Recent advancements in predictive medicine are now partly due to the implementation of artificial intelligence algorithms based on the intensive exploitation of big data collected from new medical technologies [1-3]. Usually, these algorithms can be divided into two distinct categories, namely (1) neural networks and deep learning, performing and fast, but opaque (black box type), with a traceability difficult to explain to the 4 worlds of the concerned health ecosystem, medical, para-medical, forensic and familial, and (2) classical methods playing with distances or proximities to the centroids of classes, more easily explicable, but sometimes slower. Despite major and continuous breakthroughs in both of these domains, it is interesting to note that most of algorithms fail to be successfully implemented in practice. Indeed, the medico-legal context imposes these algorithms to satisfy fundamental legal and ethic criteria not usually taken into account. In this paper, we propose a new unsupervised learning approach implemented through a "classical" decision platform named "Maxwell®" that addressed three of these criteria, namely (1) traceability in decision process, (2) consideration of the role of the human expert in the decision-making and (3) need of a feedback to the patient for increasing his empowerment. We describe first the learning characteristics of the method, and then illustrate its functioning by two examples, that are the clustering in (1) genomics, and (2) magnetic resonance imaging. Note that detailed description will be given in upcoming publications.

Methods

Maxwell's Functions and Dynamic of Processes

Maxwell is a research result in domain of data clustering leaded at Orange Labs® (France) that aims to produce an agnostic and unsupervised system for clustering and classifying heterogeneous content. Two initial postulates were defined to guide our work: (1) the ability to start building clusters with a short number of content and (2) no recourse to initial labeling.

Calculus' Principles

Depending on the algorithm's step, two types of calculus are used: (1) similar content clustering using a normalized compression distance [4-6], and (2) content classification in existing clusters. To enable incremental classification, both of these processes can be iteratively chained.

Clustering Principle

Clustering is based on building neighborhood graphs. It is initiated by computing triangles formed with the current point in a distance matrix, the first neighbor of this current point and the first neighbor of this second point. Then, surfaces of these triangles are computed as well as basic statistics such as mean, standard deviation and quantiles, are used as parameters for tuning the selectivity of the clustering process. Thus, the result is a metric space segmented in sub-graphs containing clusters.

Classification Principle

During the classification step, the system is focused on edges of sub-graphs. Classification of a new content is done by searching the nearest centroid neighbor and deciding inclusion with respect to existing cluster nodes distances to centroid. Note that unclassified content is stored in singleton clusters.

Traceability and Role of Human Expert

Cluster management can be done either by the user or by the system itself. In fact, user visualizes the clusters produced throughout the clustering/classification process. He can select elements of a cluster, or the cluster itself to be deleted. This gives the traceability of Maxwell and destroying cluster from an automatic threshold procedure or from a user decision is near of a reinforcement learning by a "punishment/reward" system. On the other side, the system will compute all consequences of a user action on clusters distribution: singletons recall (due to its unclassified added content or to a cancelling by user or machine) and new content addition, inserted in a queue in order to detect new clusters. Finally, user can also validate clusters by locking and prohibiting their destruction. This allows also the control of clusters consistency. Locked clusters are named by user in order to obtain semantic classes.

Results

Genomics

Figure 1 illustrates a classification obtained from about 120 genomes coming from different phyla (bacteria, archæa, giant viruses and virophages). The obtained clusters reveal 3 distinct classes, which present remarkable properties: (1) all the Pandora giant viruses belong to the same class 1, (2) all the genomes participating to the same "infectious" ecosystem are in the same class 2: Amœba Acanthamœba can be infected by two giant viruses, Mimivirus and Mamavirus. Both have their virophage, respectively Sputnik and Zamilon. All the corresponding genomes belong to the same class. (3) Furthermore, Acanthamœba can be parasitized by the bacteria Legionella pneumophila. It belongs to singleton class 3, but can join class 2, when compression distance between genomes is relaxed.

Figure 1 – Three Clusters Within a Set of 120 Genomes

Hence, Maxwell puts in the same cluster all the genomes participating to the same infectious ecosystem, which allows for predicting susceptibility of human to infectious agents.

BRATS Images

BraTS image dataset is a manually indexed set of brain MRI images, used for image processing challenges on MRI images. Our sample contains 1500 blood stroke 2D images (horizontal sections at different levels). Figure 2 illustrates some results using the Maxwell platform.

Conclusion

The Maxwell platform constitutes a good alternative to the deep learning approach using neural networks, being more comprehensible in the medical ecosystem both on the patient side (family, care-givers and patient), on the medical side (physicians and paramedics) and on the social side (psycho-social workers). It is not strictly antinomic with the deep learning in the sense that some parts of the classification process (in particular the refinement of some ambiguous clusters) can be reprocessed by neural networks.

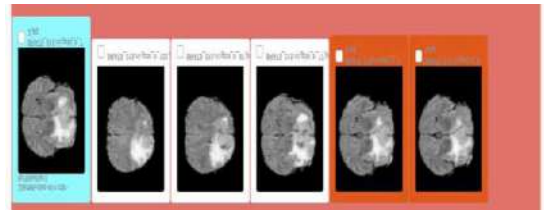

Figure 2 – Traceability: modified cluster of BRATS_015 class, before recalculation (best representative in light blue), images added in orange. All thumbnails can be selected by user to be deleted, if a better representative image is selected.

Assessing the Concordance of Clinical Classification Criteria for Lupus Between Electronic Health Records and a Physician Curated Registry

Theresa L. Walunas [a], Anika S. Ghosh [a], Jennifer A. Pacheco [a], Kathryn L. Jackson [a], Anh H. Chung[a], Daniel L. Erickson [a], Karen Mancera-Cuevas [a], Rosalind Ramsey-Goldman [a], Abel N. Kho[a]

Abstract

We developed a computable phenotype for systemic lupus erythematosus (SLE) based on the Systemic Lupus International Collaborative Clinics clinical classification criteria set for SLE. We evaluated the phenotype over registry and EHR data for the same patient population to determine concordance of criteria detected in both datasets and to assess which types of structured data detected individual classification criteria. We identified a concordance of 68% between registry and EHR data relying solely on structured data.

Keywords:
Electronic health records, phenotype, systemic lupus erythematosus.

Introduction

Clinical classification criteria are often used to understand the clinical presentation of diseases with complex or varied presentations. Electronic health records (EHR), now commonly used in the course of routine health care throughout the United States provide a rich source of data [1], including diagnoses, lab results and medication use that can be used to enhance understanding of the development, manifestation and treatment of complex disease over time.

Our team developed a rules-based algorithm to identify patients with Systemic Lupus Erythematosus (SLE), a complex systemic autoimmune disease that affects multiple organ systems and has diverse manifestations that develop over time [2]. This computational phenotype is based on the Systemic Lupus International Collaborating Clinics (SLICC) classification criteria for SLE [3].

We evaluated our SLICC-based computational phenotype in a physician-validated registry and the medical record data for the same patient population: 1) to assess the concordance of criteria detection in these two distinct datasets; and 2) to better understand whether medical records can be used as a substitute for manual chart abstraction in the identification of clinical classification criteria for a complex autoimmune disease.

Methods

Established in 1991, the Chicago Lupus Database (CLD) is a physician validated registry of 1,052 patients with possible or definite lupus according to the revised 1982 American College of Rheumatology classification criteria [4][5]. The CLD has laboratory data, symptoms and paitent demographics based on each known visit. If a patient was referred, previous history information from the notes are documented. The data is entered in MEDLOG [6] which is then compiled into the CLD.

The Northwestern Medicine Electronic Data Warehouse (NMEDW) is the primary data repository for of all the electronic health records of patients who receive care within the Northwestern Medicine system. Established in 2002, the NMEDW contains records for over 3.8 million patients. Patients in the CLD consented to allow their medical records to be used for research and their medical records can be found in the NMEDW using a medical record number (MRN) stored in the CLD. Review medical records in the NMEDW was approved by the Northwestern University IRB.

We identified 878 patients who had definite lupus according the SLICC criteria [3], as defined by meeting at least one clinical and one immunolgical criteria and meeting 4 or more criteria overall. After removing patients who did not have medical records in the NMEDW, there were 818 patients remaining. To ensure sufficient depth of data for analysis by our algorithm, we removed any patients who had less than four encounters documented in the NMEDW, reducing the cohort size to 472. Finally, we assessed our the full algorithm over the patient medical record data. Only 408 of those patients who also met the SLICC criteria for definite lupus in the CLD also met the criteria for definite SLE based on their medical record data.

The SLICC clinical criteria-based algorithm for detection of SLE was run over each patient in the cohort and each of the 17 individual criteria was scored for presence or absence in the CLD and the NMEDW. A combination of ICD9/10 codes and laboratory results were used to determine whether each individual criterion was satisfied.

