered as relevant by the community members. The survey was distributed via the Council of the European Federation for Medical Informatics (EFMI) and the GMDS mailing list. In addition, suggestions and attitudes of potential future participants and other community members were identified. Based on these results, a workshop was held at the Medical Informatics Europe (MIE) 2018 in Gothenburg, Sweden. The workshop addressed the key issues for the successful implementation of an European networking platform emerged from the survey.

Preliminary Online Survey

A self-developed questionnaire was used for the preliminary online survey. It served to collect suggestions, demands and attitudes of the medical informatics community regarding organizational structures and activities of the proposed EYouRNet. For the implementation of the questionnaire the online survey service "eSurvey Creator" [6] was used in English language to enable the participation of international community members, especially Europeans. To reach the target

group, the survey was distributed via the EFMI-Council and the mailing list of the GMDS.

The self-developed questionnaire contained twelve questions in the form of free text fields, multiple choices and Likert scales. At various points there was the possibility of introducing further ideas and sharing thoughts and comments.

Firstly, demographics and previous experiences with networking possibilities during the doctoral studies were determined. Secondly, the relevance of various topics which could be addressed in the proposed EYouRNet were inquired. Besides the rating of given topics, such as education concepts, lessons learned and career opportunities, the participants could also contribute their suggestions. Finally, the question was asked how a personal contribution can be made.

Definition of Workshop's Thematic Fields

The information provided by the participants was assessed using common descriptive statistical methods. In addition to frequencies and relative frequencies, a content analysis was conducted relating to the free text fields. Here, four thematic fields could be identified, which are decisive for the implementation of the EYouRNet. These were extended by questions stimulating the participants to discuss [7].

1. **Communication channels**
   Which communication channels are necessary and suitable?
2. **Organizational structure**
   Which structures regarding the internal organization are reasonable?
   - Who does what when?
   - Which roles/positions do we need and what are their responsibilities?
   - What may be my own contribution to the EYouRNet?
3. **Activities to be carried out**
   Which activities should be carried out by the EYouRNet?
4. **Acquisition of participants**
   How to gain interested people both participants of EYouRNet and leading people?

Workshop

A 90-minute lasting workshop was organized to take place at MIE 2018 in Gothenburg, Sweden on April 25. The workshop aimed at introducing and improving new networking and collaboration approaches between doctoral students in the European area, especially within the EFMI. The workshop was especially directed to (former) doctoral students of medical informatics and related fields of research. Nevertheless, all conference participants were invited to take part. In the context of the workshop, possible structures, requirements and needs for the networking platform along with potential future participants and other community members should be discussed. Therefore, the workshop consisted of four successive parts: (1) round of introduction (2) presentation of the results of the online survey, (3) introduction of a national concept for networking, and (4) group work and discussion.

(1) Round of Introduction

First of all, the participants were asked to introduce themselves including their name, home country and working context, as well as the information whether or not they already have a doctoral degree. In order to break the ice, the participants were given the opportunity to mark their home country on a world map with a colored adhesive dot.

(2) Presentation of the Results From the Online Survey

To initiate the discussion, the results of the previously conducted online survey were presented. This comprised the results regarding the relevance of the proposed EYouRNet, the experiences of the participants, the topics to be addressed within the networking platform and the future contribution for possible members. Thereby, visualizations like pie charts were used for a better understanding.

(3) Introduction of a National Concept

As third part of the workshop, a short introduction to a national concept for the networking of doctoral students was given. Once a year, German doctoral students of medical informatics have the opportunity to meet up at the "GMDS-Doktorandensymposium". This event is funded by the GMDS and organized by the students themselves at changing locations in Germany. The two to three day event always includes a presentation and discussion of the individual topics of the doctoral theses, an excursion to prospective employers for medical informatics specialists, and a social event [5].

In 2017 the symposium was organized by the authors of this paper at the Peter L. Reichertz Institute for Medical Informatics of TU Braunschweig and Hannover Medical School. That year's excursion led the participants to the accident research division of "Volkswagen AG".

(4) Group Work

The previously mentioned thematic fields (see "Definition of workshop's thematic fields") were presented to the workshop participants and subsequently used for a group discussion. Since the actual number of participants of a workshop at a conference is not known beforehand, two different discussion methods have been prepared.

Whereas for a small group size an open discussion format would have been used, the simple and flexible group discussion method "World café" would have been the choice for a larger amount of participants [7]. When using the second method, the entire group is divided into smaller working groups interchanging independently, for example at different tables. Each of these groups focusses on one subtopic. The discussion points and results of each group (per table) are documented. After a pre-determined time, all but one group member, the table host, switch to a different table and thus to another subtopic. This is the starting point for a second discussion session. Now the table host briefly explains the previous discussion points and results to the new table members. Building on this, the discussion is continued with the new group members. After a predefined number of iterations the results for each subtopic are presented to the entire group. This gives the participants the opportunity to express supplementary thoughts and opinions they had not dealt with before.

Results

Online Survey

The preliminary online survey was available from March 13th to April 16th, 2018. In total 76 scientists participated in the survey. 57 of them completed the whole questionnaire. This results in 19 partial answered questionnaires.

Most participants came from Germany (40), three from the Netherlands, two each from Cameroon, Kenya, Romania and one person each from Austria, Brazil, India, Mexico, Russia, Slovakia, Switzerland and the USA. For 19 participants the home country is unknown, because this question was not included in the beginning of the survey by mistake. The majority of the participants had a Master degree or Diploma (46), followed by a Doctoral degree (15) or a

Habilitation (11). Only two participants had another, unspecified academic degree.

The relevance for the implementation of the networking platform can be derived by the responses to the question of being interested in participating or supporting the EYouRNet. More than 80% of participants are interested in participating or supporting the proposed network (see Figure 2).

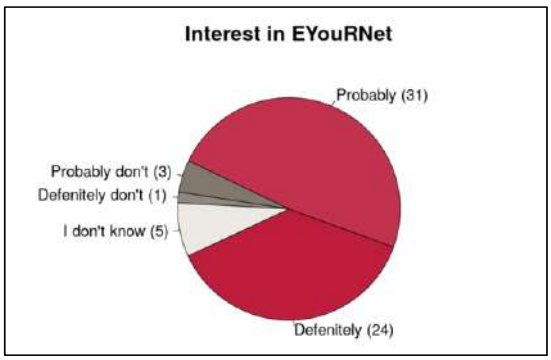

*Figure 2 – Interest of **P**articipating or **S**upporting the EYouRNet*

Participants of the survey, who have already finished their doctoral studies (19), were asked about their network experience as young scientists. Approximately one third of the respondents (7) stated that they had not received any support by networking possibilities. The remaining two-thirds were actively attending working groups (6), made informal contacts at conferences (4) or received support from colleagues (2).

With regard to the question of missed networking opportunities, only about one sixth of the respondents stated that they had not missed anything (3/17). The remaining 14 would have above all liked support in the form of networking events, informal exchanges and advices from experienced scientists, preferably also via an online platform.

The networks contribution to the doctoral student's self-management skills, technical competence and personal development was assessed. The majority of participants stated, that the impact of the networking possibilities is most important for the personal development. The contribution to the self-management skills and the technical competence were equally weighted.

The time to participate as a young researcher in such a network was indicated to be especially inspiring in the beginning of the doctoral studies. Nevertheless, also a later start has been reported as valuable and recommended.

Potential topics for the network to be addressed were also included in the survey. The results show that, apart from training concepts, all proposed topics were ranked as very important. This includes lessons learned during the doctoral studies, discussions on pitfalls in peer groups, training possibilities during the doctoral studies, cooperation opportunities, project support/exchange and career opportunities. In addition, the participants contributed the following suggestions and ideas with regard to further topics:

- Training on writing and presentation skills (2)
- Working groups on subtopics (2)
- Strengthening of social network (1)
- Get in touch with key players in the field of medical informatics and the EFMI-organization (1)
- Site visits around Europe (universities, hospitals) (1)
- Overview of common methods and tools (1)

In the concluding comments, eight participants gave valuable hints and ideas for the realization of the EYouRNet. Whereas, single individuals doubted the feasibility of the network others stated that they were happy to be a part of the realization. A major challenge is to find volunteers (students) to spread the ideas, both to interested students and to supervisors. Supervisor's role is to enable their doctoral students to participate, for example by financing an (extended) conference participation. Furthermore, supervisors play a decisive role in validating discussion outcomes and in the provision of valuable input. This goes hand in hand with the regulation of organizational issues. Here, the workshop verified the fact that face-to-face meetings require a high organizational effort, whereby they are probably most effective because they enable the participants to build direct working relationships (see subsection "Communication channels"). In addition to the face-to-face meetings, online meetings were suggested.

MIE Workshop

The workshop "Networking of PhD Students in the European Area" took place within MIE 2018 in Gothenburg, Sweden on Wednesday 25th April. 16 scientists from the field of medical informatics attended to this workshop. Their home country was mainly Germany, yet also Portugal, the Netherlands, Sweden, Finland and Ethiopia were represented. Among the participants only one had a doctoral degree.

First of all, the results of the online survey and the national concept of "GMDS-Doktorandensymposium" were presented in order to initiate the group work. Due to the amount of participants, the "World-café" format was chosen for the group discussion with two sessions each lasting 15 minutes. Four tables were prepared, each with a thematic field, the corresponding questions, and the ideas as well as the remarks from the online survey.

Communication Channels

Networking is premised on communication with one another. Accordingly, suitable channels must be identified for the communication in the network within the European area. Communication channels proposed by the survey participants were online platforms and real-life meetings. These were already noted on the prepared results document under the heading "Communication channels" (see Figure 3).

Regarding a suitable channel the participants of the workshop uttered the idea of using already existing platforms like LinkedIn, Rocket.Chat, Facebook, Google, Confluence or Zulip (see Figure 3). The use of such platforms offers the advantage of recourse to validated products with low overhead. It is important to consider where and how personal confidential data is stored. The participants explicitly whished no e-mail communication as these is difficult to manage over long periods of time with several participants and offers no possibility for new members to access historical posts.

For real-life meetings they proposed annual meetings, for example in combination with the MIE conference. They thought about a one-day meeting in advance or afterwards the conference to reduce the travel costs and organizational effort in comparison to independent meetings. Nevertheless, additional financial resources may be necessary.

Another mentioned idea was to host regular tutorials. Here, the participants thought about an list where doctoral students can add their topic-related expertise to talk about. Periodically training courses could be organized based on this list by students for students.

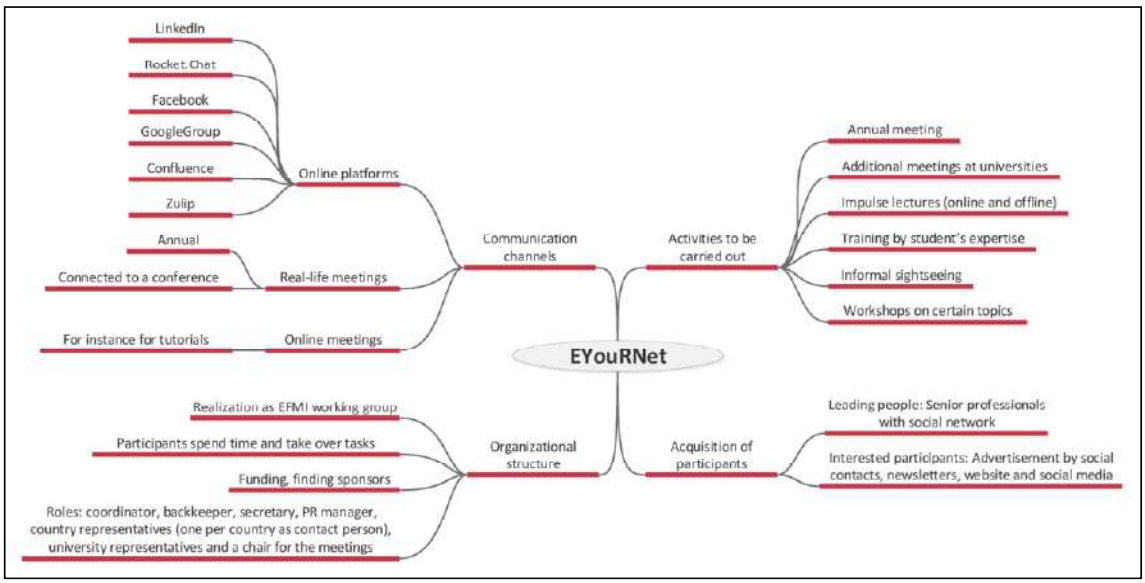

Figure 3 – Results of the World-Cafè – Suggestions and Demands of the articipants

Organizational Structure

In order to increase the chances for the EYouRNet to emerge and continue to exist, the organizational structures should be as complex as necessary, but also as simple as possible. This goes hand in hand with the lowest possible workload for (as many) members as possible. Thus, the obstacle to enter the network is small and the overall time expenditure for active members of the network stays realizable in the everyday work. The establishment of an EFMI working group represents a possibility for the realization within already existing structures.

The question "Which roles/positions do we need and what are their reponsibilities?" was answered with a list containing the following roles: a coordinator, a backkeeper, a secretary, a public relation manager, country representatives (one per country as contact person), university representatives and a chair for the meetings. The responsibilities of university and country representatives are getting in touch with (new) members and make contact to local existing student organizations.

Concerning their own potential contribution to the network the participants proposed time instead of money. They assumed, that every active member could spend up to four hours per month for the network. They also offered the possibility of couch surfing to minimize the traveling costs. Nevertheless, such a network relies on funding. Therefore, sponsors, university funding and student organizations with financial resources need to be identified and asked for their assistance. The following institutions are potential contributors: the EFMI, the GMDS, the International Medical Informatics Association (IMIA), cooperating partners, universities and the "Deutscher Akademischer Austausch Dienst*"* (DAAD), which "*[…] is the world's largest funding organization for the international exchange of students and researchers*" [8].

Activities to be Carried Out

Several activities to be carried out within the EYouRNet were identified by the workshop participants (see Figure 3). But they also perceive the organization of activities as most challenging, due to the fact that someone has to be responsible for the organization. Consequently, this person has a high (unpaid) expenditure. Moreover, the time required to prepare an activity should not be underestimated.

As most important activity annual meetings were suggested in combination with conferences so that the travel costs are minimized in comparision to additional meetings, e.g. at other universities. Organizers have to be aware of the fact, that there are often preconference workshops, which may are in temporal conflict with an EYouRNet meeting. The workshop participants also suggested informal sightseeing at the conference location. A list of sights shall be provided by local students. Formal meetings (also online) on selected topics with invited speakers were also mentioned. In addition, the participants wished for a platform to make calls for papers and other relevant content available to the community with little effort. This also includes self-organized workshops and further training of other doctoral students within the network. A list of the doctoral students' expertise can serve as a basis for such workshops and to find an appropriate topic by vote.

Acquisition of Participants

It is important to gain leading people to keep such a network running. The participants proposed senior professionals as potential leaders. However, it should be born in mind that their workload is often already very high anyway. For this reason, a self-administration of the network by doctoral students should take place.

One other important question is "how to gain the interested people as participants". Therefore, advertisement is needed by social contacts, newsletters, websites and social media. In doing so, ecpecially the personal benefits have to be communicated. For example, invited key players in the field of medical informatics can be attractive.

Discussion

In this paper, the relevance, requirements and realization possibilities for a European networking platform of doctoral students in the field of medical informatics are assessed. Therefore, a self-developed online survey with 76 participants of the community was conducted. Based upon the results of the survey a workshop with 16 participants has been carried out at MIE 2018. Here, four essential thematic fields were dealt with.

The results of the survey show the relevance and demand for the EYouRNet. More than 80% of the participants of the survey

are interested in participating or supporting the proposed network. During the workshop many realization possibilites with varying personal and financial effort were discussed. Besides regular meetings in combination with conferences, existing communications platforms such as LinkedIn, Facebook or Zulip were preferred for the interchange. Overall, the organizational structure should be small to minimize the obstacle to enter the network. In addition to a network coordinator and country representatives many other roles are needed to keep such a network running.

There are, however, some limitations to the described work. The online survey was mainly answered by german people (bias), due to the dissemination via the GMDS mailing list. Furthermore, the dropout rate was 25%. This could have been caused by a lost of interest to fillout the questionnaire. Also the amount and length of questions, as well as the time taken to answer them may have deterred people to complete them. Nevertheless, every participant who has answered the first four questions also completed the whole questionnaire. This confirmes the high level of interest in this topic. Even though not all questionnaires were filled in completely, all answers can be taken into account for the assessment. All participants answered the questions regarding their demographics and the relevance for implementing an European networking platform. The remaining questions were designed independently, thus they can be analyzed separately.

Due to the fact that the majority of the workshop participants came from Germany too, there will be a further bias. This bias could be decreased by additional interviews with scientists from other countries. It should be born in mind that both the online survey and the workshop were conducted in English language to reach international participants. Despite this bias, the results are sufficiently informative, as these are based on statements by members of the target group (young scientists). In-depth considerations of the ideas discussed in the "World-café" during the workshop are necessary in order to select suitable candidates for an initial implementation. Furthermore, maybe the presented results of the survey and the national concept "GMDS-Doktorandensymposium" influenced the participants during the workshop. However, providing general ideas and insights was a conscious decision to initiate the discussions in the rather short time of an workshop. Nonetheless, many ideas and realization possibilities were collected from the workshop participants.

So far, there has been no exchange with other working groups or organizations for the networking of young scientists. A next step could be to exchange with these groups in order to learn from them.

Conclusions

Networking is a key competence, especially for young researchers in the field of medical informatics as a highly cross-sectional discipline. Therefore, it is encouraged in many organizations like AMIA. However, within the European area, there is no such networking possibility known. In this paper the relevance, requirements and realization possibilities for a European networking platform of doctoral students in the field of medical informatics are presented. The relevance as well as first attitudes and suggestions were established by an online survey. In a subsequent workshop within MIE 2018, possible communication channels, organizational structures, activities to be carried out, and acquisition of participants were discussed with potential future participants and other community members.

Altogether, the relvance and the demand for the EYouRNet was shown. Furthermore, the general acceptance, in the surveyed group, to participate and support the network is given. Essential ideas for the implementation of the EYouRNet were collected, which can serve as a basis for the realization.

Acknowledgements

The authors would like to thank all participants of the first EYouRNet workshop at MIE 2018 in Gothenburg, Sweden, for their outstanding cooperation and inspiring discussion. Special thanks is due to Hannes Ulrich (Universität zu Lübeck, Institute of Medical Informatics), who started a first platform realization with Zulip.

Moreover the authors would like to thank Alfred Winter for the support with the implementation and distribution of the online survey and the announcement of the workshop via the mailing list of the GMDS and the EFMI-Council.

Development of a Mobile Learning System for Nurses' Cultural Competency Training

Sumi Sung[a], Hyeoun-Ae Park[a]

[a] *College of Nursing, Seoul National University, Seoul, Republic of Korea*

Abstract

We developed a mobile learning system that provides cultural competency training courses for nurses at a university hospital in South Korea using the system development life cycle. The contents and functions of the system were identified from the literature review, expert's recommendations, and the users' requirements. An algorithm, database, and user interface were designed. The system was implemented using the Newin Touchclass authoring tool. We evaluated and modified the system based on heuristics evaluation.

Keywords:

Mobile Application, Nursing Education, Culturally Competent Care

Introduction

South Korea is rapidly becoming a multicultural society. As the cultural backgrounds of patients have diversified, the need for culturally competent nursing care has emerged. In order to provide culturally appropriate nursing care to patients with culturally diverse backgrounds, it is important to train nurses on their cultural knowledge, awareness, sensitivity, and skills in nursing practices.

As most nurses work shifts and have intensive workloads, it is difficult for them to attend face to face classes [1]. Meanwhile, mobile learning enables nurses to be accessible from anywhere, can be shared instantaneously with everyone using the same content, brings strong portability, and is cost-effective [2].

The aim of this study is to develop and evaluate a mobile learning system that provides a cultural competency training course for nurses caring for foreign patients working at a university hospital in South Korea.

Methods

We developed a mobile learning system using the four stages of the system development life cycle: analysis, design, implementation, and evaluation.

Analysis

The content and functions of the mobile learning system were developed by literature review, experts' recommendations, the users' requirements through face to face interviews, and validated by experts.

We first reviewed transcultural nursing theories and models to identify a framework for the content of the system. The tools for the pre-post test were also reviewed to evaluate the effect of a mobile learning system.

Four experts, working at a university hospital as medical coordinators, were invited to identify cultural conflict examples and cases based on their experiences when brokering cultural differences between South Korean nurses and foreign patients.

Requirements of the users were identified through face to face interviews with eight nurses at a national university hospital. After Institutional Review Board approval (IRB No. H-1807-109-959), eight nurses were interviewed for about an hour with the aid of semi-structured questions regarding content, method, and time preferences related to the cultural competency training course throughout mobile learning.

The contents and functions of the system were validated based on feedback from six experts working at a university hospital.

Design

Based on the results from the analysis stage, the decision regarding which software to use was made. Choices and decisions regarding content, the configuration of learning modules, and use of multimedia (verbal, visual, or audio) were also made. Several functions available to implement in the software chosen were considered. An algorithm for learning and a database for learning modules was designed. The user interfaces of the pre-post tests and eight learning modules were designed according to the contents and functions from the analysis stage using the Microsoft Office PowerPoint program.

Implementation

We converted the slide presentations to a storyboard of learning modules using the authoring tool of Newin Touchclass on the website.

Evaluation

The heuristics of the mobile learning system on the Touchclass mobile application were evaluated using a mobile heuristic tool by four experts with majors in nursing informatics. If two or more people scored an item as one point or higher, and if any items scored four points, items were considered to have major problems and required revision.

Results

Analysis

We chose the Purnell model for cultural competence [3] as a framework for the content of the system. Two different approaches, cross-cultural approach and categorical approach, were adopted.

The users had a positive attitude toward learning general cultural competent nursing care; however, some of them only wanted to focus on the cultural information of particular cultural groups. The users required HTML-based mobile learning content rather than video content not exceeding 10 minutes to maintain their concentration. The users suggested education related to four particular cultural groups (Chinese, Russian, Mongolian, and Arab from the United Arab Emirates), feedback of cultural experts, sharing the difficulties with other nurses, and guidelines for nursing assessments.

The content of the mobile learning system consisted of eight modules. Based on the users' requests, cultural knowledge of four particular groups and guidelines of nursing assessments and interventions were included.

The functions of the mobile learning system consisted of three mobile learning strategies: guided learning, synchronous sharing, and issue-based learning. These were developed based on the literature review. Based on the users' requests, we decided to develop HTML-based mobile-learning content running less than 10 minutes for each learning module. In total, 17 cultural conflict examples, 10 cases, and three quizzes were included in eight modules. Written text with six tables, three linked YouTube videos, two videos, and 68 images were used.

From the experts' validation, a few expressions which may lead to stereotyping or increased cultural misunderstanding were revised. Common diseases and treatments of four particular groups were added to the biocultural ecology domain in Purnell's 12 cultural domains.

Design

We used the Newin Touchclass software to develop the mobile learning system. Five mobile application functions (registration, login, notices, communication, and alerts) in the Newin Touchclass mobile application development software were chosen.

An algorithm for learning was developed based on requirements of users and module contents developed in the analysis stage. The user's pre-cultural competency level was assessed. After that, the system provided the education, eight modules. When finishing each module, the user had an online discussion on the freeboard. When the user finished the course, their post-cultural competency level was assessed.

The database of the system was drawn in an entity-relation diagram. The data used in the mobile learning system was grouped into four categories: personal information, pre-test, post-test, and learning module. Data dictionaries were created with possible values, data types, and units.

The user interface in this study consists of the 17 interface categories. Login, registration, main page, my course page, noticeboard, freeboard, and pop-up window were originally designed on the Newin Touchclass software. We designed 27 user interfaces on eight learning modules with five videos, 68 images, and six tables (Figure 1). Pre-post tests were placed before and after the course.

Implementation

The operating environment of the app is iOS 8.0 and Android 4.0.3 or higher. The mobile learning modules of the system were developed using the Newin Touchclass authoring tool from September 20, 2018, to November 8, 2018.

Evaluation

In total, 18 suggestions were made by the four experts in the heuristics evaluation. Three suggestions proposed by more than two evaluators were selected, and the system was modified accordingly: "In case of an application error, the contact information is required to be presented", "Unnecessary videos are shown with liked YouTube video", and "The image that indicates going to the next page is confused whether the user should push the screen to the right or to the left."

Conclusions

We developed a mobile learning system for a cultural competency training course. The mobile learning system will be tested and used as part of the on-the-job-training courses for the nursing workforce.

Acknowledgements

This study was financially supported by Seoul National University Hospital.

Assessment of Traceability Implementation of a Cross-Institutional Secure Data Collection System Based on Distributed Standardized EMR Storage

Katsuya Tanaka[a,b], Ryuichi Yamamoto[c]

[a] *Department of Biomedical Informatics, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan*
[b] *IT Integrating and Support Center, National Cancer Center, Tokyo, Japan*
[c] *Medical Information System Development Center, Tokyo, Japan*

Abstract

This paper presents results concerning the traceability of a secure data collection infrastructure based on the Bloom Filter involving standardized electronic medical record (EMR) storage. The objective of this infrastructure is to facilitate rapid secondary use of exported EMR data in cross-patient or cross-institutional analyses based on the Standardized Structured Medical Information eXchange (SS-MIX), Japan's domestic standard for EMR export. Secondary use of EMR data should be based on the principle of patient consent. Therefore, securing the traceability of patient EMR data is important for achieving reliable data collection systems for secondary use. Blockchain is a strong candidate, and we evaluated its performance using several implementations. As shown by the evaluation, it is difficult to realize the method of recording the query history of secondary use on the blockchain. We thus propose a method for recording index information of distributed log data.

Keywords:
Privacy, Data Collection, Electronic Health Records

Introduction

Background

In Japan, the domestic standard for exporting whole electronic medical record (EMR) data to external storage is the Standardized Structured Medical Information eXchange (SS-MIX2) [1], which is based on Health Level-7 (HL7) v2 message files. This system is widely used for backing up data, regional collaboration, disease registries, and other purposes. In this standard, we can represent definite states of 37 clinical events of each patient in a hospital, including admission-discharge history, medication history, and laboratory test results using ADT/RDE/OUL HL7 v2 messages. The directory structure for stored records is based on patient ID, clinical date, and clinical event type. This structure makes it difficult to use exported data for cross-patient analyses, such as epidemiological studies. In May 2017, an amendment to Japan's Act on the Protection of Personal Information [2] designated medical information as important confidential information, requiring strict consent for its provision to a third party. Secondary use of medical information for research is permissible if utilized in accordance with ethical guidelines; however, large-scale data collection and analyses that include secondary use of information by third parties, including commercial companies, is technically difficult because of the requirement to obtain consent from each patient for information disclosure. Therefore, a new law was enacted in May 2018, under which a certified business operator can collect medical information, anonymize the information, and respond to a third party's request for the information for use in analysis. The new law allows secondary usage of patient information on the assumption of consent unless the patient specifically opts out. Patients are provided with an opportunity to opt out. Several forms of data collection are assumed, with large-scale collection using SS-MIX2 being a leading candidate. With SS-MIX2, personal information is collected and transferred to a data center without anonymization. When personal information is collected as raw data, there is a risk of information disclosure. There are also inevitable maintenance costs according to the scale of collection and storage.

To address these issues, we propose an alternative system of collecting and storing EMR data wherein only the necessary items are included, eliminating the need for identifiable patient information to be spread outside the medical institution. The proposed system facilitates EMR data distribution within each medical institution, enabling cross-patient or cross-facility data collection and analysis. Integration and encryption of extracted EMR data are achieved using the Private Set Intersection (PSI) library developed by Miyaji [2]. However, at present, consent management has not been fully discussed [3]. Consent management is a key factor for secondary research use, and several challenges have been reported[4; 5]. Our approach focuses mainly on auditing the secondary usage under opt-out style data collection research using our developed data collection system across participating medical institutions.

Research Objective

This paper investigated how to implement the capability of traceability in the developed system for secure data collection and analysis. Blockchain technology has been recently applied in health care fields, including primary patient care, data aggregation for research purposes, and connecting healthcare providers [6-8]. The system that we are developing has a second purpose: For securing the traceability of EMR data, methods to disclose the logs of secondary usage are needed. In the present situation where patients do not have any common ID, it is difficult for a patient to audit all the secondary usage logs across the distributed hospital storages which he/she visited. By blockchain technology, we expect to provide patients a common search infrastructure with immutable secondary usage logs. Thus, we plan to apply blockchain technology to the aggregation of data extraction log records. This method has several possible implementations, and they must be evaluated assuming operations in real use. The experimental results shown below mainly concern data structure and transaction performance compared to traditional implementation for achieving aggregation of distributed log records of EMR data extraction.

Methods

Overview and Concepts of the Developed System

Figure 1 presents an overview of the system. The key concepts are:

1. Each medical institution has EMR data in SS-MIX2 storage, including billions of HL7 v2 messages.
2. HL7 v2 messages are periodically parsed and stored to relational database management system (RDBMS) tables, maintaining synchronization with the billions of message files in SS-MIX2.
3. Analysis requests from researchers and data collection are managed by the PSI service on the cloud, which communicates with a client agent located at a client terminal and PSI agents located at each medical institution.
4. Target data criteria, such as diseases, age, and gender, must be defined before the PSI executes data collection. The PSI party agent deploys the target dataset in advance from the local RDBMS to memory.
5. Data collection is achieved using PSI software, which is based on Bloom Filter technology for record verification across institutions. The application of Bloom Filter technology is aimed at realizing data matching in which personal information does not leak outside each hospital while the data collection process.
6. The collected dataset can be verified considering the possibility of patient identification using the extracted attributes.
7. Patients can trace the use of their medical records during data collection.
8. If they choose, patients can withdraw consent for secondary use of their data. Consent withdrawal information is assumed to be an input to existing the EMR system and exported SS-MIX2 storage in each hospital.

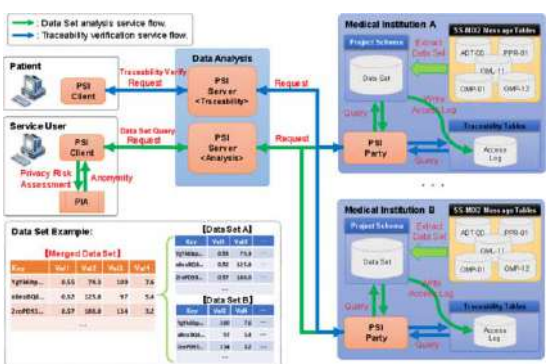

Figure 1. Overview of the Developed System for Secure Data Collection and Analysis (originally published in [3])

Traceability for Patients

EMR storage for the developed secure data collection system is supposed to process queries from clinical researchers using the standard interface implemented by the PostgreSQL database. EMR data are extracted by data extraction requests handled by the PSI service. Thus, the selected records are identifiable based on each query result, and the records represent the disclosure history of EMR data during data collection through use of the developed PSI service. By making the log record of extraction searchable by patients, we suppose that traceability in the secure data collection system will be achieved. However, because storage is supposed to be distributed at each hospital, log records must be aggregated by some secure method to be made auditable.

Log data is assumed to be represented by a combination of the following attributes:

1. Identifier of target patient (Patient Identifier)
2. Storage source (Medical Institution Identifier)
3. Disclosed destination (Extracting User Identifier)
4. Purpose of use
5. Type of extracted EMR data
6. Extraction timestamp

Attribute 1 (patient identifier) is mandatory for patient identification. At present, universal patient identifiers are not available in Japan. We assume that insurance numbers may be desirable for searching log records across medical institutions, because the patient ID at one medical institution is only applicable for searching log records at that medical institution.

Attribute 2 (medical institution identifier) is used to distinguish the institution storing the extracted EMR data.

Attribute 5 (type of extracted EMR data) is represented by HL7 ver.2 message types such as “ADT-00”,”OMP-01”,”OML-11”.

Attributes 3, 4, 5, and 6 are used to distinguish secondary use of target EMR data by patients. By verifying these attributes, patients can determine whether actual secondary usages meet their consent.

Data Structure for Query

A query for EMR storage may extract records of many patients at one time. For disclosing extracted history to patients, the extracted history should be sorted by patient and each history should include the attributes described above.

By focusing on one patient, the extracted history grows as queries hit the target patient EMR record. Moreover, this extracted history is distributed at each EMR storage site across the participating medical institutions.

For achieving desirable response, the aggregation of extracted history should be obtained in a realistic time. This is closely related to the data structure and size of each log record. Future studies should focus on data size of stored log records.

In the performance test, a simple message structure is defined as a JSON (shown in Table 1). Identifiers of patient and institution are represented as hash values. Each log record can be stored separately in the blockchain (separate style) or aggregated in a block by a patient appending records to the corresponding block (appending style). In the former method, we must gather the pieces of the records related to the patient of interest. In the latter method, the block size grows as the system is used. We examined performance differences when the data size of a record to be written is changed.

Experimental Setups

We evaluated the following three approaches to implement traceability function. Of these, two are based on blockchain

Table 1. Sample Data Representing Extraction History.

```
{
        "patientID":"781e5e245d69b566979b86e28d23f2c7",
        "insutitionID":"aabd258c8894b996e8d8561fa868364d",
        "disclosedDestination":"AnalysisUser001",
        "purposeofUse":"DrugDevelopment",
        "typeofRecords":"OMP-01",
        "extractionTime":"2018/11/12 01:23:45"
}
```

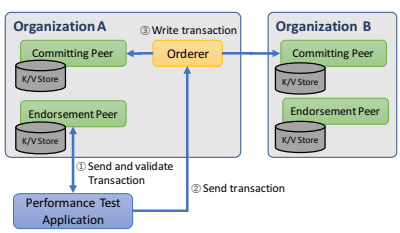
technology. The last approach uses the same method of secure data collection as PSI against log records stored in distributed PostgreSQL databases.

- Hyperledger Fabric[9]
- BigchainDB[10]
- PSI (Bloom Filter)

The experimental settings for each approach are described below. Between Hyperledger Fabric and BigchainDB, key/value store implementation for search use differs from each other.

Hyperledger Fabric

Figure 2 shows the experimental setup using Hyperledger Fabric to store query log records during data collection. Assuming two participating institutions, two nodes were set for the performance test. Native implementation only offers Key-Value storage and is applicable to a separate style. We also evaluated Hyperledger implementation with CouchDB [11], which enables query against the value of the JSON message described above. Thus, we can implement both separate and appending styles.



VM Host Machine		VM * 2 node		Middleware version	
CPU	Intel Xeon Bronze 3106 (16 CPUs @1.70GHz)	CPU	4 CPUs	HyperLedgerFabric	1.3.0
Mem	64GByte	Memory	8GByte	Docker	18.06.1
OS	VMWare ESXi 6.7.0	OS	Ubuntu 18.04.1 LTS	CouchDB	2.1.1

Figure 2. Experimental Settings (Hyperledger Fabric)

BigchainDB

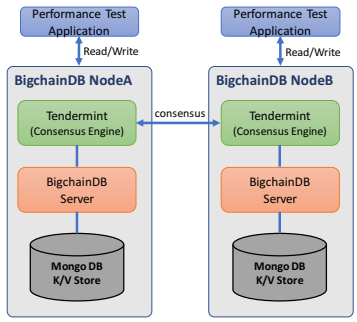
Figure 3 shows the experimental settings for using BigchainDB to store log data. As above, two nodes were prepared for evaluation. MongoDB [12] was selected as the backend database. In this case, both separate and aggregated structures are possible on the same implementation.

Query key candidate is the transaction ID of the stored block or stored JSON value.

PSI (Bloom Filter)

Figure 4 shows the experimental settings in the case of PSI implementation. The log records of data extraction are recorded at the time of extraction. Using the same method of EMR data collection, we can gather the log records against distributed storages under encryption. That is, although the search is performed by specifying the insurance number, the date of birth, the gender by patients, since the matching is performed using the Bloom Filter, these values are not directly disclosed on the infrastructure.

In this test, three nodes were prepared for evaluation, but the performance test measurement was executed on only one node.



VM Host Machine		VM * 2 node		Middleware version

Figure 4. Experimental Settings (PSI)

Results

Performance by Data Size

Figure 5 shows the performance of writing records to blockchain storage by record size for Hyperledger. In the experimental environment, it worked normally for records 7 MB or smaller. As the record size grew, the response became unstable.

Figure 6 shows the same test for BigchainDB. The maximum record size was 0.6 MB, which is much lower than that for Hyperledger. However, the transaction time to commit was larger than that for Hyperledger.

By contrast, the data size for PSI can be as large as allowed by the database system.

Transaction Performance

Figure 7 shows the performance results of writing records to blockchain storage for Hyperledger with/without CouchDB and BigchainDB under one or five thread processing.

In all cases, processing by threads contributed to storage performance, but the throughput did not increase linearly with the number of threads.

Comparing the three implementations, BigchainDB was slightly faster than Hyperledger. Hyperledger with CouchDB had the worst performance; this is likely caused by the cost of indexing within CouchDB. In the best case, 1 million records were written to the blockchain storage in 3-4 hours. This performance is equivalent to writing 10 million records or less in one day.

Comparing these implementations using blockchain technology, the performance of PSI was equivalent to the "insert" performance of the PostgreSQL database used. The necessary time for inserting 1 million records to the database was below 10 min. This performance is about 1000 times faster than the blockchain implementations.

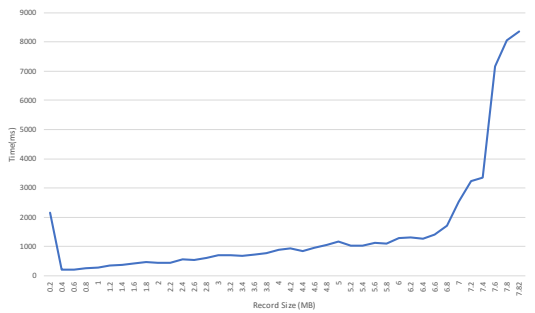

Figure 5. Performance Results by Record Size (Hyperledger)

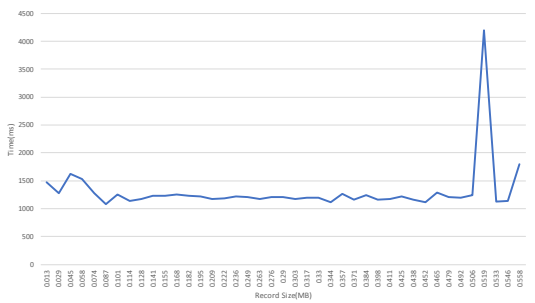

Figure 6. Performance Results by Record Size (BigchainDB)

Query Performance

Figure 7 shows the performance test results of retrieving one record from blockchain storage using four types of implementation. There were no significant differences in the query response times between Hyperledger and BigchainDB. "Hyperledger Key" and "BigchanDB transid" represent the separate style of storage, whereas "Hyperledger Value" and "BigchainDB AssetsText" represent the aggregated style.

Figure 8 shows the performance test results of query response. Query response is fast enough for actual use in the case of 1 million records in the storage. This result shows hitting 1 record and the response time linearly increases as hit records increase.

On the other hand, PSI implementation needs 1 min or less to aggregate the extracted results across the distributed databases.

Figure 8. Performance Result of Querying Records

Discussion

Based on the initial evaluations, the following recommendations are made.

Transaction Performance

The transaction performance of a blockchain network was quite low for storing massive numbers of log records generated by queries in the developed system. In the case of blockchain, at most 100 transactions per second is best for a node to register to storage. Compared to implementation with PostgreSQL, the total transactions per day will be 1000 times smaller. If we do not implement any aggregation of log records, it will be impossible to process the enormous numbers of log records generated for each EMR item. Some patient-based aggregation of log records should be considered to overcome performance limitation.

Data Size

The results by data size show the upper limit for storing log records to blockchain storage. As writing large records to storage makes the system unstable, writing in the appending style is not suitable due to the long operation time of the system. Considering the transaction performance test results above, the total number of transactions to the blockchain network per day should be limited.

Query Response

As the amount of storage increases, the search function must query all storage in the network. Whole log records thus require some possible indexes for searching by patient. The query performance test results show a good response for searching for a

log record in the blockchain network despite the increase in the number of log records.

Proposed System for Future Implementation

Based on the performance evaluation results, we decided to implement the following policy as the basis for making the search log history visible to patients when using the developed secure data collection system.

- Aggregate log data by patient in each facility
- All log records are stored at each facility
- Record the minimum amount of data, such as the log record identifier key and facility identifiable key, for retrieving index data in the blockchain
- For query log data, use personal identification information, such as insurance number, date of birth, gender, etc.

By following these policies, a patient can search the blockchain and find the storage facility. Moreover, the number of records that must be recorded per period can be reduced to the number of related patients. Figure 9 shows an overview of the proposed log search system. The log records should include:

- Facility identifiable key
- Log record identifiable key
- Digest to audit each log record
- Key to identify each patient; this could be generated by encrypting a patient identifier like insurance number, date of birth, gender, etc.

We plan to develop a log search system with the described structure.