A criterion was considered discordant when it was present in either the CLD or NMEDW (but not both) for a given patient record. A KNIME (3.4.2) workflow [7] was developed to process each patient data set and determine the number of concordant and discordant criteria. For discordant criteria, we determined whether the criterion was present in the CLD or the NMEDW. For each criterion, we used McNemar's test to see if the NMEDW and CLD results were different. A p value $< .05$ was used to determine significant difference. Descriptive statistics were calculated using SAS software version 9.4 (SAS Institute)Results

Table 1 describes the basic demographics of the cohort we assessed that met the SLICC classification criteria for definite SLE in the CLD and NMEDW. Our cohort is predominantly female, white, and had an average disease onset age of 30 years. The gender distribution and age of onset is consistent with previous studies demonstrating the predominance of SLE among women that develops relatively early in life [8]. The racial and ethnic distribution is consistent with the patient

population receiving treatment within the Northwestern Medicine System.

Table 1— Cohort Demographics (N=408)

Sex	**% of Cohort**	
Female	92%	
Male	8%	
Race/Ethnicity	**% of Cohort**	
Caucasian	48.1%	
African American	30.5%	
Hispanic	12.4%	
Asian	7.8%	
Other	1.2%	
Age	**Mean Years**	**SD**
Current	50 years	13.48
At Diagnosis	30 years	9.69

To further understand the concordance between the registry and the medical record data, we determined the number of present and absent criteria that were concordant as well as the average number of criteria detected per patient in each data set. The results of this assessment are shown in Table 2. Within the concordant criteria, on average, there were 5 that were concordant and present, 7 that were concordant but absent. When evaluating the criteria set over the CLD, on average, we detected 8 criteria per patient, while we detected 7 criteria per patient using their medical record data. A paired t-test for significance resulted in a p-value of .59, indicating that the results are not significantly different.

Table 2— Overall Concordance between Registry and Medical Record Data for Patients Meeting SLICC Criteria (out of 17 total).

Number of Criteria Per Patient	**Mean**	**Median**	**SD**
Overall Concordant Criteria	11.6	12	1.7
Present Concordant Criteria	4.9	5	1.8
Absent Concordant Criteria	6.7	7	2.0
Criteria Detected in CLD	7.9	8	2.1
Criteria Detected in EDW	7.3	7	2.1

Discussion

We developed a clinical classification criteria-based computational phenotype to identify patients with SLE in a physician validated SLE registry and in a large medical record data repository and assessed concordance of the overall algorithm and individual criteria that comprise the algorithm. For those patients who satisfied the classification criteria for definite lupus in both the registry and the medical record data set, there were, on average, 12 concordant criteria out of 17, 5 of which were concordant and present in both the CLD and NMEDW, 7 of which were concordant and absent in both the CLD and NMEDW. When we assessed concordance for individual criterion, we found that concordance was highest for criteria that were based on laboratory data. The highly discordant criteria were primarily clinical criteria detected with diagnosis codes that may not always be documented as part of routine clinical care or may be documented in locations within the medical record, such as physician notes, that are not easily queried using simple structured data elements, such as arthritis, oral ulcers, and serositis.

Conclusion

Using a computational phenotype for SLE based on the SLICC clinical classification criteria, we demonstrated an overall high concordance of 68% between physician validated registry information and data found in patient medical records suggesting medical record data can be used to supplement manual chart abstraction for the application of clinical classification criteria to patients with complex disease.

Identification of Cancer Survivors Living with PTSD on Social Media

Nur Hafieza Ismail[a], Ninghao Liu[a], Mengnan Du[a], Zhe He[b], Xia Hu[a]

[a] *Department of Computer Science & Engineering, Texas A&M University, College Station, Texas, USA,*

Abstract

The trauma of cancer often leaves survivors with PTSD. Tweets posted on Twitter usually reflect the users' psychological state, which is convenient for data collection. However, Twitter also contains a mix of noisy and genuine tweets. The process of manually identifying genuine tweets is expensive and time-consuming. Thus, we propose a knowledge transfer technique to filter out unrelated tweets. Our experiments show that our model outperforms the baselines.

Keywords:

Cancer survivors; stress disorders, post-traumatic; social media

Introduction

Being diagnosed with cancer often causes psychological distress due to painful treatments and the trauma of the experience [1]. Treated cancer patients may find themselves at risk of recurrence, which is often more traumatic than the initial diagnosis. This psychological impact can cause post-traumatic stress disorder (PTSD), a significant concern in clinical oncology [2]. Untreated PTSD patients are more likely to adopt health-risk behaviors. The lack of quantifiable data about PTSD is one of the main obstacles to making reliable diagnoses and providing effective treatment [1]. The fast growth of social media provides new opportunities for investigating mental health issues, since the simplicity of social media allows its users to easily share their daily thoughts and feelings. We propose a deep neural network (DNN)–based technique to create a labeled dataset using cancer free–related keywords and PTSD features. Our primary contributions can be summarized as follows: (1) formally defining the problem of extracting relevant tweets, (2) presenting and training a framework for identifying cancer survivors with PTSD based on tweets, and (3) evaluating the model's performance by producing a label with associated probability for new tweets.

Methods

Here, we briefly introduce our proposed framework for identifying cancer survivors living with PTSD on social media. First, we extracted patterns of words used by sufferers from conventional studies on depression. Second, the extracted patterns were used to identify tweets from the cancer survivors dataset that contain PTSD indicators. We will detail the process of our proposed framework in three subsections: (1) feature extraction, (2) knowledge transfer, and (3) the convolutional neural network (CNN) architecture.

Feature Extraction

This process requires specific extraction methods to be applied to the input data in order to create an accurate prediction model. Previous work related to depression detection using social media data has employed a crowdsourcing approach to identify tweets associated with mental illness [3] which we label as PTSD-positive, while the rest are labeled as PTSD-negative. The process continues by combining PTSD-positive and -negative datasets. The goal of this process is to understand the differences in linguistic style between the two groups. LIWC, a text analysis tool, is employed to assess the tweets for proportions of words used from several linguistic categories in the psychological expression lexicon. The comprehensive list produced by the tool automatically presents the words most frequently used by people with mental illness.

Knowledge Transfer

In this work, 'knowledge transfer' is defined as the process that uses the output from the feature extraction step to develop a labeled PTSD dataset. Diverse epidemiological samples have shown that most PTSD sufferers also have depression. This comorbidity reflects overlapping symptoms between the two disorders [4]. Therefore, even though there is no existing PTSD lexicon, we can use the depression lexicon as a proxy to identify PTSD-related tweets. We collected our raw dataset using "cancer" as a keyword through Twitter's Application Programming Interface (API) over a period of four months from October 2017 to January 2018. Then, we conducted the extraction process in two steps using two sets of keywords. First, we created the cancer survivor dataset using related hashtags and terms such as "cancer survivor", "cancer free", "i had cancer", "post-cancer", "survive from cancer", and "free from cancer" . Second, we used the depression lexicon taken from [3] to filter out tweets that contain no PTSD signals to create a ground truth dataset. We also added the word "PTSD" to filter out irrelevant tweets. This technique saved a lot of time and cost in creating a reliable dataset for training the CNN.

CNN Architecture

Our proposed CNN adopts one convolutional layer to produce results for tweet classification. We trained the CNN with the embedding layer. It requires specification of the vocabulary size, the size of the real-valued vector space, and the maximum length of words in the input. For convolutional feature maps, we used 100-dimensional word embedding for

text representation. 32 filters were applied by referring to the conservative setting for word processing, with a kernel size of 8 and a rectified linear activation function. This was followed by a pooling layer in which the filters generated feature maps and reduced the output by half. The end layer used a sigmoid activation function to output a value between 1 and 0 (positive and negative) for the tweets based on the concatenation of the previous vectors. Then, the extracted model was saved for later evaluation.

Experiment

The PTSD-positive dataset represents the diagnosed group, while PTSD-negative is the control group. For the diagnosed group, we retrieved tweets from users who publicly stated that they survived cancer and had PTSD. To construct the PTSD-negative group, we made use of tweets from the 'Twitter User Gender Classification' dataset on the Kaggle website. This dataset contains random tweets not limited to any specific topic. Both groups have the same amount of tweets (10k), which allows us to create balanced datasets. The data preparation phase consists of three tasks: (1) splitting the dataset into training (80%) and test (20%) sets, (2) cleaning the dataset to remove punctuation, stop words, and numbers, and (3) defining a vocabulary of preferred words from a training dataset by keeping only tokens that appear at least five times. All models were trained over ten epochs. The Adam optimizer implementation of stochastic gradient descent was used.

Results

To evaluate our proposed model, we chose three baseline models that are capable of handling text datasets: multilayer perceptrons (MLP), CNN n-gram, and recurrent neural networks (RNN). Our results indicate that CNN can effectively identify cancer survivors with PTSD. Experimental results in Table 1 show that the accuracy of CNN reaches 98.5%. Due to the stochastic nature of DNNs, we ran the experiments multiple times to get a reasonably accurate result.

Table 1 – Experiment Results

Method	Accuracy (%)
CNN	**98.5**
MLP	95.5
CNN N-gram	98.3
RNN	96.9

Our simple CNN-based prediction system assigns probability values for cancer survivors being either PTSD-positive or PTSD-negative. Sample tweets and our method's assignments are displayed in Table 2.

Table 2 – Predictions for New Tweets

Tweet: "I have had more difficulty post cancer than during my active treatment. To me it is a neverending path (hate the word journey)."
POSITIVE (99.96%)
Tweet: "I hate myself, I don't feel like living anymore."
NEGATIVE (99.99%)
Tweet: "I got a gold MacBook that only use for music and homework..Still keep it in apple box."
NEGATIVE (99.95%)

The system is consistently able to classify tweets correctly. For example, the second tweet is a statement with negative sentiment that is not related to the cancer survival; the system classifies it as PTSD-negative. Assigning the right label with high probability is essential for accurate diagnosis. To the best of our knowledge, this is the first work that deploys an extracted model of cancer survivors living with PTSD into a prediction system that is capable of evaluating new tweets. The outcome shows high potential for a low-cost text classification technique that may also apply to other medical conditions that can affect patients' mental health.

Conclusions

We have demonstrated that Twitter can be used to identify PTSD among internet users, presenting a CNN prediction framework that produces promising results in cancer survivors with a PTSD diagnosis. Social media users with a history of cancer who suffer from depression will benefit from the prediction framework; for instance, it can act as an alarm system by detecting the presence of depression based on users' posts. However, our model was trained solely on text-based tweets. In the future, we plan to explore the utility of other data modalities for uncovering PTSD indicators, such as audio and images, to improve our diagnoses. In addition, we hope to identify developing conditions such as suicidal thoughts and side effects of PTSD treatment.

Facilitating Clinical Trial Recruitment by Recommending Cost-Efficient Medical Exams

Bibo Hao [a], Shouyu Yan [b], Eryu Xia [a], Shilei Zhang [a], Jing Mei [a]

[a] *IBM Research – China, Beijing, China*
[b] *IBM Watson Health, Beijing, China*

Abstract

Clinical trials are key and essential processes for researchers to develop new treatments as well as evaluate their effectiveness and safety, whilst more than half of all clinical trials experience delays, which leads to a considerable amount of cost. In this paper, we present a cost-effective framework to reduce the time and monetary cost in the stage of recruiting and screening eligible clinical trial participants. By leveraging patients' observed conditions and the cost of medical examinations, the proposed framework uses collaborative filtering techniques to predict the utilized cost for the to-do medical examinations and then rank patients and medical examinations. The preliminary experiment results indicate that the framework is promising to reduce the cost spent on medical examinations by three quarters or even more and accelerate the recruitment process in the screening stage.

Keywords:
Eligibility Determination, Cost Savings, Machine Learning.

Introduction

Clinical trials, aiming at answering specific questions about the safety and efficacy of biomedical or behavioral interventions, are essential processes in medical research and innovation, in which human participants are recruited into experiments or observations. Unfortunately, recruitment is often slower or more difficult than expected, which leads to considerable monetary, time, and opportunity cost [1].

Faced with clinical trial recruitment are challenges from many aspects: fewer eligible patients than expected, fewer patients agreeing to participate than expected, etc. [2] When recruiting clinical trial subjects, it is common to see that some condition values of the patients are not available in EMRs. In a clinical trial determining the eligibility of patients with unobserved conditions is therefore difficult. To clarify, it is needed for additional medical examinations to determine the eligibility, while other patients with the history of these medical examinations, are not always eligible. Unobserved conditions can turn out to be eligible or not eligible.

Given patients and their observed/unobserved conditions, to maximize the probability of matching the patients to meet the eligibility criteria and minimize the cost of medical examinations, which patients shall be firstly selected to conduct medical examinations, and which medical examinations shall be conducted first? In this study, we formulate the problem definition and then use a synthetic dataset and a mockup clinical trial to simulate the recommending cost-efficient medical examinations scenario.

Methods

Problem Definition

Given a clinical trial that requires a set of clinical trial eligibility criteria, which corresponds to n conditions: $\boldsymbol{C} := \{C_1, C_2, \dots, C_n\}$, each condition requires one or more medical examinations to check patients' eligibility, and the cost of the evaluation is known as $\boldsymbol{E} := (e_1, e_2, \dots, e_n)^T$.

Given a patient cohort of m clinical trial participant candidates $\boldsymbol{P} := \{P_1, P_2, \dots, P_m\}$, we denote P_i's condition value on C_j as $v_{i,j}$, and we use $\boldsymbol{V}$ to denote this patient to medical examination matrix. We let the data types of the values in the matrix to be binary values or real numbers, since we can split nominal values into several binary values. The values in $\boldsymbol{V}$ can be extracted from EMRs, or they can be missing because the patients have not yet finished specific medical examination, in other words, the matrix $\boldsymbol{V}$ is sparse.

With the above conditions, from the cost perspective, we are to solve the problem of: which patients in $\boldsymbol{P}$ shall be reached first for medical examination to check eligibility and given a patient P_i, which medical examination shall be conducted first to reduce wastage.

The Cost-Efficient Recommendation Framework

To maximize the utilization of the cost used for medical examinations and accelerate clinical trial subjects' recruitment process, we propose a cost-efficient recommendation framework to measure the utilized cost for a specific medical examination to each participant candidate when the condition value is unobserved. By leveraging this framework, we can 1) rank the medical examinations for a given participant candidate to reduce the potential wastage for the individual, and 2) rank the participant candidates to reduce the potential wastage for a group of patient candidates.

Introducing Utilization and Utilized Cost

To model the utilization and utilized cost, we take two aspects into consideration in this framework:

- Cost of each medical examinations required to check the eligibility criteria, aforementioned as $\boldsymbol{E}$, which are already known and constant values for all patients.
- Patients' probabilities satisfying eligibility criteria given their unobserved conditions.

We then propose a method to measure the *utilized cost* for patients to conduct medical examinations. The *utilized cost* function of conducting a medical examination is designed as below: Given a medical examination C_j, for a patient P_i, we let the *utilized cost* $Z_{i,j} := -\ln(q_{i,j}) \cdot e_j$

where $q_{i,j}$ is the estimated probability ($q \in [0,1]$) that $v_{i,j}$ can satisfy C_j. Higher $q_{i,j}$ results to lower utilized cost $Z_{i,j}$.

Intuitively, if $v_{i,j}$ is already observed to satisfy eligibility criteria, then no cost is needed to be spent on C_j for P_i, whilst if $v_{i,j}$ is observed to dissatisfy eligibility criteria, then any other cost spent for P_i is of no utilization. So here we design the value of $q_{i,j}$ to represent the model' estimation of the probability that $v_{i,j}$ will satisfy C_j after medical examination.

If it is already observed that $v_{i,j}$ satisfy C_j or not satisfy C_j, the values of $q_{i,j}$ are *1* and *0,* respectively. If $v_{i,j}$ is unobserved yet, $q_{i,j}$ need to be estimated based on observed values in $\boldsymbol{V}$.

Estimating the Probabilities of Patients to Satisfy Criteria

As mentioned, for observed values $v_{i,j}$ in $\boldsymbol{V}$, the correspondent values of $q_{i,j}$ can be calculated as *1* or *0* based on eligibility criteria C_j. Given the sparsity of $\boldsymbol{V}$, there are also missing values in $\boldsymbol{Q}$ corresponds to unobserved values in $\boldsymbol{V}$. Therefore, we propose a method to predict those missing values in $\boldsymbol{Q}$, based on the observed values.

Based on the intuition of "patients of similar latent status will have similar conditions and phenotype", we introduce the *Collaborative Filtering* (CF) technique to predict those missing values in $\boldsymbol{Q}$. The CF technique is already widely used in the e-commerce recommender systems and has shown its values in predict users' interest to new items based on existing feedbacks. In this study, we applied two popular methods of CF: the User-based Similarity Model (UBSM) [3], and the Singular Value Decomposition (SVD) algorithm [4], to approximate patients' probabilities satisfying eligibility criteria.

Ranking Patients by Utilized Cost

After using the CF technique to approximate the matrix $\boldsymbol{Q}$, we can compute the overall utilized cost Z_i expected for each participant candidate P_i: $Z_i = \sum_j Z_{i,j}$. Patient candidates with lower utilized cost values should therefore be reached first for the screening and medical examinations. And for a specific candidate P_i, medical examinations corresponding to smaller $Z_{i,j}$ values should be conducted first.