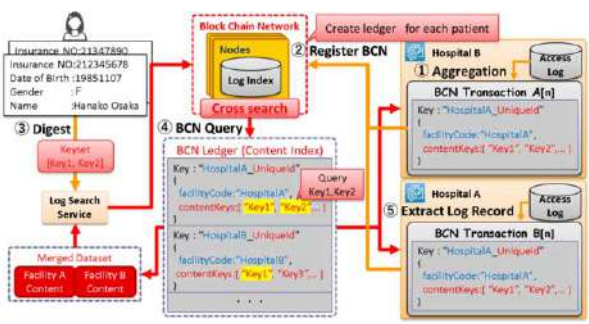

Figure 9. Overview of Proposed Log Search Service Using a Blockchain Network.

Limitations

Because we did not have sufficient time to set up larger records, performance tests were executed for 1 million records or less. As the number of records increases, the test results and system stability may change. Performance tests with more records are required in future work. Similarly, performance should be estimated for larger numbers of nodes.

Conclusions

This paper reports the initial performance results related to traceability for a secure data collection system under development. The desired data structure and system infrastructure were examined. Although blockchain implementation is a strong candidate for establishing an audit infrastructure to verify the use of EMR data for clinical research, there are some challenges for maintaining long-term operation as the amount of data increases. Thus, we proposed a data structure and querying implementation to overcome the implementation performance.

Abstract

Multifocal intraocular lens implants (IOLs) are a premium option for cataract surgery which patients may purchase to achieve improved spectacle-independence for near vision but may have trade-offs with visual quality. We demonstrate the use of sentiment analysis to evaluate multifocal lenses discussed on MedHelp, a leading online health forum. A search for "multifocal IOL" was performed on MedHelp.org on November 1, 2016, yielding relevant patient posts. Sentiment analysis was performed using IBM's Watson, which extracted 30,066 unique keywords and their associated sentiment scores from 7495 posts written by 1474 unique patient users. Keywords associated with monovision, monofocal, and toric lenses had positive mean sentiment, significantly higher than for keywords associated with multifocals, which had negative mean sentiment ($p<0.001$, ANOVA). Many keywords represented complaints and were associated with negative sentiment, including glare, halo, and ghosting. Sentiment analysis can provide insights into patient perspectives towards multifocal lenses by interpreting online patient posts.

Keywords: Natural Language Processing, Multifocal Intraocular Lenses, Social Networking

Introduction

Cataract surgery is the most commonly performed surgery in the United States, with nearly 4 million surgeries performed per year [1]. Cataract surgery restores clarity of vision by replacing the natural, cloudy lens of the eye with a clear intraocular lens (IOL) implant. Standard monofocal IOLs are designed with a single dioptric power enabling sharp vision at a pre-determined target distance. Most patients desire a distance target, resulting in a need to wear reading glasses to correct presbyopia and achieve clear vision for near- or intermediate-distance tasks. Interest in sharp spectacle-free vision at a range of target distances has paved the way for the development of premium presbyopia- and astigmatism-correcting advanced technology IOLs. Some of these lenses have been designed to mimic accommodation (Crystalens), or provide clear vision at multiple predetermined focal points simultaneously via concentric rings of multiple dioptric powers (multifocal IOLs), or, more recently, offer extended depth of focus across a more continuous range of distances (Tecnis Symfony). These lenses have been promoted as a method of achieving spectacle independence. However, patients must bear the cost of this premium IOL option out-of-pocket as insurance companies do not reimburse for the extra cost, which averages over two thousand dollars per eye in the US [2].

While multifocal and extended depth of focus IOLs (hereafter referred to collectively as multifocal IOLs) may provide a higher chance of acceptably clear spectacle-free vision, they have been reported to be associated with glare, halos, and reduced contrast sensitivity due to their complex optical design, particularly in the earliest generation models [3]. Such side effects can be potentially disabling and sometimes result in patients pursuing a second, riskier, surgery to exchange the implanted intraocular lens [4]. Achievement of improved visual acuity is not always correlated with patient satisfaction with cataract surgery, which rather may relate more to meeting patient expectations surrounding visual functioning [6]. Thus, understanding the expectations and outcomes that matter most to patients is imperative. Given the potentially high patient costs of multifocal lenses, both financial and otherwise, thorough assessment of patient-reported outcomes are important in guiding patients and physicians in their choice of lens implant and may become an important additional endpoint for clinical trials of future generations of IOLs.

MedHelp.org is one of the largest online medical communities where patients may engage in health-related discussions, with over 10.8 million discussions since its inception in 1994. From 2007 to 2014, there was an active eye care "expert" moderated sub-forum operated in collaboration with the American Academy of Ophthalmology (AAO) where members of the community could post questions to be answered by volunteer ophthalmologists. A separate eye care "community" sub-forum is also ongoing. Together, they provide a rich source of unstructured, free-text data on the patient experience with eye health and disease [7].

Natural language processing (NLP) is a rapidly advancing field within biomedical informatics that includes sentiment analysis, a discipline concerned with identifying the sentiment or position of a text towards a particular topic, classified on a scale indicating positive, negative or neutral sentiment. NLP further allows the extraction of structured concepts from free text, such as clinical concepts. With the concurrent increase in computing power and explosion in sources of unstructured text data, NLP and sentiment analysis techniques have been applied to many problems including computing consumer satisfaction metrics, monitoring social media, and forecasting financial markets, but their use is relatively nascent in healthcare. Emerging literature has suggested that patient online social media posts can be well-correlated to more formal measures of patient satisfaction, such as the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey [8]. IBM Watson, one of the most widely-recognized artificial intelligence services, has many NLP capabilities trained to extract concepts, entities, keywords, and sentiment from English language texts and has been used in healthcare to develop decision-support aids in fields as diverse as oncology [9] and radiology [10].

In this study, we sought to apply IBM Watson's NLP and sentiment analysis algorithms towards unstructured text data in MedHelp.org forum posts related to cataract surgery lens options, particularly multifocal IOLs. The goal was to identify the most popular keywords and clinical terms around multifocal IOLs used in patient discussions and their associated sentiment (positive or negative), as a generalized measure of patient satisfaction for each keyword category.

Methods

Data Source and Study Population

MedHelp.org includes an eye care "expert" forum operated by ophthalmologists (2007-2014) and an ongoing eye care "community" forum where patients discuss eye-related issues. Forums contain multiple discussion threads related to a particular topic originated by the initial user post, and each thread consists of multiple posts that are replies made by various individual users to the discussion of that topic.

A keyword search for "multifocal IOL" was performed on November 1, 2016 in the MedHelp.org eye health expert and community sub-forums, yielding the relevant discussion threads in these forums since website inception in 1994. We obtained the full text of the discussion threads, and individual posts of resulting threads were parsed for user, timestamp, and full text. Each user's profile was also analyzed for self-reported age, sex, and location information, if available. Physician profile pages on the site identified physician users, and their posts were excluded from sentiment analysis.

Natural Language Processing and Sentiment Analysis

Sentiment analysis was performed on the full text of each patient post using IBM's Watson proprietary artificial intelligence capabilities via the AlchemyLanguage application program interface (API) [11]. The public model of AlchemyLanguage is trained on English language newspapers and websites to extract concepts, entities, keywords, and sentiment. Each post was given an overall positive or negative sentiment score ranging on a continuous scale from -1 to +1, with the strength of sentiment represented by the magnitude of its numerical value. Neutral sentiments (neither positive nor negative) were assigned a score of 0. AlchemyLanguage also extracted user-generated keywords and phrases from each post and provided an associated sentiment score for each keyword or phrase for that post. Natural language processing was performed to group related keywords by converting to lowercase, removing punctuation, and stopwords (a, and, the, etc.), tokenizing (separating into distinct words, using the Treebank tokenizer [12]), and lemmatizing (transforming each word into its root word, such as making plurals singular, or transforming different forms of the same verb into a root verb, using the WordNet lemmatizer [13]). Keywords and phrases were further processed by string matching to group by clinical concept. Similar keywords and phrases were grouped by considering "IOL" and "lens" to be interchangeable. When IOL manufacturer/brand name were extracted together with the lens model as a keyword, these keywords were aggregated under the name of the lens model. Keywords mentioning "Tecnis Symfony" lenses were grouped into "symfony" whereas mentions of "Tecnis" without "Symfony" were grouped under "tecnis." If key phrases included "Crystalens" and "HD" then they were grouped under "crystalens hd" but if they mentioned "Crystalens" without "HD" they were grouped under "crystalens." All key phrases mentioning "restor", "mplus", "rezoom" were aggregated into groups, regardless of what additional accompanying words were included in the key phrase such as manufacturer (e.g., "Alcon ReSTOR" was grouped under "restor" and "Lentis Mplus" was grouped under "mplus"). If key phrases included both "multifocal" and "toric" they were grouped under "multifocal" but if only "toric" was mentioned then they were grouped under "toric." Key words and phrases associated with contact lenses were disambiguated from IOL lenses. After aggregation of common related keywords, the 250 most commonly identified keywords were examined in greater detail, from which were identified keywords representing multifocal, monofocal, and toric lenses as well as monovision and words that could be related to side effects, complications, or complaints to analyze in greater detail. A flow diagram summarizing the process of online post retrieval, sentiment analysis, and text processing is depicted in Figure 1.

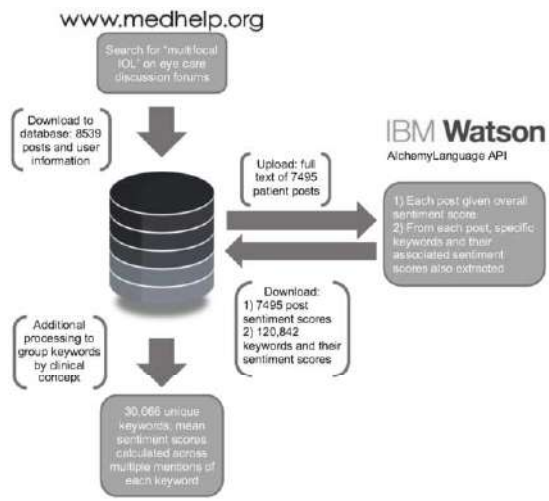

Figure 1 — Flow Diagram for Retrieval of Posts

Statistical Analysis

Mean sentiment scores and their standard deviations were calculated for each keyword across all resulting patient posts. One-way ANOVA was performed to compare mean sentiment scores between different groups of IOLs, which included monofocal, monovision (a strategy whereby each eye is implanted with a monofocal lens but with one eye targeted for clear distance vision and the other eye is targeted for near vision), toric (astigmatism-correcting), and multifocal. For the purposes of defining groups for ANOVA comparisons, the monovision group aggregated keywords "monovision", "minimonovision", "blended vision", and the multifocal group aggregated keywords "multifocal", "premium lens", "restor", "crystalens", "crystalens hd", "symfony", "rezoom", "tecnis", "mplus". Post-hoc Bonferroni comparisons were made to compare sentiment scores between groups.

We performed natural language processing using Python 2.6 (Python Software Foundation, Wilmington, Delaware) and the NLTK package version 3.2.1 (NLTK Project, Philadelphia, PA) [14]. Sentiment analysis was performed using IBM Watson via the AlchemyLanguage application program interface (API) (IBM, Armonk, NY) [11]. Statistical analysis was performed using Stata version 12 (Stata Corp, College Station, TX).

Results

Study Population and Search Results

A search for "multifocal IOL" on MedHelp.org identified 981 threads containing 8539 posts ranging from June 16, 1999 to October 31, 2016. Contributing to these posts were 1488 unique users, of whom 14 were physicians who contributed 1044 posts and 1474 were patients who contributed 7495 posts. Of the patient users, 547 (37.1%) self-identified as male, 536 (36.4%) self-identified as female, and 391 (26.5%) did not specify gender in their profile information. A total of 400 (27.1%) patient users specified an age in their profile information, which ranged from 19 to 87 years, with a mean age of 57.9 years (standard deviation 14.3).

Sentiment Analysis

Overall sentiment scores for patient posts ranged from -0.95 to 0.99, with a mean sentiment score of 0.07 (standard deviation 0.45) across all posts. A total of 120,842 specific keywords and phrases were extracted from all patient posts. Related keywords were grouped by syntax (plurals and singulars, conjugations of the same verb) and clinical concept (for example, "multifocal IOL" grouped with "multifocal lens"), yielding 30,066 unique keywords. Among the top 250 most commonly-occurring keywords were those associated with multifocal lenses and their individual models, standard monofocal lenses or monovision, and keywords that may be associated with complications or complaints (Figure 2).

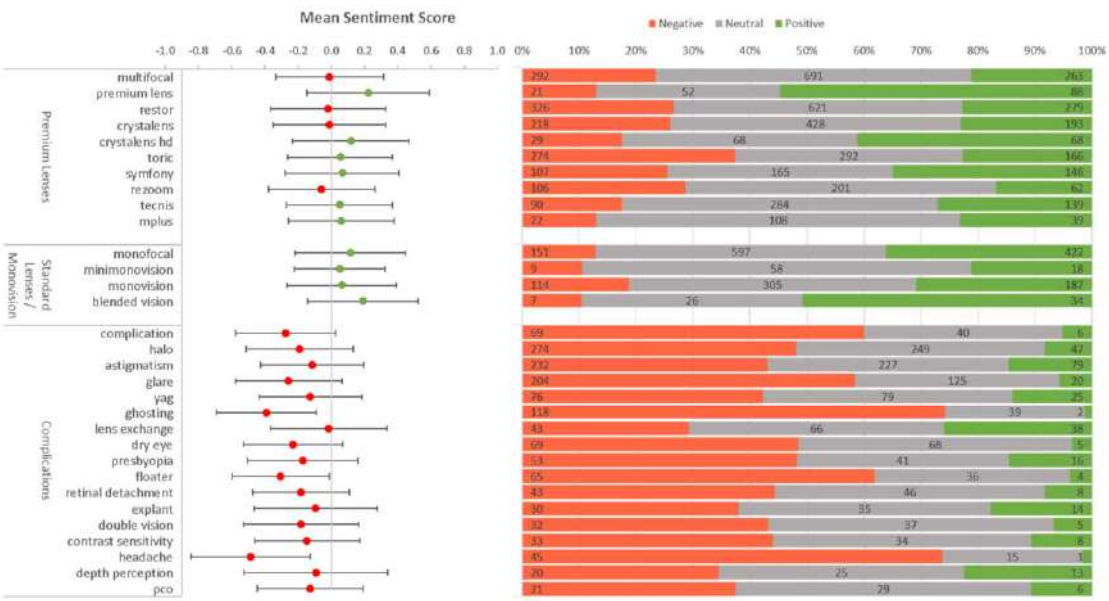

Figure 2 — Sentiment Towards Premium and Standard Cataract Surgery IOL Options and Cataract Surgery Side Effects

(Left) Mean sentiment is shown with standard deviation error bars for keywords related to premium lenses, standard monofocal lenses or monovision, and a variety of words related to cataract surgery complications, complaints, or side effects. Negative and positive mean sentiment are shown in red and green respectively. (Right) Proportion and number of positive, negative, and neutral sentiment instances for each keyword are shown in horizontal bar graph.

Sentiment analyses are displayed in Figure 2. Keywords associated with multifocal lenses (not including specific models) had slightly negative mean sentiment (N=1246, -0.010). Individual models of multifocal or premium lenses were commonly identified as keywords, with those most widely used in the US associated with a slightly negative mean sentiment (ReSTOR N=1226, -0.020; ReZoom N=369, -0.059; Crystalens N=839, -0.012), while newer lenses had more positive sentiment (Crystalens HD N=165, 0.117; Tecnis Symfony N=418, 0.065; Tecnis (non-Symfony) N=513, 0.048). Keywords associated with monofocal lenses had positive mean sentiment (N=1170, 0.11), as did keywords associated with monovision, a strategy whereby each eye is implanted with a monofocal lens but with one eye targeted for clear distance vision and the other eye targeted for near vision (monovision, N=606, 0.06; minimonovision N=85, 0.05; blended vision N=67, 0.19)

A wide range of keywords represented types of side effects or complaints by the patients and were associated with negative mean sentiment. The most common complaints included glare (N=349, -0.257), halo (N=570, -0.190), astigmatism (N=538, -0.115). Other complaints associated with very negative sentiment included ghosting (N=159, -0.392), floater (N=105, -0.305), headache (N=61, -0.485).

There was significant variation in sentiment score between four different IOL implantation strategies: monofocal, monovision, toric, and multifocal (including specific models of multifocal lenses) in ANOVA analysis (F-score [3, 7590]= 35.59, $p<0.001$) (Table 1). Post-hoc Bonferonni multiple comparison tests indicated that when compared to multifocal lenses, monofocal lenses ($p<0.001$), monovision ($p<0.001$), and toric ($p=0.024$) lenses all had significantly higher positive mean sentiment.

Table 1 – ANOVA for Sentiment Scores

Source of variation	df	Sums of Squares	Mean Square	F-Score	p-value
Between Groups*	3	11.98	3.995	35.59	<0.001
Within Groups	7590	851.94	0.1122		

*Monovision group aggregated keywords "monovision", "minimonovision", "blended vision". Multifocal group aggregated keywords "multifocal", "premium lens", "restor", "crystalens", "crystalens hd", "symfony", "rezoom", "tecnis", "mplus."

Discussion

Over 4 million cataract surgeries are performed annually in the US, with premium multifocal intraocular lens implants increasingly used to provide clear vision at multiple focal points. However, potential side effects of these new lenses are a concern, and information on patients' subjective experiences is not readily available. Mining eye-related discussion forums on the MedHelp online health forum, we found patient sentiment towards monofocal lenses was positive, while the sentiment towards multifocal lenses was mixed, but overall slightly negative, especially related to older models such as ReZoom. Furthermore, this approach also identified that newer multifocal lenses, such as Tecnis Symfony, were associated with more positive sentiment. Many side effects associated with multifocal lenses were mentioned in the forums, including glare and halos, as well as ghosting, double vision, and headaches – each associated with negative sentiment. The ability to identify patient concerns with emerging technology is essential to help guide both patients' and clinicians' treatment decisions.

Previous studies have not conclusively demonstrated a benefit in patients' general satisfaction with implantation of multifocal lenses compared to standard monofocal lenses, as overall patient satisfaction following cataract surgery is typically high in both groups [3]. However, studies suggest multifocal lenses are associated with greater reports of postoperative glare, halos, and reduced contrast sensitivity [3]. We found that sentiment towards multifocal lenses was not as positive overall as sentiment towards traditional monofocal lenses. However, when individual models of multifocal lenses were considered, newer lenses such as Symfony and Crystalens HD were associated with more positive sentiments than older lenses. The earliest available multifocal lenses such as ReZoom, Crystalens, and ReStor have been the most extensively studied, and concern for postoperative glare and halos with multifocal lenses is most reflective of these initial studies [3, 5]. As multifocal IOL design has advanced, a few studies have reported that newer IOL models may have fewer visual side effects [15–17] – consistent with our findings that sentiment towards the newer Symfony lens is more positive.

Previous studies have used a variety of questionnaires to measure postoperative satisfaction or visual function, either general visual functioning indices or more often scales developed specifically for a given study, designed to elicit reports of halos or glare [3]. In our analysis of unprompted patient online forum posts, halos and glare were among the most frequently expressed concerns, but we identified many other common concerns with associated negative sentiment including astigmatism, ghosting, dry eye, lens exchange, and double vision. Interestingly, lens exchange was associated with only slightly negative mean sentiment, nearly neutral, suggesting appropriate patient selection and perhaps good visual outcomes following lens exchange surgery. By contrast, mentions of headache, though not exceedingly common, were associated with very strongly negative sentiment.

This study has several limitations. We recognize that our analysis is limited in that it does not account for patient selection or expectations, relying on online forums, which are by nature anonymous, with limited data on users. Participation in online forums may vary by patient demographics, such that represented opinions may be skewed towards younger or more tech-savvy patients. Furthermore, there may also be considerable bias in online discussions, in that patients who are content with surgery may be less likely to post online than highly dissatisfied patients. Posts were limited to 2016 and prior period; however, it represents the dissemination of the key implants. Typographical or auto-correct errors, such as ReSTOR being typed and extracted as restore, were ignored. Users were not always specific regarding which model of lens they were referring to, so multiple models of similarly branded lenses (e.g. ReSTOR and ReSTOR low-add versions) were grouped for sentiment analysis. In addition, sentiment analysis using different algorithms may vary. Although we have utilized IBM Watson as one of the oldest and most recognizable artificial intelligence initiatives, limitations still exist in this approach. We have applied Watson's robust but proprietary general capabilities to the highly specific field of ophthalmology. Future work can improve upon this approach by training algorithms to recognize ophthalmology-specific entities and to distinguish preoperative questions from postoperative concerns. Future work to develop a more ophthalmology-specific model can address these issues.

However, despite these limitations, this study presents a novel application of natural language processing and sentiment analysis techniques to a non-traditional data source—online forum posts—in order to identify insights related to cataract surgery. This approach offers a relatively rapid and low-cost way of identifying many opinions from large groups of people on a particular topic, compared to traditional focus groups, which are labor-intensive and costly to assemble. Using this approach, the overall perception of emerging technology may be quickly surveyed to form an overall community sentiment or to identify unanticipated problems. Automated sentiment analysis may also be useful to supplement the depth and nuance of opinions obtained in focus groups with a broader sweep of opinions from larger populations, or to perform automated sentiment analysis on transcripts of focus group discussions to ensure important concepts are not overlooked. Alternatively, this approach may be utilized to analyze open-ended patient-reported outcomes collected in settings where the population is controlled, such as within the context of a clinical trial, where clinical outcomes are being measured simultaneously. Furthermore, although traditional questionnaires with Likert-scale ratings for specific outcomes allow standardized data analysis, other patient concerns may not be well captured. Using natural language processing to analyze unstructured, open-ended data has the advantage of revealing insights derived from patients' own language, and patient concerns that fall outside the confines of any particular questionnaire. These insights may be used to develop or refine patient-centered outcome measures to be more inclusive of diverse patient concerns, and to better target patient counseling efforts to address the most prevalent or highly impactful patient concerns. Despite the likely presence of some bias in online discussions towards dissatisfied patients, it is still worthwhile to investigate the sentiments of a vocal but potentially unhappy minority as concerns or side effects most discussed online may also be the most impactful when they occur in clinical practice or be the most of interest to preoperative patients who may have come across these concerns while researching their options on the internet. Patients and

surgeons may find these results important in tailoring the choice of lens for the individual patients according to their tolerance of potential side effects.

Conclusions

There is a critical need for evaluating patient-centered outcomes and detecting patients' concerns regarding emerging technology in ophthalmology where rapid surgical innovation with new technologies is transforming care. Internet health forums provide a robust platform for individuals to discuss real-time health concerns and may serve as a resource to identify patient concerns associated with emerging technologies. We demonstrate the use of natural language processing as a powerful tool to gain insight into large amounts of unstructured text data provided by the patient, in this case to understand patient perspectives towards cataract surgery options. We found that sentiment towards monofocal lenses is positive, and sentiment towards multifocal lenses overall slightly negative, though attitudes towards newer multifocal lenses may be more positive. Patients were concerned about both common and some uncommon side effects. Understanding cataract surgery from the patient perspective can be used to improve pre- and postoperative counseling to better address patient-centered concerns and to develop measures of patient-centered outcomes in the future. This study serves as an example of utilizing cutting-edge technology to understand healthcare attitudes and outcomes from the patient perspective and can be applied to many different areas of healthcare and sources of text.

Abstract

In order to improve the level of health decision-making, based on health information resources and decision support function types, this study summarized five core functions of health decision support system: information support, monitoring and early warning, analysis and evaluation, trend prediction, comprehensive optimization; And from the perspective of business functions, business processes and business activities of business domains, the demand of Health Decision Support System is refined in to six parts, such as public health, medical care, drug management, medical insurance, comprehensive management, grass-roots health. On this basis, the overall design of the system is carried out.

Keywords:

Software Design, Clinical Decision Support, Expert Systems,

Introduction

Health Decision Support System (HDSS) is an intelligent human-machine interactive information system which is oriented to semi-structured and unstructured decision in the field of medical and health care [1]. It uses the relevant theories and technologies of decision support systems to support decision-making activities of medical personnel [2]. HDSS can assist health managers in scientifically formulating health policies, rationally deploying health resources. It can help doctors to make accurate diagnoses, select effective treatment options. And it can provide assistance to public health, medical insurance, and other related workers [3]. Constructing a health decision support system and building a health informationization development model oriented to information utilization and service decision-making which have important practical significance for improving scientific management level provide practical tools for health decision-making.

This study aims to improve the level of health decision. Based on health information resources, according to the field division of health services, we analyze the needs of support systems in the areas of public health, medical care, drug management, medical insurance, comprehensive management, and grass-roots health. According to the different decision needs, the health decision system that implements the core functions of the above five aspects, such as information support, monitoring and early warning, analysis and evaluation, trend prediction, comprehensive optimization, is designed.

International Experiences

Typical applications of HDSS

Some of developed countries have already widely applied information technology to the medical and health care, formulated strategic plans to promote the use and exchange of health information, and developed many practical decision support systems for medical services, hospital management and public health management, which have achieved remarkable results [4]. Typical applications of HDSS are as follows. First, developed medical expert system for clinical medical practice, such as MYCIN in the USA, Quick Medical Reference and the Map in the NHS in UK [5]. Second, Developed hospital management decision support system to improve hospital management, such as Distributed Hospital Computer Program in the USA [6,7]. Third, developed intelligent drug prescription system to promote rational drug use in clinic, such as Computerized Physician Order Entry and Drug Therapy Screening System in the U.S.A, as well as Eprescribe in Australian. Forth, developed public health management decision support system to enhance disease prevention and control and emergency response capacity of public health emergencies, such as Panorama in Canada and National Electronic Disease Surveillance System in the USA [8].

Enlightenment to China

Compared with some of developed countries, the application of HDSS is not yet widespread in China. It is better to choose the areas where business needs are urgent and decision rules are relatively clear, and then develop HDSS for a specific topic or field. Therefore, the following will start with the needs of the main stakeholders for HDSS. On this basis, we try to preliminarily build the logical architecture of HDSS.

Demand Analysis

The main task of the demand analysis of the health decision support system is to solve the problem of "what to do" in the health decision support system which is the foundation for the design of health decision support system. It mainly includes user analysis, demand type analysis and demand description of the health decision system.

User Analysis

The users of the health decision support system have expanded from the health management department to the fields outside the health management department, from the fields of treatment and prevention and control to the fields of education and commerce, from the biological and physiological fields to the psychological field, and from technical activities to social activities. It forms into a comprehensive service. Users can be divided into the following categories: health administrative staff, medical staff, medical researchers, and the public, teaching staff, students and pharmaceutical marketers.

Health Administrative Staff

The issues they care about are decision, organization, lead, coordination, and control in management. The characteristics of the information needs are systematic and comprehensive.

The information, which is also required universality and accuracy, provides basis to make decision for policy-related, predictive and strategic work.

Medical Staff

Medical staff work in prevention, clinical frontline. Their mainly needs information service in daily work. They are the main target of health information which is mainly for medical staff to provide support in the diagnosis, treatment and rehabilitation of diseases.

Medical Researchers

The main work of medical researchers is to explore the special development policy in various fields of medicine, as well as to carry out knowledge innovation and expand knowledge system. Researchers always want to know the latest developments in related topics at home and abroad. And then they can adjust their research to improve the novelty of their own scientific research. Scientific research work is inherited and continuous, and there are inherent connections between the subjects, so their demand for information is continuous. Moreover, researchers prefer information types such as books, journals, and academic conference papers.

The Public

The public includes patients and their family members, as well as the general population. Their information needs are generally directed at the cause, treatment, prognosis and health of a disease. Health information services to patients, the person who is in a special situation or who is concerned about his or her health. It provides them health information about their illness or health status.

Teaching Staff and Students

Their work is mainly to teach students basic medical knowledge, and some also undertake some scientific research work. Students refer to people at all levels of medical colleges. The information sources they contact are mainly networks and libraries. Their information needs are relatively simple compared to the above-mentioned users, but because students have the characteristics of broad interest of young people, the information they need, in addition to the relevant knowledge of the major they are studying, also covers a wide range of subjects.

Pharmaceutical Marketers

Pharmaceutical marketers mainly refer to business operators who are engaged in market expansion, product sales, customer support, etc. of medical equipment and medicines in market economic activities. Marketers must not only grasp the various information of the products, customer information, but also the situation of partners and competitors, as well as the policy and economic situation of the place of sale. They often access information through informal channels when information services are unable to provide timely, novel, accurate, and reliable information.

Demand Types

In the perspective of the type of decision support function, the five core functions of the health decision support system are summarized.

Information Support

Information support functions are divided into two categories: external information support and internal information support. External information support is mainly to provide health administrative staff with information outside the field needed to assist decision-making. Internal information services provide decision makers with an overall level and dynamics of change of health development, such as health development status, infrastructure conditions, etc.

Monitoring and Early Warning

Through the extraction, integration, monitoring and analysis of relevant indicators in the fields of public health services, medical services, medical insurance, etc., we can timely grasp the operational dynamics of the business and existing problems, and identify the crux of the problem. For example, by analysing the rules of relation between drugs and diseases, forming a prescription model, implementing dynamic monitoring of clinical drugs, drug disputes will reduce, medical quality will improve. Through real-time monitoring of diseases, health hazards, and public health emergencies, we can keep abreast of the development of various diseases and public health emergencies to establish a sound mechanism composed of monitoring, assessment, early warning, and response.

Analysis and Evaluation

Applying appropriate evaluation methods and scientific and reasonable evaluation index system to conduct objective and scientific evaluation and analysis of health industry dynamic monitoring data, defines the actual operational effects of health-related policies, provides support for the formulation of new decisions. For example, through the use of scientific and reasonable evaluation index system, comprehensive analysis and evaluation of the operation of the fund, compensation for expenses, the benefit of the insured personnel, the utilization of medical services, and the flow of medical treatment support managers to develop more scientific and rational medical insurance related programs and systems.

Trend Prediction

Prediction is one of the important means for the health industry to make macro-decisions. It determines strategic policies and means by selecting the influencing factors that have a significant contribution to the forecasting target. It uses highly efficient tools to regularly sample health data and import it into pre-defined intelligent predictive models to predict future developments to support health service management at the regional, provincial or national level. Prediction function can be divided into three cases: predicting future operational trends based on current operating conditions; adjusting some parameter values of the operating system according to the policy, and using the model to predict the future operating status; taking corrective actions and predicting the effectiveness of it when deviations are found in the operation. For example, by analysing the frequency of use of a certain drug in a certain period of time, predicting the demand for a period of time in the future, and optimizing the allocation of drug stocks, the drug supply system can operate benign and efficient.

Comprehensive Optimization

The goal of macro decision is overall optimization, not the local optimum of a certain aspect. Therefore, through comprehensive consideration and analysis of various factors, the health decision support system explores the potential relationships among various links and coordinates them to achieve overall optimization and comprehensive optimization. For example, when dealing with public health emergencies, it is necessary to integrate dynamic monitoring information, emergency resource information, hazard information, various existing typical cases and related plans, as well as relevant knowledge and optimization models in the expert database. Then optimal contingency plans such as personnel evacuation, blood call, emergency resource optimization configuration, etc. can be generate dynamically.

Demand Description

According to the division of users and business areas of the health decision support system, decision-making needs are mainly concentrated in the fields of public health, medical care,

drug management, medical security, comprehensive management, and primary health. Meanwhile, based on the business functions, business processes and business activities of the business domain, the demands for the health decision support system are refined as follows(Table 1):

Table 1– Health Decision Support System Demands Description

Business Demands Analysis	Business Module	Business Refinement
Public Health	Prevention and Control	Infectious Disease Surveillance
		Chronic Disease Surveillance
		Occupational Health Management
		Health Hazard monitoring and Control
	Health Supervision	Health Administrative Licensing and Registration
		Health Supervision and Punishment
	Woman and Child Health Care	Woman Health Care
		Pregnant Woman and Puerpera Health Care
		Child Health Care
		Family Planning
	Command of Emergency Public Health Emergency	Emergency Monitoring
		Emergency Resource Management
		Hazard Information Acquisition and Management
		Emergency Plan Generation and Management
Medical Care	Clinical Medical Service	Disease Management
		Patient
		Surgery
		Treatment
		Clinical Outcome
	Medical Management Service	Medical Service Volume
		Medical Service Quality
		Medical Security
		Medical Cost Control
		Drug Service
Medical Insurance	Basic Medical Insurance of Urban Workers and Residents	Insured Situation
		Medical Cost Control and Prediction
		Medical Insurance Fund Analysis and Supervision
	New Rural Cooperative Medical Scheme	Participation
		Disease Incidence
		Fund Preparation and Availability
		Fund Allocation and Use
		Participant Benefit
		Participation In Medical Expenses and Medical Expenses Control
		Medical Treatment Analysis
		Cost Compensation
		Participation in the Disease Burden
		Urban and Rural Medical Assistance Beneficiaries
	Urban and Rural Medical Assistance	Disease Incidence
		Urban and Rural Medical Assistance Expenditure
Drug Management	Drug Plan	
	Drug Purchase	
	Drug Use	
	Drug Administration	
Comprehensive Management	Health Plans, Guidelines and Policies	Realization
		Classification Statistics
		Impact
	Health Resource Management	Health Institution
		Health Human Resources
		Health Facilities
		Health Expenditure
		Comprehensive Management of Various Types of Health Resources
	Health Supervision	Public Health Supervision
		Medical Service Supervision
		Medical Security Supervision
		Drug Supervision
Grass-Roots Health	Medical Management	
	Resident Health Management	
	Prevention and Health Care	

Public Health

The purpose of public health is to organize social efforts to improve environmental sanitation, to prevent and control epidemics of infectious diseases and other diseases, to cultivate good health habits and civilized lifestyles, to provide medical services, to prevent diseases, and then to promote people's health. Public health institutions defined by the new medical reform include health administrative agencies at all levels, disease control agencies, health supervision agencies, maternal and child health institutions, chronic disease prevention agencies, and public health research institutions. The public health business is more extensive, mainly including: prevention and control, health supervision, maternal and child health care, emergency public health emergency command, etc., so it is divided into several corresponding topics for analysis [9].

Medical Service

Medical services include services for diagnosis, treatment, epidemic prevention, delivery, family planning, and related services such as providing medicines, medical equipment, ward accommodation, and meals. The institutions providing medical services are called medical institutions, including hospitals, health centers, community health service centers (stations), nursing homes, outpatient departments, village clinics, maternal and child health centers, and specialized disease prevention and treatment institutions. Demand analysis is divided into two topics: clinical medical services and medical management services.

Medical Insurance

China's basic medical security system consists of urban workers' basic medical insurance, urban residents' basic medical insurance, new rural cooperative medical scheme, and urban and rural medical assistance systems. The core business of medical insurance is insurance object management,

insurance fee payment management, reimbursement management, and settlement management with medical service utilization units.

The reform of the medical insurance system involves both government responsibility and the interests of the insured units, insured personnel and medical institutions. The medical insurance decision-making is to evaluate the problems in the process of income, to distribution and use of the medical insurance fund in real time, to analyze and master the operation dynamics of the medical insurance fund in time, find out the crux of the problem, and to make scientific decision-making and policy adjustment.

Drug Management

Drug management mainly focuses on the supervision and management of drug uses, including centralized bidding and procurement of medical products of public medical institutions, supervising and managing the use of pharmaceutical preparations and drugs, guiding medical institutions to rationally use clinical drugs, organizing the implementation of national drug policies and national essential drug systems, organizing the handling of adverse drug events in medical institutions, and formulating recommended use lists for drugs, etc.

Drug management mainly includes three major processes, which is procurement, use, and drug administration. It involves many aspects such as drug plan management, drug quality management, drug information management, clinical rational drug management, prescription drug query management, etc. [10]. Due to the variety of drugs, new products, multiple purchase channels, and many complicated and complicated management links, there are often backlogs and shortages of drugs, which makes it difficult for managers to make more effective decisions. Therefore, the development of drug management decision support system is an urgent need for drug management. Drug management will be divided into four aspects: drug planning, drug procurement, drug use, and drug administration.

Comprehensive Management

The main body of comprehensive management is the National Health and Family Planning Commission and the provincial health and family planning administrative departments. The main task of health management decision-making is the corresponding health management decision services carried out by the internal organs of the medical and disease, disease prevention and control center and grassroots health management set up by the health and family planning departments at all levels.

The most basic information query demands of the comprehensive manager mainly include : completing the inquiry of the business indicators and information of each medical institution and various departments within the organization; timely getting the implementation of various health plans, guidelines and policies; timely understanding of the planning and allocation of health resources [11]; timely understanding and getting public health supervision information; timely getting major epidemic information; real-time getting business report data of various medical institutions, keeping abreast of medical quality information and the progress of major business. These provide first-hand information and scientific basis for leadership decision-making. In view of the main responsibilities of the health management department, the specific decision-making and related information demands will be explained in three aspects: guiding health planning guidelines and policies, coordinating health resources and health business supervision.

Grass-Roots Health

The grassroots health service institutions generally refer to the county, township and village level medical institutions, including county-level people's hospitals, community health service centers, township health centers, and village health centers (rooms). It not only provides basic medical services to the residents of the agency's service radiation area, but also undertakes basic public health services such as preventive health care and health education promotion. Its diagnosis and treatment subjects, number of beds, department settings, staffing, infrastructure construction and equipment are adapted to its functional positioning 12]. With the deepening of the reform of the medical and health system, grassroots health has placed greater expectations from synergistic prevention, diagnosis and rehabilitation to a sound grading diagnosis and treatment mechanism. The support of the grassroots health information system has also become an important factor in promoting the development of primary health care services. The functional demands of the grassroots health information system have risen from simple input and query to a broader level to meet the decision-making demands of different levels. According to the business function, the grassroots health decision demands analysis project is divided into three aspects: diagnosis and treatment management, resident health management, prevention and health care.

Overall System Design

The task of demand analysis is to solve the “what” problem of the health decision support system, while the task of system design mainly solves the problem of “how to do”. The design idea is, through making full use of existing decision-making resources such as models, methods, data, and knowledge and combining health decision theory with the experience and subjective wishes of health decision makers, to assist health decision makers with creative thinking, logical reasoning and judgment, help health decision makers clarify health decision-making goals and identify problems, provide various options to health decision makers, evaluate and optimize various options by analyzing, comparing and judging through human-computer interaction functions, provide effective support for health decision makers to make the right health decisions [13].

The overall logical architecture of the health decision support system [14] consists of three levels (Figure 1): 1) Data layer define and maintain the integrity and security of health data, and respond to logical layer requests, access data. This layer reads, extracts, cleans, converts, and summarizes data from hospitals, CDC, health supervision, maternal and child health care, blood centers, communities, medical insurance institutions, and health administrative departments at all levels, etc. through the data import program, and completes the data loading of the data warehouse subtopic. At the same time, the models, methods and expert knowledge of the manual decision-making process are obtained through the interaction with experts in the field of health. And they are classified, organized and managed by method library, model library and knowledge base. And the data, model, method and knowledge resources are called through the corresponding management system; 2) The application layer acts as a bridge between the presentation layer and the data layer. Its role is to respond to the decision-making requests of health decision-makers, to perform decision analysis tasks and to capture corresponding data from the data layer, to analye the corresponding DSS analysis tools such as online analytical processing, data mining, etc. and to get the decision information obtained to the presentation layer. According to different health decision-making needs, the application layer implements functions such as information

support, monitoring and early warning, analysis and evaluation, trend prediction and comprehensive optimization. 3) The presentation layer provides a visual interface for health decision makers, that is, decision-making users can input decision-making demands or obtain decision information through the presentation layer.

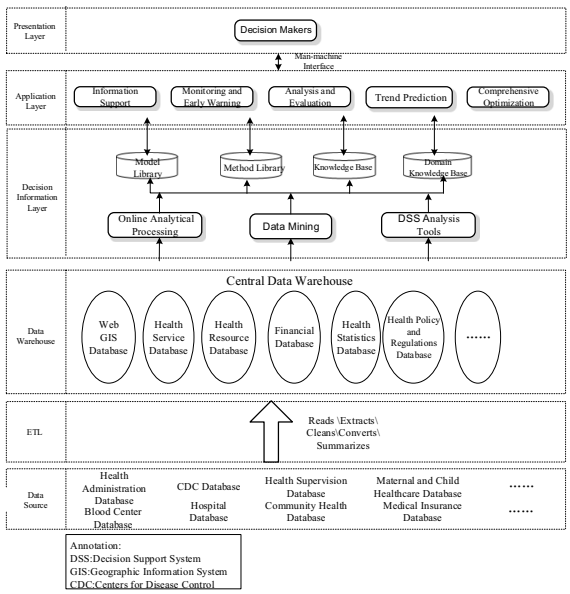

Figure 1–Overall Logical Architecture of HDSS

Abstract

This paper analyzes the development strategy of population health informatization in China, and summarizes the measurement direction and evaluation elements of population health informatization. ***Methods:*** *Literature and field investigation, expert consultation and PEST analysis were used to determine the development level measurement and evaluation framework.* ***Results:*** *Based on the PEST analysis framework, the development level measurement and evaluation factors were defined, and the evaluation framework was established, which included system construction, IT application, information financing, information personnel, information policy and management, and information application effect. The information from hospitals and grass-roots medical and health institutions was also provided. From the perspective of the level of development, the framework of informatization evaluation is further refined.*

Keywords:

Health Information Management, Population Health, China

Introduction

Population health informatization is a general designation of the process that the organizations in health and family planning system use modern network and computer technology to collect, organize, store, use and provide services for population health information, further which rationally organizes and controls the information activities and factors in the field of health and family planning in order to realize the rational allocation of information and related resources so as to meet the information service and management needs of the health and family planning industry[1]. At present, the construction of population health informatization in China has been greatly developed, and will play a more important role in the development of health and family planning in the future [2]. The planning, input, policy and output of population health informatization should be supported by appropriate evaluation theory and practice [3, 4]. The evaluation theory of population health informatization in China is not feasible, and there is only a few evaluation system applied to practicing and guiding informatization construction [5, 6]. Especially with the government as the main body of evaluation, there are few studies on the evaluation of the development level of regional population health informatization [7]. This study combines the actual and future situation of population health informatization development, comprehensively applies multiple scientific research methods, analyzes the development strategy of population health information in China, and summarizes the measurement direction and evaluation factors of population health informatization to provide reference for the measurement of population health information development level in China and different provinces.

Methods

Research object

This paper determined the weight of the indicator system by the analytic hierarchy process. This study focuses on the development level of population health informatization in the province and below, including the basis of population health information, information resources, technology application, talents, financing and policies, planning, standards, etc. The above are the core elements of the regional population health information construction and the key links involved in the implementation process, as well as the application effects.

Research methods

Literature research

Through systematicly reviewing Wanfang, Tsinghua Tongfang, PubMed, OVID and other domestic and foreign full-text databases, relevant institutions' websites and other network resources, we collect domestic and foreign informationization evaluation theories, indicators and methods, including regional informationization, enterprise informationization, and education informationization, health information, e-health, information systems, etc. we collect and sort out foreign population health assessment frameworks and indicator systems, providing reference for China's population health informationization evaluation framework.

Site investigation

This study conduct on-the-spot investigations on some provinces with more developed population health informatization like Beijing, Jiangsu, Zhejiang and Shanghai. Meanwhile, this paper researches on the development status of informatization, review relevant data, and conduct interviews with insiders. The interviewees mainly include the head of the health administrative department, the person in charge of the information center, and the medical staff at the grassroots level.

Expert advice

In this study, 16 experts were selected to determine the comprehensive evaluation index of population health informationization construction level through letter or expert consultation. Expert selection criteria: leaders of health and family planning administrations, experts and scholars in the field of population health information management, and researchers and business personnel in other related fields; leaders with intermediate or intermediate titles or above; work there in professional field for more than 5 years; be interested in this research and willing to cooperate with expert consultation. Main consultation content: guide and consult on

project design and implementation such as value judgment criteria, determination of evaluation framework and selection of evaluation indicators, weight calculation of indicators, and recommendations for research reports, etc.

PEST analysis

PEST analysis is often used to analyze the background of a company, which evaluates the strategic formulation of a company from the four aspects of politics, economics, society, and technology. This method is increasingly applied to various research fields. This study uses PEST analysis to analyze population health information from four environments: policy (P), economy (E), social culture (W) and technology (T). It will help to grasp the development trend of population health informationization, clarify current obstacles and problems, and propose future development strategies.

Delphi expert consultation

After two rounds of Delphi expert consultation, experts were asked to score the importance of primary indicators. In the third round, experts were invited to measure the weight and combination weight of each index according to the steps of analytic hierarchy process. And then comprehensive index method were used to construct and improve the evaluation framework and index system of population health informatization.

Results

Analysis of population health informationization development strategy

PEST analysis of development strategy

As an important support for the development of health cause, population health informationization is also the inevitable application result of information technology in the field of health care. Its own construction and development is affected by many factors, such as politics, economy, culture, society and technology. Analysis of its influencing factors will help to grasp the development trend of population health informationization, clarify current obstacles and problems, and propose future development strategies. This section analyzes population health informationization from the four environments of policy (P), economy (E), social culture (S) and technology (T) by PEST analysis.

(1) Policy environment: In the field of health care, health departments and other ministries and commissions issued policy documents one after another, or stressed the importance of health information construction, or directly encouraged the construction of health information. From the perspective of policies and regulations at the national level, the health sector has guided, encouraged and regulated population health informationization from the aspects of strategic planning, system construction, and system function norms. In addition to the policies promulgated by the health department, the State Council has also promoted the construction and application of information technology in the field of health care from the perspectives of "big data", "internet+" and "information benefiting the people" [8].

(2) Economic environment: In 2008, the total cost of health in China was 1,435.54 billion yuan, three times that of 2000. The total health expenditure in China in 2016 was 4,414.5 billion yuan, nearly three times that of 2008.Since the new century, the growth rate of total health expenditure has been higher than that of GDP growth, and the proportion of the former in the latter has also increased year by year. It is worth mentioning that the proportion of government health expenditure to total health expenditure has increased from less than 10% to more than 30% in 2016, and the proportion of personal health expenditure has declined year after year. These conditions have put forward new requirements for health care industry to expand supply, optimize service, improve quality and improve management level. However, the reality is that the supply of health care services in China is generally inadequate, and the distribution of quality medical resources is uneven, while the training and establishment of medical institutions is relatively slow. In this case, the use of information technology to extend services, improve efficiency, and improve quality is a very reasonable choice. Corresponding to the rapid growth of the medical industry, China's information industry has also grown rapidly.

(3) Social and cultural environment: In 2014, China's elderly population aged 60 and over reached 212 million, accounting for 15.5% of the total population. This size is comparable to the current population of the three major European countries (Germany, France, and the United Kingdom). Scholars predict that the peak population will appear in the 2030s and 2040s, and the aging rate will accelerate significantly in the next three or four decades. Especially until around 2040, the proportion of the elderly over 65 years old in China will exceed 20%, and this proportion will continue to increase by 2050, reaching 20%-24%. The changes of disease spectrum, health demand and dependency ratio brought about by population aging will bring challenges to the future health care service supply. The rigidity of demand for chronic disease management, remote monitoring, health file management, and combination of medical care and maintenance will become more and more strong, and will become an important development direction of population health informatization [9].

(4)Technical environment: Benefiting from the rapid development and application of information technology, population health information technology has also undergone different technical stages. Technologies such as the Internet of Things and cloud computing have stepped onto the stage, and today the society has entered the era of big data. Telemedicine, teleconsultation, cloud hospital, cloud medical are constantly developing to realize convenient and efficient technical exchanges and cooperation in different time and space. The connotation of medical services is very broad, and it needs to rely on high-quality equipment, a wealth of sample banks and doctors to meet the needs of patients from prevention, medical care, health care to rehabilitation, as well as the experience of patients. "Internet + medical" has become an important breakthrough in the development of hospitals. "Wearable mobile medical devices" have had an important impact on people's lives and work [10].

Analysis of development measures and evaluation factors

Through PEST analysis and strategic analysis of the future development of population health information in China, this study considers that the development level of population health informatization involves multiple dimensions such as information technology utilization and its own business development. Considering the multiple dimensions involved in the development level of population health information, the evaluation elements should include seven aspects: information resource construction, China Unicom and information technology application, information financing, informationized talents, information policy and management, and information application effects.

Improve the measurement index system of the population health information development level

Through PEST analysis and evaluation factors of China's population health information development strategy, the evaluation framework of population health information

development level is formulated, and the measurement index system of development level is further improved according to the optimization strategy. Based on the principle of "measurable and comparable", the measurement index system of population health informationization development level is revised and improved through the method of expert consultation. The evaluation index system optimization focus: continue to optimize the adjustment index weight setting; improve the score differentiation of some indicators; appropriately update the indicator content; simplify some indicators calculation formula. Finally, a three-level structure model including seven primary indicators, 16 secondary indicators and 38 tertiary indicators is established, which includes system construction, unicom and information technology application, information financing, information personnel, information policy and management, and information application effect. Defining the evaluation subject: the competent department of population health informationization; the evaluation target: the level of regional population health informationization development, including the software and hardware level, technology application and output from the perspective of information technology, and the coverage and protection of the population from the perspective of population health development level and information resource sharing.

Table 1–Measurement and evaluation system of population health informationization development level.

Primary indicator	Secondary indicators	Three-level indicator
1 Information resource construction	1.1 Construction and application of electronic medical record	1.1.1 Construction and coverage of electronic medical record database in the region
		1.1.2 Medical institution electronic case database usage rate
		1.1.3 Application of regional electronic medical record database in connection with other business systems
	1.2 Construction and use of resident electronic health records	1.2.1 Electronic health record data update rate
		1.2.2 Regional Electronic Health Archive Database Connection Range
		1.2.3 Business scope covered by the regional electronic health record database
		1.2.4 Application of regional electronic health record database in connection with other business systems
	1.3 Construction and use of the information database for the entire population	1.3.1 Whether the entire population information database is fully covered
		1.3.2 Frequency of update of data of the entire population information base
		1.3.3 Application of full population information database in connection with other business systems
2 Infrastructure and information system construction	2.1 Computer network facilities construction	2.1.1 Business scope covered by the health information private network
		2.1.2 Community Health Service Center / Township Health Center Network Bandwidth
	2.2 Information System Construction	2.2.1 Provincial business information system construction rate
		2.2.2 Use and availability of basic business information system functions
		2.2.3 Construction of health care big data application system
	2.3 Information Security	2.3.1 Machine room security level
		2.3.2 Information system information security and other security levels
3 Unicom and information technology applications	3.1 Unicom and data sharing	3.1.1 Repeated entry of information in primary medical institutions
		3.1.2 Communication between business information system and regional information platform
		3.1.3 Sharing health and medical data with related fields
	3.2 Internet + Medical Services	3.2.1 Proportion of open registration and inspection results of medical service institutions
		3.2.2 Proportion of medical institutions that carry out telemedicine through information systems
		3.2.3 Proportion of medical institutions that conduct two-way referrals through information systems
4 information financing	4.1 Investment scale	4.1.1 Ratio of construction funds and operation and maintenance funds to total health expenditure at the same time

	4.2 Informatization financing sustainability	4.2.1 Construction funds and operation and maintenance funds are included in the regular budget
		4.2.2 Social capital participation in information construction
5 informational talents	5.1 Informational Talents assign	5.1.1 Proportion of informationized personnel in the proportion of health technicians
	5.2 Informational Talent Structure	5.2.1 Proportion of persons with master's degree or above and intermediate titles
		5.2.2 The proportion of composite information personnel
6Information Policy and Management	6.1 policy and planning formulating	6.1.1 policy and planning implementation
	6.2 Construction and management of Information Construction Project	6.2.1 Pre-project evaluation
		6.2.2 Post-event supervision of the project
7 information application effect	7.1 National Health Information Platform Application Effect	7.1.1 Integration of information and data resources
		7.1.2 Key business synergy efficiency
		7.1.3 Data statistics and performance appraisal
	7.2 Health and medical big data application effects	7.2.1 Accurate evaluation of health data
		7.2.2 Application of supplementary medical insurance control fees
		7.2.3 Public health decision-making management capabilities

Multidimensional refinement of the evaluation framework of population health informatization development level

Although the evaluation framework of the development level of population health informationization gives a quantitative analysis to the regional population health informationization on the whole, it lacks effective research and analysis in the sub-segments of population health informationization, such as health and family planning administrative agencies, public hospitals, primary health care institutions, disease prevention and control centers [11]. For example, in the course of the investigation, the overall score of a certain area is relatively high, but the informationization of the primary health care institutions is difficult to meet the requirements of the medical reform policy of graded diagnosis and treatment. Therefore, on the basis of the overall evaluation, it is also necessary to refine the evaluation index framework from multiple angles to achieve more refined and standardized evaluation and analysis. From the perspective of the level of informatization development of hospitals and primary health care institutions, the evaluation framework of population health informationization development level is refined to make up for the shortcomings of the overall evaluation framework. First, the evaluation framework of hospital informatization was constructed with the main framework of capital input, organization and management of hospital informatization, construction of hospital informatization infrastructure, information security, construction and application of hospital information system and performance of information construction. It contains 6 first-level indicators, 20 second-level indicators and 63 third-level indicators. Secondly, this paper constructs an information-based evaluation framework for primary medical and health institutions with five dimensions: information resources and infrastructure, information system construction and application, information sharing and technology application, informationization benefits, and information security, including 5 first-level indicators, 15 second-level indicators, and 53 third-level indicators.

Discussion

Comprehensiveness of evaluation perspective and pertinence of content

The construction of population health informatization in China is still the government-led mode, which is affected by the information technology level differences, policy environment support, and the level of security, so it needs to be considered as a whole. In the past, research focused on the application of information systems in a single business field, which is relatively microscopic, especially in the absence of technical considerations [12]. In the selection of indicators, this study strives to get rid of the single perspective of technology and add more macro policy indicators. At the level of evaluation operation, regional population health information evaluation mainly includes three types: "measurement of development level ", "performance evaluation" and "assessment evaluation". The horizontal measurement focuses on understanding the overall situation, and compares in the space and time; the performance evaluation pays attention to the results, and measures the information efficiency, effect and benefit; the assessment helps the evaluation object to find the lack and improve. At present, there is no unified construction mode for population health informationization construction, and the government-led information construction has a relatively strong public product attribute, and it is difficult to see actual benefits in the short term. Therefore, this study defines this evaluation as the basic regional population health informationization level measurement, appropriately highlighting development strategy at the emergence stage, and specifically reflecting the development of the main attributes in the informatization process.

Method selection of index weight assignment

In terms of the weight assignment of the index system, there are Delphi method, analytic hierarchy process, fuzzy analysis method, data envelopment analysis method, gray evaluation method, etc. Each method differs in subjective and objective assignment, qualitative and quantitative expression, and data integrity. In the measure of the development level of population health information, the subjective opinions of experts are indispensable, and some qualitative data are also inevitable. It is more appropriate to use AHP. The analytic hierarchy process describes the problems of complex systems as well-organized sets of hierarchical structural factors, qualitatively judges the elements of each level, and uses mathematical methods to obtain quantitative weight results, which achieves a

combination of quantitative and qualitative, overcoming the arbitrariness of the subjective valuation method, and avoiding the dilemma of the objective assignment method requiring long-term complete statistical data and the arbitrary judgment of throwing away from the empirical judgment. However, there are certain limitations in the actual use process. The comparison index of the two pairs is generally no more than seven, because the more the comparison, the more likely the logic confusion, the worse the consistency of the score. In order to effectively overcome the above problems, the number of indicators in the same root in each level of this study is no more than four, so that the results of expert scoring have a good logic, which ensures the scientificity of the evaluation system.

Practicability and reliability of index evaluation model

The completion of the hierarchy of the indicator system and the determination of the weight of the indicators are only part of the evaluation work. It is necessary to construct a comprehensive evaluation model, which combines the actual data with the index weight, including the conversion of the actual data into the index value and the combination of the index value and the index system. This study has developed detailed scoring rules for each of the three indicators, including indicator interpretation and calculation formulas, mainly in three cases. Firstly, qualitative indicators are converted into numerical values, and hierarchical values are assigned according to the rank. Secondly, indicators which cannot be directly calculated from the survey data are assigned to the corresponding indicators in segments for convenience, and the continuous "rate" value is converted into grade scores, and then the average calculation of the region is carried out. Thirdly, there are many administrative levels involved in the indicators, and the construction quantity, difficulty and importance of each level are not consistent. Each electronic medical record database cannot be treated equally. It must be dealt with at different levels, and the construction rate of each level corresponds to its own weight coefficient. The construction rate of each level corresponds to the respective weight coefficient. As the current population health informationization has no recognized "gold standard", the associated calibration validity cannot be measured. The content validity is generally not quantitatively measured. This research has been evaluated by experts to construct an evaluation index system, and there are detailed indicators calculation methods, which can be considered as good content validity.

Value of the research

The subjects, methods and objects of population health informationization evaluation in the world are diversified, and the goal orientation is obvious. Compared with international researches, China had carried out health informationization evaluation later than developed countries, and the early evaluation work mainly centers on the construction of hospital information system. In recent years, it has also made some progress in community health informationization, regional health informationization and comprehensive evaluation of health informationization. The evaluation of population health informationization in China is mainly based on index screening and weight testing. The evaluation object is single. It is difficult to measure the effectiveness and development level of health informationization comprehensively and scientifically because of the lack of thinking on how to evaluate and serve the government as the main body of information management. This research has filled in the gaps in this field.

Limitations

Different regions have different levels of health informatization in China, especially grass-roots institutions, which has weak foundation of informatization. Therefore, it had a certain impact on data collection from these institutions. It is necessary to further understand the detailed situation through field investigation in order to improve the accuracy of evaluation.

Conclusions

The index system is scientific and reasonable, and can be used for comprehensive evaluation of the development level of population health informatization, which has a certain guiding significance for the development of population health informatization.

Abstract

This study used Amazon Mechanical Turk to crowdsource public opinions about sharing medical records for clinical research. The 1,508 valid respondents comprised 58.7% males, 54% without college degrees, 41.5% students or unemployed, and 84.3% under 40 years old. More than 74% were somewhat willing to share de-identified records. Education level, employment status, and gender were identified as significant predictors of willingness to share one's own or one's family's medical records (partially identifiable, completely identifiable, or de-identified). Thematic analysis applied to respondent comments uncovered barriers to sharing, including the inability to track uses and users of their information, potential harm (such as identity theft or healthcare denial), lack of trust, and worries about information misuse. Our study suggests that implementing reliable medical record de-identification and emphasizing trust development are essential to addressing such concerns. Amazon Mechanical Turk proved cost-effective for collecting public opinions with short surveys.

Keywords:

Crowdsourcing, data collection, privacy

Introduction

Secondary use of electronic health record (EHR) data offers promise in advancing clinical and translational research. Access to electronic patient data promises efficient research at scale and at lower cost. However, such research also faces significant barriers [1], such as controversy around ownership of medical information and difficulties in sharing information among clinical researchers or across institutions. This can result in information fragmentation and lack of transparency. Due to HIPAA regulations, the need for consent to capture patients' willingness to share their medical records has hindered research by informatics investigators [2]. Patient-led sharing of medical records for research is seen positively in several parts of the world, but barriers to patients' willingness to share medical data for research remain common. In a study conducted in Australia, 95% of participants believed that medical research with data sharing was necessary in general [3]. Only 73% of these participants, however, were willing to share their own data for research. Investigators have studied differences between those willing and unwilling to share their medical records data. Buckley et al. found in a cohort that healthy controls were less willing to share their medical data [4], while Shavers et al. found that race played a factor; for example African Americans were found to be less likely to participate in research [5].

Although several studies have been published regarding different aspects of record sharing, little is known about the feasibility of engaging the public to archive the clinical phenome for medical research [6]. To investigate what lies behind the general unwillingness to share medical data for advancing science and to learn how we can increase the public's willingness to share, we conducted a crowdsourced survey on individuals' willingness to share medical data. This is the first study of thematic trends in free-text survey comments relating why individuals might be unwilling to share their own or their family's medical data.

Methods

We used a survey instrument previously published by a panel of natural language processing experts [7]. It included questions on demographics, willingness to share medical records for research (with and without identifiers), and willingness to share specific types of health information (also a first), such as medications, laboratory test results, and chronic illnesses. We asked respondents if they would be unwilling to share their own or family members' clinical information for research purposes, and, if not, why not.

We surveyed the opinions of the public who live in the United States and who speak English using the Amazon Mechanical Turk (AMT) system. AMT is an online crowdsourcing marketplace that recruits human workers to perform tasks for a nominal fee ($0.10 for completing this entire survey). Only one response was allowed from each AMT worker.

For data quality control we inserted two common-sense knowledge questions: "*What is the first month of the year*?" and "*Who is the current president of the United States*?" in the survey to identify valid responses. Any respondent who failed to correctly answer these two questions was removed from the analysis. Pearson's $\chi 2$ tests were used to examine relationships between respondent characteristics and willingness to share medical records. Free-text responses were categorized thematically.

Following widely accepted guidelines for thematic analysis, two independent coders performed the analysis. Each coder first familiarized themselves with the data and then generated initial codes separately. Then the two coders met to compare the codes and reach consensus. Each coder independently searched for themes in the codes that were relevant to the research question of this study: *Is the public willing to share their medical records for research? What are the barriers?* Multinomial regression was used to generate probability matrices to evaluate the predictive probability of gender, age, and education on willingness to share and reasons not to share.

Results

1,774 AMT workers completed the survey, of whom 1,508 answered the common-sense knowledge questions correctly and were included in the analysis. Among these respondents, 58.1% were male, 54.5% had not completed a college degree, 41% were students or unemployed, and 84.2% were younger than 40. This cohort appears relatively young and well educated. The demographics are shown in **Table 1**.

Table 1 – Demographic Characteristics of Study Participants

Variable	Value	n (%)
Gender	Female	623 (41.31)
	Male	885 (58.69)
Age	18-25	668 (44.3)
	26-40	603 (40.0)
	41-55	176 (11.7)
	56 or older	61 (4.0)
Education	Less than high school	10 (0.7)
	High school/GED	159 (10.5)
	Some college	646 (42.8)
	Bachelor's degree or college graduate	547 (36.3)
	Graduate or professional degree	146 (9.7)
Employment	Religious	3 (0.2)
	Nonprofit organization	31 (2.1)
	Government and public administration	58 (3.8)
	Education	89 (5.9)
	Health care and social assistance	89 (5.9)
	Homemaker	107 (7.1)
	Scientific or technical	142 (9.4)
	Not employed	223 (14.8)
	For-profit business	354 (23.5)
	Student	403 (26.7)

Willingness to Share Medical Records

AMT workers were asked to pick an answer that best described how they felt about sharing medical records for research. This included their perception of how willing they felt the general public was to share their medical records for research, how willing they were to donate medical records of deceased family members for research, and how willing they themselves would be to share their own medical data (both with identifying information and without), as shown in **Figure 1**. Over 74% were at least somewhat willing to donate their de-identified records for research. 32.4% thought others "might be willing" to share medical records of deceased family members for research, while only 4.2% stated they thought that others would definitely share their medical records. 35% said they would share their deceased family member's records for research, with 6.8% saying they would not share their family's records. Only 13.9% expressed willingness to share their identifiable medical records for research. 20% replied they would not be willing to share their data with identifying information, whereas only 5.3% expressed unwillingness to share de-identified medical records. 50.3% indicated willingness to share their de-identified medical records for research.

Willingness to Share Specific Health Information

AMT workers were asked to indicate their willingness to share different aspects of their medical records for research (**Figures 2-3**). Respondents checked whether they were "*willing to share*," "*not willing to share*," "*not sure*," or "*not applicable*" with regards to health information such as lab results, medications, diagnostic reports, chronic illness, mental health, cancer, disabilities, and more. Respondents were most willing to share information on their demographics (**Figure 2**), childhood diseases, substance abuse, alcohol and tobacco use, cancer, and surgeries (**Figure 3**).

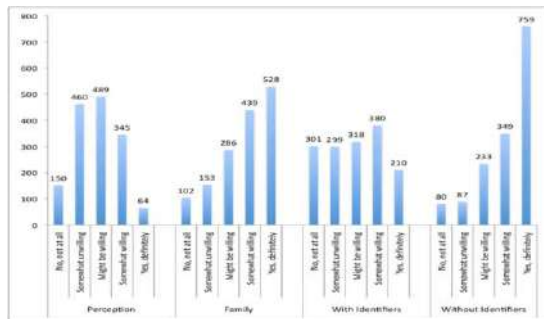

Figure 1 – Willingness to Share Data

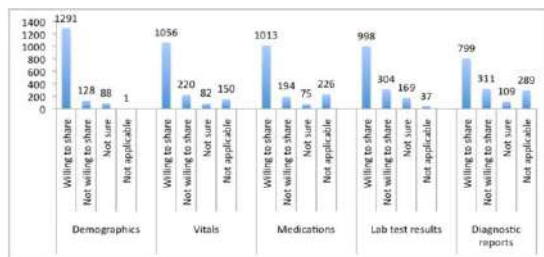

Figure 2 – Willingness to Share Specific EHR Data Types

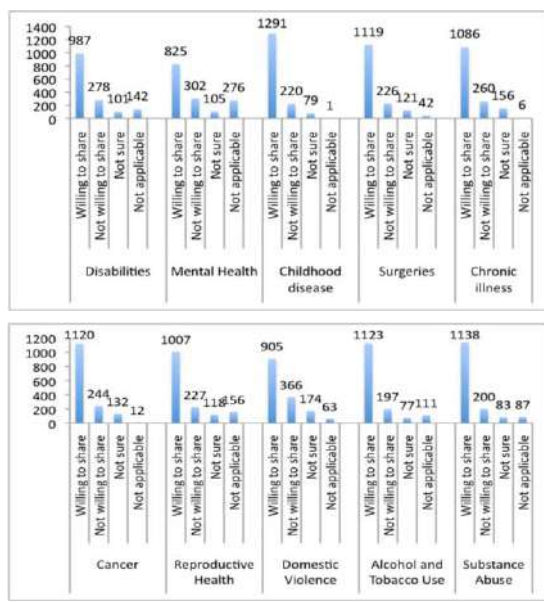

Figure 3 – Willingness to Share Data about Specific Conditions

The five types of health information that the respondents were most unwilling to share were domestic violence, diagnostic reports, lab test results, mental health, and disabilities. Respondents were most unsure about domestic violence, lab test results, chronic illness, cancer, and surgeries. Many respondents found diagnostic reports, mental health, medications, reproductive health, and disabilities to be "not applicable". All descriptive statistics are in **Table 2**.

Table 2 – Descriptive Statistics of Participant Willingness

Willing to Share Records [1=not at all, 5=definitely]	**Mean**	**SD**
What other people think	2.83	1.04
Expired family member	3.77	1.22
Identified	2.98	1.34
De-identified	4.09	1.15
Willing to Share Conditions	**Freq**	**%**
Demographics	1,291	85.61%
Childhood disease	1,291	85.61%
Substance abuse	1,138	75.46%
Alcohol and smoking	1,123	74.47%
Cancer	1,120	74.27%
Surgeries	1,119	74.20%
Chronic illness	1,086	72.02%
Vitals	1,056	70.03%
Medications	1,013	67.18%
Reproductive health	1,007	66.78%
Lab results	998	66.18%
Disabilities	987	65.45%
Domestic violence	905	60.01%
Mental health	825	54.71%
Diagnostic results	799	52.98%

Reasons for Being Unwilling to Share

Respondents were asked to make one to three selections for why they would be unwilling to share their medical records for research, including an option for, "Not applicable, I am willing to share this information." 203 respondents marked two responses, 251 checked three, and 39 marked more than three responses (results in **Figure 4**).

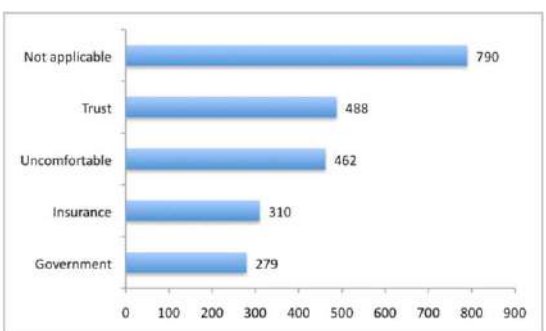

Figure 4 – Concerns Behind Unwillingness to Share

763 (50.6%) AMT workers solely checked, "*Not applicable because I am willing to share my medical information,*" along with 27 who also made other selections. 488 respondents checked "*I don't trust that my information will be kept confidential.*" 463 marked, "*It would make me uncomfortable to share this information.*" 310 respondents checked, "*It may compromise my future health care or insurance,*" and 279 felt, "*I am afraid my information will be used by the government*."

The last question in the survey asked respondents to share any other reasons they would be unwilling to share their medical records for research, with a text box for free responses. Of the 1,508 workers who took the survey, 689 (45.7%) provided a response for the final question in the survey. Only three respondents declared that they were unwilling to share without a reason, while 105 respondents stated they were willing to share. The remaining 581 respondents indicated issues or reasons that caused them to be unwilling to share, or conditions that would make them willing to share their medical information for research. Each response was coded to match one or more of the 13 codes listed in **Table 3**. Respondents had the most concerns with sharing identifying information, privacy, and potential harm caused by sharing. A total of 681 codes for reasons unwilling to share were applied to these responses.

Table 3 – The Thirteen Themes Behind Unwillingness to Share

Theme	**Total**	**% of those unwilling to share**
Risks with identifiable information	155	26.70%
Potential harm	116	20.00%
Risks with privacy	116	20.00%
Unauthorized access to or sharing of information	53	9.10%
Lack of knowledge of research study	49	8.40%
Improper/unauthorized use of information	33	5.70%
Compromised confidentiality	32	5.50%
Uncomfortable sharing medical data/records	29	5.00%
Beliefs on information sharing	28	4.80%
Specific health information	26	4.50%
Medical data handling	23	4.00%
Distrust in government	13	2.20%
Insufficient compensation/no benefit to participant	8	1.40%

Including identifying information generated the most concern from respondents. Respondents expressed worries about the information being traced back to them. One respondent posed the idea of potential harm from unauthorized sharing of medical data, "*I would only be concerned about sharing my personal, identifying information because I'd be concerned it might get shared -- even inadvertently or accidentally*." All respondents expressed some willingness to share their medical data for research if identifiers were removed, and some distinctly stated they would be unwilling to share if identifiers were not removed. Privacy and potential harm tied for being the second most concerning issues.

Of the 690 respondents who provided a response, 116 expressed a desire for privacy. A strong sensitivity to the right to privacy was expressed by several respondents, e.g., that it was "*nobody's business,*" that the information was "*too personal to share*," and that it would be "*an invasion of*

privacy." One stated, "*My medical records are between me and my doctor and I don't believe they are anyone else's business*." Some respondents also felt that their privacy would not be guaranteed if they shared their medical data for research.

Several respondents were concerned that harm may come to them from sharing their medical data. Specific concerns included identity theft, missed job opportunities or loss of employment, and medical care and health insurance discrimination. A total of 112 respondents were unwilling to share medical data because of a perceived risk of harm from sharing their information. One respondent stated, "*I can see the results being used against me for jobs or health insurance*." Another felt that not sharing medical data/records would prevent potential harm, saying he would be unwilling to share to "*Protect identity [and] prevent gossip regarding my health from people who would recognize my name*." Several other respondents likewise were concerned about being judged by their information.

Confidentiality, handling of medical data by the researchers, and the likelihood of information being accessed and shared by people other than researchers was also an issue. Respondents expressed concerns over the researchers' capabilities to keep the data secure and whether their information really would be kept confidential. 33 respondents indicated that they were concerned about confidentiality, and 23 were unwilling to share due to uncertainty in how their medical data would be handled and kept safe. One respondent posted, "*Most importantly, I have no control over what is done with it, and question how securely the data is protected*." 53 respondents believed it was possible that their medical data could be hacked, leaked, or accidentally shared. One stated, "*I would be afraid my personal information would get out and I'm not comfortable with that.*"

3.8% of participants demonstrated concerns about accessibility, applicability, and the necessity of sharing their medical records for research. Some felt that too much information on individuals was already available for others to see ("*I feel that people can find out enough about anyone. Why give out more*?"), or that sharing medical records was not necessary ("*I feel that this information is very personal and doesn't need to be shared for researching*."). Others stated that they could not share because they did not have access to their own records ("*I don't even have access to them*."), or that they were unwilling to share information for specific kinds of research, such as chronic disease, since they did not have a chronic disease or information believed to be pertinent to the research. "*I do not have cancer. There is no domestic violence, nor alcohol, nor substance abuse. If any of this applied to me, I would share that info*."

Sharing specific types of health information was another concern. A variety of respondents indicated that they were unwilling to share some types of health data. A few respondents demonstrated that they would be unwilling to share a given type of information specificially because sharing made them feel embarrassed. One respondent stated, "*I'd be willing to share my medical data/records except for things that are personally embarrassing*."

Respondents also shared that their willingness to share was dependent on specific knowledge of the research study, such as the research purpose and who the researchers and associated academic institutions were. Some participants also stated that they were unwilling to share because they were unable to contribute to the assessments being made by researchers.

32 respondents were unwilling to share because they believed their medical records may be used for research they disapproved of or would be used for marketing purposes or for profit. Some respondents also felt that their records may be used unethically. Less than 4% of respondents were unwilling to share due to distrust in the government or because they felt they would not receive any benefit by sharing. 15 respondents were concerned about government involvement in research and healthcare, feeling the government had too much access and involvement with personal data already. A respondent said, "*NSA already has all this info*," while another stated "*I'm not comfortable trusting the government with my medical information*." For some, being compensated was a significant part of being willing to share medical data for research. One respondent stated, "*If the price is right then I would gladly share my information. That's the only reason. I still wouldn't trust that my information would be kept confidential, but it wouldn't be the motivating factor. I'd want to be compensated.*"

Barriers to sharing medical records included the inability to track the uses and users of their information and a lack of trust in researchers' intent. Explanations for their answers were provided by 960 (54%) respondents. The primary concerns on this point were (1) lack of tracking of the users and uses of shared information; (2) fear of being harmed, including loss of medical care or insurance, identify theft, being discriminated against by future employers, and being selected for targeted advertising; and (3) lack of trust in the data collectors.

Discussion

In this study, Amazon Mechanical Turk proved to be a cost-effective method of collecting public opinions for biomedical research. Using AMT was also more representative of a broader population than conducting surveys among medical center personnel, although respondents did have to be computer literate. Also, the AMT survey took only a couple of days and $20 to collect responses from 1,774 respondents, while it took months for our surveys in medical centers to collect 400 responses.

The majority of participants were willing to share their medical data for research in some manner. We discovered a variety of reasons why patients may be unwilling to share their medical data for research. Some of these reasons are addressable. For example, some respondents stated they would be willing to share if they had more information on the research study, researchers, or the associated academic institution. If respondents were provided with more information and were guaranteed that their data would be protected, kept confidential, and not used by the government, willingness to share increased. Factors that are hard to address but that affected willingness to share were desire for privacy and discomfort sharing specific types of medical data. Reliable de-identification methods for medical records and trust development are critical for addressing these concerns.

Responses to the last, open-ended question of the survey were similar to responses in Weitzman et al.'s focus group study [8]; however, due to the large number of respondents who took the survey and the application of codes to the responses, we were able to determine the strongest and most prevalent concerns with sharing medical data for research. "Identifying information" was the most frequent code. Removing patient identifiers, such as name, address, and social security number, would cause the largest increase in willingness to share. This was confirmed by the increase in respondents indicating they

would be willing to share medical data without identifiers over the number of those willing to share with identifiers. This pattern was also seen in a study comparing attitudes towards sharing of medical data in healthcare settings between U.S. and Japanese populations [9].

Privacy, potential harm, and unauthorized access to or sharing of information were the next most common concerns. These, along with compromised confidentiality, improper or unauthorized use of data and sharing specific types of health information stem from sharing identifying information. This concurs with the findings of a study evaluating the effect of authorization forms used by hospitals on likelihood of consent which found that requesting social security numbers negatively effected the return rate of authorization forms, while distinguishing the hospital name on the forms increased the return rate [10]. The present study disagrees with prior reports of biases in willingness to share specific types of medical data. Respondents were least willing to share information about diagnostic reports, mental health, and domestic violence, while being most willing to share demographics, childhood diseases, and substance abuse.

Comparison to Survey Results from Academic Centers

In a previous study, we conducted a similar survey of 2,140 highly-educated professionals, students, and staff in two academic medical centers [7]. 56% of respondents were "somewhat/definitely willing" to share clinical data with identifiers, while 89% of respondents were "somewhat" (17%) or "definitely willing" (72%) to share without identifiers. Results were consistent across gender, age, and education, but there were some differences by geographical region. Individuals in that study were most reluctant (50-74%) to share mental health, substance abuse, and domestic violence data, but remained fine sharing diagnostic data. Mental health and domestic violence seem to be sensitive areas not likely to be shared in either study cohort. The public in the present study were more willing to share substance abuse information than health professionals.

Limitations

There were several limitations to this study. Presenting most questions with predefined answer options may have prevented more freestyle responses. 54.3% of respondents did not provide an answer to the free-text question of the survey. Results of our study should be applied with care, as respondents were not asked where they currently live nor what their citizenship is. A research group at the University of California-Irvine surveyed MTurk HIT workers to evaluate their demographics and MTurk habits. It was found that 57% claimed to live in the U.S., while 32% were in India [11]. Asking for nationalities of our AMT respondents would have helped us understand how we could overcome barriers in willingness to share medical data in specific regions. Finally, people dealing with serious illnesses often have different conceptions of privacy than those who are not and, therefore, may be more willing to share health information. Our survey did not ask for health status of the respondents. In the future, we would like to study which patients are willing to share and which are not by collecting a richer variety of respondent characteristics.

Conclusions

This study is the first to leverage a crowdsourcing approach to efficiently collect the public's preferences and concerns around sharing medical records for the advancement of science. This study sheds light on the opportunities and challenges when engaging the public on the subject of donating their medical records to support research, as well as on the need to balance privacy and specific patient needs for health information in the age of participatory health, the "measured self," and social media.

Abstract

Efficient access to clinical data by investigators is critical for data-driven biomedical research. Mediated query is commonly adopted to facilitate data access for investigators. However, the query mediation process remains a black-box. This study analyzed the email-based dialogues between investigators and clinical data query mediators from three institutions. We identify discussion topics and their frequencies, model task flows, and analyze user needs for query mediation support revealed from the dialogues. While the datasets between different institutions are distinct in some notable respects, we find that together they provide common insights for streamlining data access. From our findings, we conclude an intelligent dialogue-based query support model is feasible to automate human-mediated clinical data access for investigators and stakeholders.

Keywords:

Information storage and retrieval; Interdisciplinary communication; Needs assessment.

Introduction

Big data in healthcare offers immense research potential. In practice, much of the data access is mediated by query analysts who have the adequate technical knowledge, e.g. structured query languate (SQL), to pull information from complex databases. Clinical data access for biomedical researchers is limited not only by patient privacy and data governance but also ineffective communication between clinical researchers and query analysts. In addition to logistic barriers such as lengthy institutional paperwork for approving data requests, there are interdisciplinary communication barriers due to vocabulary differences, conceptualization discrepancies, and knowledge gaps impeding efficient delivery of accurate data sets. With proliferating data, human-mediated data queries are difficult to scale.

The underlying biomedical query mediation (BQM) process is an iterative question-answering process between investigators and query analysts. BQM centers on the investigators' definition of a research statement followed by more precise specifications of the clinical process in question so that query analysts are able to locate the appropriate data elements. In the process of BQM, contextual data constraints often guide revision of the researchers' data queries [1]. The more complex or granular databases are, the more complex BQM may inherently be due to iterative refinements and understanding of the precise information needed from both parties.

Currently, there is minimal literature detailing BQM and much of the underlying communication space exists in a "black-box" in which the actual needs of researchers and the methodology of query analysts' work are not always transparent to each other, which is reflected by the iterative nature of BQM.

Increasing the transparency of the BQM communication space is thus an important first step into understanding how to better streamline data access, as understanding the processes underlying information retrieval can lead to informed redesigns of communication and information flow [2].The biomedical query negotiation can generally be seen as a continuum of automated information retrieval and human-centered communication (e.g. conversations or email exchanges). Depending on the information task, automation can be substituted for in-person communication [3], which is by direct conversation or email, is not always efficient.

In this paper, we investigate email communications during BQM since email exchanges are an excellent candidate for a computational decision-support paradigm in which elements of information flow can be automated. In our analysis of the email communications from three institutions, we attempt to understand how researchers and query analysts negotiate data needs via email and identify knowledge gaps between biomedical researchers and query analysts. We use insights from task and temporal communication patterns, categorization of questions, sender-recipient networks, and the results of predictive text models to better understand email-based BQM in evaluating whether we can feasibly design an automated dialogue-based query support system.

Data and Methods

Email communication for 20 self-reported critical incidents for BQM totaling to 307 emails at an average of 15 emails per case with a standard deviation of 19 were collected from 3 query analysts from three institutions. These cases were exchanges characterized by logistical inefficiencies and communication gaps. Most of the variability in case size comes from Site 3, which also makes up 80% of the email messages. Cases from Sites 1 and 2 average 5 to 6 emails per case with a standard deviation of 2 emails. Cases from Site 3 average to 23 emails per case with a standard deviation of 22. Case 3's variability comes from an outlier case containing 93 emails (Figure 1).

Data De-identification and Structuring

De-identification of sensitive information was done manually by replacing sender names, including titles (e.g. Dr., MD), and associated email addresses with generic codes. In addition to signatures, institutional footers were removed from messages.

Figure 1 - Distribution of cases by number of emails

Telephone numbers, addresses and locations, passwords, and file names of attached documents were deleted from the text. To ensure further data privacy, the delivery context of emails, e.g. 'Sent from my iphone', were removed from all emails. The structure of all emails was standardized to allow easier parsing of the text. Junk delimiters, excluding message separators, such as > and Original Message identifiers were cleaned from the dataset. Non-alphanumeric text was deleted unless it was related to the data or query commands in an email. Any Date delimiters were changed to Sent. Times were truncated from hour-minute-second format to hour-minute format to ensure uniform precision in temporal analysis of emails. Completed recipient information could not be imputed in all emails in cases where copied (cc'd) recipients were not explicitly denoted in abbreviated email headers. Actual email text was demarcated with the MESSAGE tag and additional tags were added to identify task domains and communication parties.