Evaluating the Cost Efficiency

Here we use this metric to measure the efficiency of the methods – specifically, we calculate the cost spent on medical examination to recruit *K* eligible participant.

Experiment

Dataset and Pre-Processing

To simulate the process of recruiting clinical trial participants, we used the open-source *Synthea Patient Generator* [2] software to generate synthetic patients and synthetic electronic healthcare record dataset. In our experiment, the simulated cohort includes 7,889 and their 846,073 condition values in 136 different LOINC codes – 21.14% of the condition values are not yet observed. To simplify the experiment, we removed all 20 nominal features except for sex (binarized to 1 or 0).

Experiment Setup

Given the above cohort, we set up a mocked clinical trial and corresponding eligibility criteria to simulate the screening process, and the corresponding medical examination costs are estimated by searching the internet. We first selected the patients who have the above condition values observed, so that we can take them as the ground truth to evaluate our method. Secondly, to simulate the unobserved values, we randomly erased 25% of condition values related to eligibility criteria to empty values. Apart from the two CF methods, we also set up a baseline method, which simply conducts all correspondent medical examinations to participant candidates for unobserved values.

Experimental Results

Listed in Table 1 are the evaluation results of the baseline and two CF techniques.

Table 1 – Number of patients conducted examinations in a simulated clinical trial recruitment screening setting

Method	Cost on medical examination to recruit K eligible participants ($)			Number of participant candidates who conducted medical examinations		
	K=50	K=100	K=200	K=50	K=100	K=200
Baseline	3382.0	6587.0	13357.0	208	391	780
UBSM	78.0	310.0	3031.0	21	55	209
SVD	9.0	204.0	2856.0	5	55	207

Conclusions

In this paper, we adopt the collaborative filtering technique to resolve the unobserved patient condition values in screening clinical trial participants and improve the cost efficiency of the medical examinations. The proposed method also provides a framework to reach clinical trial participant candidates in a proactive way, which is promising to reduce the time cost in the screening and recruitment stage.

Using FAIR Metadata for Secondary Use of Administrative Claims Data

Christian Haux, Petra Knaup

Institute for Medical Biometry and Informatics, University of Heidelberg, Heidelberg, Germany

Abstract

The FAIR principles require the reporting of rich metadata. However, when researchers use data for secondary use from external data owners, the FAIR principles require a different implementation as if the researchers would describe their own data. In this paper, we specify how FAIR metadata can be implemented for secondary data analyses and provide a suggestion for relevant metadata.

Keywords:
Metadata, Data Collection, Data Curation

Introduction

The FAIR (Findable, Accessible, Interoperable and Reusable) principles [1] aim to achieve high reusability of data that were used or produced by researchers. By providing metadata, data become interpretable and easier to be found and used by other researchers [2]. Therefore, some funding agencies require to implement the FAIR principles in data management plans, to ensure that data from publicly funded research projects can be used further by other researchers [3].

Because the FAIR principles itself do not provide or require a specific implementation that defines the FAIRness of data, several metrics and implementations exist [2,4]. For example, researchers can use the GO-FAIR metadata to assess the FAIRness of their datasets [5]

The FAIR principles and metadata can be well applied to data sets that are produced by researches and that can be made available by researchers. However, if researchers use data from external data owners for secondary analyses, they often do not have data sovereignty. This applies, for example, when administrative claims data are used by researchers for secondary analyses. The datasets that are provided to researchers, further called analysis datasets, are often generated for a specific research purpose. Therefore, the FAIR principles require a different implementation and should be used to describe the data that were used for analysis, how to acquire the data and under which license the data can be used [1,6].

In this paper, we analyze how the FAIR metadata can be implemented when researchers use administrative claims data from external data owners to conduct secondary analysis. We further provide suggestions for metadata that are needed when administrative claims data are used by researchers for secondary use.

Methods

The FAIR principles [1] and the GO-FAIR metadata layers [5] as well as the "REporting of studies Conducted using Observational Routinely-collected health Data" (RECORD) [7] and "Strengthening the Reporting of Observational Studies in Epidemiology" (STROBE) [8] statements as existing guidelines for using routinely collected data were analyzed.

The requirements for the GO-FAIR metadata layers were compared with the results of a qualitative content analysis of data usage agreements from a secondary analysis of routinely collected administrative claims data [9]. It was determined, which FAIR metadata can be provided by researchers that used claims data for secondary analysis. and recommendations for metadata were developed.

Results

The results of the qualitative content analysis revealed that data owners of administrative claims data put different conditions on the release of their data for research. For reasons of data minimization, data owners generate specific analysis datasets for researchers instead of grant access to their complete database. The analysis datasets only contain the attributes and entities that are needed for the research question of the researchers. Further, the agreements often stated that the analysis datasets have to be deleted after the end of the analysis by the researchers.

Therefore, it must be distinguished whether the analysis datasets or the data source of the data owner is described with FAIR metadata. Whereas the description of the analysis datasets provides metadata to published analyses, The description of the data source should provide general metadata about the data of the data owner and how other researches can access it.

Our analysis resulted in the following concept for the GO-FAIR metadata to describe both the analysis datasets and the data source:

(i) The **Data Repository Metadata** should be used to describe data provenance of the data source from that the analysis data sets were generated from. Data provenance includes a "description of the origins of a piece of data and the process by which it arrived in a database" [10]. For the secondary use of routine data, this means to create an audit trail of the data that includes the point of data entry at the data consumer, data extraction and processing, and research output. To assess the representativeness of claims data, data owners should share descriptions of the composition of the policyholders and available ranges. Descriptive statistics should be used to provide general information about the data. If data from multiple data owners are used, such a description should be provided for each data source.

(ii) If the data repository is organized in groups, such information should be provided for each group as **Catalogue Metadata**.

(iii) The **Dataset Metadata** describes the analysis datasets that were provided by a data owner. Researchers should provide a description of the datasets they received from a data owner. The FAIR principles further require that the data are assigned a globally unique and persistent identifier to make them findable and citable. However, the qualitative content analysis showed that analysis datasets often have to be deleted by the researchers after the intended use. In some cases, the data owner retains the analysis datasets. Therefore, it might be problematic to apply a persistent identifier to the analysis datasets. Instead of assigning the identifier to the analysis datasets, it can be assigned to the data source in general.

(iv) The **Distribution Metadata** describes how data were made available for researchers.

Researchers should provide a description of how they accessed the analysis data sets and which license was associated with the data. For example, it can be described if the analysis data sets were transmitted to the researchers or if the data access was only possible in the premises of the data owner.

Because licensing for secondary use of routine data is often regulated individually, it can differ between data owners and usage scenarios. For this reason, secondary users can not provide general information about licensing. They rather should provide a description of the license under which they got data provided by the data owner. Qualitative content analysis can be used to compare usage requirements from multiple data owners.

(v) The **Data Record Metadata** layer contains information about the structure and the content of the data set. Therefore, data owners should provide data descriptions or codebooks that contain information about the columns, attributes, and variables of the data sets. If data linkage across multiple analysis data sets is planned, it should be analyzed which attributes in one data set the map to corresponding attributes in other data sets. A matching of attributes in the data sets can be achieved with a spreadsheet-based harmonization table [11]. This approach can also be used to reveal data conflicts in the data.

Privacy regulations require that data owners remove sensitive information to protect the privacy of individuals before data are shared with researchers. This can cause the problem, that in research projects, that involve the usage of data from multiple data owners, each data owner may apply different sanitization methods. Therefore, a description of how each data owner sanitized the data should be provided, as well as an assessment of the data quality and if data linkage across multiple data sets was possible, despite the sanitization.

Conclusions

Making claims data permanently available is difficult because licenses with data owners often require that the data are destroyed after the end of an analysis.

In this paper, we specified how FAIR principles and GO-FAIR metadata can be implemented for secondary data analyses and provided a suggestion for relevant metadata. The suggestions can be used to describe how researchers accessed and used data for their analysis. The implementation can be used by researchers that want to provide information about which data they used for their studies and how other researchers can access these data.

Exploring the Discrepancies in Actual and Perceived Benefits of Dietary Supplements Among Obese Patients

Zhe He[a], Laura A. Barrett[a], Rubina Rizvi[b], Seyedeh Neelufar Payrovnaziri[a], Rui Zhang[b]

[a] School of Information, Florida State University, Tallahassee, Florida, USA,
[b] Institute for Health Informatics and Department of Pharmaceutical Care & Health Systems, University of Minnesota, Minneapolis, Minnesota, USA

Abstract

Dietary supplements (DSs) have gained increased popularity for weight loss due to its availability without prescription, relatively low price, and ease of use. Consumers with limited health literacy may not adequately know the benefits and risks associated with DSs. In this project, we found a knowledge gap between reported benefits of major DSs by adults with obesity in the National Health and Nutrition Examination Survey 2003-2014 and those reported in existing DS knowledge databases.