Coding Book for Hierarchical Task Analysis

We defined email tasks, i.e. email events, as what the sender wants to accomplish with the primary recipient. All emails were manually tagged with domains and sub-domains using this coding book (Table 1).

We append an additional identifier Communication Party, an indicator variable of whether a sender is a query analyst retrieving data or biomedical researcher requesting data. Because a sender does not necessarily always communicate with the opposite party, an additional tag Target Party was created to account for researcher-to-researcher and analyst-to-analyst communications in addition to the communications between biomedical researchers and query analysts.

We ran basic email counts across sites, computing min, max median, mode, and standard deviation in the number of emails in a case to get a basic sense of communication volume. We constructed a basic box-plot view of email counts across sites. For each critical incident, we looked at which communication party (researcher, query analyst, or other/unknown) was initiating the thread of the critical incident, as a percentage of the number of cases in each site. We determined the number of emails sent by different communication parties as a percentage of the total number of emails in each site. We additionally determined the number of party-to-party (i.e. researcher to query analyst, query analyst to researcher, researcher to researcher, and query analyst to query analyst) communication flow as a percentage of the total number of emails across sites. We furthermore broke down task domains as well as task sub-domains by researcher and by query analyst across sites.

Table 1 - Domains and Sub-domains for Task Analysis

Domain	Subdomain	Definition
Inquiries		
	Task Request	the recipient is asked to assist with a data request by sending information, modifying the structure of the data, supplying additional information and detail, retrying a solution with new information, or confirming feasibility
	Clarification	the recipient is asked to clarify detail on information sent or confirm and make sure of whatever information was previously provided
	Follow-up	a check-in for updates on progress from recipient
Meetings		
	scheduling	Schedule a meeting
	Meeting confirmed	Confirm the schedule
	Meeting completed	Close the conversation
Resolution		
	Resolution Pending	a sender states that progress will be made or is currently being made. This can include mention of failed attempts at a solution or data request acknowledgements by a data team processing the request
	Resolution Offered	the sender offers at least one part of a larger solution or notes which information is already readily available
Other		
	Notice	a general information email, generated without regard to a particular data request
	Forward	an email in which the purpose of the message is to forward a communication
	Introduction	An email in which a new researcher or query analyst introduces himself or is being introduced into the email thread
	Acknowledgment	an email in which the sole purpose of the message is to acknowledge the resolution offered or the progress being made

The interrogative pronouns *'who', 'what', 'which', the adverbs 'where', 'when'*, and the conjunctions 'if', 'whether' characterize straightforward questions can be automated by a database. The interrogative adverbs 'how', 'why' may be more open-ended and less likely to be candidates for the computational paradigm in communication. Better understanding of these grammatical identifiers helps us better understand the nature of questions in email-based BQM. In a representation based on these

grammatical terms, we categorize our questions as Identification questions involving 'who', 'what', 'where', 'when', 'which' inquiries, Choice questions involving queries of 'whether', 'if', 'or', Quantification questions involving 'how many', 'how much', 'how long', 'how far', 'how often', 'how high', 'how long', and Discussion-oriented inquiries represented by 'why' and other forms of 'how' like 'how do' and 'how would'. We filtered on emails whose task domains include inquiries and whose specific sub-domains exclude stand-alone follow-ups. In the filtering, we were thus able to focus more on questions related to the data request at hand. Our results are represented by researcher and by query analyst.

The bag-of-words model is popular for document classification. Given that emails are labeled with the task domain, task sub-domain, communication party, and target party, we approach task and party identification as a supervised learning problem. Representing email messages as multi-sets of words that only take into account word multiplicity but disregard word order and grammatical structure, word frequencies in the multi-sets are used as a feature in training a multinomial naive Bayes classifier. Multinomial naive Bayes assumes independence between features for a multinomial event model, which are our task and party classifications.

In task identification, we first predicted general domains. Because multiple domains can occur together in an email, we separately ran the model for each general domain and predicted the binary indicator of that particular domain. We then performed a nested prediction, in which we predict specific task sub-domains conditional on the corresponding general domain, extracting only emails for which that domain is the only domain tag. We applied the same algorithm in predicting communication and target parties. For each prediction set, we performed randomized cross-validation in 1000 iterations and noted the range of accuracies with the middle 800 values, i.e. accuracies at the 10th and 90th percentiles.

We developed a simpler classification algorithm premised on the concept of a codebook; that is, a set of key terms and phrases representative of an aspect of the conversation such an email task domain. Unlike bag-of-words, our codebook-based classification gives consideration to word order since it extracts one to four-word phrases in common among at least two messages of a certain category. For domains, we looked first at matches between single-domain messages and then matches of those single-domain messages with multi-domain messages. For sub-domains, we again conditioned on the relevant broader domain first, as in our bag-of-words-based prediction. For domains, sub-domains, and communication parties, we ensured that the codebooks constructed do not overlap between their different classifications so that the set of codes is unique to that particular classification.

The construction of codebooks allows us to understand the language surrounding an email task or communication party. We hence made another probe into the language of biomedical researchers and query analysts using part-of-speech (POS) tagging to determine the most frequent nouns and verbs, and their overlap, among different communication parties. We adapted a script for noun-phrase extraction. Frequent topics are the functional foundation of automated dialogue-based query support and we hence computed the frequencies of our extracted topics across sites.

We examined how tasks follow from one another across emails. We computed a ranked moving average of the number of task sub-domains across emails. We looked at the intra-message and inter-message relationship between tasks, respectively, in computing the most frequents tasks concurring with a specific task and the most frequent tasks preceding or following that specific task. We constructed network visualizations specifically for clarifications and task requests to better understand the events surrounding the iterative question and answer process. For cases without any missing timestamps we visualized the time lengths between conversations in a box-and-whisker plot and analyzed task domains and sub-domain at peaks, i.e lags, in response times. To understand how involved the communication networks are, we plotted a color-coded network visualization of senders, primary recipients, and secondary (cc'd) recipients who are neither senders nor primary recipients. We then generalized the communication interactions to four different network models.

Results

Communication Volume and Communication Networks

In the breakdown of thread origination across sites, we look at which communication party, i.e. researchers or query analysts, are initiating the conversation. While most cases begin with contact by a query analyst with institutions 2 (100%) and 3 (55%), with institution 2 being entirely analyst-initiated, institution 1 is predominantly researcher-initiated (Figure 3a). The researcher to query analyst communication volume among individual email messages is about the same as the query analyst to researcher volume for Sites 1 (40%) and 2 (38%), and is slightly higher with Site 3 (45%) (see Figure 3b).

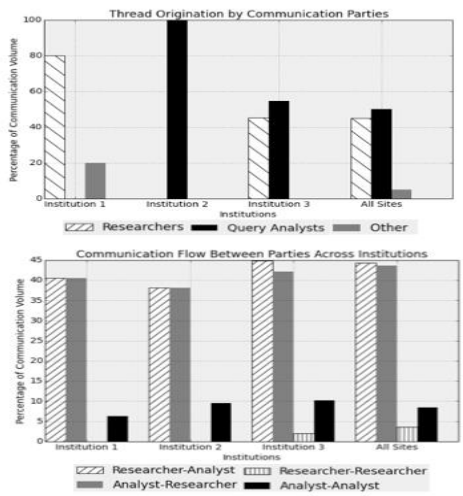

Figure 3 - Breakdown of pairwise communication

Interestingly, exchanges are not simply between opposite parties. Across all three institutions a non-negligible portion of the communication volume occurs between query analysts themselves, and for Site 3, there are also some smaller number of exchanges from researcher to researcher (see Figure 3b).

Communication networks represent the complexity of conversations between senders and primary recipients for an entire critical incident. Two-node interactions are the most common and simplest network type in our data, with nine critical incident cases following this prototype. Linear three-node networks are represented in four cases, where the additional third node can be any party. In linear three-node structures, the two relationships could be bidirectional relationships among the same parties and between different parties. Our cases also include the instance of both bi-

directional and unidirectional interactions among the two pairs of different parties. Triangular three-node structures, represented by four critical incidents, can have one to three bi-directional graph edges and, in our data, roughly the same number of cases involves the majority of the nodes being of either party. Complex networks are the rarest case, represented by only three cases, all within Site 3. The first three network models all exist in exchanges from each of the three institutions.

Task domains are split almost evenly between researchers and query analysts, with insignificant variations between specific domains and sites (see Figure 4a). In the small set of cases from Site 2, there are no emails requesting, confirming, or referencing meetings. Within the inquiry domain, most questions are straightforward identification or choice questions as opposed to quantification questions and more involved, discussion-oriented inquiries (see Figure 4b).

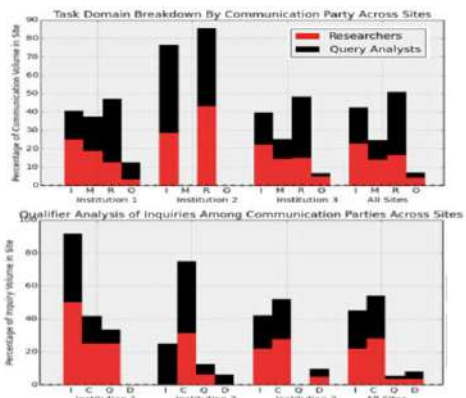

Figure 4 - Breakdown of tasks and classification of inquiries. (a) Task domain breakdown by communication party across all sites. I = Inquires, M = Meetings, R = Resolutions, O = Other. (b) Question breakdown by communication party across all sites. I = Identification, C = Choice Between Options, Q = Quantification, D = Discussion

Predictions of Tasks and Communication Parties

The bag-of-words algorithm with naive bayes assumptions on our multinomial event model for domains and sub-domains has generally good predictive performance. For the middle 80 percent of values within the 10th and 90th percentile of prediction accuracies, we find that single-domain prediction of inquiries, meetings, and resolutions range from 61-74%, 73-84%, and 60-71%, respectively. Because we approached this as binary a prediction for each domain, these results are better than a 50% random prediction.

For the nested prediction in which we condition in the presence of a particular single-domain, we again have better-than-random results. For inquiries, we find that task requests, clarifications, and follow-ups have 80 percent of their accuracies at 50-78%, 50-78%, and 61-83%, respectively. The similar and slightly lower range of prediction accuracies for task requests (i.e. information requests, and clarifications) reflect the similarity in these two sub-domains as they are both inquiries specifically regarding the data at hand, as opposed to questions following up with progress or requesting meetings.

In the conditional predictions with single-domain meetings, we find that meeting scheduling, meeting confirmations, and completed meetings have most of their accuracies at 62-92%, 62-92%, and 100%, respectively. In conditional prediction with single-domain resolutions, we find that pending resolutions and definitively offered resolutions can be mostly predicted within 65-87% and 61-87% accuracies, respectively. Looking at party predictions, we find the party originating the email message can be predicted mostly within 64-77% accuracy for both biomedical researchers and query analysts. The party to which the message is targeted can be accurately predicted within 58-70% and 57-70% accuracy for researchers and query analysts, respectively. The general domains of inquiries, meetings, and resolutions are accurately predicted with 42%, 75%, and 61% accuracy, respectively. Within inquiries, task requests, clarifications, and follow-ups are correctly predicted 20%, 43%, and 85% of the time. Within meetings, meeting scheduling, meeting confirmations, and completed meetings are respectively determined with 54%, 95%, and 96% accuracies. Within resolutions, pending solutions and definitively offered solutions are respectively determined with 33% and 38% accuracy. Communication parties are determined with 50% accuracy.

Topic Extraction

The codebook approach provides a basis for assessing the common language used in dialogue-based query mediation. Looking at the nouns and verbs, the basic elements of topics, we see some overlap among researchers and query analysts and because of the different sizes of word sets, we measure overlap with respect to the smaller word set. Looking specifically at noun topics, we find that between researchers and analysts, there are 43%, 39%, and 58% overlaps across Sites 1, 2, and 3 respectively. Between researchers these overlaps are 15%, 41%, 39%, and between query analysts these are 29%, 34%, 37%. The smaller overlaps within the same parties make sense as each critical incident represents a distinct data request. The more significant overlaps in noun topics between opposite parties is reasonable since a common language is needed to mediate information requests. Looking at the most frequent topics in our subsequent noun-phrase extraction, we see that important common topics across all cases include logistic terms such "MRN," "codes," "data," "warehouse," and "ICD9" as well as more medically-focused concepts such as "adenovirus," "hemoglobin," "ulcer," and "creatinine." Common to all sites are terms such as "lab," "dates," "IRB," "gender," and "diagnosis." Common to Sites 1 and 2 are terms such as "admissions" and "months." Sites 1 and 3 share terms like "control," "age," "medication," "reaction," "demographics," "ICD9," and "MRI." For Sites 2 and 3 we see common terms such as "chronic" and "surgery." These frequent topics serve as the core of dialogue-based query mediation.

Task Flow and Temporal Analysis

In determining the most common tasks preceding, concurring with, and following particular task sub-domains across sites, we found that the email tasks surrounding clarifications and task requests, i.e. information requests, are quite similar across sites. Within the ongoing process of BQM, both task request, i.e. information request, and clarification events tend to be preceded by clarifications, task requests, and definitively offered resolutions, and they both tend to be followed by clarifications and definitively offered solutions. Moreover, these two email events tend to coincide with a clarification or task request alongside an offered resolution.

Whereas meetings will attempt to be scheduled following a clarification, these task events tend to coincide with or precede a task request. Completed meetings also coincide with task requests. Task requests can also commonly occur in response to forwarded messages, whereas clarifications can occur in response to follow-ups suggesting that clarifications intuitively

highlight bottlenecks in the information retrieval process.

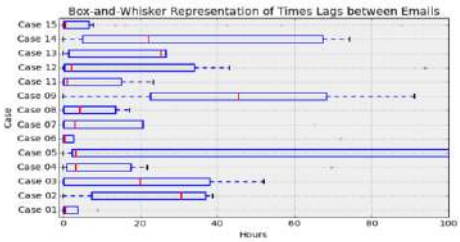

Figure 5 - Distribution of times between emails within a critical incident. Box-plot representations with median and quartiles shown for cases with complete time data. Case 5 has significant variation in email response times with its box-plot extending outside the timescale range used in this comparison chart

There is significant variation in the time durations of our critical incidents (see Figure 5). Analyzing the temporal lags, we find that most frequently preceding time peaks, query analysts have completed a meeting, have offered a resolution, and are currently working on another solution. At the opposite end of the time lag researchers typically contact query analysts with information requests. During the course of exchange, there seems to be no regular pattern among institutions in how the number of distinct task sub-domains change, whether they are generally increasing, decreasing, or peaking midway, emphasizing BQM to be a non-linear process.

Discussion

Communications between query analysts in some of these critical incidents suggests that database querying is not a straightforward process that can always be directly handled by a single mediator. The somewhat smaller proportion of researcher-to-researcher communications suggests that an understanding of the clinical process can also be quite involved. However, these represent a minor proportion of the communication flow and for the most part, BQM is an interaction between opposite parties, mostly having simple communication network structures. That task domains are roughly broken down equally between parties suggests that there is as much of a need and refinement both for the specifications of the clinical process and for the data obtained.

This study complements earlier work in BQM focusing on in-person communication. In-person conversations that comprise non-electronic BQM are an important part of the information retrieval process [4]. Indeed, in 14 out 20 threads that set up meetings, 7 of those threads reference information from that conversation. However, while meetings are important, they are not critically necessary to BQM. Not only are meetings the smallest volume of task domains among our three major task domains, Site 2 does not involve meetings at all and six critical incidents across the entire dataset altogether exclude this task domain. This strongly suggests that BQM, or at least parts of it, can be taken to a computational model.

In fact, there is notable structure and predictability in BQM. On one hand, the volume of distinct events over the course of an exchange does not seem to follow any consistent patterns among our sites. On the other hand, our network analysis of task events surrounding information requests and clarifications confirms the iterative question-and-answer model of BQM discussed in earlier research. Our topic analysis is integral to understanding this iterative nature. Our findings of both logistically-oriented terms such as "codes," and "ICD9," in addition to the medical jargon, can guide the construction of an automated dialogue-based query support, as these codebooks can inform references within automated dialogue-based support that model the actual conversational support found in emails.

Intelligent query formulation relies on the ability to automatically understand the flow of a conversation and we have observed that much of the mediation process can be predicted at a high level. The content of email conversations moreover suggests that BQM is an ideal candidate for the computational design-support paradigm as many of the questions are straightforward inquiries, e.g. questions regarding basic identifying information and questions regarding choices between alternative sets of information. The relevant information for such inquiries can be autonomously accessed by researchers given the appropriate interface support [5; 6].

This study is limited by the small sample of emails from a small number of institutions for 20 critical incidents, thus not providing a complete representation of the entire BQM space. Nonetheless, we offer important initial insights into the dynamics of human-mediated query support, confirming earlier research in BQM as well as providing promising insights into the potential for automating BQM. Our codebook-based algorithm extracted a unique set of codes for a particular domain/sub-domain classification, codes common to two different domains are not used in the determining the classification of a message. This suggests that many domains may occur together, as we see in later analysis.

Conclusions

This study contributes an analysis method for understanding interdisciplinary communicaiton and early insights into the black-box biomedical query process. We conclude that Dialogue-based decision support is needed and feasible.

Abstract

Clinical data, such as laboratory test results, is increasingly being made available to patients through patient portals. However, patients often have difficulties understanding and acting upon the clinical data presented in portals. As such, many turn to online resources to fill their knowledge gaps and obtain actionable advice. In this work, we present a content analysis of the questions posted in a major social Q&A site to characterize lay people's general information needs concerning laboratory test results and to inform the design of patient portals for supporting patients' understanding of clinical data. We identified 15 information needs related to laboratory test results, and clustered them under four themes: understanding the results of lab test, interpreting doctor's diagnosis, learning about lab tests, and consulting the next steps. We draw on our findings to discuss design opportunities for supporting the understanding of laboratory results.

Keywords:

Consumer Health Information, Information Seeking Behaviors, Patient Portals.

Introduction

Advances in personal health record technology, such as online patient portals, empower patients with easy and full access to their clinical data (e.g., laboratory results, radiology reports, and clinician notes) [1]. This access, in line with general interest in patient-centered care, has proven to foster patient engagement, enhance patient-provider communication, and ultimately, improve health outcomes [2]. These potential benefits, along with the financial incentives provided by the U.S. government [3] and the OpenNotes initiative [4], encourage healthcare organizations to increase patients' access to their clinical data via patient portals.

Among the many portal functionalities, access to laboratory test results is an area of high interest to patients; growing evidence suggests that patients are increasingly interested in timely and easy access to laboratory test results [5]. However, patients' current use of test result data is significantly limited due to several reasons [6]. For example, many portals present clinical data to patients in the same way as it is shown to healthcare providers, while patients may not have sufficient health literacy to process and understand the technical nature of the language (e.g., medical jargons) used in the laboratory test reports [7,8]. In addition, patients hope to find useful information, such as actionable knowledge, in online portals, rather than just reviewing the data [9,10]. These findings suggest that while healthcare organizations are increasing patients' access to their clinical data via patient portals, this technology has not adequately met patients' information needs.

Therefore, patients often turn to online resources (e.g., search engines, health forums, and social media) to fill their knowledge gaps. In fact, a recent Pew Research Center study reported that over 70% of adult Internet users in the U.S. searched online for health information [11]. As one of the most popular activities online, health information seeking has been the focus of many studies over the past few decades [12]. However, to date, only a few studies have started looking into patients' online health information seeking behaviors in the context of understanding laboratory results. For example, Reynolds et al. [8] examined the type of supports patients need related to their laboratory data through analyzing questions in an online health forum (medhelp.org). In particular, they found that patients tend to ask questions pertaining to several topics: diagnosis, management/treatment, laboratory report, test, risk, and prognosis. Their study also preliminarily assessed the feasibility of identifying and characterizing the nature of patients' questions related to laboratory results. Building upon their work, we conducted an explorative study to gain further insights into patients' general information needs concerning laboratory test results.

In this paper, we analyzed the questions that users posted on a major social Q&A site, Yahoo! Answers. Among various online forums containing health communities, Yahoo! Answers allows patients to seek information through raising questions and receiving answers from others (e.g., peer patients, health professionals) who are willing to share their knowledge and opinions [13]. Unlike queries submitted to search engines, the questions posted on these platforms are expressed in natural language. These questions also tend to contain more contextual information, such as patients' medical histories and symptoms. Therefore, Yahoo! Answers is a good resource for examining lay people's health information needs [12,13]. As this study is exploratory in nature, we chose to focus on a specific chronic disease, i.e., diabetes, rather than multiple conditions. Diabetes is an ideal condition for us to investigate lay people's information needs regarding laboratory test results. That is, diabetes is recognized as one of the most important public health problems with escalating health concerns [14], requiring long-term management and regular laboratory tests. Addressing the barriers of understanding laboratory test results will benefit a broad population and the society at large. Furthermore, laboratory tests vary across different types of conditions and diseases. Thus, focusing on one condition allowed us to generate comprehensive search terms for data collection.

In this study, we began our inquiry by asking: What are lay people's information needs in making sense of their laboratory test results? We identified 15 information needs related to laboratory test results, and clustered them under four themes: understanding the results of lab test, interpreting doctor's diagnosis, learning about lab tests as a source of information, and consulting the next steps. This study highlights the need to address the gap between patient knowledge and limited contextual information presented on their lab reports.

Methods

Data Collection

Using the application program interface (API) of Yahoo! Answers, we collected a total of 58,422 questions in the diabetes category between 2009 and 2014. The questions were downloaded and loaded to a MySQL database. We then extracted 8,655 posts using keywords suggested by the guidelines and recommendations for laboratory analysis in the diagnosis and management of diabetes, such as HbA1c, glucose, and creatinine [15]. The complete search terms and the number of posts retrieved by each term are listed in Table 1. The terms "glucose" OR "blood sugar" yielded the most posts (87.1%). The study was approved by the institutional review boards at Pace University and Florida State University.

Table 1. Search terms and the number of retrieved posts.

Search Terms	Number
"lab" OR "laboratory"	243
"A1c" OR "HbA1c" OR "hemoglobin A1c"	427
"glucose" OR "blood sugar"	7,536
"blood pressure" OR "systolic" OR "diastolic"	338
"creatinine"	111

Data Analysis

We generated a random sample of 1,619 posts of the potentially relevant question posts (8,655 posts containing keywords). Then two researchers independently reviewed posts for relevance. Duplicate or irrelevant posts were discarded. The posts were determined to be irrelevant if they did not contain any laboratory results or questions related to laboratory tests. This screening resulted in 967 posts eligible for further analysis. The relevant posts were then transferred into NVivo, a program for organizing, storing, and manipulating qualitative data. The research team performed content analysis on these relevant posts. The analysis was performed independently by three researchers and consisted of multiple steps (Figure 1).

The first step was to iteratively develop a codebook using the open coding technique. Two coders, C1 and C2, independently analyzed 240 randomly sampled posts until saturation was reached. The initial list of codes was generated and then discussed in a group session to determine which codes to keep, merge, or remove. After the list of codes was set, we created a data dictionary defining each code to standardize the coding process. Our final coding scheme contained a total of 15 codes, which were clustered under four themes: understanding the results of lab test, interpreting doctor's diagnosis, learning about lab tests as a source of information, and consulting the next step (see Table 2).

Next, a third coder (C3) coded 100 randomly sampled posts from the rest of the posts to check for exhaustiveness of the themes. Once confirming that the themes were comprehensive, C1 and C2 independently coded another set of 100 posts to check for inter-rater agreement using Cohen's Kappa coefficient. The resulting kappa value was analyzed using the kappa interpretation scale suggested by Landis and Koch [16]. The coders presented "Almost Perfect" agreement (kappa value of 0.851). The disagreements were mainly due to the interpretive differences attributed to "Confused about doctor's suggestions or diagnosis" and "Seeking confirmation of doctor's diagnosis" codes; all the disagreements were resolved through discussion. After conflict resolution, C1 and C2 coded the rest of the posts to conclude the analysis.

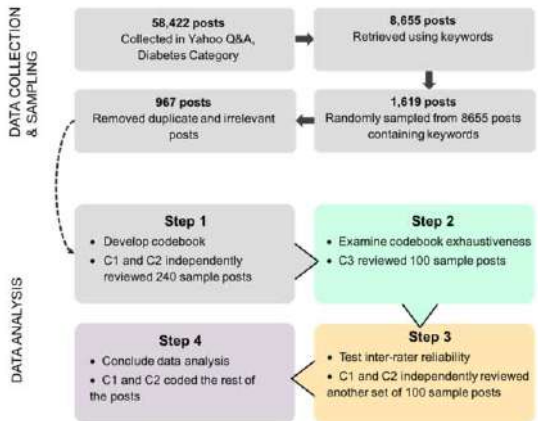

Figure 1– Data Collection, Sampling, and Analysis Process

Results

People come to Yahoo! Q&A to request advice, suggestions, information pertaining to laboratory test results. Their information needs are multi-faceted, manifested in their different but related questions. In this section, we will describe these information needs that people expressed in the questions. We will use representative quotes to illustrate the salient themes.

Understanding the Results of Lab Test

Requests for understanding laboratory test results were by far the most common in this sample (85% of the total posts). That is, posters shared parts of the report content and asked the community to explain their lab test results. As Table 2 shows, posters needed help in understanding different aspects of their lab content, including the meaning of lab value, specific terminology, and the effects and causes of abnormal and/or inconsistent results.

The most common questions in this category were related to understanding the meaning of lab values (74% of the total posts). We found that people had different needs in making sense of their lab results, which may be due to different levels of health literacy, knowledge and experience [17]. For example, a post sought clarification on whether a specific lab value falls into the normal range: *"Is GFR of 73 and creatinine 1.1 normal?"* In other cases, posters often asked the community for diagnosis or opinions, by providing substantial portions of their reports and relevant medical history, medication information, and symptoms. For example, a post sought opinions on what the lab results indicated:

"I am an 18-year-old male. […] Some of the statistics from the report were as follows: high alkaline phosphatase levels, elevated T3, elevated Hbg levels. […] My AbC1 level was 6.1.

What do these elevated levels seem to point to? Can anyone make sense of what might be wrong from my lab results?"

Posters also requested explanation of technical jargon, i.e., terminology. For example, a post asked for the clarification of a specific term: *"Does anyone know what is the meaning of 'Lymph' on blood labs?"* This observation suggests that people have difficulty understanding medical terminologies, even though some patient portals have started implementing consumer-friendly vocabularies [18].

Finally, people wanted to know the effects and/or causes of abnormal lab results. For example, a post asked for advice on the consequences of high creatinine level: *"A recent pathology test states that my creatinine is 6.28. […] What are the effects of such high levels?"* In other cases, people expressed concerns about inconsistent lab results they received from different laboratories or over a period of time, as one post stated: *"My creatinine level increased from 1.0 to 1.1 with a span of 10 days' period. What is the reason?"*

Table 2. Summary of themes. Some posts fell into multiple themes, so percentages add up to more than 100%.

Theme	% (n)
Understanding the results of lab test	
Meaning of lab value	74.3% (418)
Specific terminology	1.7% (9)
The effect of abnormal/inconsistent results	1.1% (6)
The cause of abnormal/inconsistent results	7.3% (41)
Interpreting doctor's diagnosis	
Confused about doctor's suggestions/diagnosis	1.6% (9)
Seeking confirmation of doctor's diagnosis	4.6% (26)
Concerned about doctor's misdiagnosis	0.7% (4)
Learning about lab tests as a source of information	
Inquire information about a specific lab test	34.1% (192)
Ask for lab test recommendations	1.2% (7)
Look for comparison among tests	1.6% (9)
Concerned about lab procedure	2.1% (12)
Consulting the next steps	
Healthcare consultation	27.7% (156)
Treatment options	4.1% (23)
Taking medication	4.1% (23)
Life-style	21.3% (120)

* The percetages are calculated using the number of posts in each category divided by the total number of posts (N=967).

Interpreting Doctor's Diagnosis

Sometimes people posted questions after they discussed the results with their physicians and cited several reasons for doing this. First, people may have doubts about, disagree with, or mistrust their physician's diagnosis, thus seeking a second opinion on their physician's conclusions and/or interpretations (referred to as *seeking confirmation of doctor's diagnosis* in Table 2). For example, in one post the person stated: *"My 4-year-old [child] had all the symptoms and signs of type 1 diabetes so his doctor run test for him. What came back was Glucose, Blood 71, Insulin, Fasting 1.2, Low, C Peptide 0.4 Low. Doctor says there are a few low things, but nothing to worry about. I in my gut don't think that is right. Can someone else help me out?"*

Second, people seemed to be confused about their physician's diagnosis or suggestions as to what to do next and whether or not the treatment is needed. Therefore, they turned to online forums to seek clarification or explanation regarding the information they received from their physician: *"Why do I need to test my creatinine level every three months as being suggested by my doctor?"*

Lastly, a few posters talked about perceived misdiagnosis by their physicians. Often the language used by these patients indicated some level of distress, fear, or other negative emotions. In one post, for example, the poster wrote: *"My wife's doctor, at a prominent San Diego hospital, failed to notice her declining kidney function until she was in end stage kidney failure. […] Is it common for physicians to ignore kidney function and obsess over diabetes labs?"*

These findings reveal a communication gap between health care providers and consumers. Misunderstanding or confusion about doctor's diagnosis may adversely affect patients' access to health information, resulting in poor patient understanding, trust, and satisfaction.

Learning about Lab Tests as a Source of Information

This category concerns questions related to lab test itself. For example, lack of sufficient knowledge about lab tests led people to inquire general information about them (referred to as *inquire information about a specific test* in Table 2), as shown in one post: *"What is creatinine cholesterol?"* In other cases, people asked for some other general information about lab tests, including relationship between lab tests and symptoms (e.g., *why are urea and creatinine levels raised with dehydration?*), how often should one take a specific lab test (e.g., *how often should creatinine and eGRF levels be checked?*), and treatment options (e.g., *my creatinine is 1.6, what is the treatment for it?*).

People also inquired about the diagnostic abilities of a specific test and sought recommendations on which lab test to take (referred to as *ask for lab test recommendations* in Table 2). As this data sample focused on a diabetes online community, the questions therefore were related to lab recommendations for diabetes: *"Which laboratory test is diagnostic for diabetes?"* Similarly, people also sought comparison among different types of test (referred to as *look for comparison among tests* in Table 2): *"Advantages and disadvantages of creatinine clearance test vs. plasma creatinine?"*

Lastly, posters asked questions about the lab procedure. Sometimes, they posted questions while they were waiting for the tests. At this stage, posters asked questions concerning various aspects of the lab procedure, such as what they will go through during the test: *"I am going to the lab to get tested for hypoglycemia (low blood sugar) tomorrow, what exactly will they do?"* Others looked for information as to what they should do or not do to prepare for the upcoming tests: *"This is a lab test for diabetes, blood sugar, cholesterol etc. And I am wondering how long should I fast and can I drink water?"* Similarly, people also posted questions after taking their tests to inquire the turnaround time of their test results: *"How long should it take for a doctor office to call you about lab results?"* These posts tended to exhibit language indicative of distress: *"I had lab work done last Thursday and I am still waiting to hear what my A1C and all else [the doctor] had me*

tested for. Shouldn't they call you with results sooner? What if something is really wrong?"

Consulting the Next Steps

Sometimes people also consulted the community about what they should be doing next. One reason was that people may be waiting for an appointment to discuss the results with their physician, but they wanted to obtain actionable suggestions from the online community first: *"I have lupus [and] my routine blood work shows the ck enzyme at 271 (ref range is 26-192). I have an upcoming doctor appoint. What can I do?"*

They also asked for the community's assistance in assessing the need for a healthcare consultation or further lab test (referred to as *healthcare consultation* in Table 2). For instance, a poster expressed the lack of confidence in the accuracy of lab results and asked for advice as to if it is necessary to re-do the test or take a different test: *"High blood sugar – should I get a second opinion from a different lab? This is too important not to double check with a different lab; last reading was 6.4. This doctor was wrong before about different things."*

Of these posts, people also asked for treatment advice (referred to as *treatment options* in Table 2). For example, one poster wrote: *"A recent pathology test states that my creatinine is 6.28. Does it require dialysis to be done? What can cure this high level?"* In such cases, people also wanted to know what medication and/or whether changing life style (e.g., diet and exercise) could be of any help (referred to as *taking medication* and *life-style* in Table 2), as one post stated: *"My mother aged 45 and has only one kidney. [Her] creatinine level [is] 4.2, Urea [is] 50. What diet she should take and what medicine?"*

Discussion

In the study, we characterized lay people's general information needs related to laboratory test results, such as understanding test results, interpreting doctor's diagnosis, learning about lab tests, and making decisions on the next steps. This study presents an early investigation for our long-term goal of guiding the design of patient portals that can provide more informative and personalized healthcare information. Building upon prior work [8], our study provides a more comprehensive, fine-grained description of lay individual's information needs about their laboratory test results. For example, Reynolds et al. [8] highlighted that patients have confusion about the laboratory report; our study further revealed the aspects of laboratory report that patients had difficulties with, such as the meaning of lab values, medical terminologies, and the causes and effects of abnormal lab results. While this study only examined a subset of questions in an online forum setting, our findings reveal that people need support in interpreting and acting on clinical data, as well as making personalized decisions. Below, we draw on our findings to discuss five design opportunities for supporting the understanding of laboratory results in patient portals.

Providing consumer-friendly and credible information to assist the reading of lab results. Our findings suggest that the design of test results in patient's portal seems to assume that patients have sufficient medical knowledge about their test results. Consequently, patients often did not receive explanatory information or result interpretation in the portal at the time they received the result, and they would search online to make sense of their results. It is therefore crucial to provide more useful information that patients need at the point of viewing their laboratory results in patient portals. For example, patient portals could provide links to consumer-friendly and credible information sources (e.g., entries in MedlinePlus) to help patients better understand the lab results; the portal could also suggest basic healthcare management advices, such as diet and life style.

Accomendating people with different health literacy. People have different levels of health literacy and numeracy as well as potential biases and personal beliefs. For patients who were recently diagnosed, they may not be literate enough to understand the terminology and the results, and thus may ask basic questions such as whether a particular lab value falls into the normal range. In contrast, some patients who have had chronic conditions may have been self-educated on relevant health knowledge (e.g., medical terminology, normal ranges of a test) and therefore need help with more comprehensive questions (e.g., how to interpret the lab results in the context of their medical history). Given such a fact, patient portals need to be designed taking into consideration of people's health literacy differences [19].

Considering the temporality and illness trajectory of patients. We also observed that patients' information needs had a temporal dimension—the nature and extent of the needs may be different at different stages of patients' illness trajectory [12]. For example, right before getting a medical test, patients may want to know how to prepare for the test and what they will go through during the test. Upon receiving their test results, patients may ask for interpretation of what the results mean and what they should be doing next (e.g., make an appointment with their physicians). This observation shed light on portal design with regard to temporal organization of information materials so as to provide relevant health information to patients according to their illness trajectory.

Facilitating shared decision making through personalized and contextualized information along with lab results. An interesting observation is that patients provided contextual information (e.g., medical history, symptom) along with their lab results in order to seek personalized advice and treatment options. This observation suggests that the same lab results may have different indications in different contexts (e.g., family history). In addition, prior work has recognized that personalized healthcare information within a shared-decision making framework leads to better patient engagement, better outcomes, and an increased level of trust between healthcare providers and patients [20]. As such, patient portals should provide more personalized content.

Supporting the sharing of personal stories between patients who are "in the same boat". Sometimes, patients sought health information due to their suspicion about a certain diagnosis made by their physician. This means that patients not only need objective explanations of terms and values in test results, but also other patients' opinions and experiences. Such behavior constitutes reflection upon and distrust in doctors' explanations. It seems that when authoritative explanations lost credibility in certain cases, patients were in urgent need of a second opinion, especially from patients with similar symptoms and conditions. This observation suggests that a social network in patient portals could benefit patients by connecting them with peers (even anonymously) who have similar conditions. This also suggests that patient portals should provide a more streamlined communication channel between healthcare providers and patients in order to resolve any misunderstandings in a timely manner.

Limitation and Future Work

Our study has several limitations. First, our study focused on a single disease, namely diabetes, one type of health information, laboratory test results, and one health forum, Yahoo! Answers. While our findings pertain to the

characteristics of the specific domain, the results may not be generalizable to other types of diseases and types of health information. Our future work will expand to other health conditions (e.g., cancers), other health forums (e.g., eHealth.com, healthboard.com), and include other types of health information (e.g., radiology report, physician notes, discharge summaries) to assess the generalizability of our findings. Second, we did not discuss how the questions were answered on this Q&A site. In our future work, we will synthesize the types of information people gain from the online communities and how these answers were constructed to meet their needs. Lastly, due to social media data availability, we could not collect posters' demographic data, such as level of disease severity, gender, age, and different stages of life/illness trajectory.

Conclusions

This study explored lay people's various information needs related to lab results through analyzing forum posts collected from a social Q&A site. Our results highlighted the need to address the gap between patient knowledge and limited contextual information presented on their lab reports, and provide essential insights into improving the design of patient portals to fully meet patient needs in understanding the lab results. Our findings provide a foundation for our future work, including qualitative studies (e.g., interview with clinicians and patients) and analysis of medical record data to understand how to best provide personalized information and present clinical data in patient portals.

Abstract

To improve user experience, many health IT systems provide personalization options allowing end users to tailor the software to their needs and preferences. However, few studies have investigated if healthcare professionals actually make full use of this feature. As an initial step towards understanding end users' software personalization behavior in healthcare, we conducted a pilot study to examine how clinicians, staff, and researchers customized a search engine designed to facilitate information retrieval from electronic health records. The results show that a majority of the end users (82.4%) did not make an effort to modify the system's default settings. Among those who did, they more often changed its 'look-and-feel' than its functionality offerings. We conclude that future research is warranted to study the rationale underlying healthcare professionals' software personalization decisions both to optimize user experience and to avoid building complex and costly personalization options that are unused or underutilized.

Keywords:

Software, Electronic Health Records

Introduction

The lack of usability has been a prominent barrier to the adoption and use of current generation health IT systems [1–4]. Numerous efforts have been attempted to address the issue, e.g., through introducing usability guidelines and incorporating user-centered design requirements into the health IT certification processes [5, 6]. However, no "one-size-fits-all" solutions exist capable of meeting the diverse needs of all healthcare organizations and individual users [7]. Different healthcare organizations have distinct contexts and requirements. At the individual level, users of the same profession and medical specialty may have vastly differing opinions regarding how a health IT system should be designed, reflecting their unique cognitive styles, job routines, prior experiences, and perception of the role of technology.

Through software modularization and local configuration, vendor products can be tailored to meet the needs of specific healthcare organizations. To accommodate variation at the individual user level, one approach is to allow the software to be "personalized" based on the preference of each of the individual users [8]. Personalization strategies have been widely applied in modern software, including operation systems, productivity suites, and games (e.g., Windows' "Control Panel" and Macintosh's "System Preferences") [9]. Modifying a software system's default settings allows end users to not only fine-tune its visual appearance, such as font and color, but also its functions and interaction modalities, such as the expert vs. novice mode.

A significant challenge to software personalization is balancing flexibility and uniformity. While a rigid software design could diminish user experience and result in inefficiencies and dissatisfaction, a fully flexible system that does not work optimally without extensive customization may also cause confusion and fail to deliver 'best' experience uniformly to all users [8]. Further, systems that offer a wider range of personalization options are more difficult to develop, maintain, and support. Different software companies seem to favor distinct design philosophies. For example Apple Inc. values simplicity and provides users as few personalization options as possible, whereas other companies opt for the other extreme.

Health IT personalization design decisions are by and large made by vendors and software developers. While work has been done in other industries [8, 9], no research, to the best of our knowledge, has investigated how healthcare professionals personalize their software. This paucity of knowledge could result in suboptimal software designs that adversely affect user experience. It may also incur unnecessary costs in implementing complex and costly personalization options that may later prove to be of little value. In this paper, we report a pilot exploration that represents an initial step toward addressing this knowledge gap.

The system that we studied, the Electronic Medical Record Search Engine (EMERSE), is a full-text search engine designed to assist clinicians, administrators, and researchers retrieve information from narrative documents stored in electronic health records (EHR) [10]. It provides many personalization options for end users to tweak its look-and-feel, as well as functionality, such as how synonyms should be handled in a search. This study leveraged the audit trail data automatically captured in EMERSE, recording each user's interactions with the system, including modifications made to its default preference settings. In the study, we are primarily interested in answering three empirical questions: (1) whether the users of EMERSE modified the system's default appearance and functions; (2) what types of default settings tended to be altered more often than other settings; and (3) whether certain user characteristics, such as gender and clinical role, may be associated with how end users personalized the software.

Methods

The EMERSE System and the Empirical Study Setting

EMERSE is an application developed at Michigan Medicine [10]. The system was designed to facilitate information retrieval from EHRs to support administrative coding, chart auditing, and patient eligibility screening for clinical trials [11–13]. Its target users include clinicians, medical coding personnel, and clinical and translational researchers.

The system functions similarly to Google™. End users construct and submit their search queries via a web-based interface. Then, the system processes the queries in its information retrieval engine against a large repository of EHR documents, and returns documents ranked by key attributes such as relevance, genre, and time of creation. Many visual aids help users browse returned documents to quickly identify the information of interest. Since its initial deployment in 2005, the system has been routinely used by many clinical, operational, and research teams at Michigan Medicine.

Table 1 (on page 5) lists all personalization options that EMERSE offers. Items 1 through 10 fine-tune the visual appearance of the system (e.g., color and font); Item 11 instructs the system how to highlight matched keywords in monochrome printing; and Items 12 through 15 set parameters governing the system's functional behavior such as how to process user-submitted search queries and how to retrieve documents from the backend EHR database. Some simple personalization options are provided on the screen where actions take place. More complex, system-wide options can be modified through a dedicated "preferences" feature.

Figures 1 through 3 are screenshots of several representative personalization settings in the system. As shown in Figures 1 and 2, most of these settings are straightforward to use and only require one or two mouse clicks. The only exception is the heat-map preference pane (Figure 3), which offers a range of relatively complex parameters that users can tweak to control heat-map visual elements, such as colors and color gradations, for highlighting the relevance of search results.

Figure 1- A sample personalization setting for altering the system's visual appearance

Figure 2 - A sample personalization setting for altering the system's functionality

Empirical Dataset and Data Analysis Methods

The empirical data analyzed in this study were collected from

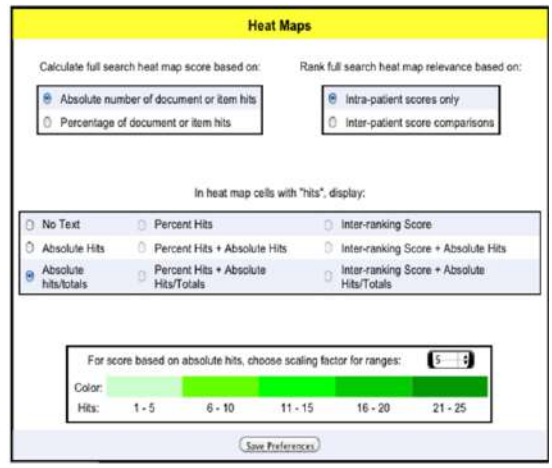

Figure 3 - Heat-map settings: the most complex personalization option provided in EMERSE

the audit trail logs automatically recorded in EMERSE. A total of 558 active users were registered when this study was conducted. Inactive users, who created an account but logged into the system less than five times, were excluded.

A user's usage level of the system might be a factor affecting personalization behavior: the more often a user used the system, the more likely s/he would make an effort to personalize it for better user experience. To test this hypothesis, we used "the number of times a user logged into the system" as the measure to determine a user's level of utilization (hereafter referred to as "system usage"). Other potential measures, such as number of searches performed or number of EHR documents retrieved, were also considered, but were not used as they are heavily task dependent. Number of searches performed, for example, might be artificially inflated as a user could revise and resubmit the same search query multiple times using different combinations of date ranges and patient lists.

Because of the small sample size of this pilot study, we only included two dichotomous variables to characterize the users: gender (female vs. male) and clinical role (clinician vs. non-clinician). Clinicians were those who had active patient care duties at Michigan Medicine based on the employee database provided by the human resources office. Non-clinician users were typically administrators, medical coding staff, IT personnel, and researcher coordinators and research assistants. We included the clinical role variable because frontline clinicians might use the system in distinctive ways compared to other 'back-office' types of users.

To determine whether the three explanatory variables examined in the study, i.e., system usage, gender, and clinical role, may predict an end user's software personalization behavior, we estimated three logistic regression models in which the dependent variable respectively represents (1) whether the user accessed the preferences feature provided in EMERSE (Model 1); (2) whether the user modified any of the system's default settings (Model 2); and (3) if the default settings were modified, whether the user customized the system's functionality or its visual appearance (Model 3). In addition, we also performed a drill-down analysis to examine if heavy users of the system might demonstrate distinct software personalization behavior compared to casual users.

To determine an approximate cutoff between 'experienced' and 'novice' users, we iterated the Model 2 regression by incrementally dropping infrequent users until the association

between system usage and personalization behavior disappeared. Then, we re-estimated each of the models using the data respectively generated by the 'experienced' user group and the 'novice' user group. In all models, we treated system usage as a continuous variable, and gender and clinical role as binary variables.

Results

Table 2 shows the descriptive statistics of the data. The 558 active EMERSE users logged in 157 times on average (median: 42); 378 of them were females (67.7%), and most were non-clinicians (83.3%). Less than one third of the users accessed the preferences feature provided in the system (29.9%); only 98 users (17.6%) actually modified the system's default settings. Among those who did, only 17, or 17.3% of the 98 users who personalized modified the default functionality settings.

Table 2 - Descriptive statistics

Measure	Result
Number of active users	558
Female	378 (67.7%)
Clinician user	93 (16.7 %)
Users who accessed any of the personalization settings	167 (29.9%)
Users who modified default settings	98 (17.6%)
Users who only modified default settings on functionality	17 (17.3% of 98)

Table 3 reports the modification frequency of personalization options. A majority of the frequently altered settings were related to the system's visual appearance. Very few functional settings were ever changed. Heat-map settings, the most complex personalization option provided in EMERSE (Figure 3), were barely touched by users. Nonetheless, "Heat-Map: Color Palette" was the second most frequently modified personalization setting. As detailed in Table 1, this setting is provided on the search results screen that users could access without invoking the heat-map preference pane.

Table 3 - Modification frequency of personalization settings

Type	Personalization setting	Modifying freq.
Visual effect	Highlight Viewed Notes	41
Visual effect	Heat-Map: Color Palette	39
Visual effect	Surrounding Context	19
Print	Highlight in Print	22
Visual effect	Color of Viewed Notes	13
Functional	History of Recent Queries	10
Functional	Spelling Alternatives	5
Visual effect	Line Wrapper	3
Visual effect	Heat-Map: Text	2
Functional	Synonyms: Negation List	2
Functional	Auto-Correct Search Terms	2
Visual effect	Heat-Map: Scaling Factor	1
Functional	Synonyms: Search Query	1
Visual effect	Show All Matches	0
Visual effect	Heat-Map: Score	0
Visual effect	Heat-Map: Relevance	0
Functional	Recommend Synonyms	0

Table 4 shows the regression results of the logistic models. System usage is significantly associated with whether a user would access (Model 1) the personalization options or change (Model 2) the system's default settings ($P < 0.05$ and 0.01, respectively). While gender does not predict a user's actual personalization behavior, females were more likely than males to view the system's personalization options (Model 1; $P < 0.05$). "Clinical role" does not predict a user's personalization behavior; clinicians and non-clinicians behaved similarly across all models. Lastly, whether a user would only modify the system's visual appearance, rather than its functionality, is not associated with any of the explanatory variables (Model 3).

Table 4 - Logistic regression results

Variable	Model 1: Assessing personalization settings		Model 2: Modifying system defaults		Model 3: Modifying visual appearance only	
	Odds Ratio	95% CI	Odds Ratio	95% CI	Odds Ratio	95% CI
System usage	1.00*	[1.00, 1.00]	1.00**	[1.00, 1.00]	1.00	[1.00, 1.00]
Female	1.54*	[1.01, 2.35]	1.22	[0.74, 2.03]	1.42	[0.44, 4.54]
Clinician user	1.04	[0.62, 1.76]	1.05	[0.56, 1.97]	0.54	[0.14, 2.08]

* $P < 0.05$; ** $P < 0.01$.

The drill-down analysis results show that the significant association between system usage and personalization behavior disappeared among those who logged in 48 times or more often (mean: 316; median: 137). Among the 'experienced' users ($N = 259$), 81 were females (31.3%) and 198 were non-clinician users (76.4%). With this information, we re-estimated each of the three models and found that among the 'experienced' users, gender no longer predicts their viewing of the personalization options. The results on the effect of clinical role continue to hold for both usage groups.

Discussion

Software personalization is a common strategy to accommodate heterogeneous needs and preferences by individual end users, especially when customization is flexible, and easy to use and understand [14]. In addition to improving utility and efficiency, personalization is associated with increased sense of control and identity [15]. However, in the human–computer interaction literature, it has been documented that users often do not take advantage of the benefits that personalization offers [8, 16, 17]. For example, Mackay (1991) studied how users personalized a Unix environment and found that most did not want to 'sacrifice' their time to modify the software's default settings [8]. Likewise, Manber et al. (2000) examined how web surfers personalized Yahoo! Applications, and concluded that people simply "take what is given to them and never customize" [16]. The results of this pilot study align with these earlier findings, as less than one third of EMERSEs active users accessed any of its personalization options, and only 17.6% modified the default settings.

This exploratory study is not positioned to provide direct evidence as to why the EMERSE users did not fully utilize personalization. The literature does provide some leads. The time and mental effort it takes to customize a software system is frequently quoted as a key reason for end users' lack of personalization [8]. Further, people fear errors of commission more than errors of omission (omission bias), thus are willing to forgo improvement opportunities in order to avoid making a bad choice [18]. People are also change averse (status quo bias), and tend to trade longer-term benefits (e.g., better future user experience) for short-term discomfort (e.g., coping with

suboptimal default settings) [8, 19]. This law of "power of defaults" has been noted in medicine, and advocated as possible leverage to improve quality of care through its strong influence on the decision-making processes of patients, families, and providers [20].

Although inconclusive and not necessarily generalizable, the findings of this pilot exploration might demonstrate the potential importance of 'defaults' in health IT design and the need to carefully calibrate the default behavior of a health IT system before releasing to end users. For example, as shown in the study, considerable time and effort was spent on building complex personalization settings in EMERSE, such as the heat-map preference pane, which were barely utilized by any of the end users. This suggests that understanding healthcare professionals' personalization rationale is crucial to informing design decisions, such as what personalization options to offer, and what not to, in order to avoid unnecessary software development costs. Further, the fact that the EMERSE users frequently modified the "Heat-Map: Color Palette" setting suggests the users still desired and were willing to personalize, but only through intuitive and readily accessible options that do not require laborious and cognitively challenging steps.

This study has several limitations. First, we only investigated a homegrown EHR search engine designed to support very specific information retrieval tasks. The idiosyncrasies of the system and of its user population may thus limit the generalizability of our study findings. Second, while this pilot exploration quantifies the EMERSE users' personalization behavior, it does not provide direct insights as to why some users chose to personalize the software and more importantly, why some others did not. Future work should therefore use qualitative approaches, such as observations and interviews, to better understand the rationale underlying healthcare professionals' software personalization decisions. Third, due to the small sample size, we were only able to characterize the users using two dichotomous variables: gender and clinical role. Future work may consider incorporating additional individual characteristics, such as age, medical specialty, computer literacy, and clinical experience.

Conclusions

In this paper, we reported a pilot exploration that examined whether and how end users utilized the personalization options in an EHR search engine system. We found that a majority of the users did not make an effort to modify the system's default settings. When they did, most modifications were related to the system's visual appearance rather than its functionality offerings. The lack of end user adoption of the personalization feature might result in lost opportunities for improving the system's performance and user experience. It might also diminish the value of building and implementing complex and costly personalization options in the system. As personalization can be essential to the usability and effectiveness of computerized systems in healthcare, future work is needed to develop a better understanding of healthcare professionals' software personalization behavior in order to inform more useful and more cost effective health IT development efforts.

Table 1. Personalization settings provided in EMERSE

	Personalization setting	Description	System default
1	Highlight Viewed Notes	A composite option that instructs the system how to render the font color of a returned document that has been previously viewed (i.e., visited links).	Off
2	Color of Viewed Notes		Blue
3	Line Wrapper	A toggle option instructs the system whether to place each matched keyword and surrounding document snippet on its own line for easy human inspection. When turned off, all snippets would be strung together to save screen space.	On
4	Show All Matches	Instructs the system whether to display only the first matched instance of a keyword that may have multiple matches in a returned document.	On
5	Surrounding Context	Sets the character length of the text snippets to be displayed adjacent to the matched keyword in the source document. Longer snippets provide more contexts but are more likely to result in visual clutter.	20
6	Heat-Map: Scaling Factor	A set of parameters that defines the appearance of heat-maps provided to visualize the level of 'relevance' of the returned documents to the search query. On a heat-map, color gradations are proportional to the number of matches found for a particular patient and for a particular document category (e.g., pathology vs. radiology reports); see Figure 1*a* in Seyfried et al. (2009) [12].	5
7	Heat-Map: Relevance		0
8	Heat-Map: Score		0
9	Heat-Map: Text		6
10	Heat-Map: Color Palette	Defines a range of colors that will be used to highlight matched keywords on a heat-map visualization; see Figure 1*a* in Seyfried et al. (2009) [12]. Unlike the other heat-map settings, the Color Palette can be assessed through the search results screen where the heat-map is displayed, without invoking the heat-map preference pane.	Blue, orange, green, purple, red, and black
11	Highlight in Print	As color highlights do not work well in monochrome printing, users may use this option to instruct the system to highlight matched search terms using a combination of bold, italics, or underline font styles when appearing in a printed document.	Off
12	Spelling Alternatives	EMERSE has the ability to detect spelling alternatives, i.e., words contained in a document that may appear to be the alternative or misspelled forms of the search terms that the user entered. This option instructs whether the system should identify spelling alternatives in the source document (when the option is turned on) or ignore them (when the option is turned off).	Off
13	Auto-Correct Search Terms	When this option is on, the system will automatically correct misspelling (e.g., "infectoin") or logic errors (e.g., an incorrect regular expression formula) found in the query.	On
14	History of Recent Queries	Sets the number of recent search queries to be saved in the system for future reuse.	100
15	Recommend Synonyms	EMERSE provides a synonym recommendation function that suggests interchangeable or related terms which the user may consider including in the query (e.g., "renal" ⇔ "kidney", "flu" ⇔ "influenza"). The "Search Query" option instructs the system to expand the keywords included in the search query itself; whereas the "Negation List" option instructs the system to expand the keywords included on the list set to be ignored in the search.	On
	Synonyms: Search Query		On
	Synonyms: Negation List		On

Skin Lesion Detection with Support Vector Machines on iOS Devices

Bianca Schnalzer, Baptiste Alcalde

Institute of eHealth, University of Applied Sciences FH JOANNEUM, Graz, Austria

Abstract

Automated wound detection has become a common issue in health care. A broad variety of image processing algorithms already exist, but they are very power consuming on mobile devices. Meanwhile the use of machine learning algorithms is on the rise and new frameworks have been developed to use these techniques with improved on-device-performance such as Apple Core Machine Learning Interface. In this paper, we evaluate the performance of libSVM for wound detection in practice.

Keywords:
Wounds and Injuries, Machine Learning, Image Processing, Computer-Assisted

Introduction

Skin lesion boundary detection is a fundamental necessity for medical documentation and treatment evaluation. Several well known image processing techniques already exist for identifying edges on images. However, it is a time-/resource consuming task on mobile phones. Trained machine learning models used on Apple Core Machine Learning (ML) focus on on-device-performance and are therefore less power consuming [2]. Once a trained algorithm has been integrated in mobile application, it can easily be used for detection of various features. The goal of this paper is to identify, implement and evaluate suitable and supported frameworks for skin lesion boundary detection

Methods

First, a literature review was conducted to identify suitable models and algorithms for skin lesion boundary detection. Second, the suitable models were analysed in more detail to identify pros and cons. Then, this paper deals with the feature selection and algorithm training as well as testing the usability of training and implementing such models.

The main families of techniques that are described in the literature related to wound classification are image processing algorithms, neural networks and Support Vector Machines. Although image processing methods and algorithms can provide good results, they often need several processing steps and possible server communication and can be a drain. Image processing was used for skin lesion boundary detection for instance in [4]. [6] summarized current work on wound segmentation, monitoring and software tools.

Support Vector Machines (SVM) are suitable to perform edge detection [7][8]. Features were composed of color, texture, region morphology and topology. SVMs appeared to be mature enough for the purposes of our project

Therefore, we focus on SVM techniques and evaluate SVM frameworks for iOS devices in this paper.

Results

Technical Information

Since iOS 11.0, Apple has provided Core Machine Learning Tools for the integration of machine learning models in apps. An advantage of having on-device machine learning algorithms is to enhance security, privacy and improve speed.

To date, many different kind of functionality have been built on the top of the CoreML layer such as Vision (for object or face detection) or Natural Language (for speech identification or speech recognition). The complete list of pre-trained models of Apple Core ML is available under [1]. However, none of these models could answer the needs of this project. Therefore, one of the contributions of this research was to develop a trained model for wound detection for iOS devices.

To use a trained model in a SWIFT project in XCode (developer environment for iOS), the model has to be converted. Conversion was done via Python [11] and coreml-tools [3]. Coreml-tools provides various scripts to model, utilize and convert supported models. CoreML restricts the choice of tools based on the desired model. To use SVM within CoreML, scikit-learn 0.18 and LIBSVM 3.22 can be used. In this paper, LibSVM [5] was identified as the most suitable framework.

Image Processing and Feature Detection

Several pre-segmented and labelled datasets are available for machine learning [10]. Unfortunately, no segmented medical image datasets were available. Therefore, another contribution of this paper was to take images from [13], preprocess and label them. Many features were examined during image processing. Texture and color information were identified as the main image features, as confirmed by [14].

Framework Evaluation

As mentioned before, LibSVM [5] was identified as a suitable framework for the needs of the current research. However, LibSVM only supports numerical data and the file format has to comply with a specific structure, where an indexed set of features is associated to a class. For image processing, MatLab [12] as well as ImageJ [9] were used.

The only supported version of LibSVM at the time of our experiments was 3.22. In this project, LibSVM was used via command line and Python. A main step was to evaluate suitable

training parameters for the given problem. LibSVM supports one-class and multi-class classification as well as regression.

The most important parameters, e.g., kernel-type (-t), degree of kernel function (-d), coefficient, cost function (-c) and gamma of kernel function (-g) as well as epsilon (termination criterion) can be set [5]. An essential criterion in classification result was to keep gamma high, because gamma reduces misclassification. Short classification time was also an advantage of the reduced model.

The image data set contained 16 kinds of wounds. Several patches (image crops) were created to categorize pixels in 3 classes (wound, skin and background).

Initially, default training was conducted with all image patches. Additionally, randomly selected data points were taken to train the classifier. Producing the training set was carried out via a Python script (subset.py), which is available within the LibSVM library. Table 1 gives a brief overview of the training parameters of the five best-performing models.

Table 1 – Overview of training parameters of the five different models.

Model	Parameters
reducedDataSet	-s 0 -t 2 -c 10 -g 1000 -h
reducedDataSet2	-s 1 -t 2 -c 10 -g 1000
woundDetectionReduced5000	-s 1 -t 2 -c 10 -g 1000
woundDetectionReduced50000	-s 1 -t 2 -c 10 -g 100
woundDetectionFULL	-s 0 -t 2 -c 1 -g (1/num of features)

The model with 5000 randomly taken data points had the best performance (76%) during the testing process and was selected for further refinement and integration in an app. The model expects a pixel input in a multi array and provides a pixelwise classification.

Discussion

We clearly see an opportunity of future works in the direction of CoreML tool compatibility. For instance, TensorFlow has a huge acceptance in the developer community and is to-date not included in the list of supported tools, even if Keras can use it as Backend.

Related to this project, feature selection enhancement is still a possible task. Mean colour and dominant colour can possibly be added as additional features. Some researchers postulated integration of texture information to gain better results. Feature dimension reduction, e.g., with PCA (Principal Component Analysis), could possibly reduce training time.

In this work, we used only freely available skin lesion images. As a result, our image dataset was limited. In order to have a performant app, we would need a larger skin lesion image dataset and a professional labelling of these images.

Conclusions

The goal of the current paper was to evaluate machine learning techniques and frameworks for skin lesion boundary detection suitable for deployment on iOS devices, and to develop an App using the selected solution. We identified SVMs as a mature candidate for our project. Then, we developed a labelled image dataset based on [13], as well as a MatLab script for the conversion into the LibSVM data format. Furthermore, we implemented a pre-trained model for skin lesion boundary detection, integrated this model in an App and performed a practical evaluation.

An Ontology for Describing Health IT Interventions: Methodological Considerations

Elske Ammenwerth[a], Verena Dornauer[a], Maryam Ghalandari[b], Franziska Jahn[b], Nicolet de Keizer[c], Alfred Winter[b]

[c] *Department of Medical Informatics, Amsterdam University Medical Center, Netherlands*

Abstract

Health informatics as a young, interdisciplinary discipline lacks a unified terminology in some areas. This is especially true when trying to properly describe health informatics interventions developed and deployed to improve quality and efficiency of patient care. We aim at developing a health IT ontology which allows systematically describing health IT interventions. To achieve this, we combine a deductive and an inductive approach. First results are promising and may later be extended by a folksonomy.
Keywords:
Medical informatics applications, terminology, classification

Introduction

As part of evidence-based health informatics, researchers and practitioners need to be able to describe health IT interventions precisely to allow the publication and aggregation of related evidence. Unfortunately, available terminological systems such as MeSH terms, ACM computing classification systems or IEEE thesauri do not allow a specific description of health IT interventions. As another challenge, terminology in health IT is full of synonyms and homonyms increasing the difficulty to identify a specific intervention. Also, health IT interventions can range from quite small interventions such as a functionality (e.g., an overdosing alert) to more complex interventions (e.g., a full-fledged CPOE system).
The reason for missing comprehensive terminological systems for health IT interventions may be that health informatics is a comparably young and interdisciplinary discipline, and fast technological developments make clear and stable definitions of health IT interventions challenging. We observed this problem when developing and maintaining a health IT evaluation database [1]. We did not find a practical health IT intervention terminological system that we could use for describing and searching for health IT evaluation studies.
Our idea is to build an ontology for health IT interventions. An ontology is a (formal) specification of concepts, relations and functions in a domain. Such an ontology would help us properly describe various types of health IT interventions and their impact by defining concepts and their semantic relationships.
Our research question is therefore: How can we develop an ontology for describing health IT interventions that allows describing health IT interventions in a structured, sufficiently detailed way? In this paper, we describe our methodology consideration for ontology development. The research takes place in the context of the project "HITO: A Health IT Ontology", funded by the Austrian Science Fund FWF (I 3726-N31) and the German DFG fund (WI 1605/11-1).

Methods

We started with the methodology for taxonomy development by Nickerson [2]. A taxonomy aims at structuring and organizing knowledge (i.e., concepts) of a field, often in a hierarchical way [2]. An ontology extends a taxonomy by adding information on semantic relationships between concepts. We thus found the structured approach by Nickerson adequate as a first step.
The method by Nickerson proposes a mix of deductive and inductive steps. Nickerson argues that intuitive, "ad hoc" methods for building a taxonomy, where the researcher just relies on his knowledge, should be avoided. We endorse this and strive for a reproducible taxonomy development.
The inductive approach involves observing empirical cases (here: health IT evaluation studies) that are then analyzed to determine dimensions and characteristics of the taxonomy. The deductive approach derives a taxonomy from theory or conceptualization. Both approaches are used in an iterative manner until predefined ending conditions are met [2].
Before starting inductive or deductive activities, Nickerson proposes to determine the meta-characteristics of the taxonomy that will serve as the basis for defining the purpose of the taxonomy and the expected users.

Results

Following the Nickerson method for taxonomy development, we first define the meta-characteristics, users and intended use of our planned health IT intervention ontology.
We define a health IT intervention as any IT-based intervention that has a potential impact on the process or outcome of patient care. The term "IT-based intervention" can comprise of an IT-based functionality within an application component (such as a new dosing alert within a medication system), an application component with a set of functionalities (such as radiology information systems), or a combination of application components (such as a clinical information system comprising a medication system and a patient portal). AnIT-based intervention can also comprise of a set of physical data processing components (such as tablets). Most often, an IT-based intervention will comprise of both software and hardware components.
The intended users of the health IT ontology are health IT researchers, health IT managers, and health IT users. These

groups are interested in evidence on the impact of health IT interventions on patient care. They are more interested in high-level characteristics of a certain type of health IT intervention than on technical specifications, as these are quite context-dependent and may quickly change over time due to technological developments.

The ontology should help these user groups in the following situations:

- A researcher wants to publish a health IT evaluation study. In the publication, he wants to clearly describe the health IT intervention using the ontology.
- An IT manager searches for available evidence on the impact of a specific type of health IT intervention. The ontology allows him to clearly describe which type of health IT intervention he is looking for.
- A researcher wants to conduct a systematic review on the impact of a given type of health IT intervention. The ontology allows him to clearly describe which type of health IT intervention he is looking for to find all published evaluation studies on this intervention.
- A researcher wants to develop a map for evidence-based health informatics. This map should visualize how much evidence has been published for which types of health IT interventions. The ontology is the basis of this map.

Our ontology thus aims at carefully describing health IT interventions and to distinguish between various types of health IT interventions and their characteristics. We started with a manual review of available health IT taxonomies through a literature search and by analyzing health IT taxonomy reviews such as [3]. We identified e.g. the following taxonomies:

- A taxonomy for rule-based functionality of CPOE systems with four dimensions and up to six characteristics in each dimension by Wang (2002);
- A list of fifteen types of application components by Ammenwerth & de Keizer (2005);
- A taxonomy of CDSS systems with five dimensions and up to six characteristics in each by Berlin (2006);
- A taxonomy of hospital functions by Winter (2011);
- A taxonomy of front-end capabilities of CDSS systems with six dimensions and up to 14 characteristics in each dimension by Wright (2011).

At the moment, we are mapping the identified taxonomies to each other to identify both overlapping and unique dimensions and/or characteristics helping to describe unique attributes of health IT interventions. The result of this deductive approach will be a first proposal of dimensions and characteristics for our ontology.

We also started with the inductive approach and conducted a manual qualitative content analysis of five randomly selected recent evaluation studies using the software MAXQDA. From these studies we were able, in the first iteration, to identify dimensions and related characteristics for describing a health IT intervention:

- User group: Physician, nurse, other clinical user group, patients/relatives, administrative staff, other.
- Organizational unit: Location of intervention; such as surgery, psychiatry, primary care, etc.
- Type of application system: For example, lab information system, nursing documentation system
- Name of software product
- Offered software features: For example, taken from the HL7 EHR-System Functional Model [4].
- Supported enterprise function: For example, hospital administration, quality management, decision making, or patient information.

Before continuing the inductive approach with other types of health IT interventions, we will now combine the results of the deductive literature review with the results of the inductive approach. The results will be a first iteration of an ontology of health IT interventions. Further, inductive steps will analyze evaluation studies of other frequent types of health IT interventions. Results will then be added iteratively to the ontology, until the ending conditions as defined by Nickerson are reached.

Conclusions

The presented methodological considerations should lead to an ontology for health IT interventions that is parsimonious regarding the number of dimensions, robust to clearly differentiate health IT interventions, comprehensive to be able to describe studies, extendible and explanatory, as demanded by Nickerson [2]. We plan to make the contents available via Linked Open Data.

One idea for future work is to use the resulting health IT ontology to infer new knowledge, such as a better definition of various types of application components via a cluster analysis of characteristics.

Another idea for future work is using the vision of a folksonomy [5] which is a user-generated system of classifying and organizing health IT evaluation studies by the use of metadata such as tags. These tags could be used to identify and add missing parts in our ontology.

Abstract

Grenoble Alpes University Hospital (CHUGA) currently deploys a clinical data warehouse PREDIMED to integrate and analyze for research, education and institutional management the data of patients treated at CHUGA. In this poster, we present the methodology used to implement PREDIMED and illustrate its functionality through three first research use cases.

Keywords:
Big data, medical informatics, data warehouse

Introduction

Large quantities of data are generated by healthcare and the volume is increasing every year [1]. This data is diverse and includes electronic health records, -omics, imaging, sensor and textual data, which are complex, heterogeneous, poorly annotated and generally unstructured [2]. The application of big data in healthcare is, nowadays, a fast-growing field [3-4]. Health datasets have been widely reused for research in numerous studies [4]. In particular, Clinical Data Warehouses (CDW) collect and reuse healthcare data for various applications covering all domains of medicine worldwide. For data of such volume, novel powerful technologies are required: non-relational and distributed databases for data storage and handling, artificial intelligence, machine learning and, more specifically, deep learning algorithms for data analysis. A number of reviews have been published focusing on the applications of deep learning in healthcare [2], in particular, in medical imaging [5] and –omics [6]. For diabetic retinopathy [7], skin cancer [8] and breast cancer [9] deep learning algorithms have demonstrated the ability to diagnose pathologies using medical images with at least the same performance as medical experts.

CHUGA is the 12th largest hospital and the first trauma center in France. Having a powerful technical environment, with all patients' data including new data sources (genetics, internet of things, medical imaging, surgery videos), would certainly increase the re-usage of the data produced by CHUGA.

In the following, we describe the methodology used to implement PREDIMED (acronym in French for: Plateforme de Recueil et d'Exploitation des Données bIoMEDicales), a CDW designed to reuse the data of patients treated at CHUGA. We then present the chosen architecture and illustrate the functionality of PREDIMED through use cases. We believe that this work is valuable for any healthcare institution considering building a CDW.

Methods

To implement a CDW, a group was created gathering specialists from transverse departments of CHUGA (Public Health, Imagery, Biology, Information Systems, and Pharmacy) as well as specialized medical experts. The expected work was divided into 9 work packages (WP) that we describe below.

Results

WP1 Possible CDW use cases. A survey was taken on the possible use of a CDW by medical staff and researchers and the results fall into four major categories: *research* (population cohorts and analysis of the corresponding data), *education* (providing real-life cases for teaching), *institutional managemen*t (healthcare organization and optimization) and *healthcare* (patient-specific diagnostics and treatment). It was decided to use PREDIMED for the first three use cases and not to consider the last one for legal and maintenance reasons.

WP2 Choice of the technical solution. State-of-the-art solutions were compared in their functionality, maturity, scalability, security, conformity to the applicable laws, and costs (both material and human resources). Modular open source architectures were chosen for PREDIMED to freely develop new functionalities and algorithms, as well as (we believe) to reduce costs. Powerful and scalable big data technologies were chosen over relational databases as they allow for distributed storage and analysis as well as for text data exploration. Modern machine learning, deep learning and data mining algorithms perform well on these architectures.

WP3 Data model and data import. Graph data model suitable for a general hospital was created to avoid 'data swamp'. The advantages of a graph model are more flexible navigation and easier data interconnection and refinement. The first PREDIMED data sources are: patients, visits, diagnoses, texts, healthcare professionals, laboratory results, structure of medical units, medical imaging, and drug prescriptions. Some of the data was loaded partially for the proof-of-concept.

WP4 Confidentiality and security. PREDIMED contains personal data and thus has to be authorized by the independent supervisory authority in terms of the GDPR (CNIL in France) to switch to the operational phase. This authorization is expected in 2019. Every project using PREDIMED data must also be declared to the supervisory authority. A high-level of security is provided for PREDIMED, e.g. all access to the data will be tracked and daily logs will be analyzed automatically.

WP5 Architecture implementation. We deployed several tools for multiple views on the raw data. Hortonworks Data Platform (HDP) enables agile application deployment, machine and deep learning workloads, security and governance. ArangoDB (a powerful multi-model NoSQL database) and ELK stack allow to navigate through the data model for cohort data selection, analysis and visualization. PREDIMED data is accessible via scripting notebooks (with spark, scala, python, R, SQL, Hive, SolR, etc.), and via developed API features.

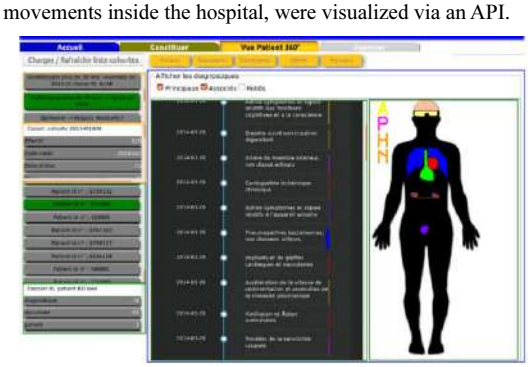
WP6 Governance. To regulate the access to the PREDIMED data, a governance model was developed. Every project requesting PREDIMED data must be approved by: Steering Committee (evaluating the feasibility and estimating the necessary investment), Scientific and Ethics Committees and obtain the legal authorizations if needed.

WP7 Interoperability. A survey on the thesaurus used in CHUGA by medical specialty was taken and has shown that in medical practice local codes are more common than international dictionaries (with rapid mappings), but for medico-administrative activities standardized codes are used.

WP8 Business model. A business model was developed as it was shown in literature that the CDW can generate benefits [10]: each project using PREDIMED data participates in its development in terms of human resources and/or hardware.

WP9 Proof-of-concept through three use cases. A proof-of-concept demonstrator was built and PREDIMED usage was illustrated on 3 research use cases on populations of moderate size (the same code can be used in the future on more data).

In the first use case, we studied the feasibility of real time selecting a population of patients according to diagnoses (diabetes), demographics, and treatment criteria, using the graph query interface that we designed using ArangoDB graph navigation features and visualizing corresponding data using ELK stack. The data of individual patients, such as timelines summarizing their documents, prescriptions, diagnoses and movements inside the hospital, were visualized via an API.



In the second use case, we investigated somatic mutations in 60 onco-hematology patients to determine the genetic signature of the patients' clinico-biological characteristics by linking multiple data sources, including genetics. We characterized patients' populations by mutated gene and combined the mutational status with biological values. We looked for keywords in the patient's documents to find the frequent comorbidities and cancer relapses by mutated gene. Kaplan-Meier survival curves by mutated gene were plotted.

In the third use case, we selected 300 patients with lung cancer by searching for keywords in patients' documents, and linked all data available for these patients with their medical images (raw data and metadata of DICOM files), and plotted the greyscale histograms. The two last cases were coded on the HDP platform via Zeppelin scripts by one engineer.

Conclusions

We have reported the CHUGA's experience of implementing a CDW PREDIMED: we show that we are able to take data out of silos, link this multimodal multisource data and access new data (textual and genetic data, raw data as image pixels), explore, analyze and visualize data, and thereby implement use cases for research, education and hospital management.

PREDIMED aims to be as exhaustive as possible in terms of data available for the CHUGA patients. Thus, important future work includes integration of more internal data sources (service-specific databases), and external databases, such as research, environmental and open data. Another direction of future work concerns the heterogeneous quality of the source data that should be measured and controlled. Interoperability (technical and semantic) is crucial for projects at a national and worldwide level and CHUGA is an active participant of a French national initiative aiming to group local CDW into an interoperable network – a Health Data Hub.

Abstract

To describe information content in an automatically generated patient summary worksheet (PS) comparatively to electronic health records (EHRs) for 90 patients. The PS was more focused on the cure than person-centred care. Ergonomic solutions based on the users' needs should enhance shared decision-making and improve the healthcare professional-patient relationship.

Keywords:

Electronic health records, electronc data processing, patient education handout

Introduction

General practitioners (GPs) were assigned with the mission to update a patient summary dataset with electronic health records (EHRs), according to the French interoperability framework of health information systems (CI-SIS) **[1]**. The patient summary worksheet (PS) automatically generated from the patient summary dataset was expected to improve care coordination and personalised care planning **[2]**, especially in multidisciplinary primary care organisations and for telemedicine. Despite incentives, little was known about the patient summary management in primary care.

Objective

To describe information content in the automatically generated PS comparatively to information contained in EHRs.

Methods

A cross-sectional study was conducted in 2017 in three primary care structures in the department of Alpes-Maritimes in the southeast part of France. Nine GPs were recruited from the Department of General Practice, University of Nice. Five GPs used one electronic health record system (system A), and four used another one (system B). After performing tests, 90 EHRs (10 per GP) were selected and compared to the 90 PS. Items were classified as present (present in PS) or absent (in EHRs but absent from PS). Medical history was recorded according to the second edition of International Classification of Primary Care (ICPC-2). Multimorbidity was defined as the presence of two or more chronic conditions [3]. Negative signs and spontaneous recovery from isolated acute medical conditions like seasonal or common viral infections were not compared. Drugs and vaccines were recorded according to the Anatomical Therapeutic Chemical (ATC) classification. Drugs in the PS were compared with the regular treatment reported in EHRs. A logistic regression was performed to identify factors associated with a low rate of absent items. Statistical significance was defined as $p<0.05$. All analyses were performed using R® packages for statistical analysis.

Results

EHRs were selected for 49 females (median age: 71, 29-91 years) and 41 men (median age: 69, 29-91 years). 86% of the patients were multimorbid.

2311 items were reported: 1747 items (mean: 19, 1-52 items) were present in patient summaries while 564 items (mean: 6, 0-38 items) were in EHRs but not in PS (Table 1).

Vaccines	**0**	**55**	**0**	**55**	**0**		**110**	**(19%)**	**110**	**(5%)**

Table 2 – Factors associated with low absent items

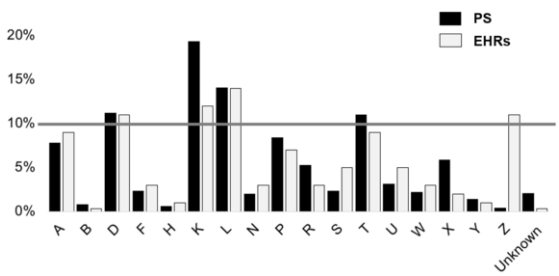
Absent items	Simple logistic regression			Multivariate logistic regression		
	Coeff.	**OR [95% CI]**	***p***	**Coeff.**	**aOR [95% CI]**	***p***
Patient age	0.01	1.01 [0.98-1.04]	0.535			
Male gender	–0.19	0.83 [0.35-1.97]	0.671			
Chronic conditions	0.005	1.004 [0.86-1.17]	0.951			
EHRS – system B	1.47	4.33 [1.77-11.15]	0.002*			
Medical history	–0.04	0.96 [0.90-1.01]	0.108	–0.12	0.88 [0.81-0.96]	0.004*
Present drugs	0.17	1.19 [1.10-1.31]	< 0.001*	0.24	1.28 [1.15-1.46]	<0,001*
Ended or stopped drugs	0.12	1.13 [1.01-1.28]	0.041*			

Coeff: coefficient; aOR: adjusted odds ratio; * significant *p*-value

Fifty-four percent of the drugs in PS did not match with the regular treatment: 46% (401 drugs) were ended or stopped, 8% (72 drugs) were redundant. Only 8% of drugs were in EHRs, but 84% of them had an important therapeutic value and 37% added at least one interaction.

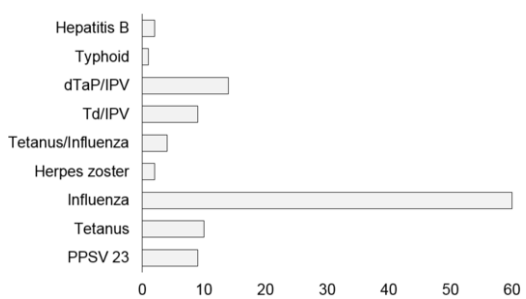
In PS, 78 items were redundancies in medical history, especially 72 redundancies between past medical history and current conditions. The rate of items in PS was higher than 10% for digestive (D), cardiovascular (K), musculoskeletal (L) and metabolic (T) chapters. The chapters with a rate of items higher than 10% in EHRs were almost the same as those in PS, but social problems (Z) were also pointed out in EHRs (Figure 1).

Figure 1– ICPC-2 chapters



All vaccines were in EHRs, but none were in PS (Figure 2). Items in EHRs were retrieved more frequently in medical notes (33%) and in discharge summaries or after-visit summaries from other healthcare providers (32%).

Figure 2– Items for immunisation in EHRs but absent in PS



After univariate analysis and elimination of too strongly correlated variables, two variables remained in the stepwise regression model: the number of items in medical history and the number of drugs present in PS (Table 2).

Conclusion

The PS was more focused on the cure than person-centred care. The rate of absent items would be a poor relevant indicator of the quality of a patient summary. Further studies could be conducted to assess the influence of physical and cognitive ergonomics upon the healthcare professional-patient relationship and the shared decision-making process. However, the secondary use of patient summary datasets to build predictive models in context of data-driven medicine raises major ethical issues.

Abstract

We present the regional professional network to support the Renal Epidemiology Information Network (REIN) registry in maintaining high quality data production and information analyses in Ile-De-France region. The network is based on a long term partnership between the nephrologists and a regional methodology support unit. It integrates clinical research assistants for data quality control. We also present organizational methods on maintaining the registry and enhancing information analyses and automating analyses reports.

Keywords:

Registries, Data Science, End-Stage Renal Disease, Data Quality, Summary Report.