Keywords:
Obesity; Dietary Supplements; Nutrition Surveys

Introduction

Obesity, a complex chronic medical condition having multifactorial etiology, is on the rise not only in the US but also around the globe [1]. In the US, the prevalence of obesity among the 18 years or older population has increased from 33.7% in 2007-2008 to 39.6% in 2015-2016; whereas, the prevalence of severe obesity in adults has increased from 5.7% in 2007-2008 to 7.7% in 2015-2016 [2]. Many patients who are overweight and obese consider using dietary supplements (DSs) for weight loss. Currently, there are a number of available options out there, either to simply maintain a healthy weight or to actually treat people who are overweight/obese and are at high risk of weight-related comorbidities; however, the vast majority of treatment around lifestyle changes often fail due to noncompliance resulting from various factors e.g., poor motivation, lack of time, gaps in knowledge/awareness, and lack of strong and prolonged commitment to observe the actual results [3]. On the other hand, most of the pharmacological and surgical procedures are associated with a substantial health risk at a high cost [4].

The popularity of complementary alternative medicine, especially the use of dietary supplements for weight management, has gained much popularity. Aside from the health benefits resulting from weight loss, there are various other reasons (several of them being misconceptions) for people to turn to DSs for losing weight and/or maintaining a healthy weight, such as DSs being a natural product, effective, fast acting, associcated with minimal side effects, easily available, and at relatively low price. Often consumers swtich to DSs in frustration resulting from failures in previous weight loss attempts following strict diet and exercise regimens.

Interestingly. earlier studies have revealed that use of DSs is more commonly preventive with an aim to maintain and improve overall health, rather than being therapeutic to treat obesity. In this project, we aim to gain a better understanding of the use of DS products among obese people as well as their perceived benefits of these products. We used the combined National Health and Nutrition Examination Survey (NHANES) data from 2003-2014 to answer two research questions (RQ): RQ1: What are the perceived benefits of DS usage among obese patients? RQ2: Is there a knowledge gap between their perceived benefits and those reported in existing DS knowledge bases?

Methods

NHANES is a continuous cross-sectional health survey conducted by the National Center for Health Statistics [5]. It evaluates a stratified multistage probability sample of the non-institutionalized US population. We first extracted the demographic, examination, and dietary data from NHANES for survey years 2003 – 2014 (6 survey cycles). To strengthen the analytical power of the study, survey data from multiple survey cycles were combined for the following analyses. Inclusion criteria for the cohort include: (1) BMI $\geq$ 30 kg/m^2, and (2) age $\geq$ 18. This left us with a cohort of 11,959 participants. DS use was pulled for this cohort. Total and individual DS use was available for all survey cycles although detailed data was inconsistent for years 2003-2004 and 2007-2008. These inconsistencies caused minor issues with data processing but not with the data validity. This data was used for the demographic data. DSs used for specific reasons were grouped into types based on product information for the analysis.

Data Analysis

We first created a profile of obese adults in the cohort with respect to gender, age, race, and household income. Using the 2007-2014 data with the needed variables, we assessed the major perceived benefits of the DSs used by obese adults in the cohort, stratified by specific DS type. In our previous study [6], we learned that the Natural Medicine Comprehensive Database (NMCD) [7] is the most comprehensive resource, providing DS information that is reliable, clinically relevant, and evidence-based. Hence, in this study, we compared the reported benefits of obese adults in NHANES with NMCD aiming to identify the knowledge gap.

Results

Out of 11,959 survey participants, 5,421 (45.3%) self-reported taking at least one DS. The maximum number of DS used by an individual was 20. Survey participants were taking a total of 8,057 DSs , out of which they took 5,591 (69.4%) DSs on their personal will, and they took the remaining 2,466 (30.6%) DSs on their clinicians' advice. We looked at individual reasons for DS use between the years 2007-2014. Participants were given a list of top five reasons for DSs intake where they could choose 1 or more options (Table 1). We also looked at DS use reasons '*For Weight Loss*' and '*To Maintain Blood Sugar/Diabetes*'. These reasons were matched to specific DS type. Overall, this same group (2007-2014) used 6,929 DSs.

Table 1– Reason for DS use matched to type of DS

Reason (Total Responses)	Highest Type	# of responses for this DS type	% of total responses for this reason
General Overall Health[a] (5,313)	MVMM[c]	1,677	41.0%
Bone and Joint Health[b] (1,569)	Calcium / Bone/ Joint	834	57.7%
To Supplement Diet/Food Not Enough (941)	MVMM	462	49.1%
Heart Health/Cholesterol (787)	Omega-3	410	52.1%
To Get More Energy (737)	MVMM	316	42.9%
For Weight Loss (184)	Botanical[d]	55	29.9%
To Maintain Blood Sugar/Diabetes (125)	Botanical[d]	40	32.0%

a: Includes: To prevent health problems (813), to improve my overall health (2170), to maintain health/to stay healthy (1734), and to prevent colds/boost immune system (596). 4090 total responses once duplicative response were removed.

b: Includes: For healthy joints/arthritis and for bone (522) health/build strong bones/osteoporosis (1047). 1446 total responses once duplicative responses were removed.

c: Multivitamins/multiminerals

d: DS classified as a botanical if it is part of a plant, tree, shrub, herb, etc.

In addition, we investigated if the information provided in the existing knowledge base aligns with the reported use of a particular DS. We found consistency between the reported use of a particular DS and its use/effectiveness as provided in the existing knowledge base (NMCD) for improving certain conditions, e.g. general overall health, bone/joint health, heart health/cholesterol, and as a dietary supplement. In fact, we found useful information about the primary use of a DS in addition to its other common uses, e.g. use of calcium for bone and joint health other than to improve general health. For the remaining three conditions, i.e., getting energy, losing weight, and maintaining blood sugar, we found that consumers were taking DSs indiscriminately without sufficient, current, and scientific knowledge on how a particular DS impacts the human body, e.g. the use of MVMM and Vitamin B-complexes for weight loss and/or maintaining blood sugars among diabetic patients, rather than the intended role of a diet supplement in people with restricted diets.

Discussion and Conclusions

In this study, we used the NHANES data to assess the use and perceived benefits of dietary supplements among obese adults. Demographics clearly play a role in DS use. We found that females were more likely than males to use DSs. With respect to age, the older the respondent was, the more likely he or she used at least one DS. These results conclude that there is lack of adequate knowledge about specific DS use and their resulting benefits, esepcially among consumers who are taking DSs for obesity and/or related conditions. Even though they consider obesity as a health concern, they are not using DSs for actual weight loss. This includes the use of MVMM and Vitamin B complexes for losing weight and/or maintaining blood sugar among diabetic patients rather than their actual dietary supplment role for people with restricted diets. We found that consumers were taking DSs indiscriminately without sufficient, current, and scientific knowledge on how a particular DS actually impacts the human body e.g., use of calcium for heart health, despite a considerable number of risks [8]. Overall, we found NMCD to be reasonable in finding the relevant information for most ingredients/products despite few challenges. This study pinpoints the gaps of the perceptions of dietary supplements among the general public, thereby informing informaticians of the opportunities for developing informatics tools to disseminate the "accurate and factual" knowledge to the consumers.

Patient-Pivoted Automated Trial Eligibility Pipeline: The First of Three Phases in a Modular Architecture

Paul M. Heider[a], Stéphane M. Meystre[a]

[a] *Biomedical Informatics Center, Medical University of South Carolina, Charleston, South Carolina, USA*

Abstract

Automated extraction of patient trial eligibility for clinical research studies can increase enrollment at a decreased time and money cost. We have developed a modular trial eligibility pipeline including patient-batched processing and an internal webservice backed by a uimaFIT pipeline as part of a multi-phase approach to include note-batched processing, the ability to query trials matching patients or patients matching trials, and an external alignment engine to connect patients to trials.

Keywords:

Eligibility Determination, Natural Language Processing, Machine Learning

Introduction

The success or failure of clinical research studies depend heavily on patient enrollment. Achieving sufficient levels of enrollment is an expensive endeavor in terms of both time and money [1]. Unfortunately, patients are commonly not enrolled in relevant trials because of their doctor's lack of awareness rather than the patient failing to meet eligibility criteria [2]. Natural Language Processing (NLP) and machine learning (ML) can be used to automatically extract relevant evidence from a patient's electronic health record (EHR) regarding their eligibility to participate in a clinical research study. Importantly, NLP and ML can glean these details from the structured fields (easily accessible through common database queries) and the unstructured clinical notes, which often lay untouched. Automated eligibility criteria extraction has been shown to significantly decrease enrollment time [3].

Building off our prior experiences developing an eligibility criteria extraction engine for breast cancer trials [4] and competing in the 2018 n2c2 Shared Task on Cohort Selection [5,6], we have found a gap in the discussion and documentation of trial eligibility approaches, especially with respect to balance between component reuse vs. customization to accommodate an ever-changing list of trials. We are in the first phase of three to evaluate and distribute a modular architecture for extracting trial eligibility criteria from EHRs.

Modularity comes in various forms and abstraction levels in the architecture. First, within the clinical research domain, new trials are constantly introduced and old trials are phased out. As such, the architecture needs to accommodate a formalism for describing criteria and their relationship to trials to allow trials to be easily added and removed from the monitoring cycle without heavy re-engineering of the core application.

Second, the constant turnover of trials requires that the extraction engine be able to accommodate new concepts. As such, there must exist modularity in the engine itself to allow for the easy extension of the core application.

Third, treating the patient as an individual is the ultimate goal of care but documentation of that care occurs in more quantal units. As such, the architecture needs to be able to integrate together extractions from individual notes (i.e., these quantal units) and structured data into a single picture of eligibility.

We propose that, just as automated trial eligibility surveillance can decrease enrollment time and costs over fully manual efforts, trial eligibility surveillance systems balancing a stable core application against the three needs described above decrease development time and costs over fully bespoke applications. For the first phase, we have focused on developing towards the first two needs, as described below.

Methods

Figure 1 shows the high-level architecture of our initial phase implementation. At the heart of our architecture is an Apache UIMA pipeline [7]. UIMA (Unstructured Information Management Architecture) is designed to be a highly modular system for processing documents. With uimaFIT, specific modules can be activated for a document on-the-fly based on general program arguments or properties of the document itself. This two-fold modularity allows weaving together off-the-shelf components developed as part of other clinical data-oriented information extraction tools (e.g., from cTAKES [8]) with custom modules. While pre-existing tools like cTAKES are a good stepping-off point, such generalized systems are missing some required algorithms and concept extractors. We can easily add, remove, or upgrade concept extraction modules to match the evidential needs of new trials, as per our second need above. Overall, the system extracts eligibility criteria from clinical notes and aligns those criteria with trials for optimal pairing of patient to trial. (Details can be seen in Figures 2 and 3, below.)

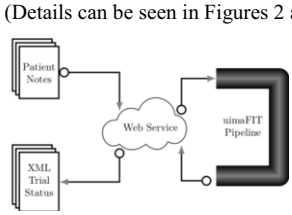

Figure 1 – High-Level Architecture of a Service-Based Pipeline Treating Patients as the Primary Pivot

The most significant deviation from a standard UIMA pipeline is our use of the OMOP Common Data Model (CDM) [9] as our underlying data model for eligibility criteria. The two implications of this formalism are found in Figure 2. First, we

developed a module to standardize all other concept representations into a OMOP CDM representation.

Second, we developed eligibility criteria aggregator modules for each trial which programmatically filter documents just as OHDSI's ATLAS tool allows users to define cohorts. The parallels between these implementations is intended to eventually allow for migration of definitions between the two. Quarantining the eligibility determination logic for each trial into its own module allows us to easily add and remove modules to match the flow of trials, as per our first need above.

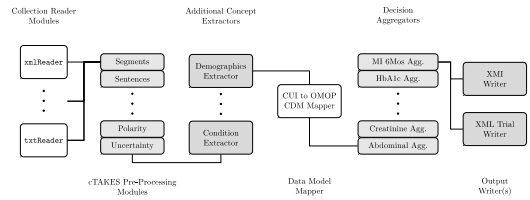

Figure 2 – Six Conceptual Classes of Pipeline Modules in Use

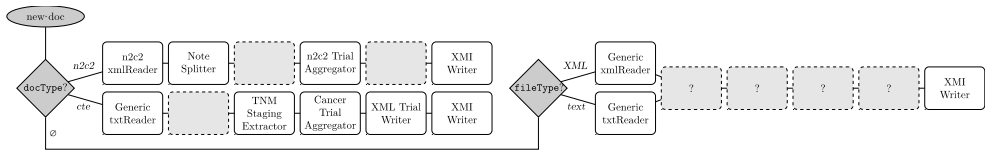

Figure 3 – Configurable paths through uimaFIT. Light Gray modules are not used by default but can be parametrically called.

A webservice sits in front of our UIMA NLP application to allow users to batch process patient records. As an early and partial implementation of our system, we currently only support treating a document as a self-contained representation of a patient. A patient's eligibility is determined based on the contents of a single document rather than on the accumulation of evidence over time.

Results

A simple webservice was developed in Java using the Spring Java framework. It accepts a single document or a batch of documents such that each document contains the entire collection of notes associated with a given patient.

General guidance on processing documents can be passed to the engine via the parameters of *document-type* and *annotators-list*. The former is used when the document fits squarely into a predefined limited set of known documents types (e.g., 'cte' type documents are processed as per the cancer trial eligibility pipeline we developed prior to this work). The latter allows the user to specify additional modules to run on the documents beyond the standard core pipeline. Figure 3 depicts a simplified view into several common flows through the pipeline.

Due to the uncertain nature of how long processing takes, the webservice does not hang while waiting to return results. The user must re-query the webservice with a provided batch-key (which uniquely identifies a batch) to get the break-down of eligibility by trial and criteria per patient in a JSON file.

Discussion

The next phase of development will be to accumulate extracted information about a patient across notes and structured data and improving the pipeline's flexibility. Webservice query parameters cannot yet fully control the system. Finally, trial eligibility criteria are programmatically determined. Ideally, this alignment between patient information and trial would be done externally and be less rigidly defined (e.g., through a spreadsheet, which we have experimented with through OHDSI's ATLAS, or using machine learning algorithms).

We have consolidated the development wisdom from separate applications built for similar tasks within the domain of eligibility surveillance. The shared components will reduce development and upkeep costs and will help us better clarify our abstract representations of trial criteria, as experimented with using OHDSI's ATLAS tool.

Abstract

The health concept has evolved throughout history. The people health level is determined by the perception that each individual has of it. It is a dynamic process over time, so the variations can be see from one moment to another. In this way, knowing the health of the patients you care for will facilitate decision-making in the treatment of care. To know the level of health of the people, a technological tool is presented that calculates the people health level through the Health Variables and Nursing Outcomes Classification (NOC) labels.

Keywords:

Health Care Technology, Population Health, Health

Introduction

The present study starts from the following research aim: Design an application for calculate the people health level based on the health variables.

Today in Spain, the so-called "Health Indicators" are used to establish the health level of a population. These indicators can be found in the health indicators document “Evolution of the indicators of the state of health in Spain and its magnitude in the context of the European Union” [1]. However, no tools have been found that determine the level of health of people, understanding that health goes beyond the absence of the disease, as proposed by WHO [2].

The objective of the research presented in this article is to design a computational tool that determines the level of health of a person at a given time. For this, a study has been carried out in which the logical formalization of the WHO Health concept takes place. This formalization allows to represent all those potential health states of a person [3].

Methods

The present study used deductive type methodology and was developed in four phases:

1. Extraction and representation of knowledge.
2. Design and development of the prototype tool.
3. Specification of Soft-ware Engineering Requirements through the Standard “IEEE Recommended Practice for Software Requirements Specification ANSI/IEEE 830-1998”.
4. Verification of the tool by group of experts of the MISKC Research Group, Alcalá University.

Results

Definition of Health Variables

The first result obtained derives from the extraction and description of the variables that constitute the concept of Health proposed by the WHO. This set of 11 variables has been called health variables.

- Physical Functioning: Functioning of the apparatuses and corporative systems of the person. It has a reversible character.
- Mental Functioning: In order to determine the mental functioning, the state of consciousness, spacetime orientation, behavior and language will be valued. It is reversible.
- Social Functioning: To determine the social functioning of a person will be assessed the ability to communicate and interact with other people. It is reversible.
- Confort Status: The welfare of the person, their tranquility, personal security, adaptation to the environment will be valued.
- Material Resources: Set of material goods needed to live [4].
- Time Resource: Temporary availability to carry out your care [4].
- Sings Presence: Sign measurable and valuable by the healthcare professional.
- Symptoms Presence: Manifestations of each person.
- Physical Condition: Sequel of irreversible character in the functioning of the body.
- Mental Condition: Sequel of irreversible character in mental functioning.
- Social Condition: Sequel of irreversible character in social functioning.

Tool Design

The computational tool will collect information about the health status of the person through NOC indicators. For its development, each one of the 11 variables of health were correlated with a label of the Taxonomy of NOC Result Criteria (Nursing Outcomes Classification) [5].