Introduction

The Renal Epidemiology and Information Network (REIN) registry [1,2,3] is organized at French national and regional levels, around a network of professionals and public health decision makers involved in ESRD health care and concerned by questions raised by kidney replacement therapies. The network contributes to the elaboration and assessment of health care strategies to improve ESRD prevention and patient care. REIN registry is supported by the Agence de la Biomedecine (ABM) [4] and by the Société Francophone de Néphrologie Dialyse et Transplantation (SFNDT) [5]. Data production started in January 2002, and was progressively extended to cover all French metropolitan regions by the end of 2010 and French overseas regions in 2012. REIN registry relies on primary data sources directly collected at bedside in the dialysis units. In contrast, the United States Renal Data System (USRDS) [6] and with the European Renal Association - European Dialysis and Transplant Association (ERA-EDTA) [7] both rely on secondary data sources.

Regional organization level was privileged since the inception of the REIN project. The region represents an appropriate level of proximity for patient data collection, quality control and data analyses. It is adapted for networking between professionals and decision makers at the regional institutions. REIN regional committees involve nephrologists, decision makers, public health insurers, methodologists and patient representatives. A nephrologist is elected as the REIN-regional program coordinator. Partnership between nephrologists and data analysis methodology departments, are highly recommended to guarantee resources, expertise and added value for data quality control, analyses and epidemiology studies. Nephrologists in dialysis care units in Ile-de-France region (about 12 million inhabitants in 2016) [8] have been participating since 2005 in the REIN registry. Data production in Ile-de-France was considered exhaustive and stable since year 2007.

Methods

REIN Regional Network Organization

The "Agence Regionale de Santé Ile-de-France" (ARS-IDF) represents the Public Health Ministry in the region. It plans ESRD related care strategies and manages resource allocations and authorizations for replacement therapy centers. Nephrologists gathered in "Association des Néphrologues d'Ile-de-France (ANEDIF)", to assure the deployment, development and management of the REIN project in the Ile-de-France region [9].

The Biostatistics Unit at Necker University Hospital actively participates in the promotion of the REIN project and developed an application called MSIS (Multi-Source Information System), used from 2002 to 2014, to facilitate REIN' data production and regional deployment [10]. The Biostatistics Unit assists and accompanies ANEDIF members in:

- Supervising the clinical research assistants training and missions.
- Developing methods and applications for assuring data integrity and quality.
- Providing methodology and application support for data analyses.

Clinical research assistants participate in ensuring the respect of the REIN charter [4] and interacting with nephrologists in the care units' environment. They consolidate data and give the start-signal for data analyses. Clinical research assistants facilitate communication and play a major role in maintaining the vivacity of the regional network and registry.

Analyses corpus contents

Regional data to be analyzed are presented in the form of CSV files and require minimalistic data re-arrangement. R statistics scripts are developed for analyses [11]. A data model adapted to statistical analyses is developed as a first step. Study patient populations are then filtered as a function of the analysis purpose: demographic, geographic, public health, disease and specific research topics, etc.

General outline of the statistical analyses subsets are agreed upon over time. They are systematically and longitudinally represented in the annual report. A final collegial proof-review validates the information in the synthesis report and presented to the annual assembly of the ANEDIF.

Report enhancements

Methods to automate the analysis processes from data source reading to producing analytic results in a suitable, easy to read and quality document are developed. R statistics remains the statistical software for data analyses. Related packages for tabular and graphics are used. Knitr package, is tested to automatically edit the results using LaTeX editor and to publish the report in a portable format document (.pdf) [12].

Results

Network status

Nephrologists in 215 care units participated in the producing quality data to the REIN regional registry. Their commitment through the ANEDIF association to the regional network remained active from more than a decade. The role of the clinical research assistant is essential for assuring the completeness of data production and quality control as well as for the regional network animation.

Data production and analyses improved over the years in the region. ANEDIF and the regional supporting Biostatistics Unit at Necker University hospital are the privileged interlocutors of the ARS-IDF for ESRD related decision making and care strategy policies. Nephrologists used the information presented in the annual report for improving their knowledge and as a support in discussions with local supervising authorities.

Report automation

REIN regional annual report in Ile-de-France has been finalized and automated. Its contents and organization have been accepted among professionals involved in the regional REIN network. It took few minutes to edit an updated report. Annual variations were commented as necessary. Results were presented in the form of free text comments, tables and graphics. For example : Flow diagram of ESRD patients in the region represent ESRD patient incidence in Ile-de-France which concerned 1864 new cases of resident patients, 12 non-residents and 95 ESRD patients who received transplantation as inaugural replacement therapy. ESRD prevalence in Ile-de-France 8106 ESRD resident patients in Ile-de-France were treated by dialysis on 31^{first} 2017, 58 resident patients were treated out of the region. Departmental disparities representing standardized ESRD incidence in Ile-de-France, were observed. Prevalence evolution shows a regular growth of an average of 160 patients per year during a 6 years study. The causes of re-hospitalizations in the context of ESRD are dominated by the context of pre- or post-kidney transplantation, vascular diseases, heart diseases, infectious disease and dialysis arterial-venous fistula.

Conclusion

Regional professional network to support REIN registry in maintaining high quality in data production and information analyses are described. The network organization is based on a long term partnership between the medical domain professionals, organized in agreed-upon association, a regional epidemiology and methodology supporting unit. It integrates from the start the clinical research assistants, for supporting the clinicians in data production and quality control. Methods on how to maintain and improve the network activities are extended to additional medical domain, e.g., Neurodevelopmental Disorders, in a project entitled “Troubles Envahissants du Dévelopment - Information System” (TEDIS).

Standardizing Data from the Dead

Shamsi Daneshvari Berry[a] and Heather J.H. Edgar[b,c]

[a]Department of Health Informatics and Information Management, University of Mississippi Medical Center, Jackson, MS, USA
[b]Department of Anthropology, University of New Mexico, Albuquerque, NM, USA
[c]Office of the Medical Investigator, University of New Mexico, Albuquerque, NM, USA

Abstract

A database of full-body CT scans and associated lifestyle and health data from decedents who underwent an autopsy at the Office of the Medical Investigator (OMI) is under construction. The dataset has 68 metadata fields containing data from the OMI's database and interviews with next of kin. Some metadata fields could be mapped to existing standards, but the majority of fields required some modifications to current standards or the creation of new standards.

Keywords:

Vocabulary, controlled; imaging, three-dimensional; forensic anthropology

Introduction

Informatics is most commonly focused on using data from the living to improve the health of the living. The research presented here takes a novel approach, using data from the dead to create a database that can be used to improve the health of the living. Medical examiner data is a great resource for informaticians due to a number of factors, the most important of which is known cause of death.

The Office of the Medical Investigator (OMI) is a statewide, centralized medical examiner's office for the State of New Mexico. Any individual who is found dead with an unknown cause of death or who has died in a sudden, violent, untimely, or unexpected manner is routed to the OMI for a possible autopsy. In 2010, the majority of cases were deaths from natural causes (25%) or accidental deaths (35%), followed by suicides (17%), deaths from unknown causes (13.5%), and homicides (9.5%) [1]. The makeup of those cases closely mirrored the ethnic and racial composition of the state [2].

The Center for Forensic Imaging at the OMI was awarded a grant from the National Institute of Justice in 2010 to evaluate whether postmortem computed tomography (CT) scans could supplement or supplant a traditional autopsy. Between 2010 and 2017, this work produced over 15,000 whole-body 3D CT images.. The trove of image information is enormous; however, the scans were not associated with any organized metadata about lifestyle, health, or cause of death.

In 2014, a study was performed to determine a minimum data set using a modified Delphi method [3]. Researchers from a wide variety of fields (anthropology, medicine, forensics, informatics, epidemiology, biomedical research, and dentistry) used an iterative process to select 59 variables that they believed to be essential to making the CT scans useful for researchers in multiple fields.

The National Institute of Justice awarded a grant in 2016 (2016-DN-BX-0144) to create a database of deidentified CT scans along with associated lifestyle, health, and cause of death data. The associated information includes nine additional variables that are derived from the investigator's research. The data for all variables are derived from both VAST (the OMI's primary database, used to track the investigation of causes and manners of death) and phone interviews with next of kin.

Data in VAST is primarily stored in unstandardized free-text fields. The lack of standardization limits the ability to retrieve information effectively and necessitates a significant time investment to clean the data before it can be used. In its current form, as data complexity increases, data recovery becomes less accurate.

The New Mexico Decedent Image Database (NMDID) is available at NMDID.unm.edu.

Methods

Once the metadata fields were operationalized, each field was searched as a term in the Unified Medical Language System (UMLS) [4] to determine which data standards already existed for that concept. Each data standard was investigated and its ability to capture the appropriate level of data was analyzed. For example, some data was coming from next of kin and could not be expected to be at as technical a level as other data coming from medical records in the VAST database.

Vocabulary standards were selected, modified if necessary, and implemented in the database. For those metadata fields where no known vocabulary standard existed, the authors determined a new standard for this particular data set.

Results

After determining which variables needed to be combined, which needed to be separated into two or more fields, and adding those from the author's research, we had 68 metadata variables in three areas: census, health, and circumstances of death.

There were three categories of vocabulary standards for metadata capture:

1. An existing data standard that required no modification;
2. A data standard that existed but required modifications;
3. No appropriate data standard existed, so a new standard was created.

18 of the 68 metadata fields had existing standards that could be applied without modification. Standards were derived from multiple sources including LOINC (including trial codes), SNOMED CT, internal standards specific to the OMI, ISCO, ICD-10, and RxNorm [4].

Five of the 68 metadata fields required a modification from an existing standard. These standards were primarily from LOINC (including trial codes) [4].

The remaining 45 metadata fields did not have an appropriate data standard to draw upon. This included simple metadata fields like year of death or length of time at current occupation,

which was easily described as {yyyy}. However, creating standards for other fields was more difficult; for instance, when working with medical diagnoses, a balance had to be struck between knowledge of next of kin and medical detail.

Conclusion

Vocabulary standards are of the utmost importance in the creation of databases in order to ensure interoperability. As such, we searched medicine, forensics, anthropology, and other fields for standards to apply to our new database. 26% of the metadata fields could be mapped directly to existing standards. This included fields such as smoking status, sex, gender, and marital status. Seven percent required a modification of the standard to be applied to this particular database. Among those modified were birthplace and drug usage. The majority of the metadata fields (66%) required new standards to be developed. Many of the fields used in medical examiner data are not yet standardized, as the data historically have been in a free-text format.

Medical examiner data is an underused resource for public health data, because, unlike vital statistics data, it has generally been unavailable to the research public. However, medico-legal data has several advantages. For instance, it is associated with lifestyle and health data unlike vital statistics, which, while easily available and standardized, are not very rich. The NMDID is an entirely new resource that will provide over 15,000 CT scans and their associated metadata to researchers. NMDID sets a precedent, and perhaps some new standards, for the use of medico-legal data from other resources worldwide.

Linked Open Data in the Biomedical Information Area: A Keywords Analysis

Stefano Bonacina

Department of Learning, Informatics, Management and Ethics, Karolinska Institutet, Stockholm, Sweden

Abstract

The objective of this paper was to determine the extent of the usage of "Linked Open Data" within biomedical literature. Applying PRISMA statement for literature reviews, forty-six papers were included in the analysis and keywords identified. Keywords have been classified according to MeSH categories, when possible. Twenty-three keywords had a frequency > one, 146 keywords had a frequency equal to one. Two MeSH categories were recurring. Future work includes applying association rules learning to keywords.

Keywords:

Semantic Web, Review Literature as Topic.

Introduction

Based on protocols defined by the World Wide Web Consortium (W3C), Semantic Web allows data sharing among applications and application-application cooperation, even without human intervention [1].

In the context of Semantic Web, the term "Linked data" is about linking and sharing resources of data (e.g., datasets, knowledge bases) generated and exposed by heterogeneous authors (e.g., governmental departments, research institutions, industry) [1]. When linked resources of data, e.g., heterogeneous datasets connected each other, are exposed through open access, the "Linked Open Data" paradigm is fulfilled, according to the "Linking Open Data" community project [2]. Operatively, "Linked Data" resources are represented with the Resource Description Framework (RDF) [3], a family of standardised data formats (RDF is explained briefly in the next section).

In 2016, we published a review paper that gave a view of research relating to "Linked Open Data" (LOD) in the area of health- and clinical-care [4]. Widening the scope, and including publications from the last two years, the objective of this paper is an attempt to determine the extent of the usage of linked open data within biomedical literature. The main questions guiding this review were as follows,

1. To what extent "Linked Open Data" is used within Biomedical Information research?
2. How could it be represented in a synthesised way?

The rest of the paper is organized as follows. The next section is a short background on Semantic Web technology, and RDF data format. Then, the methods used in the research and the obtained results are presented. Finally, some concluding remarks end the paper.

Semantic Web

Semantic Web stack is a set of protocols and computer languages, organised according to a layered structure, where communication is allowed between adjacent layers [5]. Semantic Web stack has been implemented to achieve data sharing among applications. In the stack, three main computer languages are: the Web Ontology Language (OWL) [6], the Resource Description Framework (RDF) Language [3], and the SPARQL Protocol And RDF Query Language - SPARQL language [7], which has a recursive acronym. OWL and RDF are for specifying ontologies, which are collections of data and meta-data exposed to the web and shared among computer applications [1,6]. Similarly to a simple sentence in English (which is composed by a Subject a Predicate, and an Object), a RDF triple - the basic element of this language - is composed by a Subject, a Predicate, and an Object. An example is, "The patient is suffering from diabetes", where "The patient" is the Subject, "is suffering from" is the Predicate, and "diabetes" is the Object. Then, , a set of triples is represented by a graph, where the nodes of the graph are the Subjects and the Objects, and the edges are the Predicates. Triples are stored according to the Extensible Mark-up Language (XML) [3].

Methods

To answer the first research question, a review of the literature has been performed, following the different phases of a systematic review (PRISMA Statement), described in [8]. Then, to answer the second research question, MeSH hierarchy has been used to aggregate concepts represented by the keywords associated to each paper. The following sub-sections describe the applied methods in detail.

Search strategy

The author searched online bibliographic databases for relevant papers. Specifically, PubMed/Medline, Scopus, Web of Science (MEDLINE), Web of Science (All the other Indexes), and IEEE Xplore - Digital Library were enquired, using "Linked Open Data" as main search term. Because Scopus, Web Of Science (All the other Indexes), and IEEE Xplore - Digital Library are not specific to biomedical literature, the searches on these databases were limited to the following subject areas: Biochemistry, Genetics and Molecular Biology, Medicine, Pharmacology, Toxicology and Pharmaceutics, Psychology, Immunology and Microbiology, Neuroscience, and Nursing. In this way, the search was limited to papers in the Biomedical Information area.

Inclusion and exclusion criteria

Inclusion criteria were as follows: 1 - Journal articles in English published from 1st January 2009 to 13th August 2018 (the date of searches); 2 - Papers published on journals related to Linked Open Data within the Biomedical Information Domain; 3 - Abstract and full text pdf are available; and 4 - Papers should describe Linked Open Data solutions within the Biomedical Information Domain.

The exclusion criteria were complementary to the inclusion criteria. In addition, duplicated items were considered and deduplicated. The final selection of papers was performed by screening title, abstract, and through reading the full text, when more details were needed.

Data extraction

To answer the second research question, keywords associated to each paper were extracted. Keywords are descriptors of the content of a publication, and in the present research, they have been preferred to the title, as the titles cannot reflect the contents of a publication [9]. Keywords are defined by the authors, even according to a specified vocabulary (e.g., Medical Subject Headings-MeSH). Publications indexed in Medline database are also described by MeSH terms. Publications in IEEE are indexed according to IEEE descriptors.

Keywords describing the papers selected from the previous phase of the research have been collected in a MS Excel spreadsheet and then processed according to the following steps. First, keywords on the full text pdf have been considered; then, if they were not included, the journal web page describing the paper has been considered, and the keywords available there collected. After that, if the keywords were not available on the web site, MeSH terms have been considered for the publications available on Medline. With this process all the papers had a set of words associated to them.

The phrase “Linked open data” and combinations of those words have been excluded, as the main query in the search phase was that one (i.e., to retrieve papers having LOD as main topic), duplications have been removed, and acronyms have been used to replace their explanations (e.g., RDF instead of “Resource Description Framework”). After that, the entire list has been alphabetized and the frequency of each keyword counted, and stored in the spreadsheet. Finally, a MeSH term and a MeSH category have been connected with each keyword, when possible.

Results

The search phase provided 181 potential articles, and following the four-phase flow diagram [8], 46 have been included in the analysis. Due to space limitation, the references of the 46 included papers are not included in the present manuscript; however, they are available upon request. The analysis of the 46 papers gave 265 keywords, including duplications. After processing the keywords according to the methods explained in the previous section, 225 keywords had been obtained, including duplicates. 169 distinct keywords were extracted; 23 had a frequency from 2 to 15 (maximum frequency), while 146 had a frequency equal to one. The most recurrent keyword was “RDF” (15 times), followed by “Semantic web” (9 times), “Electronic Health Records” appeared 4 times, and “Unified Medical Language System” – UMLS appeared 3 times. The main MeSH categories matched by the keywords were "Information Science Category" (45 keywords) and "Analytical, Diagnostic and Therapeutic Techniques and Equipment Category" (12). Unfortunately, it was not possible to associate 80 keywords to a MeSH term (and category).

Conclusions

The objective of this paper was to determine the extent of the usage of linked open data within biomedical literature. Applying the PRISMA statement for literature reviews, forty-six papers have been included in the analysis and their keywords identified. Twenty-three keywords had a frequency greater than one (and the maximum frequency was 15), 146 keywords had a frequency equal to one. "Information Science Category" and "Analytical, Diagnostic and Therapeutic Techniques and Equipment Category" of MeSH were the main MeSH categories keywords belong to. Future work includes applying association rules learning (shopping basket analysis) to the keywords.

Abstract

Standardization is essential for information sharing among different health care institutions. Our objective was to identify the essential oral health attributes to include in an electronic health record for primary care. This action research study utilized a Definer Group, which selected attributes as a mind map, into four main pillars: Data Collection, Diagnosis, Care Plan and Evaluation. This research applied the practice of knowledge leveling, favoring the interaction of dental specialties and identification of attributes.

Keywords:

Oral Health; Primary Health Care; Dental Records.

Introduction

There is no health care without information. "The collapse of comprehensive health care and the inadequate use of financial resources are directly associated with a lack of access to readily available and reliable information, as well as rework and lack of support for clinical decision-making" [1].

Clinical decision-making based on fragmented and impaired information has a direct impact on the prognosis and outcome of health care treatment. Longitudinal monitoring and multiprofessional health care are also compromised and even impossible to perform [2].

Primary health care is the main gateway for the individual in the Brazilian Unified Health System (SUS). This reinforces the importance of a ready and trustable information access system, since this level of health care aims to develop comprehensive care that impacts the general health status, the autonomy of people, and the determinants and health conditions of the collectivities [3].

Standardization is essential for information sharing among different health care institutions and health professionals. This requires a national effort in e-health, with large investments, participation of various segments and health actors, which several countries have carried out [3]. The e-health is defined as "the combined use of electronic information and communication technology in the health sector for clinical, educational, research, and administrative purposes, both at the local site and across wide geographic regions" [4]. In Brazil, guidelines and actions established in the e-health vision [5] already reveal the prioritization of the subject by Brazilian government. However, what data should be recorded?

Despite the advance of e-health in the SUS [5], most of the information provided by its various systems relates to administrative management, to feed health indicators that provide partial or skewed information by registry instruments. Clinical information focusing on the individual, sufficient for clinical decision-making, is not yet available in an integrated and longitudinal format.

The development of the interoperable Electronic Health Record (EHR), in particular for primary care, will require a great effort. It must involve different health care professionals working to define the information model, aiming to ensure the completeness and interdisciplinary that primary health care needs [6].

In 2016, the researchers' group of this study proposed an informational model that meets the principle of integrality in health care, with a comprehensive approach [6]. This model intends to be the starting point for the different primary care professions to define, with greater granularity of details, the set of essential information to be registered. Dentistry makes up a set of health professions that work in primary care, and based on the information model mentioned, the objective of this study was to identify the essential attributes on oral health to be contemplated in a multiprofessional electronic health record for primary care.

Methods

This observational, exploratory, cross-sectional and action research study was approved by the Ethical Committee at Universidade Federal of Goiás, Brazil (protocol 2,206,915).

It included five steps: a) Selection of the experts' panel in dentistry (Definer Group - DG); b) Action research - knowledge leveling workshop; c) Individual activity by specialty (comparison of the health record used by the dental specialties with the defined semiological tree); d) collective activity (proposal of Oral e-health as a mind map format); e) selection of attributes for validation and modeling.

The DG was composed of five dental specialties, representing the areas of Stomatology, Periodontics, Collective Health, Pediatric Dentistry, and Endodontics. These specialists fulfilled the inclusion criteria and agreed to participate in the study, comprised of three males and three females [7].

Of the eight invitations sent, two professionals did not accept for the unavailability of time. In terms of professional training, all participants were masters, with publications and dissertations defended in one of the following areas: Semiology, Stomatology, Endodontics, Periodontics, Public Health, or Pediatric Dentistry. Of these, 83% completed their doctorate degree, 17% had their doctorate in progress, and 66% had at least one specialization.

[1] Panel of Specialists in Health - Definer Group, see the Appendix A.

All participants have been teaching, performing research, or other extension and oral health care activities.

The DG performed action research, by means of knowledge leveling workshops on health information collection, mediated by professors from the area of Semiology in Dentistry [8].

The result of the collective workshops, face-to-face, and distance meetings allowed building a mind map, using the FreeMind tool. This strategy resulted in a model, the Oral e-Health, integrated to the multiprofessional information model.

Results and Discussion

The mind map, a product of more than 50 hours of meetings, contained four pillars: Data Collection, Diagnosis, Care Plan and Evaluation. A total of fifteen face-to-face workshops were held with the DG, in addition to approximately twenty hours of individual meetings.

In this first step of defining Oral e-health, the DG focused its work on the data collection pillar of the multiprofessional information model [6], a priority for the continued development of the integration of dental health attributes to the general health of the individual in the other pillars (Diagnosis, Care Plan and Evaluation).

The mind map, a product of the workshops performed with the DG, resulted in the modification, detailing, and inclusion of several items related to Data Collection. The complete mind map version is available in FreeMind format at https://github.com/professorarenatabraga/Oral-e-Health.

The mapping of this set of attributes to the construction of an electronic health record is an important activity; perhaps, it is one of the highest priorities, which requires the involvement and collaboration between professional with diffferent areas of knowledge [3].

This action research was interdisciplinary, since the DG performed the investigation of the essential attributes of each dental specialty simultaneously with the collective knowledge leveling of semiological concepts; this has contributed to each professional understanding the importance of attributes of the other specialty, their overlaps, the need for exclusion or inclusion of terms, and how to present and organize the information used in their routine clinical practice.

The profile of the professionals that composed the DG, determined by the criteria adopted in the selection, ensured the scope of primary care, without losing the detail and flexibility necessary for evidence-based clinical decision-making in a multiprofessional context [1,8].

The use of the mind map allowed the DG an easy navigation, as well as an extended and at the same time detailed view of the set of attributes that was being delineated [9]. The mind map included the essential attributes for oral health in the scope of primary care, integrated with those of general health, and will be the basis for the elaboration of an informational model, taking into account the guidelines and actions proposed by the Ministry of Health [5].

The attributes presented in the mind map, besides serving as a basis for the elaboration of the information model, also constitute the basis for the construction of archetypes, an independent approach of technology. The use of archetypes and terminology standards is decisive for the promotion of the desired level of interoperability of health information record systems and their consequences: search and sharing of health information with quality, and improvements in health care, like in Norway, Germany, New Zealand and Australia [3].

Conclusions

The main contribution of this study was to increase the level of detail, completeness and pertinence of the essential attributes for oral health primary care, presenting a methodological approach to do it. The intervention of the action research was crucial to leveling semiological knowledge, favoring the interaction of different dental specialties on establishing essential information for an oral health register. The workshops allowed a reflection on the essentiality of the information that each specialty required individually and how they could be rearranged collectively to the individuals' general health register.

Specialists interaction as a Definer Group was fundamental for identification of Dentistry´s concepts, in the primary health care context, that will require a formal clinical modeling using the standards adopted by the Brazilian Ministry of Health.

P-Hacking Lexical Richness Through Definitions of "Type" and "Token"

K. Bretonnel Cohen[a], Lawrence E. Hunter[a], and Peter S. Pressman[b]

[a]Computational Bioscience Program, University of Colorado School of Medicine, Aurora, Colorado, USA
[b]Department of Neurology, University of Colorado Hospitals, Anschutz Medical Campus, Aurora, Colorado, USA

Abstract

"P-hacking" is the repeated analysis of data until a statistically significant result is achieved. We show that p-hacking can also occur during data generation, sometimes unintentionally. We use the type-token ratio to demonstrate that differences in the definitions of "type" and "token" can produce significantly different results. Since these terms are rarely defined in the biomedical literature, the result is an inability to meaningfully interpret the body of literature that makes use of this measure.

Keywords:

Language, vocabulary

Introduction

There is a growing awareness that many published scientific results are not reproducible. Statistical practices are one of the most common factors blamed for this "reproducibility crisis," as it has come to be known [1]. There are many aspects of the contributions of statistical malpractice to the reproducibility crisis, including an increasingly recognized practice known as p-hacking. *P-hacking* is the act of repeatedly re-analyzing data until a statistically significant result is achieved [1; 2]. One method of p-hacking is varying aspects of the hypothesis tests themselves until a positive finding is reached; another is reselecting subsets of the data. However, there are other ways that p-hacking can be done, without "cherry-picking" hypothesis tests *or* data – as this paper shows, it can also be done at the data generation phase. This kind of p-hacking is especially pernicious for at least four reasons: (1) it leaves no trace in the form of questionable statistical assumptions that might otherwise be noticed by a reviewer, (2) it leaves no trace even when using publicly available data sets, since the data itself is unchanged, (3) it is not difficult to justify to oneself, and (4) publication practices make it quite easy. The approach in question is especially relevant to the computational bioscience community because it is easily illustrated with a measure that is widely used in neuroscience, psychiatry, developmental psychology, and neurology: the type-token ratio.

We illustrate the issues with the concept of "lexical richness" because its calculation seems very straightforward but is quite nuanced in practice. Informally, *lexical richness* refers to the quality, variability, and sophistication of the vocabulary of a speaker or a text. It is usually defined by some form of the *type-token ratio,* calculated as the number of distinct words (*types*) divided by the total number of words (*tokens*). It is commonly used in several biomedical fields [3]. Despite the prevalence of this measure in the scientific literature, it is unclear how to interpret the literature using the type-token ratio because papers typically do not define what they are counting as types and tokens, and there is no consensus definition for either.

Publication bias in the literature on diagnostic use of measures of lexical richness may promote p-hacking and unreliable results. We know that the tendency is not to be able to publish negative results [4]. Do people sometimes modify those "simple" decisions perfectly innocently, without actually realizing their linguistic consequences, until they get a positive finding on a subsequent statistical hypothesis test—a positive finding that would in fact be a negative finding if they made different preprocessing decisions? It is not difficult to do so, because "type" and "token" are generally not defined when used in the literature or elsewhere. We present modeling results that explore the implications of failures to consistently define those variables. If we find that modifying the definitions of "type" and "token" can affect whether or not statistically significant differences are found in the type-token ratio, then it should be clear that these terms *must* be defined when using them. If, in fact, they are *not* typically defined, then there is a problem in our field, and we should be aware of it and take action by being explicit about those definitions.

Materials and Methods

The materials are drawn from the CRAFT corpus of biomedical journal articles [5]. We modeled two different definitions of *type* and three different definitions of *token.* Definitions of "type" unavoidably interact with definitions of "token", which can result in different classifications of the same term depending on precedence orderings, so we processed all data sources using 10 random orderings of random subsets of five sets of type and token definitions. We used the conservative (nonparametric) Wilcoxon signed rank test to look for statistically significant differences between the distributions of type-token ratios in the outputs. The null hypothesis is that there is no effect of different definitions of the variables. For our definitions, we used observations from three comprehensive analyses of tokenization [6-8]. See the code available on GitHub for how we handled phrasal verbs (e.g. *have_to* versus *have to*), negative clitics (e.g. *do n't* versus *don't*), and repetitions. Type definitions applied here include normalized or unnormalized digit types or letter cases, punctuation inclusion in or exclusion from the token counts, and different treatments of hyphens and underscores. (See [9] for how contentious any of these decisions can be.) There are interactions between any definition of type or token, so we ran different combinations of the various definitions of each and their orderings, all randomized, for 10 combinations of definitions and orderings. Type-token ratio was calculated as

the count of types divided by the count of tokens for the complete text.

Analysis of the resulting distributions follows the approach of [10] (see also [8; 11]). Figure 1 shows the distributions of the type-token ratios for 10 randomly selected permutations of type definition, token definition, and order of application. Results cluster into groups with two widely differing magnitudes, one just below a type-token ratio of 0.5 (1, 3, 5, and 10) and the other around 0.2 (2, 4, 6, 7, 8, and 9); clearly, the definitions of type and token can have an enormous effect on the magnitude of the type-token ratio. In no case are the type-token ratios normally distributed, meaning the type-token ratio is vulnerable to Type I errors from parametric hypothesis tests.

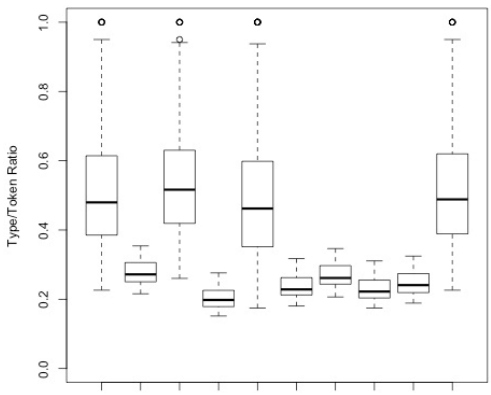

Figure 1 – 10 random permutations of subsets of the definitions of type and token. Each data point is the type-token ratio for one paper. Each column represents one permutation.

The distributions of the permutations with the highest and lowest median type-token ratios in the low-magnitude group were significantly different ($p < 0.001$); within the high-magnitude group, however, they were not. We also tested all pairs of permutations within the two groups. Table 1 shows that more than 40% of the definition set pairs did not yield statistically significant differences, while nearly 60% did, suggesting that there are many ways that statistically significant differences can be found (or not) based only on the different definitions of "type" and of "token". Like typical p-hackers, we did no multiple testing correction.

The complete code base and outputs of all steps of the analysis are available on GitHub.

Table 1 – Number of pairwise differences between sets of definitions of type and token, divided into groups with high- and low-magnitude type-token ratios.

Group	Pairs	Significantly different (%)
High	7	0 (0%)
Low	16	13 (81%)
All pairs	23	13 (57%)

Discussion

These results demonstrate that there are many "minor" preprocessing decisions that can be the difference between having statistically significant results and not, independent of any actual differences in the underlying data.

Conclusions

The precise definitions of "type" and "token" are so important that, if they are absent, research findings based on the type-token ratio are essentially uninterpretable. In fact, precise definitions of these terms are rarely given in the biomedical literature — even in work on tokenization [11]! We have shown that type-token ratios can be significantly different based only on differences in how "type" and "token" are defined. These results suggest that the relevant literature should be read with caution. Talking about his initial work on this problem. J. Simmons, the originator of the term "p-hacking," says that "we realized entire literatures could be false positives" [12]. If research using measures of lexical richness is to avoid turning out that way, future work in the field should always give the precise definitions of "type" and "token" that were used.

Mapping Medication Metadata from the ABDA Data Model to an OpenEHR Medication Archetype: A Qualitative Analysis

Tobias Bronsch[a], Ruwen Böhm[b], Claudia Bulin[b], Björn Bergh[a], Björn Schreiweis[a]

[a] *Institute for Medical Informatics and Statistics, University Hospital Schleswig-Holstein and Kiel University, Kiel, Germany*
[b] *Institute of Experimental and Clinical Pharmacology, University Hospital Schleswig-Holstein and Kiel University, Kiel, Germany*

Abstract

Integrating data from various source systems to gain knowledge and meaningful data about patients for care and research is challenging. This work demonstrates how medication knowledge data from the database of the Federal Union of German Associations of Pharmacists (ABDA) can be used for storing and annotating medicinal products in an openEHR medication archetype.

Keywords:

Electronic Health Records, Datasets as Topic, Health Information Exchange

Introduction

Medical data are reused for both patient care and biomedical research, not only within the boundaries of healthcare institutions, but very often also across multiple sites. However, data are often not findable, accessible, interoperable and reuseable (FAIR Data Principles [1]), as they are missing common terminologies for semantic interoperability. The German Federal Ministry for Education and Research (BMBF; ger: Bundesministerium für Bildung und Forschung) is tackling these issues with the German Medical Informatics Initiative (MII) by funding university hospitals to implement Data Integration Centers to make data available and interoperable on a national and international level [2]. University Hospital Schleswig-Holstein (UKSH) joined HiGHmed, one of the four MII-projects, and is implementing the HiGHmed use case cardiology [3]. For this use case among other data, medication data need to be integrated.

At UKSH, the management and documentation of medication data is based on names and identifiers of a de-facto-standard database provided by the Federal Union of German Associations of Pharmacists (ABDA) [4].

The objective of this work is to show the extent of overlap between the ABDA metadata and an openEHR medication archetype. Our aim is to provide a first step for storing and annotating medication data in openEHR archetypes using ABDA information.

Methods

ABDA Database

ABDA provides a comprehensive drug database with information on all medicinal products on the German market and its contents are constantly updated every 14 days. It comprises particularly details on active and inactive ingredients using different naming conventions, pharmacological classification systems, pharmaceutical and clinical instructions, summary of product characteristics as well as package inserts [4].

OpenEHR

OpenEHR describes a platform approach enabling open electronic health record (EHR) architectures using archetypes which are shared nationally and internationally [5].

In order to integrate data of source systems into openEHR-based systems, data need to be mapped and transformed.

Mapping of ABDA Metadata Items to an OpenEHR Archetype

For the mapping of the ABDA data model the tables ‘medicinal products’ (FAM_DB), ‘substances’ (STO_DB) and ‘names of substances’ (SNA_DB) were considered. In total 79 ABDA metadata items were used for the mapping.

Two medical informaticians (TB and BS) separately analyzed the 79 metadata items and mapped them to an openEHR archetype. Inter-rater reliability for TB and BS was calculated afterwards. Next, they compared their results per item and discussed disagreements to agree upon a mapping per item. In cases where the discussions did not lead to an agreement, a pharmacologist (RB) was included in the discussion and helped resolve the mapping.

Results

The ABDA metadata were mapped to the openEHR medication archetype (namely openEHR-EHR-CLUSTER.medication.v1).

The independent mapping of 79 ABDA metadata items to the archetype leads to initial agreements on 54 out of 79 ABDA metadata items (68.4 %) with disagreements for 25 ABDA metadata items. 26 ABDA metadata items could not be mapped to the archetype. Inter-rater-reliability is $p_o = \frac{54}{79} \approx 0.684$. Dicussions on the disagreements could resolve 23 out of 26.

However, 36 out of 79 ABDA items (45.6 %) were mapped to the generic free-text item ‘description’ of the archetype for integrating structured ABDA information.

Discussion

Mapping structured ABDA metadata items to free-text openEHR items results in loss of information. Therefore, more structured items that fit to structured ABDA items may be necessary in openEHR archetypes.

Instead of integrating ABDA information into openEHR archetypes, openEHR patient medication data could also be linked to the ABDA database by using a unique identifier from ABDA and reference that identifier together with the version of ABDA that was used.

This could be done using a unique identifier from ABDA to identify a specific medicinal product or substance in the openEHR medication archetype item 'Name' as an openEHR DV_CODED_TEXT (e.g. 'Tamoxifen beta 20'). This item is specified by an openEHR CODE_PHRASE (e.g. terminology_id = 'ABDA2016.FAM_DB.Key_FAM' and code_string = ' 3340739900') using a terminology mapping (openEHR TERM_MAPPING).

The pros and cons of that alternative need to be further evaluated.

Related Work

Other work has been done using openEHR archetypes to represent medication information before, like Chen et al., who showed that using openEHR archetypes for managing chemotherapy information and representing chemotherapy guidelines in openEHR is possible [6]. Marco-Ruiz et al. built an archetype-based data warehouse, but are focusing their information model on laboratory data [7].

Medication information has previously been transformed and mapped to other data models. E.g. HL7 Fast Healthcare Interoperability Resources (FHIR) was used to implement a system storing structured medication information retrieved via an NLP pipeline from unstructured documentation [8]. Sinha et al. built a clincial decision support system for safe opioid prescription based on FHIR [9].

Limitations

This work has to be considered a preliminary step for integrating medication data in an openEHR environment.

In addition, the ABDA database is specific to Germany. Although it contains both foreign pharmaceutical products and substance names this database might not be sufficient for international purposes.

Since the effort presented in this work has to be conducted once and only future changes of ABDA metadata need to be included, an automated mapping system was not considered. Structural changes to ABDA happen once per one year or every second year. The mapping does not imply regulatory or ethical challenges, due to metadata being mapped and not contents.

Conclusions

The selected metadata items concerning medication information can be mapped from the ABDA data model to an openEHR medication archetype. Based on these results our next steps are the integration of medication information in an openEHR Clinical Data Repository.

Abstract

Prostate cancer (PCa) data is of public health importance in South Africa. Biopsy data is recorded as semi-structured narrative text that is not easily analysed. Our study reports a pilot study that applied predictive analytics and text mining techniques to extract prognostic information that guides patient management. In particular, the Gleason score (GS) reported in a number of formats were extracted successfully. Our study reports that predominantly older men were diagnosed with PCa reporting a high-risk GS (8-10). Where cell differentiation was reported, 64% of biopsies reported poor differentiation. The approaches demonstrated in our study should be extended to a larger dataset to assess whether it has the potential to scale up to the national level.

Keywords:

Prostate cancer, Gleason score, Risk, Cell differentiation

Introduction

Prostate cancer (PCa) is an important non-communicable disease (NCD) in South Africa with a reported age-standardised incidence rate of (ASIR) of 67.9 per 100 000 in 2012 [1]. Local studies have reported that African men present with advanced and aggressive PCa reducing the opportunity for remission [2]. Local guidelines indicate that patient management is directly linked to Gleason score (GS) grading, percentage and numbers of cores as well as ancillary information such as seminal vesicle involvement and peri-neural invasion [3]. Prostate biopsy results are stored as semi-structured narrative text that cannot be easily analyzed. The GS is captured as follows; (i) major score, e.g. 4 and (ii) minor score, e.g. 3. This equates to a 4+3=7 GS. This data is captured in multiple formats depending on reporting practices at each laboratory. For example, a GS of 3+4=7 could be reported as follows; (i) major 3 and minor 4 = 7, (ii) 3+4=7, (iii) (major pattern 3 + minor pattern 4) = 7, (iv) 3+4=7 and (v) (3+4)=7. The number of cores, GS and cell differentiation provides valuable insights to assess late presentation and poor prognosis [3]. The objective of our study was to investigate the use of big data analytics (text mining) to extract meaningful data from narrative prostate biopsy results.

Methods

The retrospective descriptive study design was used to analyse laboratory data between 2006 and 2016 for men 30 years and older. The sample population of 1000 cases was randomly selected from prostate biopsies with an adenocarcinoma histological finding determined using Systematized Nomenclature of Medicine (SNOMED) morphology codes [4]. Convenience sampling was used. Local guidelines were used to categorise PCa risk using the GS as follows; (i) GS 2-6: low-risk disease (LRPCa), (ii) GS 7: intermediate-risk disease (IRPCa) and (iii) GS 8-10: high-risk disease (HRPCa) [3]. An example of a fictitious biopsy narrative report is provided:

> EPISODE NUMBER: ABC1234 SPECIMEN DETAILS: PROSTATE BIOPSIES. CLINICAL DETAILS: THE PATIENT IS 66-YEAR-OLD MALE WITH AN ENLARGED PROSTATE AND A PSA LEVEL OF 20.8. PROSTATE CORE BIOPSIES WERE SUBMITTED TO EXCLUDE CARCINOMA OF THE PROSTATE. MACROSCOPY: SEVEN CORE BIOPSIES ARE RECEIVED, RANGING IN LENGTH FROM 25MM TO 10MM. PATHOLOGICAL DIAGNOSIS: PROSTATE CORE BIOPSIES, WITH REPRESENTATION OF THE SEMINAL VESICLE: INVASIVE MODERATELY DIFFERENTIATED PROSTATIC ADENOCARCINOMA. GLEASON SCORE = MAJOR 3 + MINOR 4 = 7 THERE IS PERINEURAL INVASION IDENTIFIED. NO LYMPHOVASCULAR SPACE INVASION IS PRESENT IN THE SECTIONS EXAMINED. THE TUMOUR IS PRESENT IN 2 OUT OF 7 CORE BIOPSIES WITH AN APPROXIMATE BULK OF 20%.

Figure 1: Fictitious prostate biopsy narrative report

This study applied text mining techniques and specifically made use of regular expressions to address the complex relationships among the data [5], including structured, unstructured and semi-structured data [6]. Prostate biopsy reports data were extracted and loaded to the Spyder Integrated Development Environment (IDE) which uses the Python programming language [7]. Spyder IDE offers features such as advanced editing, debugging, profiling, data exploration and interactive execution [8-10]. The data was first pre-processed and cleaned using tokenisation and stop word removal. Stemming was used to derive the root word. Using feature generation, the bag of words was developed and n-grams generated. Feature selection was used to develop a vector space by selecting a subset of features from the biopsy reports. Regular expressions representative of the GS target feature such

as “gleason”, “Gleason”, “GLEASON”, “Gleeson”, etc. were used to identify the target feature. Lastly, the required data was then extracted for each biopsy and produced as an output extract that was analysed and visualised. The output variables included; (i) episode number (ABC1234), (ii) age (66), (iii) cell differentiation type (moderate), (iii) number of cores (7), (iv) type on cellular invasion (Perineural) and (v) GS (3+4=7). The ages extracted from the biopsy report were correlated against the manually captured values. The data reported includes; (i) GS, (ii) percentage of biopsies by cell differentiation and (iii) distribution of the number of cores submitted. Age were categorised as follows; (i) <50, (ii) 50-59, (iii) 60-69, (iv) 70+ and (v) “Age not stated”.

Results

The episode number was extracted for all biopsies (100%). The age was extracted for 893 biopsies (89%). An age was captured for 877/1000 (88%) of biopsies compared to 956/1000 (91%) in the LIS. There were 17 biopsies where different ages were recorded (2%); 3/17 likely transcription errors, e.g. 6 recorded instead of 60. The majority of biopsies were requested for men ≥60 years (86%).

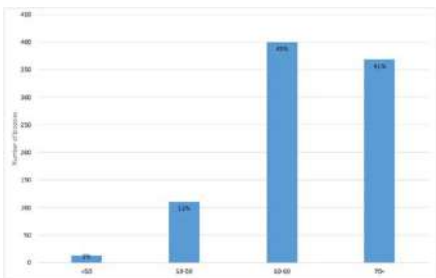

Figure 2: Distribution of the extracted age

Of 1000 biopsies, 286 reported cell differentiation characteristics (29%). Poorly differentiated adenocarcinoma was reported for 64% of biopsies followed by 29% for moderate differentiation.

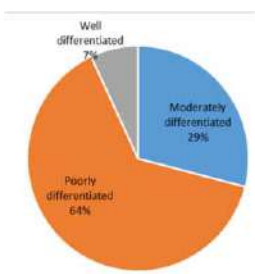

Figure 3: Cell differentiation distribution

The GS was extracted for all 1000 biopsies. A GS of 3+3=6 and 5+4=9 was reported for 18% of biopsies each (total of 26%). This was followed by the 4+3=7 GS (16%). Half of the patients reported a high-risk GS (8-10: 47%).

Conclusion

The use of predictive analytics holds tremendous potential especially in a resource-poor setting where documented clinical data is poor or absent. The prognostic information could be used to categorise patients into risk groups. The accrued laboratory

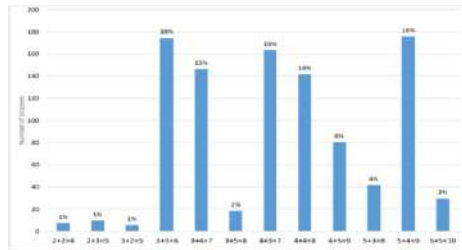

Figure 4: Distribution of Gleason score risk category

data could enable an understanding of PCa differentiation and GS by unlocking clinical information captured in the narrative reports. This could enable real-time cancer data analysis (as opposed to cancer registry reporting that is delayed). The approach reported in our study should be extended to a larger dataset to assess the ability to scale up to the national level.

Evaluating the Performance of a Terminology Search Engine Using Historical Data

José Castaño[a], Hee Park[a], Pilar Ávila[a], David Pérez[a], Hernán Berinsky[a], Laura Gambarte[a], Carlos Otero[a], Daniel Luna[a]

[a]*Departamento de Informática en Salud, Hospital Italiano, Buenos Aires, Argentina*

Abstract

Clinical terms are noisy descriptions typed by healthcare professionals in Spanish language in the electronic health record system (EHR). Thus, an evaluation of terminology search engine that extends SNOMED CT and an approach that uses historical data of clinical terms is described. We show how to measure precision and recall using historical search data, and we show how the performance of the search engine can be improved significantly using the technology available in the search engine.

Keywords:

Systematized nomenclature of medicine, Search engine, Electronic health records

Introduction

Some electronic health records (EHR) implementations allow users to introduce free text descriptions even in structured data entries. Free text descriptions enable more expressiveness, ease of use and flexibility to physicians. Description terms must be encoded to be mapped to concepts in a controlled vocabulary. The Hospital Italiano de Buenos Aires (HIBA) has a Spanish interface vocabulary [1] where each term is mapped via a direct relation or using compositional post-coordinated expressions to SNOMED CT.

An enumeration of desirable characteristics [2] has been stated for an interface terminology including normalization, completion, spell correction and matching. These are related to string representation and similarity matching problems.

As far as we know, there is no established methodology to evaluate the results of querying a large terminology server. We propose an information retrieval-based methodology to evaluate its performance.

Methods

The HIBA EHR initially allowed healthcare professionals to type free text entries in its problem list. Later, an interface terminology for physicians was developed where they could choose available descriptions for a given problem or a procedure. Some examples of description terms that map to the same concept are the following:

- Neoplasia maligna de pulmón – cáncer
- Neoplasia malignant of lung – cancer of the lung

Compilation of Historical Data

We used the information that has been logged in our system. We analyzed a period of 5 years (2012-17) depicted in Table 1.

Table 1– Data Set Description

Description	Quantity
Number of Registers	2,679,848
Number of Concepts	54,280
Number of Users	4,719
Number of Unique Queries	146,412

An analysis of this data, considering user behavior, shows that most users have recorded less than 500 concept instances (registers) and that 90% of the users recorded less than 1500 registers. Most users are probably medical residents that have been at the hospital for less than 3 years; therefore, there are not many registers per user. This is reasonable also because the HIBA is a university hospital. We could also observe that most users use very few concepts.

Evaluation: Precision and Recall in Information Retrieval

Evaluation is a critical component of information retrieval (IR) [3]. We use precision at *n* (*P@n)*, i.e. at a given cut-off rank [3]. Information retrieval in the medical domain has a strong tradition [4,5], and it has been a difficult domain [6]. In a classical information retrieval model, more than a single document are usually relevant for a given query. This is not the case here: a healthcare professional is looking for a single description term that depicts the problem that has to be registered in the EHR. Therefore, for any number of returned results, there is most of the time only one *relevant* result, as shown in the following examples where the first element in each pair is the query and the second element the selected description:

- (CPS, control de salud)
- (GME, adult health examination)

Evaluation data-set and measures

We collected a number of tuples consisting of (typed term, selected term, corresponding concept). The output of the system to be evaluated is a list of ranked concepts, and each concept is depicted by the corresponding canonical description term.

Given there is only one relevant result chosen, recall at *n* (*R@n*) measures how many times the right concept is returned within the *n* first ranked results. Therefore *R@1* tells us how many times the correct result was the first ranked one and *R@10* tells us how many times the correct result was within the 10 first

ranked results. In this context Precision at *n* (*P@n*) will tell us the same information that *R@n*. We propose here an alternative *P@n* measure (related metrics based on semantic distance have been proposed [7]). We cannot decide, based on historical data, whether a description term (a concept) is *relevant* for a given query, but we do know which term was chosen by the user. We can calculate the semantic distance between two given concepts based on the hierarchical structure of an ontology [8]. We propose 1-Precision distance, considering 1-relevant results also those concepts at a distance ≤ 1 from the relevant concept for a given query.

Results

We built concept, specialty/service area, and user models based on logged data corresponding to 10 years of patient health records, using as features, description terms, concept-id, specialty, user and the corresponding vectors based on the frequency of use.

A large combination of features combinations was tested using Elastic Search (https://www.elastic.co). Tests were performed over of 100,000 records. We used stemming, indexing of common abbreviations, stop words, a spell-checker and automatically detected synonyms. We also made a careful selection of the set of indexed terms, filtering low quality infrequent terms. It was rather surprising that specialty and user information did not improve much the performance. The following Table 2 shows some of the recall results which showed larger differences in the performance for some feature combinations. Best results are in column **n-gram full** (n-gram based search, vs word and word with spell checker) where the largest number of features were used. It can be seen that there is no significant difference with the next column (**n-gram part**) that uses fewer features.

Table 2– Experiments with different features using historical frequencies

#Results	Word	WordSpell	n-gram f	n-gram p
R@1	87.77	88.35	**90.11**	90.16
R@3	92.03	92.18	**94.33**	94.20
R@5	93.19	93.5	**95.35**	95.28
R@10	94.12	94.55	**96,32**	96.24

We also compared the current implementation deployed in the EHR, which we designate as (A), versus the best combination of features (n-gram full) in Table 2), which we designate as (B) in Figure 1. The current implementation uses Lucene off-the-shelf similarity metrics and spell corrector. All the terms at the HIBA thesaurus are indexed. Figure 1 shows that there is a significant improvement in the performance even if the metrics for the current implementation are good, from an information retrieval perspective. They also show that both alternatives soon reach a plateau @5 with little improvement afterward.

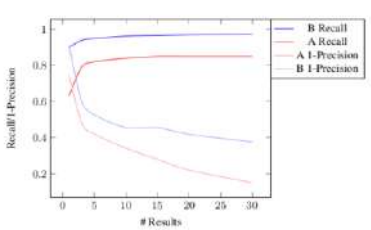

Figure 1–Precision and Recall for (A) Current vs. New (B) Implementation

Discussion

We have presented a methodology to evaluate the performance of a terminology server based on the information retrieval notions of query and relevant concept using historical data.

There is not a single factor contributing to improving the performance, some of them are idiosyncratic to the HIBA interface vocabulary (such as decisions on what description terms need to be indexed). Weight schemas combinations provided by the search engine, use of n-grams, stop-word combinations, use of abbreviations, and other features enabled a considerable improvement in the performance reaching a 90% recall at the first ranked results.

Conclusion

The use of an information retrieval engine customized to noisy user-generated queries was able to deal with string issues stated as desiderata for a terminological server. The use of historical data and associated term weights showed an improvement in the performance of the previous system. However, we were not able to build a proper model for individual users or groups of users (services or specialties). A fine-grained analysis of the results might enable improvements in the performance from a user perspective.

Abstract

Unstructured clinical notes contain a huge amount of information. We investigated the possibility of harvesting such information through an NLP-based approach. A manually curated ontology is the only resource required to handle all the steps of the process leading from clinical narrative to a structured data warehouse (i2b2). We have tested our approach at the Papa Giovanni XXIII hospital in Bergamo (Italy) on pathology reports collected since 2008.

Keywords:

Natural Language Processing, Biomedical Ontologies, Data Warehousing

Introduction

i2b2 is a data warehouse supporting clinical and biological research [1]. Its structure contains both data (clinical events such as diagnoses, therapies and laboratory tests, as well as genetic data [2]) and metadata (the terminologies which the data refer to, hierarchically represented). C*oncepts* and *modifiers* are essential elements of the *metadata* structure; the latter are useful to expand and differentiate the meaning of the former. To increase the value of clinical narratives as sources of information, Natural Language Processing (NLP) pipelines are run, which are able to extract structured data from unstructured sources. The extracted information can be saved as i2b2 *observations*. Many existing methods can process English narratives, but the same research in other languages is quite limited; for this purpose, we have designed and developed an ontology-based NLP pipeline [3]. Our ontology follows the OWL (Web Ontology Language) language [4] which allows the definition of elements and relations between them; moreover, its elements are enriched with information on how to perform the NLP tasks and to build the i2b2 taxonomy and data.

Methods

The main goal of the developed system is to maintain a single resource to configure all the processes between a repository of clinical narratives and a data warehouse that enables querying the information extracted from them.

OWL Model

The ontology is the core of the system; it guides the information extraction from the reports, defines the i2b2 *metadata* structure and helps in the storage of the extracted data as i2b2 *observations*. The first step to building a new ontology is defining the entities. The most important Entities are in the class hierarchy. The second step is to create object property entities that link two different classes. Annotation properties are instead entities that can be attached to a class. The two main types of classes in our system are called "Event" and "Attribute".

Workflow

1. Building up the OWL Ontology

The design of an ontology is a complex process in which the needs and knowledge of different stakeholders must be taken into account. An important task is also to organize this knowledge, where possible, to standard terminologies, such as SNOMED-CT, ICD9CM, LOINC and ATC. The ontology development involves many (re)design-and-feedback iterations in order to leverage the outputs of the clinicians without abandoning the standards. Along with a close interaction with clinicians, especially in the first phases of the process, a preliminary automatic analysis of the sample corpora of narratives is useful to recognize usage of some elements and try to change the classes accordingly. A technique that is suitable to be used for this purpose is extracting the most used N-grams in the texts.

2. From OWL to i2b2 Taxonomy

Once the ontology is ready, it can be processed to build the *metadata* taxonomy in i2b2. In most cases events and attributes will be saved respectively as *concepts* and *modifiers*. The taxonomy building process is governed by object properties: *subClassOf* contains the parent class entity and is used to maintain the original hierarchy both for events and attributes; *isModifier* tells which event the attribute will refer to in the form of a *modifier*. The remaining information required to populate the *metadata* tables are retrieved from annotation properties of the classes.

3. From OWL to NLP Extraction

Our NLP pipeline is ontology-based: it uses some of the properties of the ontology elements to extract events and attributes from the text. The first step consists in searching the events in the text. For this first task, annotation properties are used to point out which regular expressions must be used to find each event, or to focus the process to specific parts of the analyzed texts. The second step is to search attributes that refer to the events just found; the *hasModifier* object property is used to identify them. As happens with events, attributes

have annotation properties which drive the extraction of the terms.

4. From NLP Extraction to i2b2-Data

A final ETL (Extract, Transform and Load) task is required to store the NLP output to the i2b2 data warehouse. The new *observations* are aligned with the i2b2 taxonomy created at point 2, in order to be retrieved in the form of *concepts* and *modifiers* of belonging. Each extracted event is stored as an i2b2 *observation*; similarly, the linked attributes will lead to the creation of additional *observations* with the associated *modifiers* as well as with the *concepts* of the event.

Results

The Papa Giovanni XXIII, a general hospital located in Bergamo (Italy), has more than 200,000 pathology reports collected from 2008 (to 2018). The methodology described in the paper has been applied to these documents as a test case. In particular, the reports that have undergone this procedure are pathology reports describing breast cancer cases. The reports are composed mainly of three sections: the list of specimens received, macroscopic description of the specimens and diagnosis conclusions.

OWL Model

Important elements described in the pathology reports have been listed among the events in the ontology: the type of specimen analyzed, the associated diagnosis and other findings. These events have been further specified with child events and linked attributes.

Workflow

1. Building up the OWL Ontology: Breast Cancer Case Scenario

BioPortal PATHLEX [5] was used as a starting point defining various entity and attribute classes. Analyzed anatomic pathology reports were focused on breast cancer, so the specimens and diagnoses are relative to this domain. The final list of possible diagnoses was therefore not very long, discriminating between benign and malign tumor. The specimens group was a broader and more heterogeneous one, including biopsies and various surgical resections. Moreover, N-gram extraction was used to support this phase. As mentioned, the process was conducted based on repeated interactions with clinicians. For this preliminary task 20 reports were used as training examples for the creation of the ontology.

2. From OWL to i2b2 Taxonomy: Preparing i2b2 Metadata for Future Observation

The breast cancer ontology's hierarchical structure and event-attribute links are faithfully represented in the i2b2 taxonomy thanks to the object properties *subClassOf* and *isModifier*. For instance: "/Event/Predictive_Prognostic_Factors/Ki67" *subClassOf* "/Event/Predictive_Prognostic_Factors/" allows the Ki67 leaf to be correctly placed into the i2b2 hierarchy.

3. From OWL to NLP Extraction: Information Extraction Task on Pathology Reports

Our NLP pipeline is the extension of a previous pipeline used in the cardiology domain [3]. One of the key features of the approach is a single resource (i.e. the owl ontology in protege) allowing the governance of different processes interconnected with each other.

For example, the "Ki67" test is found thanks to the associated regular expression that considers different aliases. When the event is found the system looks at the associated attributes (percentages). A validation was performed on a small subset of 34 randomly selected documents to evaluate the NLP extraction performance. After the information extraction the NLP output was exported in a human readable text file, aligned with the original text of the reports; domain experts were trained to manually recognize errors in the extraction. The measured performance demonstrated a good quality (>90%) in precision, recall and F1 score [6].

4. From NLP Extraction to i2b2-Data

After the extraction the last step is to import specimens, diagnoses and other findings into the i2b2 database. This step is governed by the same ontology used in the NLP information extraction task and in the i2b2 taxonomy creation. As a practical rule, all *observations* imported in i2b2 have been associated with the date of their corresponding reports, while the associated visit ids were the ones reported in the documents.

Conclusions

We started the ontology curation steps by integrating local domain knowledge with an existing ontology from BioPortal. Raw reports were analyzed with a Natural Language Processing (NLP) pipeline that extracts structured data from unstructured narrative sources. These steps were in the anatomy pathology ward of the hospital 'Papa Giovanni XXIII' in Bergamo in the context of breast cancer.

Expansion of EHR-Based Common Data Model (CDM)

Wona Choi[a], Soo Jeong Ko[a], Hyuck Jun Jung[a], Tong Min Kim[a], Inyoung Choi[a]

[a] *Department of Medical Informatics, College of Medicine, The Catholic University, Seoul, Republic of Korea,*

Abstract

We expanded and constructed a Common Data Model (CDM) based on hospital EHR to enable analysis and comparison of Adverse Drug Reactions(ADRs) integrated with external organizations with different data structures. This is significant in that it is possible to conduct joint research, analysis, and comparisons among institutions with the same type of CDM constructed, and provide the basis for conducting the same research simultaneously on various data sources.

Keywords:
Electronic Health Records, Observational Study, Database

Introduction

Traditionally, we have relied on the information obtained from clinical trials on drug side effects and post-marketing individual patient case reports to identify potential safety issues of marketed drugs [1; 2]. In fact, Korea has been surveilling drug side effects through the spontaneous ADRs reporting system.

However, in addition to the recognition that the spontaneous reporting system is not the only means that is effective in monitoring drug side effects [3; 4], and there is a growing interest in the monitoring of ADRs using hospital EHR.

Most hospitals in Korea use their own EHR system, and many Korean codes for diagnosis, medication, and treatment are not compatible with international coding systems [5]. Due to the differences in the data structure, format, and terminology used in these individual data sources, it takes a lot of time to analyze data and it is difficult to compare the results of studies using different databases [1].

The purpose of this study is to expand and build a common data model based on EHR to enable systematic analysis of different databases.

Methods

Data Source

The Catholic University of Korea Seoul St. Mary's Hospital is a tertiary university hospital with 1,356 beds and over 10,000 outpatient visitors per day. The hospital has a Clinical Data Warehouse (CDW) that extracted EHR data such as patient visits, examination, diagnosis, prescription and nursing needed for clinical research. We would like to convert the data stored in CDW of Seoul St. Mary's Hospital to CDM format.

K-CDM(Korean Common Data Model)

The Korean Common Data Model (K-CDM) has been defined in 2017 by the Ministry of Food and Drug Safety [6] through the optimization and localization of Observational Medical Outcomes Partnership Common Data Model (OMOP CDM) [7] and Sentinel Common Data Model (Sentinel CDM) [8]. K-CDM includes 8 tables (Person, Visit, Procedure, Condition, Observation, Drug, Measurement, Vital signs).

Code Mapping

The in-hospital codes in the EHR are mapped according to the international standard terminology system.

For the 584 drugs in the hospital, containing the designated 288 components, the component and in-hospital code were mapped at 1:N. The items including combination in the same component name were mapped as RxNorm and ATC by separating the single agent and the complexing agent. All in-hospital diagnosis codes for diagnosis and treatment and the in-hospital codes for 138 designated tests were mapped at 1:N to SNOMED-CT and LOINC, respectively.

Extraction, Transformation, Loading (ETL) Process

The ETL process involves the entire process of taking data from a database system and moving to another database system[5]. We created SQL statements for each table in the K-CDM and extracted, transformed, and loaded the patient, medication, diagnosis(condition), and test information(Measurement) according to the K-CDM format from the CDW(*figure 1*).

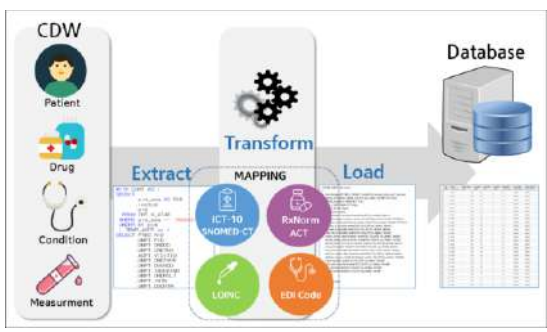

Figure 1 – ETL Process

Database

We used PostgreSQL, an open source object-relational database management system (ORDBMS), which is used as a medical information database to load data [9].

Data Analysis

Allopurinol is a kind of xanthine oxidase inhibitor that is commonly used as a preventive and therapeutic agent in

diseases that uric acid is excessively produced such as gout, uric acid nephrolithiasis, intracellular erythropoiesis, chemotherapy of lymphoma, Lesch-Nyhan Syndrome, chronic renal failure [10; 11].

Based on pervious study [12], data extraction and analysis were performed to confirm the association of allopurinol and TSH levels, which were not reflected in the Korean authorization.

Results

We extracted EHR data of 3,212,915 patients from Seoul St. Mary's Hospital from January 1, 1997 to December 31, 2017, transformed them into K-CDM format and completed the loading. The items used with in-hospital codes and domestic codes were mapped with the international standard terms, and data quality was verified using ATLAS and ACHILLES.

A Patients group (5,148 people) and a control group (20,581 people) were extracted from the established DB.

Table 1 – Number of Data

	Patient Group	Control Group
Number of group	5,148 (100%)	20,581 (100%)
Male	1,845 (35.8%)	7,377 (35.8%)
Female	3,303 (64.2%)	13,204 (64.2%)
Taking allopurinol		
Yes	172 (1.5%)	207 (1.0%)
No	4,976 (96.7%)	20,374 (99.0%)
Age-yr	56.06 ± 14.15	55.88 ± 13.93

Conditional logistic regression model was used to analyze allopurinol and the risk of elevated TSH levels (odds ratio, OR). As a result, the odds ratio was 3.46 times (95% CI: 2.91-4.26).

Discussion & Conclusion

We expanded and constructed the common data model based on hospital EHR to enable analysis and comparison of adverse drug reactions integrated with external organizations without releasing hospital EHR data to outside. This is significant in that it is possible to conduct joint research, analysis, and comparisons among institutions with the same type of CDM constructed, and perform the same research on various data sources simultaneously.

In fact, a multicenter study has been conducted on the subject of our study (risk of elevated thyroid stimulating hormone levels in allopurinol), and we hope to have meaningful results.

Our study has the following limitations. By applying a domestic common data model named K-CDM, part of OMOP CDM format was applied, which is widely used internationally. This can lead to limitations in international research, and supplementation is necessary in the future. In addition, governance for international standard medical terminology should be actively and specifically made at the national level, and many studies using medical data that are being accumulated infinitely in each hospital should be conducted in the future.

Acknowledgements

This research was supported by a grant from Korea Institute of Drug Safety and Risk Management in 2018.

Abstract

Clinical information in electronic health records (EHRs) is mostly unstructured. With the ever-increasing amount of information in patients' EHRs, manual extraction of clinical information for data reuse can be tedious and time-consuming without dedicated tools. In this paper, we present SmartCRF, a prototype to visualize, search and ease the extraction and structuration of information from EHRs stored in an i2b2 data warehouse.

Keywords:

Electronic Health Records, Information Storage and Retrieval, User-Computer Interface

Introduction

A significant part of data daily produced in Electronic Health Records (EHRs) is either in an unstructured (free text) or semi-structured (forms) format [1]. Bordeaux University Hospital is no exception to this observation. Information extraction (IE) for secondary use of clinical data consists in transforming heterogeneous data in an EHR to a structured format of a case report form (CRF). A CRF is a specialized document used in clinical research to collect standardized information about a patient for further statistical analysis [2]. So far, researchers needed to transcribe the data from an EHR to a CRF manually. With the ever-increasing amount of information in patients' EHRs, this task has become tedious and both time and cost-consuming [3]. RAVEL [4], a previous research project carried on in Bordeaux has shown the importance of search engine and data visualization tools to retrieve information in EHRs.

The objective was to develop an interface to speed-up information extraction (IE) task for researchers.

Methods

Bordeaux University Hospital deployed an i2b2 [5] data warehouse for secondary use of medical data. Multiple data sources were integrated such as claims data, lab tests, drug prescription and dispensing, discharges summaries and radiology reports. On the top of i2b2, we've developed two tools for patient centered information retrieval and exploration:

- **i2b2 webclient timeline plugin**: This plugin was developed using D3.js library. The plugin interacts with the i2b2 data warehouse to retrieve data. A simple free text search engine was added in order to find relevant observations.
- **Standalone prototype for data exploration and CRF data capture**. Unstructured data of an electronic health record is first normalized, tokenized and lemmatized with Stanford NLP tools and TreeTagger [6] for French language. Then, noun phrases are extracted with linguistic methods and regular expression [7]. These extracted terms are then indexed in ElasticSearch™ for autocompletion and information retrieval. A web interface was developed with the Shiny package [8] of the R programming language to visualize information in an EHR.

Results

I2b2 webclient timeline plugin

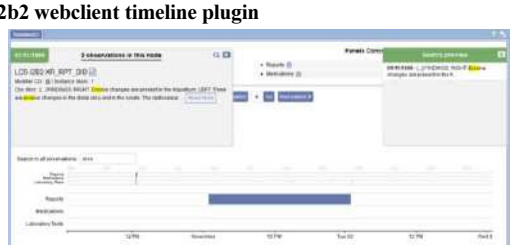

Figure 1 Search in the i2b2 timeline plugin

Figure 1 is a screenshot of the i2b2 timeline plugin. Selected observations were filtered using the search engine with the term "eros". The timeline shows a preview of the records that matched the query. Detail can be obtained by clicking on the preview panel. The term searched is highlighted. The timeline can also manage numerical values. The plugin is available under a GPL-3.0 license[1].

Standalone prototype for data exploration and CRF data capture

An EHR overview is displayed with a timeline (figure 2). The user can zoom in and zoom out the timeline. Each element on the timeline is clickable to show its content. Every element of a same data source has the same background color and different elements within a data source have different colors icons. For example, each ICD-10 category has a specific icon to represent the disease, disorder or symptom.

[1] https://github.com/vianneyJouhet/TimelineD3

Figure 2 - Timeline of a single patient's EHR. Each element is clickable to display its content. Each background color denotes a data source (claims data, lab tests, discharge summaries and medical forms).

The search engine suggests several noun phrases when a user starts typing (figure 3). Autocomplete finds terms present in the EHR and speeds up human-computer interactions.

Figure 3 - The search box. Only the sentence containing the word is displayed in the results and the term being queried is highlighted.

A wordcloud of symptoms / diseases is displayed by default (figure 4). Each term weight corresponds to its Term Frequency-Inverse Document Frequency (TF-IDF) value. A click on a term triggers a search query in the search box. Special focuses on structured data are available: a sunburst displays all ICD-10 (International Classification of Diseases, 10th revision) codes and a scatterplot shows numerical values of selected lab tests. Each sub-element of interest, like a lab test result or an ICD-10 code can be added to the timeline. The idea is to have an adaptive interface where user could decide what he wants to display for a specific IE task. For example, if the user must enquire about a past history of anemia for a set of patients he can choose that hemoglobin test and ICD-10 codes of anemia must appear on the timeline by default and the wordcloud must show terms found in unstructured data related to this disease.

To extract information, an annotation module lets the user select a textual content or a code and stores it in a database.

The prototype is open-source[2] and can be tested online[3]. The prototype was tested by medical users that provided valuable feedback to improve the interface and human-computer interactions. A software version based on this prototype is currently developed to be fully integrated in an i2b2 module.

Our next objective will be to connect the interface directly to REDCap (Research Electronic Data Capture) [9], an electronic CRF application, used in our hospital to store data of clinical studies. The REDcap export module allows the user to export data in specific formats for different analysis software.

[2] https://github.com/scossin/SmartCRF

[3] http://www.smartcrf.fr/

Figure 4 - The wordcloud. The bigger the term, the higher the TF-IDF value of that term. A click on a term triggers a search.

Conclusion

In this article, we present a clinical information extraction prototype to speed-up clinical research and facilitate data reuse in EHRs. Our next objective will be to develop an industrialized version fully integrated in our i2b2 data warehouse and to evaluate its performance in terms of usability and precision/recall for data extraction tasks.

Detecting Child Autism Using Classification Techniques

Md Delowar Hossain, Muhammad Ashad Kabir

School of Computing and Mathematics, Charles Sturt University, NSW, Australia

Abstract

Autism spectrum disorder (ASD) is a brain development disorder that restricts a person's communication abilities and social interaction capabilities from natural growth. In this paper, we have applied various supervised classification techniques to detect the presence of child autism. Our findings show that the Sequential Minimal Optimization (SMO) classifier performs best to detect ASD cases with the highest accuracy and minimum execution time and error rate. We also identify the most dominant features in dectecting child autism.

Keywords:

Autism Spectrum Disorder, Supervised Machine Learning, Child

Introduction

Autism spectrum disorder (ASD) is considered as a neurodevelopment disorder that hinders daily communication and social behavior from natural growth [1]. Data mining classification techniques can be applied to detect ASD cases. The main objectives are to reduce the diagnosis time in order to get quicker access to healthcare services, improve diagnosis accuracy, and finding the highest ranked features of ASD.

There are number of prior studies that have applied classification techniques on adult ASD data. For example, K. Basu *et al* [2] analyzed the Adult Autism screening data set using supervised data mining techniques and showed that Support Vector Machine (SVM) classification technique outperforms other classifiers. Later, Brian McNamara *et al* [3] classified the same dataset by applying decision tree and random forest classifiers. They pre-processed the dataset by removing the records with missing categorical instances and less significant variables, before applying the classifiers. They found that random forest outperforms over decision tree classifier.

Compared to the aforementioned research, in this paper, we apply supervised learning techniques on child ASD data. To the best of our knowledge, our study is the first one that applied supervised learning techniques on ASD dataset of children aged 4 to 11 years. Our goal is to analyze the dataset using existing classification techniques and classify them in one of the two categories: "children having ASD" or "children not having ASD". We compare the performance of various methodologies to determine the best classification technique for this dataset. Our results show that Sequential Minimal Optimization (SMO) classifier performs best amongst all the supervised classifiers. We also analyze the dataset to find out dominant features that cause ASD based on the answers given to the ASD questionnaire.

Methods

In this section, we present our approach for detecting ASD cases using various classification techniques. It includes several steps such as dataset exploration, data preprocessing, and classification.

Data Set Exploration

We used the dataset from UCI Machine Learning Repository [4]. The child dataset contains ten binary features (A1_Score to A10_Score), two numeric features - age, results, and categorical variables such as gender, ethnicity, jaundice status, family member having PDD (Pervasive Developmental Disorder), country of residence of the person who answered the survey, used the screening app before, age description, and ASD class. The dataset contains 292 records and 19 attributes after selecting the screening type.

Data Preprocessing

In order to simplify our analysis, we discarded less significant variables such as used_app_before, country_of_res, and age_desc [2, 3]. By analysing the "results" feature, we found that result score =>7 indicates ASD positive and score <7 indicates non-ASD. So, we excluded this attribute before classification to avoid predefined situation where the output is already known. We removed all of the records containing missing values. We found 43 ethnicity entries missing in the dataset, so we removed those records. We also noticed "age" was missing for one record. So, we replaced this missing value with the median value of age. Finally, our observations on final datasets count are shown in Table 1.

Table 1- Final Child Dataset

Female	Male	ASD_Class
38	85	No (123)
36	90	YES (126)
Total number of cases:		249

Results

We analyzed the child dataset and applied 28 supervised classification techniques of different groups such as Rules, Bayes, Function, Lazy, Meta (Decision Tree used a base algorithm) and Tree. We applied pruning for Tree base algorithm. We used WEKA data mining tool and applied 10-fold cross validation. We found the classifiers from "Function" such as Multilayer Perceptron, Simple Logistic, SMO, classifiers from "Meta" group such as Iterative Classifier Optimizer, LogitBoost, and Real Adaboost, and LMT (classifier from Tree group) result in 100% accuracy, precision, recall, and F-measure (Table 2). We also determined the dominant features for child Autism by analyzing the LogitBoost supervised classifier and performing weight-based analysis. We found the following are the most dominant features in detecting child autism:

- *A4_Score*: S/he finds it easy to go back and forth between different activities
- *A10_Score*: S/he finds it hard to make new friends
- *A8_Score*: When s/he was in preschool, s/he enjoys playing games involving pretending with other children

Here, *A4_Score* is related to child's intellectual disability. *A10_Score and A8_Score* are related to social interaction abilities. Autistic child find it difficult to make new friends and sometimes they enjoy playing games involving pretending with other children. This implies that difficulty with social interaction is a key symptom of ASD. Answering "yes" to these questions are dominant contributors to the model prediction.

Table 2- Classifier Performance Statistics for the child dataset

Classifier	Accuracy	Precision	Recall	F-measure
ZeroR	50.60	?*	0	?*

LMT	**100**	**1**	**1**	**1**
NBTree	95.18	0.96	0.93	0.95
Random Forest	96.78	0.97	0.95	0.96
Random Tree	80.72	0.83	0.76	0.79
SysFor	86.34	0.85	0.87	0.86

Note. *no result produced

We observed different types of error during the classification time such as mean absolute error, root mean square error, relative absolute error, and root relative squared error. These errors are the outcome of the difference of our predicted model and observed data. We determined which classifier has the least error or is totally free of errors.

From Table 3, we can see that the best performing classifier is SMO which implements John Platt's sequential minimal optimization algorithm for training a support vector classifier.

Table 3- Comparison of Classifier's Error and Execution Time

	Mean Absolute Error	Root Mean Square Error	Relative Absolute error	Root relative squared error	Execution Time (sec)
Multi-layer Perceptron	0.005	0.026	1.102	5.357	1.22
Simple Logistic	0.061	0.117	12.20	23.50	0.24
SMO	**0**	**0**	**0**	**0**	**0.06**
Iterative Classifier Optimizer	0.098	0.156	19.73	31.22	0.3
LogitBoost	0.098	0.156	19.73	31.22	0.1
Real Adaboost	0.069	0.13	13.90	25.99	0.03
LMT	0.061	0.117	12.20	23.50	0.14

It breaks the problem into a series of smallest possible sub problems, which are then solved analytically. As a result, this classifier has least execution error (0 in this case) and execution time (0.06 second).

Conclusions

In this study, we classified ASD child dataset using supervised classification techniques and found that SMO classifier performs best in terms of accurate prediction of child ASD. Additionally, SMO is also free from classification errors, suggesting that it aligns well with 10-Fold cross validation. By analyzing our experimental results, we also identified the most dominant features that significantly contribute to detecting child autism.

TBench: A Collaborative Work Platform for Multilingual Terminology Editing and Development

Panpan Deng, Yujing Ji, Liu Shen, Junlian Li, Huiling Ren, Qing Qian, Haixia Sun

Institute of Medical Information, Chinese Academy of Medical Sciences, Beijing, China

Abstract

Terminology facilitates consistent use and semantic integration of heterogeneous, multimodal data within and across domains. This paper presents TBench (Termilology Workbench) for multilingual terminology editing and development within a distributed environment. TBench is a web-service Java tool consisting of two main functionalities that are knowledge construction (i.e.extended model based on ISO25964, batch reusing and constructing multilingual concept hierarchy and relationships) and collaborative control in order to achieve custom extensions, reuse, multilingual alignment, integration and refactoring.

Keywords:

Controlled Vocabulary, Software, Architecture

Introduction

Many terminology, taxonomy and ontology editing tools have been developed, and some are world-famous, such as Protégé [1]. However, many domain experts, even terminology experts, still think that there are no suitable tools for them to build what they want. In addition to economic factors, complexity of operations and cognitive burden may be two important reasons. The former is usually manifested as new hierarchy trees and relationship instances, which can only be created one-by-one. Other lingual terms can only be created as non-preferred terms, are unable to reuse related thesauri and ontologies flexibly, have difficult to extend attributes and relationships for knowledge units, and so on. The latter is mainly manifested as lack of understanding of the meaning of user interface function labels. Motivated by these shortcomings, TBench was designed and developed.

Methods

TBench is based on a classical three-tier architecture (Figure 1), structured through a data layer, a functional layer and an interface layer.

Data Layer Design

Data Description Format Design

According to SKOS and ISO25964 [2], TBench has a customizable data model including core and extended models for all knowledge units (versions, thesaurus, concept group, concept, term, note, etc.) respectively. Each terminology system or top concept tree can define its own extension model on term type, hierarchical and semantic relationships, descriptions of attributes, etc.

Data Storage Format and Data Format Converter Design

All data are stored in an Oracle relational database. To facilitate users conversions of data between different formats (TXT, JSON, XML and RDB) and semantic description models (SKOS, OWL and RDF), data format converters are also designed.

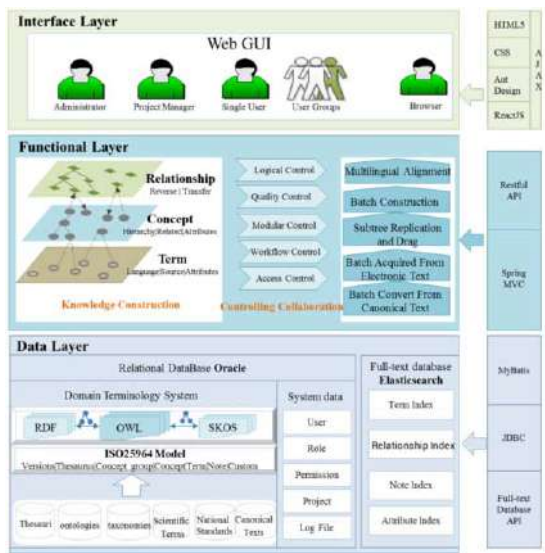

Figure 1- The Architecture of TBench (Termilology Workbench)

Functional Layer Design

The functional layer consists of two main parts: knowledge construction and collaborative control. In addition to basic editing functions, batch construction and multilingual mechanisms are also designed and developed to support cross-language knowledge construction easily and efficiently.

Batch Construction by Flexible Reuse and Operation

Multiple ways are designed for reuse and batch construction, inculding:

1. Using automatic batch conversion techniques, canonical text can be batch converted to hierarchical structure, sibling concepts, non-preferred terms and semantic relationships.

2. Through grammatical rules, concepts and relationships from electronic text are quickly acquired and integrated with a clear workflow.
3. For reuse and integration, fast replication and simple drag operations of subtrees within or between terminology systems are designed and implemented.
4. Some objects having common features can be batch created using 'indication' relationships with the same domain.

Multilingual Mechanism Design

In order to create a terminology system containing multilingual terms, each concept has a preferred term in every language. To provide the culture feature, all objects (concepts, relationships, attributes, etc.) of TBench have a 'language' description. Exact, inexact and partial equivalence mappings among preferred terms of the same concept in different languages can also be created to reveal cultural differences. For instance, the mapping between 'aircraft' and '飞机' is inexact.

Controlling Collaboration Between Users

A role-based access control (RBAC) model was adjusted to support flexible configuration between users, roles, permissions, and task state automatic transitions by using direct permissions setting and the introduction of resource work states. Locking and unlocking were used to resolve knowledge unit conflicts during real-time collaborative editing.

Interface Layer Design

Different Tasks, Different Workflows, and Different User Interfaces

To provide multi-user personalized usability, customizable user interfaces were also designed. Users can choose the function modules, data items in modules, and system labels. For instance, menus, buttons and attributes can be described in natural language depending on the user.

Results

TBench has been developed (Figure 2) in Java™. In addition to the data converter, all the above designs have been implemented. It is being used for cross-institutional constuction of the Chinese Clinical Terminology System (CSCT), consisting of 14 categories of 207,000 concepts organized hierarchically, and 65 semantic relationships.

Conclusions

TBench, a web-service tool, can be used for collaborative building and maintaining of controlled vocabularies, thesauruses, classifications, taxonomies and ontologies. It improves several key points, such as customizable data models and interfaces for different users, batch construction operations for relationships and concept hierarchies, and so on. The reliability of TBench is being tested and verified with CSCT. Crowdsourcing of construction will continue to be studied in the near future.