Health Variables	NOC Related
Physical Functioning	Personal Health Status (2006)
Mental Functioning	Personal Health Status (2006)
Social Functioning	Personal Health Status (2006)
Confort Status	Estado de comodidad (2008)
Material Resources	Health Belief: Resources Perception (1703)
Time Resource	Health Belief: Resources Perception (1703)
Signs Presence	Knowledge: Disease Process(1803)
Symptoms Presence	Knowledge: Disease Process(1803)
Physical Condition	Personal Health Status (2006)
Mental Condition	Personal Health Status (2006)
Social Condition	Personal Health Status (2006)

Figure 1 – Relationship between Health Variables and NOC Related

In this way, when relating the variables of health with NOC labels, they are related to their scale of measurement, being said scales those used to determine the people health level.

IEEE 830 Requirements Specification Interface

The application (app) is intended for all healthcare professionals. Then, this is the last of the results, the Specification of Software Engineering Requirements through the Standard "IEEE Recommended Practice for Software Requirements Specification ANSI/IEEE 830-1998", through the developed interface. The start screen of the app is shown in Figure 2.

Figure 2–Principal APP Interface

Once the user has accessed the app, an information screen appears in which clicking on each one of the health variables will show its definition. Finally, Figure 3 shows what the health calculation tool would look like, in which health variables are identified along with the Likert-type scale based on the NOC taxonomy.

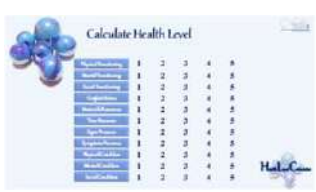

Figure 3 – Health Level Calculator

Discussion

7 out of 10 Spaniards consider that their state of health is good[6]. These data are based on the results obtained after the National Health Survey, in which the section of the health status module asks the population of the type: "Would you say that your health has been very good, good, regular, bad, very bad?", "Do you have any chronic or long-term illness or health problem?" or "What type of problem is the cause of its difficulty in carrying out the activities that people usually do?" [7]. However, no tools have been found that determine the level of health of people who go beyond the impact that health problems have on the individual.

Conclusions

The analysis of the data obtained will draw a graph where one can observe how the level of health of each participant is modified throughout a certain process. Determining the level of health of a given population facilitates the establishment of assessment criteria and health management, allowing prediction and prioritization of different health care strategies.

Network-Based Prediction of Major Adverse Cardiac Events in Acute Coronary Syndromes from Imbalanced EMR Data

Abstract

The low proportion and the rapid evolvement of major adverse cardiac events (MACE) present challenges for predicting MACE by machine learning models. In this paper, we propose a method to predict MACE from large-scale imbalanced EMR data by using a network-based one-class classifier. It only used the reliably known MACE samples to establish the hyperspherical model. Experiments show that our model outperforms the state-of-the-art models.

Keywords:
Acute coronary syndrome, machine learning, algorithms

Introduction

Acute coronary syndrome (ACS) is a group of diseases, resulting from a sudden decrease of blood flow in the coronary arteries and cardiac tissues leading to cardiac insufficiency or death. Given the fatal impact of MACE on ACS patients, researchers have consciously collected a large number of resident admit notes at the early stage of hospitalization, making the risk prediction of MACE a resoluble data analysis problem. In this state, two main methods are developing around this problem. The more traditional MACE prediction method is to use the risk score model. For example, TIMI [1], GRACE [2] and other tools introduce the factor score model into pre-selected risk factors to realize MACE risk prediction. Such approaches have a few drawbacks, they only apply to small sample evaluations, and they have strict requirements on data integrity, that make them difficult to deploy effectively in various real environments. A recent class of approaches advocates the use of supervised learning algorithms to directly model large-scale EMR data, and models can predict new cases of ACS patients in different environments [2]. In particular MACE, as a rare event, brings label imbalance to the prediction work. For example, only 3.5% of ACS patients in the data set we collected have MACE. However, existing machine learning models that have been improved to address imbalances still have several limitations that cannot be avoided for low level performance, resampling training data, and the false negatives of negative samples in the actual case data. Therefore, we present a Network-based Support Vector Data Description, called N-SVDD, to learn a similarity network of ACS patients as a new network representation and training of diagnosed MACE samples by Support Vector Data Description.

Methods

Cohort Construction

The multicenter, retrospective cohort study was conducted in 38 urban and rural hospitals in three provincial-level regions of China. Adult inpatients who were diagnosed with ACS at the time of death or discharge were recorded in the data set. We tooke an intermittent acquisition mode to record ACS patients corresponding to hospitals of different scales. A total of 26,986 selected patient samples were included in this study. Overall, there were 955 MACE records, only 3.5% of the total sample. The patient data were collected from the information system of each hospital and reviewed by investigators with professional knowledge and experience in the process of summarizing, to establish a clinical archive set. Our previous study [3] has assessed the association between all available patient variables and MACE. On this basis, we screened out 41 variables as train features; including age, demographics, diabetes mellitus, personal history, living habits, ACS type, Killip class, etc. as Figure 1 shows. The missing values were re-estimated by multiple imputations, the predictive mean matching was used for continuous variables. We performed one-hot encoding on categorical variables with more than two classes. Also, to standardize the continuous values, we removed the mean and scaled the unit variance.

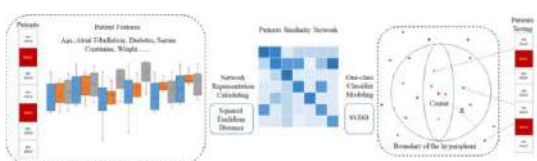

Figure 1–Flow diagram of N-SVDD.

N-SVDD (Network-SVDD)

The procedure of the proposed N-SVDD is shown in Figure 1. N-SVDD converts the patient features to the left of the figure into the similarity network representation in the middle of the figure, and then sends it to the one-class classification model training to the right of the figure, and predicts whether the new patient will suffer from MACE. Suppose that we have *n* patient samples and *m* feature variables, then we transform the original patient features into a similarity network based on these associations. A patient similarity network is represented as a

graph $G = \{V, E\}$ with a two-element tuple, where $V = \{u_1, u_2, \dots, u_n\}$ is a set of vertices representing n patients in a network, and the $E = \{e_{ij}\}$ is a set of edges. E is made up of the similarity of the paired elements in V. To achieve a similarity matrix of patients, we assess nodes similarity by the use of Squared Euclidean distance as it is good at evaluating the interrelationship between continuous data [4]. Support Vector Data Description (SVDD) [5-6] is a sophisticated one-class classification model whose goal is to determine whether a test sample should be classified as a specified category. Typically, patient variables of one class samples contain only feature information which is expressed by such samples. Instead, the sample trained by N-SVDD already contains many more representations by introducing the patient-patient similarity network. Suppose that there are k ACS patients labeled MACE, all the N-SVDD used samples should be represented as $X = [x_1, x_2, \dots, x_k]^T \in L^{n \times n}$, where $k < n$. Given the n network representations, such as for the training features, SVDD first maps the new input representation with a nonlinear transformation to a new feature space via a mapping function $\varphi(.)$. Then, it determines a sphere with a minimal volume containing all or most of the mapped patients in the new space. Let a center α and radius R express the hypersphere, the SVDD by using a minimum radius of hypersphere to describe the input samples, makes the minimum volume of hypersphere surround the patient samples as much as possible. When testing whether an ACS patient will have MACE or not, we calculate the distance from the test object z to the center of the hypersphere. When the distance is smaller than the radius R, the test object z is considered to have MACE.

Results

Due to that our ACS dataset has a high class imbalance, we use a 5-fold cross-validation for testing. Since the reliable positive samples are too small this may lead to no positive training samples if randomly dividing the dataset. We separate positive and negative samples and divide both into each fold equally. At present, many studies are subtly designed for predicting the MACE in ACS patients. We selected four comparison approaches; including two traditional models: SVM and Random Forest, and two models especially proposed for imbalanced data: SVM-BS and SVM-SMOTE [7]. The prediction task of unbalanced data cannot evaluate the prediction performance with common standards, and the evaluation metric must be able to weigh many true negative results. The area under the ROC curve (AUROC) has been proven to be able to avoid the influence of a large number of negative samples well and has become the evaluation standard for unbalanced tasks [8]. We compared the best AUROC scores of the N-SVDD with the above approaches.

Table 1– The average AUROC of proposed N-SVDD and comparison methods for the four imbalanced patient datasets.

	Data Set			
Method	**A (8098)**	**B 11980)**	**C (6890)**	**All (26968)**
N-SVDD	**0.713**	**0.739**	**0.751**	**0.760**
SVM-BS	0.659	0.671	0.662	0.673
SVM-SMOTE	0.701	0.705	0.701	0.703
SVM	0.568	0.575	0.562	0.577
Random Forest	0.692	0.697	0.677	0.695

Table 1 shows the AUROC scores of N-SVDD on the datasets of three provinces (A, B, C) and the consolidated dataset (All). As the results look like those shown above, the prediction accuracy of the proposed N-SVDD is superior compared to all methods on four datasets.