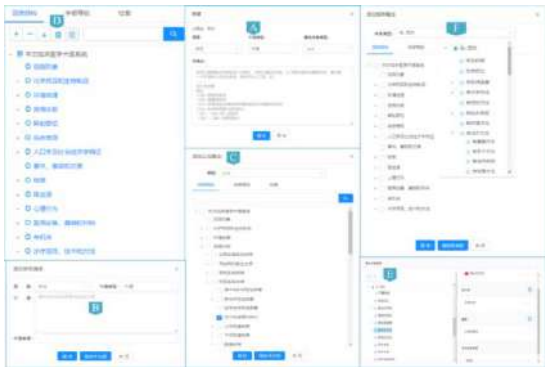

Figure 2 – TBench (Terminology Workbench) user interface. (A) Concept creation interface. It can automatically batch convert from canonical text and configuration language, term type, and relationship type. (B) Non-preferred terms batch creation interface. (C) Upper concept configuration interface. Selecting multiple upper concepts is an effective way to establish poly-hierarchical relationships. (D) Tree structure interface enables users to create, delete, copy, cut, paste and drag a concept or subtrees. (E) Relationship configuration interface enables users to customize various new relationships with their domain and range. (F) Relationship instances with the same domain can be batch created by choosing multiple concepts as a range.

AdhereR: An Open Science Approach to Estimating Adherence to Medications Using Electronic Healthcare Databases

Alexandra Dima[a], Samuel Allemann[a,b], Dan Dediu[c]

[a] *EA 7425 Health Services and Performance Research, Université Claude Bernard Lyon 1, Lyon, France,*

[c] *Laboratoire Dynamique du Langage, Université Lumière Lyon 2, Lyon, France*

Abstract

Adherence to medications is a key performance indicator and behavioral outcome in healthcare. Electronic healthcare databases represent rich data sources for estimating adherence in both research and practice. To build a solid evidence base for adherence management across clinical settings, it is necessary to standardize adherence estimation and facilitate its appropriate use. We present the recent development and oportunities offered by AdhereR, an R package for visualisation of medication histories and computation of adherence.

Keywords:

Medication Adherence; Medical Records; Reproducibility of Results

Introduction

Taking medication as prescribed (medication adherence) is essential for treatment effectiveness. Current research estimates total annual costs from suboptimal medication adherence of up to 50000 USD per patient [1]. Effective adherence management in routine care requires appropriate measurement and interpretation of medication use in real-life settings. For long-term treatments, medication use involves multiple prescription and dispensing events, recorded in administrative or clinical databases. These data have been successfully used to detect delays or interruptions in medication acquisition, suggesting lower use or interruption of treatment. However, there have been substantial variations in algorithms to estimate adherence, and minor differences in algorithms have been shown to impact results [2]. This raises concerns over the validity of adherence evidence and highlights the need to standardize analysis and encourage reproducible science. We therefore developed functions to facilitate reproducible adherence calculations in the statistical environment R [3].

Methods

We reviewed current guidelines for adherence definition and methodological literature on calculating adherence from electronic healthcare data (EHD). We developed several flexible functions in a new R package (AdhereR) and training materials to facilitate all stages of data analysis, from data preparation to visualisation and calculation of estimates. The 3-component consensus taxonomy for medication adherence [4] was used to build separate functions for initiation, persistence, and implementation.

Results

Currently, AdhereR is released as an R package (library). Its core functionality is written in pure R and is optimised for various use scenarios, being able to effectively scale up from the analysis and displaying of a few patients on a consumer-grade laptop to the batch processing of millions of records on parallel heterogeneous compute clusters. It can use data stored in various formats, from "flat files" in CSV, Excel, SPSS, Stata or SAS files to large relational databases using SQL or other architectures such as Hadoop.

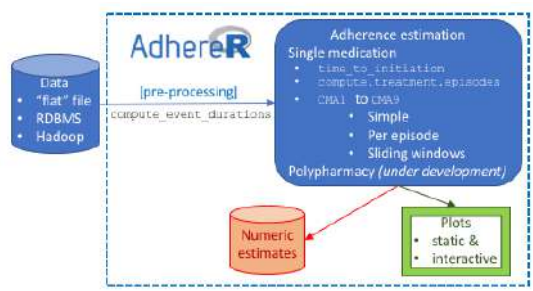

Figure 1– Schema of the AdhereR Package Functions, Input and Output.

Didactically, we can distinguish three main classes of functionalities implemented by AdhereR (Figure 1). First (and optionally), prescription, dispensation and hospitalisation data can be pre-processed to extract the type of information used by the subsequent steps, namely the patient unique ID, the date and the duration of each event, and possibly its medication class and dosage (compute.event.durations). Second, these data can be used for the estimation of initiation (time_to_initiation), (non-)persistence (compute.treatment.episodes), and various types of implementation estimates: simple, per-episode, and sliding-window Continuous Medication Availability (CMA) functions. Among the "simple" numeric CMAs, eight (CMA1–CMA8) are implemented from the literature and one (CMA9) original; these differ in the assumptions they make about the underlying processes, possibly being appropriate for different scenarios and sometimes resulting in drastically different estimates. Moreover, we have developed two "temporal" CMAs that produce a time series of CMA estimates, one based on the idea that there are separate treatment episodes (defined in various ways), the other defining regularly spaced (and possibly overlapping) sliding windows of fixed duration. These

functions are currently available for single medications, and equivalent functions for polypharmacy are under development.

Finally, AdhereR can produce publication-quality static plots of the data (and possibly of adherence estimates) or interactive graphs which react in real-time to the user's input (currently using Shiny, HTML5, CSS and JavaScript, which can be run in a standard web browser). These allow data exploration and may be used to examine the influence of analysis assumptions on the adherence estimates for individual medication history, thus guiding the expert validation of parameter choice for adherence calculations. Figure 2 shows an example plot for one of the implementation functions (CMA9) calculated over an observation window of 6 months within a follow-up window of 2 years. In the interactive plotting function (plot_interactive_cma), parameters can be modified to select various time windows and CMA functions and observe their effect on the CMA value. Further information is available in the extensive help and vignettes included in the package, as well as online at www.adherer.eu.

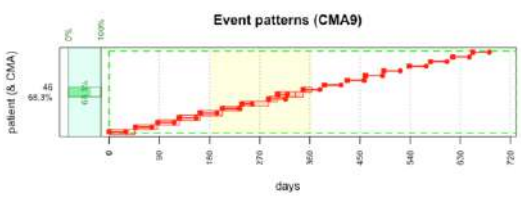

Figure 2– Visualisation of a Patient's Medication Event Patterns (Red Bars) across 730 Days (x-axis), with CMA9 over 182 Days (Yellow Area) as 68.3%. Horizontal lines represent the calculated period covered by the supply prescribed or dispensed during an event.

It is important to note that such numeric estimates and plots of adherence represent only part of a broader, integrated approach to addressing the root causes of non-adherence, which must include specific training of the healthcare professionals in interpreting these indicators, in interaction with the patients. Issues of data quality need to be acknowledged, and the interpretation of the results must provision for various sources of error and missing data. Moreover, we must stress that there is no single 'best measure' of adherence that fits every clinical setting, research question, or individual patient. Therefore, the selection of adherence measures and plotting must consider the specificities of each particular case.

Conclusions

AdhereR represents a proof-of-concept for reproducible and transparent research on EHD. The package is under intense development on three mains axes: first, we are developing a set of functions that compute the adherence to polypharmacy, which represents an important and complex set of use scenarios; second, we are exploring advanced longitudinal analyses that better reflect the temporal dynamics of adherence; finally, we are improving the technology powering interactive plotting, aiming towards better performance on thin clients with a reduced need for costly server-side processing.

Abstract

We completed a pilot study to guide the development of the VA Research Precision Oncology Data Commons infrastructure as a collaboration platform with the greater research community. Our results using a small subset of patients from the VA's Precision Oncology Program demonstrate the feasibility of our data sharing platform to build predictive models for lung cancer survival using machine learning, as well as highlight the potential of target genome sequencing data.

Keywords:

Machine Learning, Lung Neoplasms, Precision Medicine

Introduction

The Massachusetts Veterans Epidemiology Research and Information Center (MAVERIC) launched the Research for the Precision Oncology Program (RePOP) and the Precision Oncology Data Repository (PODR) in 2016 to acquire the knowledge necessary to improve care for Veterans with cancer. In the fall of 2017, MAVERIC entered a partnership with the University of Chicago to establish a VA Research Precision Oncology Data Commons (RePODC) to provide greater access to both VA data and robust computing resources to the research community external to the VA. We conducted a pilot study to guide the development of the RePODC infrastructure for data sharing and to demonstrate the feasibility of building predictive models with both clinical and genomic data. .

Methods

The exploratory dataset contained 60 instances, each of them a patient record containing a preselection of 153 features based on targeted genome sequencing, an extract from the VA's comprehensive clinical information on each patient, as well as basic demographic data. Following previous work by Lynch et al [1], a small number of candidate features were selected based on their potential relationship with survival time, including both continuous and categorical variables, for a total of 16 attributes. Among the selected features we included the presence of tumor variants for CDKN2A, KRAS and TP53, the number of primary tumors, tumor stage and location, histological findings, exposure to radiation protocols, and the sequence of radiation with surgery. Logistic regression and random forest algorithms were used to predict survival status at 24 months after diagnosis. Ten-fold cross validation was used to assess accuracy.

Results

Cross-validated accuracy was 0.886 for for both the logistic regression and random forest classifiers. In order of importance, the random forest algorithm identified primary tumor location, age, surgery primary site and the variant CDKN2A as the most relevant features to predict survival stage, with higher scores than other features of known importance like stage or histology.

Conclusions

Our results, using a small subset of patients from the VA Research in Precision Oncology Data Commons, demonstrate the feasibility of using this data to build predictive models for lung cancer survival using machine learning methods, and particularly highlight the potential of targeted tumor sequencing data for building predictive models of survival. This work suggests that by expanding access to VA data, we enable use of modern machine learning methods and advanced analytics to contribute to scientific knowledge and improve Veterans' healthcare.

Semantic Data Integration Service for eHealth Applications

Arthur Domingues, A. Sousa Neto, A. Freitas, S.D. Silva, A. Félix, F.M. Mendes Neto

Abstract

Technologies for health have been receiving considerable attention with the popularization of devices for internet access. The Internet can be seen as a repository of knowledge due to its large amount of available information; however, on the other hand, in the midst of this vast amount of content, there is information either scientifically inaccurate or incomplete. This work presents a semantic integration service to provide information of diabetes from medical databases to eHealth applications.

Keywords:
Content; Information Retrieval; Search Engine.

Introduction

The term health education, according to the World Health Organization [1], refers to a set of practices that contribute to the development of autonomy of the population regarding the maintenance of their health. Technology applied in health education narrows the relationship between health professionals and patients, in addition to renewing the understanding of health practices [2]. Besides, with the growing expansion of the Internet and information available on it, it is essential that the individual seek this knowledge to become an active member in the management of their health, thus sharing a responsibility that was previously exclusive of the health professionals.

A survey conducted by the Britsh United Provident Association (BUPA) in 2011, illustrated that 86% of Brazilians seek health content on the internet, but only 25% confers the source. The research illustrates that the absence of Internet content quality standards can pose a great risk in the health area, both among health professionals and among patients[3].

In this regard, systems that integrate and make available specialized database information appear as solutions to the problem of the lack of credibility of data sources. Data integration combines information residing in different sources and provide the user with a unified view of that data [4].

It is in this scenario of technology used to health information retrieval that the present work is grounded and developed. The work presents a service to integrate information of diabetes from medical databases to eHealth applications. The purpose of the service is to enable eHealth systems to provide reliable content to the reality of their users, seeking a better and greater knowledge of health and, consequently, improvements in the quality of life.

Methods

The integration service was developed in PHP language. The data captured by the service is stored in a MySQL database. The architecture of the proposed integration service consists of three components: Search Interface, Crawler and Indexer.

Search Interface works like as mediators between the requests and indexed documents [5]. The search interface is the communication channel between eHealth applications and the integration service. This component has the function of receiving the search parameters such as quantity and content types, and also returning the corresponding contents.

Crawlers are generally deployed to retrieve documents for search services [6]. Crawler is responsible for periodically visiting the databases automatically, in order to collect content. Crawler captures the XML file for content, performs tag read, and stores the information in service database. The contens are provides by medical specialists and health professionals databases. Contents are described by metadata and made available in the form of scientific articles, videos and electronic records on health and human well-being. The bases chosen were: Brazilian Virtual Health Library, Medline and Webmd. Contents collected by the crawler are sent to the indexer.

In search and retrieval services, indexers works like as collections of data sources that use some technique to rank information [7]. Indexer component store lists of the contents of the databases. After crawler finds contents, indexer use an ontology to store and rank the retrieved contents.

The ontology was described in OWL language through the PROTEGÉ tool. Ontology has integrated into the indexer, by OWL-API. Through the API was possible to indexer create and manipulate ontologies. The terms and concepts of this ontology are widespread by the Brazilian Society of Diabetes and American Diabetes Association. The ontology is formalized by terms referring to diabetes, such as: causes, symptoms and treatments. The ontology accomplishes the classification of the meta data, and returns to the indexer an index of semantic relation of the contents with the diabetes. The indexer returns to the search interface a list with the classified contents. In Figure 1, the architecture is represented graphically.

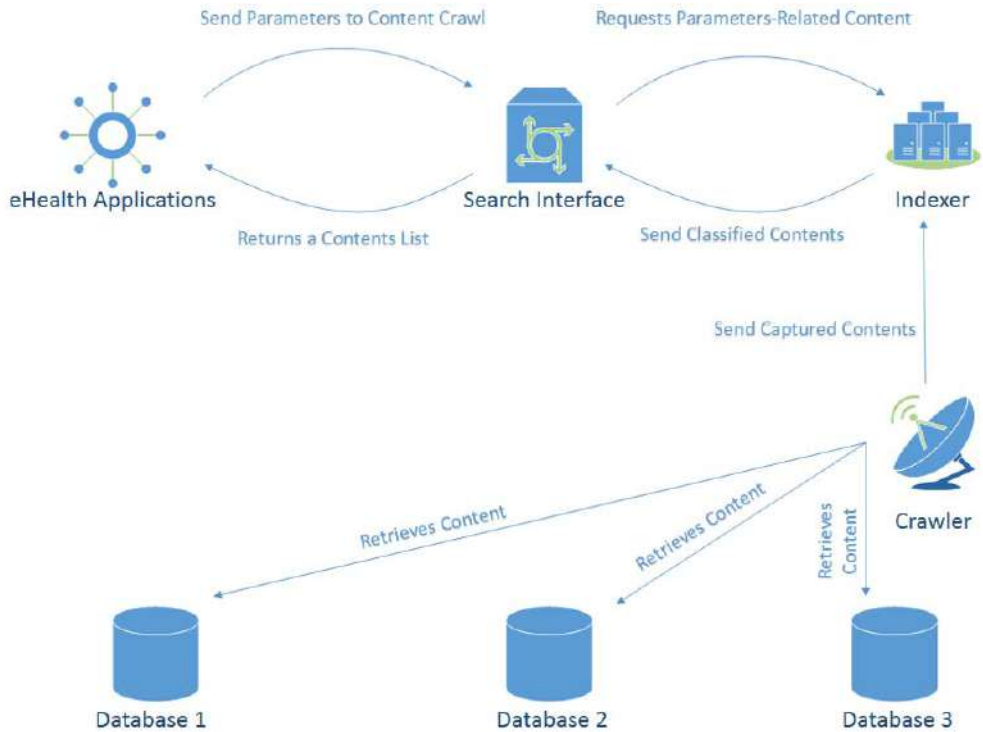

Figure 1. Architecture of Integration System

Conclusions

This work presented an integrated service with information from health databases. The purpose of the integration service is to ensure that eHealth systems provide its users correct and scientifically relevant content in the context of diabetes.

The service works as a middleware between the eHealth systems and the health databases. The service components perform all the process of reading the request of the applications, verification of corresponding information and semantic relation of the results with the parameters.

In order to evaluate the results obtained, the service will be integrated to MobiLEHealth. The MobiLEHealth is as a recommendation and informal learning system in the context of Health 2.0 that performs the monitoring of web content and social media accessed or generated by users, through their interactions [8].

Identifying Patients with Significant Problems Related to Social Determinants of Health with Natural Language Processing

David Dorr[a], Cosmin A. Bejan[b], Christie Pizzimenti[a], Sumeet Singh[a], Matt Storer[a], Ana Quinones[a]

[a] *Oregon Health & Science University, Portland, OR, USA;*
[b] *Vanderbilt University, Nashville, TN, USA*

Abstract

Social and behavioral factors influence health but are infrequently recorded in electronic health records (EHRs). Here, we demonstrate that psychosocial vital signs can be extracted from EHR data. We processed structured and unstructured EHR data using expert-driven queries and Natural Language Processing (NLP), validating results through structured annotation. We found that although these vital signs are present in EHRs, with 681 structured entries identified for psychosocial concepts, NLP identified a nearly 90-fold increase in patients.

Keywords:

Social Determinants of Health, Natural Language Processing

Introduction

Social determinants of health (SDH) – the social circumstances that shape health risks and outcomes, such as behaviors, social connections, and housing – comprise a large percentage of overall health and well-being across the lifespan. In the United States, medical professionals are increasingly being asked to consider pertinent social determinants in their care, and to act on them when appropriate. However, psychosocial assessments are infrequent, incomplete, and are often not captured as discrete data elements within the electronic health record (EHR).

One strategy to identify patients with SDH needs is to extract these concepts from narrative text. In prior studies, we found that primary care practices caring for persons with multimorbidity both recorded social and behavioral constructs as narrative text [1,2]. Here, we investigate how best to detect key psychosocial variables in a broad dataset by adapting a data-drive process developed by Bejan et al [3].

Methods

Overview

The phenotypic profiles for four key psychosocial vital signs were extracted from EHR data using queries and notes using lexical associations expanded by expert input. Then, for each psychosocial vital sign, we manually reviewed the retrieved charts.

Data Set & Study Design

We extracted and standardized into a common data model EHR data from 2 hospitals, 30 primary care practices and 90 specialty clinics in Oregon representing 3.28M patients with a mix of ages and insurance types. From these individuals, 22% had multimorbidity defined by two of 21 chronic illnesses common in risk scores. From this set, we extracted a subset from 2017 data; these 358k patients had 89.2M notes during 2017.

We selected 4 psychosocial vital signs in this study: chronic stress, social isolation, financial insecurity; and one replication – housing insecurity or homelessness – from previous work by Dr. Bejan [3]. We used lexical association measurements and expert input to identify seeds, or word expressions, that were likely to be used in narrative notes to represent the 4 psychosocial vital signs; then, we ran an information retrieval system over the entire dataset using the identified seeds as query input, validated the retrieved results, and modified the seeds in an iterative process.

Query expansion based on lexical association

Starting with all the notes from the data extract, the method first selected all the documents with at least 1 seed word. Next, the content of these documents was tokenized, the tokens were converted to lowercase, and the low frequency tokens and punctuation marks were discarded. After this preprocessing step, each word w occurring in the context of a seed was ranked according to the following formula:

$$score(w) = \log \frac{LAM(w,S)}{(1+f(w))^{\lambda}}$$

Here, $f(w)$ represents the frequency count of w, λ is a parameter that controls the degree to which the inverse word frequency of w should weight in the relevance score, and LAM denotes a metric of lexical association between w and the seed words in S. The query expansion based on lexical association for extracting the final query terms was performed on the clinical notes from the Vanderbilt EHR [3]. The lexical association measures used in our experiments include the χ^2 test.

To assess the relevance of patients to a psychosocial vital sign, we calculated the similarity of the corresponding patient notes to the psychosocial vital sign query by the standard term frequency–inverse document frequency (TF-IDF) weighted cosine metric such that the most relevant patients to the query were ranked on top of the retrieved patient list. Notably, each patient in our framework was represented as a meta-document that included all the patient notes. To weight the query term i in the meta-document of patient j, we computed the TF-IDF weighting scheme as follows:

$$w_{i,j} = tf_{i,j} \cdot \log \frac{N}{df_i}$$

where $tf_{i,j}$ is the number of occurrences of the term i in the meta-document of patient j, df_i is the number of patients whose corresponding meta-documents contain the term i, and N is the total number of patients in the data extract.

Annotation

Three assessors who were either faculty or research assistants collaborated to design an annotation process that assessed the accuracy of the results. For each concept, a specific set of instructions and a data collection template were created. These

were tested with 5-10 retrieved patients, then revised. For the formal collection, 30 retrieved patients (out of the 600 most relevant) were selected by one annotator, with a third each coming from highest, medium, and lowest relevance. A Likert scale of 0-5 was used for confidence of whether the concept was present; a score of 3 or greater was deemed a true positive. These were randomized and another annotator completed the manual chart review. For a subset of 25%, two independent annotations were done and compared, with disagreements resolved by consensus.

Query reformulation based on relevance feedback

Query reformulation was completed based on the initial annotations. We adopted this approach to improve each search by iteratively refining the 4 psychosocial vital sign queries. For this, the assessors reviewed the chosen notes to manually detect recurrent keywords. The most prevalent and relevant keywords from each run were selected for each reformulation. During this process, the selection of terms to be checked for negation was also performed. Once this was completed, the annotators completed the extraction again, repeating the same process. Reformulation was considered complete after 4 cycles or when precision was greater than .90.

Analysis

We describe the general demographics of included patients. We provide average and 95% confidence intervals for relevance and inverse patient frequency (IPF). We used the manual chart review as true positives (TP) and calculated precision based on TP/all retrieved meta-documents.

Results

In all, there were 358,244 patients with 86 million notes. Their average age was 43.0 ± 25.5 and 55.1% were female. Overall, 82.6% were Caucasian, 3.9% were Asian, and 3.4% Multiracial. They had 2.3 outpatient encounters on average. Overall, there were 358,244 patients with 89.2 million notes. This approach matched between 375 and 54,950 of patients across the concepts. The IPF range was wide, from 1.9 – 7.5 in chronic stress to 6.5-12.7 in financial insecurity. Relevance scores for the first 600 patients ranged from 12.3 to 267.3. Initial precision varied; homelessness was replicated on the first evaluation, with a patient level precision of .93. Other concepts ranged from .60-.68. For the iterations, each improved significant in IPF or relevance. Precision, our primary outcome, achieved levels of > .90 in all except social isolation. Our preliminary error analysis of social isolation identification indicated that most of the false positives were generated due to occurrences of negated social isolation expressions in patient notes. For that concept, once negation was resolved, it achieved target precision. Average scores improved as well, with initial seeds ranging from 2.75-2.9/5 and final seeds from 3.8 to 4.9/5. Higher relevance scores were more associated with matches, indicating reasonable calibration.

Conclusions

We were successful in implementing an iterative query approach using lexical associations, achieving our goal precision of > .90. NLP produced a nearly 90-fold increase in patient retrieval relative to querying structured data elements. By querying across a dataset for rarer conditions, we may more quickly allocate resources to needs. This method demonstrates a significant improvement in detection of persons who may be eligible for care coordination or social services to address these concerns.

Abstract

Standardised, automated quality reports were generated at three pilot locations of the decentralized translational research network DKTK with separated local data warehouses (LDW), for assessing syntactic conformity against common data element definitions deposited in a central metadata repository (MDR). Deviations in the LDW were categorised, and locally corrected. Comparisons of reports from two time points confirm a major improvement in data quality in terms of syntactic conformity, an essential prerequisite for network-wide data integration.

Keywords:

Common Data Elements, Metadata, Data Accuracy

Introduction

The German Consortium for Translational Cancer Research (DKTK) [1] is a network of more than 20 institutions at nine locations, pursuing the aim of efficiently transferring results from cancer research into the clinical practice. The DKTK implements a federated data storage concept, interconnecting LDW with so-called bridgeheads [2]. In order to allow comparisons between the partners' data on clinical cases and biomaterial, the network has agreed on a common data set (MDS) with defined data elements and their permitted values, which has been deposited in a central metadata repository (MDR) [3,4]. An essential prerequisite for the success of data integration processes within decentral research networks is high data quality [5,6]. For the assessment of data quality (here: syntactic conformity [7] with the MDR) we implemented a quality report generator (QR-generator), which can be installed at every network location, in order to perform an alignment of data in the LDW against the centrally defined data definitions in the MDR [8,9].

Methods

The QR-generator installed at a given network location produces quality reports in Excel format as described in [8,9]. Briefly, this report lists all values recorded for each data element in the LDW, highlighting each value that is not concordant with the respective definition specified in the MDR. In addition, the report provides statistical calculations for each data element with regard to completeness and syntactical correctness. Upon production of a report, all errors are manually categorised, compared with network partners' errors, and suggestions are given for solutions to be implemented by the site. Then a second report is produced and compared with the previous one, in order to assess changes in data quality. Though the reports provide detailed mismatch information on a per-patient basis to the local sites, the results described here are summarized on a per-data-element basis for data protection reasons.

Results

QR-generators were installed at each of the nine DKTK locations. In a pilot study, sets of quality reports have been produced at three network locations, allowing the sequential assessment of data quality over a period of 8-10 months.

At the Charité in Berlin, the LDW in the bridgehead serves as the primary tumour documentation system. Quality reports have been produced in March and December 2017 (104.000 and 137.000 patients in the LDW, respectively). The following error categories have been identified: deviations in the source system (including the usage of special codes that are not conformant with the German cancer coding system); minor syntactic errors such as differences in capitalisation; missing mappings of local values to the MDS; technical errors, e.g. with regard to date definitions. Error correction strategies included re-documentation in the source system under controlled conditions based on SOPs; adjustment of the technical interfaces to correct systematical deviations as well as mappings at the level of data elements or their values.

Out of 52 data elements assessed, 21 were syntactically correct from the beginning (Figure 1). Two data elements were fully corrected directly in the source system. Other data elements, showing capitalisation errors or additional text following a systematic pattern, could be corrected by adjustments to the technical interface, improving MDR conformity considerably, in six cases to more than 95%. For three data elements, an additional adjustment of the mapping at value level led to complete MDR conformity.

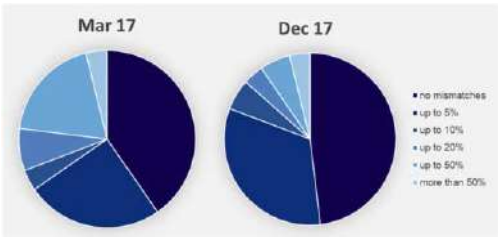

Figure 1 - Assessment of 52 data elements at the Charité, Berlin, at two time points

In Munich, there are two university medical centers hosting their own bridgeheads, namely the MRI, and the KUM. Both institutions provide an LDW in the bridgehead purely dedicated to making data available to the DKTK network. Data from the primary tumour documentation systems are transferred to the LDW via "extract-transform-load" (ETL) processes. ETL processes are well suited to handle systematic deviations. The major challenge here consists in the identification of the correct mappings between the primary systems and the LDW. The error categories identified were: missing data elements (not found); non-MDR-conformant value mappings (mismatch); correct element mapping with some remaining individual errors (partial match). Error correction strategies relied mainly on adjusting the local ETL processes, as well as centrally provided adjustments to the technical interface.

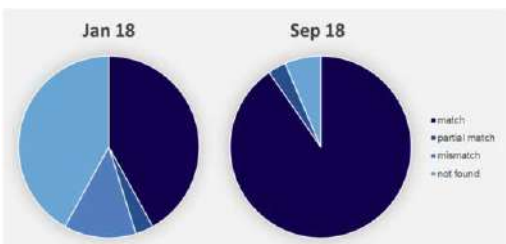

Figure 2 - Assessment of 62 data elements at the MRI at two time points

At the MRI, out of 62 data elements assessed in January 2018, 26 showed a perfect syntactic match (Figure 2). Another 26 data elements were not found in the LDW, while 10 data elements had mismatches or partial matches. At re-assessment in September 2018, the vast majority of data elements (90%) were fully MDR-conformant, with only 6 elements not being found or showing partial matches.

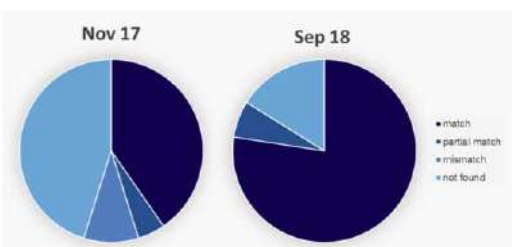

Figure 3 - Assessment of 62 data elements at the KUM at two time points

At the KUM, the data element status at the beginning (November 2017) was very similar to the MRI (Figure 3). Here, 48 out of 62 data elements (77%) showed full MDR-conformity at re-assessment in September 2018, while 14 elements were not found or had partial matches. Five of the data elements are missing due to the fact that the biobank could not yet be integrated into the LDW for organisational reasons.

Conclusions

Standardised quality reports represent suitable tools for the assessment and continuous improvement of data quality at DKTK locations. Moreover, they facilitate the exchange and consolidation of data within the network and help the local documentation systems in identifying and correcting errors. Given the dynamic of newly added data elements and growing patient numbers, the monitoring of data quality represents a continuous challenge.

Abstract

This work investigates the capability of SNOMED CT to encode microbiology laboratory data with the goal of fully describing multidrug resistance and breakpoint assignment by specimen.

Keywords:
Systematized Nomenclature of Medicine; Microbiology

Introduction

Antimicrobial resistance (AMR) is transforming the treatment of common infectious diseases. There is a strong international call for actions [1; 2] which include improved data sharing to support secondary usage of medical data [1].

Clinical microbiology laboratory data plays a key role in the fight against AMR [3]. Recording lab data without systematized nomenclature, such as LOINC & SNOMED CT interoperability standards, creates a burden for primary and secondary users of the data [4]. Initiatives in several countries demonstrate the added value of nomenclature standards to support national AMR surveillance [5]. Adopting standards by *in vitro* diagnostic (IVD) systems manufacturers should help microbiology labs report data to local, national and international AMR surveillance systems.

bioMérieux's (IVD solutions provider for the diagnosis of infectious diseases) VITEK®2, VITEK® MS, ETEST® & VIDAS® systems, have [6] >99% LOINC coverage and 90% coverage of nominal SNOMED CT observation values and 60% of SNOMED CT ordinal values. We have identified actions to help close the remaining gaps.

The work presented here describes (1) how we plan to complete the SNOMED CT encoding of our microbiology laboratory data using analytics ; (2) analyze the capability to SNOMED CT to represent and support analysis of MultiDrug Resistant Organisms (MDRO) [7] and (3) initiate SNOMED CT mediated laboratory data analytics.

Methods

Biological specimen

Specimen used in bioMérieux MYLA®, ARGENE® CONNECT systems are grouped according to their implied semantic and business role. Those groups were manually mapped to SNOMED CT (sub-) hierarchies concepts (table 1). The mapping was guided by the HL7 SPM segments.

Table 1– SNOMED CT hierarchies for each group & link to HL7 SPM segment

Group	SNOMED CT hierarchy or sub-hierarchy	HL7 (SPM)
What	*105590001 |Substance (substance)|*	4, 5
Where	*442083009 |Anatomical or acquired body structure (body structure)|*	8, 9
How	*71388002 |Procedure (procedure)|*	7
Why	Out of the scope	--
Status	*362981000 |Qualifier value (qualifier value)|*	24

Antibiotic

Antibiotics supported by bioMérieux VITEK®2, ETEST® & ATB™ antibiotic susceptibility testing systems were semi-automatically mapped to SNOMED CT subtypes of *410942007 |Drug or medicament (substance)|* using the process described in figure 1.

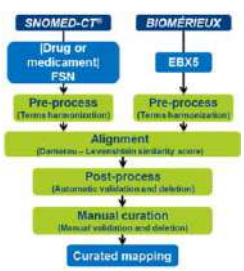

Figure 1

Workflow of antibiotics mapping to SNOMED CT

SNOMED CT mediated labs data analytics

The specimen analytics were performed using the OWL version of SNOMED CT integrated in the Jena Fuseki triple store. The endpoint analysis, Figure2, used SPARQL queries.

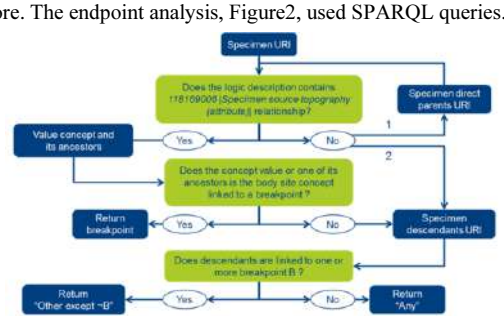

Figure 2– Workflow to run the appropriate sample preparation workflow

Representing MDRO in SNOMED CT

MRDO may be defined through rules in the form of <species name> and ((<susceptibility testing result> to <drug name>) or (<test result> to < Susceptibility test name >)). We used "methicillin resistant *Staphylococcus aureus*" (MRSA) as a test case to examine SNOMED CT's ability to described MDRO by:

1. Pre-coordination of the concept model.
2. Post-coordination of concepts and SNOMED CT compositional grammar expressivity.

SNOMED CT

We used the July 2018 International release of SNOMED CT for all our work.

Results

A total of 107 internal specimen concepts were mapped to SNOMED CT with a 70% (75/107) coverage. 19 additional mappings are under validation by an expert biologist. We used 358 antibiotics form 3 antibiotic susceptibility testing systems; SNOMED CT mapping gave an 88% (316/358) coverage.

Our data analytics use case is based on drug clinical breakpoints [8; 9]. Those are key to interpret antibiotic susceptibility testing results. Breakpoints are applicable for microbial isolates originating, in the case of *Streptococcus pneumoniae* from 'non meningitis' (understood here as 'pneumonia') or 'meningitis' or 'neither pneumonia nor meningitis' specimens origin [9]. We defined 'pneumonia' breakpoint origin as "a specimen obtained from a body site subtype of *20139000 |Structure of respiratory system (body structure)|*" and 'meningitis' breakpoint as "a specimen obtained from a body site subtype of *1231004 |Meninges structure (body structure)|*". Under the working assumption that a lab may use other specimen than in the above mentioned mapping ; we considered all SNOMED CT subtype of *123038009 |Specimen (specimen)|*. Breakpoints were identifed through the *118169006 |Specimen source topography (attribute)|* relationship that tie specimen to body structure. All cases allowed to identify the breakpoints to be applied.

"Methicillin resistant *Staphylococcus aureus*" analysis, as an archetype of MDRO, shows that MDRO concepts themselves do exist in SNOMED CT. Nevertheless, they exist as primitives, and thus do not embark definition supporting future analytics. It appears that (1) some concepts needed to post-coordinate MDRO rule do also exist and (2) that compositional grammar syntax allows building some MDRO rules but not all. The limitation lies in both the SNOMED CT concept model (implemented in the MRCM) and in EL++ that do not support the exclusive disjunction 'XOR' as described in the SNOMED CT Editorial Guide.

Conclusions

Although, SNOMED CT is able to encode biological specimen and antibiotics for the bioMérieux systems analyzed, it does not contain some of the higher-level microbiological concepts required for tracking antimicrobial resistance concepts

Our mediated analytics shows that one can use the SNOMED CT concept model to identify high level ARM concepts if a biological specimens origin is available so clinical breakpoints can be identified. We will continue to investigate this aspect based on additional relationships and usage of LOINC codes to refine and improve our analysis.

In the future we would like to model the microbial phenotypes MRSA and MDRO using pre or post-coordinated analysis of SNOMED CT concepts. Additionally, we would like to supplement our analysis by including the LOINC code mappings. Those do conflict with the SNOMED CT concept model and EL++ expressivity.

CONCERN Factorial Design Survey (FDS) Methods Test: Using REDCap as a Survey Platform

Jose P. Garcia, Jr.[a], Sarah A. Collins[c,d], Kenrick D. Cato[d], Suzanne Bakken[c], Haomiao Jia[d], Min J. Kang[a,b], Christopher Knaplund[d], Kumiko O. Schnock[a,b], Patricia C. Dykes[a, b]

[d] Columbia University, School of Nursing, New York, NY

Abstract

We assessed the feasibility of using REDCap as a factorial design survey (FDS) platform. REDCap lacks randomization and automation functionality, requiring the development of a workaround. A template survey was created containing all vignettes, copied for each survey instance and edited to hide unwanted content. REDCap configuration required three hours for forty-two surveys. The utilized "copy-and-hide" workaround was successful, providing quasi-automation and reasonable labor-time. Additional strategies are planned using REDCap's Data Dictionary and other survey software.

Keywords:

Survey Methods, Clinical Decision Support Systems

Introduction

Previous research shows that the effectiveness of clinical decision support (CDS) systems decreases when clinicians are presented with a high frequency of alerts that are not perceived as clinically relevant, leading to overriding or ignoring alerts [1]. Factorial design is an experimental design that contains two or more factors, which consist of discrete levels, whose experimental conditions take on all possible combinations of levels across all factors, referred to as *vignettes*. For example, a study containing three factors, each with two levels, has a total number of six possible combinations (2 x 2 x 2 = 6), or six vignettes. A factorial design survey (FDS) does not study the effects of individual factors, but enables researchers to draw conclusions about the significance of the vignettes. It allows researchers to study clinician decision-making, such as which combination of statistically significant factors are perceived as clinically significant [2]. In turn, this helps yield more generalizable conclusions. In the context of our Communicating Narrative Concerns Entered by RNs CONCERN study, vignettes provide scenarios that can be indicative of patient deterioration in clinical documentation, and we are performing FDS to determine the perceived clinical relevance of these scenarios for our CDS model.

REDCap is a software tool for survey generation and electronic data capture, but it has limitations when serving as an FDS platform. Although REDCap contains subject randomization capability, it lacks survey field randomization and automated field population that can help relieve the burden of this complex survey design on the researcher. This case study outlines a workaround developed to circumvent REDCap's limitations and to facilitate its use to run a factorial design survey.

Methods

A pilot survey trial was conducted using a workaround, referred to as "copy-and-hide". Four factors, each with two levels, were used in the pilot (Table 1). We sought to test surveys containing four of the sixteen total vignettes (Table 2). To assign which vignettes were tested in each survey, block randomization was performed off-platform. Each vignette was numbered (1-16), and a function in Excel was created that randomly assigned four numbers out of the 16 respectively to four surveys. A template survey containing fields for all sixteen vignettes was created in REDCap's Online Designer. Every field in the template survey containing a vignette had the action tag "@HIDDEN-SURVEY" applied, which hides fields from survey participants' view. For every consecutive test survey created, the template survey was copied, and the fields containing the assigned four vignettes to be tested in that survey had their action tags removed. This allowed participants to see and score these four vignettes in their survey and left the remaining twelve hidden from view.

Table 1– Pilot Factors and Levels

Factor	Levels (count)	Factor Level Values
Factor 1. Vital sign frequency	2	≤ 22 sets of vital signs in the last 48 hours > 22 sets of vital signs in the last 48 hours
Factor 2. Note / comment frequency	2	≤ 5 comments/notes in the last 48 hours > 5 comments/notes in the last 48 hours
Factor 3. Highlighted Oxygen saturation comment/note	2	Yes No
Factor 4. Highlighted blood pressure comment/note	2	Yes No

Table 2- Sample Vignettes

Vignette Number	Vignette Content
1	Patient chart shows the following: • ≤ 22 sets of vital signs in the last 48 hours • ≤ 5 comments/notes in the last 48 hours • A highlighted Oxygen saturation comment/note • A highlighted blood pressure comment/note
8	Patient chart shows the following: • ≤ 22 sets of vital signs in the last 48 hours • > 5 comments/notes in the last 48 hours • No highlighted Oxygen saturation comment/note • No highlighted blood pressure comment/note
11	Patient chart shows the following: • > 22 sets of vital signs in the last 48 hours • ≤ 5 comments/notes in the last 48 hours • No highlighted Oxygen saturation comment/note • A highlighted blood pressure comment/note

Results

Forty-two surveys were created and disseminated to forty-two participants in three hours. Thirty-one responses were returned. Extracted data table was sized 43 by 821 cells.

Conclusions

The significance of this work is that we identified limitations of available survey software for performing a factorial design survey. Factorial design is an experimental design that necessitates multiple iterations of a survey, where its components' material and order change from iteration to iteration. REDCap's lack of randomization and automation functions are limitations. The "copy-and-hide" method was a successful workaround in that it provided our team a reproducible method with reasonable labor time (~4.5 minutes/survey). However, the reliance on manual input in this method introduces increased potential for human error when scaled up. Additionally, REDCap cannot differentiate between hidden and unhidden cells when a user extracts data, which created a large spreadsheet with numerous empty cells for the hidden fields that were not scored during our pilot. To sacle up this method for FDS with hundreds of surveys would yield a cumbersome data workbook for researchers. A second pilot test is planned utilizing REDCap's Data Dictionary, which is a completely off-platform survey designer that we hope will decrease labor-time further by allowing us to rapidly create smaller, specialized surveys which we can upload onto the software and streamline data extraction by decreasing the number of empty cells in the spreadsheet. Additionally, we plan to run an FDS pilot using other popular survey software and compare results.

Abstract

In the 5P medicine (Personalized, Preventive, Participative, Predictive and Pluri-expert), the general trend is to process data by displacing the barycenter of the information from hospital centered systems to the patient centered ones through his personal medical records. Today, the use of artificial intelligence for supporting this transition shows real limitations in its implementation in operational practice, both at the level of patient care, but also in the general daily life of the health professional, because of the medico-legal imperatives induced by the promises of the '5P medicine'. In this paper, we propose to fill this gap by introducing an original artificial intelligence platform, named Maxwell, which follows an unsupervised learning approach in line with the medico-legal imperatives of the '5P medicine'. We describe the functional platform characteristics and illustrate them by two examples of clustering in genomics and magnetic resonance imaging.