Conclusions

In this paper, we have proposed a novel machine learning approach called N-SVDD to predict MACE of ACS. It is a unique approach in the sense that it represents an attempt to make use of one-class network representations to predict the potential MACE of ACS patients. The experimental results show that N-SVDD can predict MACE accurately. The proposed model is also used in comparison with the state-of-the-art algorithms on four datasets, with approximately 7 to 13 % improvement of AUC values over the compared methods. The prediction accuracy of N-SVDD enables it to be used in clinical MACE prediction. N-SVDD can be a promising, intelligent tool for assisting in decision making related to the ACS treatment. It has good potential to improve the efficiency and effectiveness of automated clinical diagnosis.

Prediction of Synergistic Drug Combinations by Learning from Deep Representations of Multiple Networks

Pengwei Hu[a], Shochun Li[a], Zhaomeng Niu[b]

[a]*IBM Research, Beijing, China*
[b] *Rutgers Cancer Institute of New Jersey, New Brunswick, USA*

Abstract

Drug combination therapy can improve drug efficacy, reduce drug dosage, and overcome drug resistance. Many studies have focused on predicting synergistic drug combinations. However, existing methods fail to consider the heterogeneous characteristics of drugs fully, and it is difficult to identify effective drug combinations. Therefore, we propose a new integrated prediction model based on deep representations by integrating information from multiple domains to accurately and effectively predict drug combinations.

Keywords:

Heuristics; Deep Learning; Drug Therapy, Combination

Introduction

It is common for providers to prescribe a single drug that is precisely targeted to a diagnosis. However, in some cases, single drug use limits the efficacy of the drug and the condition's resistance to that drug [1]. One application of drug combination that covers a large number of people is the treatment of chronic diseases. In general patients with chronic diseases are older, with multiple diseases, and need two or more doses of drugs in daily treatment [2]. This type of synergistic drug combinations aims to cover all therapeutic targets and reduce the off-target effect.

Similarly, cancer treatment is also a difficult task that needs to be solved with polypharmacy. The identification of effective combinations of drugs is crucial to finding effective treatment for drug-resistant cancer. Recently, regulators have treated drug combinations as new, special drugs for the treatment of various cancers [3-4]. Although the combination of drugs is effective, it is not feasible for doctors to screen all possible drug combinations when prescribing. In addition, it is extremely time consuming to find effective compound drugs through biological experiments.

Many studies have shown that multiple biomedical variables are associated with patients' responses to drugs [5]. With the emergence of various related databases and the development of EMR systems, integrating various biomedical information to predict effective drug combinations will be an ideal clinical tool for medication treatment. Currently, machine learning methods based on drug features are the main methods used to predict synergistic drug combinations. One study has proposed a new prediction method for synergistic drug combinations, combining molecular and pharmacological information [6]. Further, more sophisticated algorithms have integrated a series of related properties such as drug-drug interactions, protein-protein interactions, and pathways together, and then use random forests with feature selection methods to predict synergistic drug combinations [7]. Ding et al. [8] introduced more related features of drugs, converted feature expressions into similarity networks, and integrated multiple networks to achieve the purpose of prediction with ensemble learning. Unfortunately, these methods directly concatenate the features, failed to keep the network structure information, and performed network embedding after concatenating.

To address these challanges, we propose a deep representation model to fuse multiple similarity networks for synergistic drug combination prediction called DSDC. The experimental results presented here indicate that our method outperformed the state-of-the-art approaches on the real-world dataset.

Methods

Figure 1 displays the the procedure of the proposed DSDC. We first constructed the similarity networks for various properties that could be calculated according to object features. Then we applied the network integration method to fuse the multiple similarity network to one network. Deep Auto-Encoder was used to conduct network embedding, and the classifier used the network representation to train the prediction model.

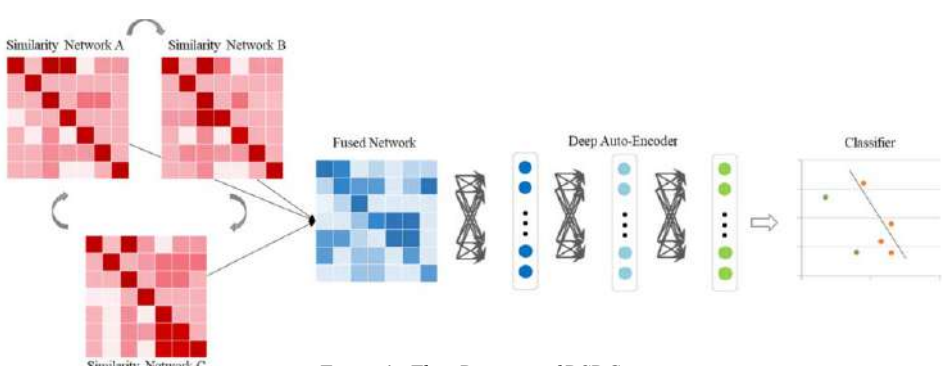

Figure 1– Flow Diagram of DSDC

Materials

Synergistic Drug Combination

The drug combination information used in this study was obtained from a widely used database, DCDB (http://www.cls.zju.edu.cn/dcdb). The validated drug combinations recorded (1363 records) by database records were collected from the FDA, clinicalite.gov, and PubMed literature. To obtain various types of measurements, we used the methods of Bai et al. [9] to collect transporters, targets, pathways, enzymes, and side effects of drugs from multiple data sources for the drug similarity network learning.

Similarity Network Learning

Suppose we have n samples and m measurements; this means there are m networks for one kind of drug properties. Let $G = \{V, E\}$ represent one kind of network, where $V = \{u_1, u_2, \dots, u_n\}$ is a set of n nodes representing all the drugs in the network, and the $E = \{e_{ij}\}$ is the edge set containing the edges between pairwise drugs, and their values represent how similar these nodes are. The edge weights are constructed by an $n \times n$ similarity matrix N.

Network Integration

Since the influence of each attribute on the target is different, a weighted combination strategy was used to integrate the similarity in order to adjust the deviation of each similarity and balance multiple networks. In order to achieve an integrated network from multiple networks, DSDC used m weight parameters to control the weight for each network. The integrated similarity network IS can be defined as follows: $IS = \frac{\sum_{v=1}^{m} W_v N_v}{\sum_{v=1}^{m} W_v}$, $v = 1,2,3, \dots, m$.

Deep Representation and Prediction

Then, we imported Stacked Auto-Encoder as an unsupervised learning model to get new deep representations from the integrated network. One effective classifier was used to predict whether a given drug-target interaction was positive or not according to the gold standard dataset. Finally, Support Vector Machine (SVM) was used as a classifier to train the new deep representations.

Results

The experimental results are presented in Table 1. We use 5-fold cross-validation, where each fold leaves out 20% of the positive and negative samples for testing. At present, many studies are proposed for predicting the synergistic drug combinations. We further considered several important studies of feature-based and network-based models which have been implemented in the prediction of synergistic drug combinations. We selected three studies to include two feature-based machine learning approaches (Ensemble model and SVM) and a method using the drug similarity network. When we compared the the DSDC score using these methods against the best AUROC scores, DSDC performed better.

Table 1– The average AUROC of proposed DSDC, NLLSS, Ensemble model, original SVM

Methods	NLLSS [10]	Ensemble model[9]	SVM	DSDC
AUROC	0.783	0.801	0.652	0.825

Conclusions

This study shows that the network integration method can effectively use the network representation of various properties to predict the potential SDC. In the context of clinical treatment, providers can quickly identify which drugs play an auxiliary role according to the prescribed primary drug. In the future, if we further combine the personal information of patients with the properties of drugs, we hope to provide more reliable synergistic drug combinations.

Abstract

A comprehensive scheme of patient similarity based on different types of patient features and the corresponding similarity measurements was proposed. Patient similarity was used in building a predictive model where training samples similar to the index patient were selected instead of randomly selected samples. The predictive models using the proposed patient similarity measurement outperformed those using Euclidean distance based similarity and those not using patient similarity.

Keywords:

Patient Similarity, Electronic Medical Records, Disease Prediction

Introduction

Recently, predicting the onset of a certain disease for individuals applying machine learning technology based on patient similarity became an important and prevalent research in personalized healthcare. Since patients similar with a certain patient may provide similar information on disease history and treatment history which may facilitate building effective predictive models, accurate identification of similar patients became a fundamental and crucial step [1], and there has been rapidly growing research of calculating and applying patient similarity for personalized analytics [1-4]. However, a series of questions have emerged with the development of patient similarity research, such as which feature(s) will be more reasonable for computing the patient similarity, and how to integrate the feature similarities into the patient similarity?

In this study, we conducted an exploratory study on the Patient Similarity Measurement (PSM) where the similarity at the patient level was calculated directly from four similarities at the feature level. The proposed PSM was then used to select similar patients for predicting the disease status of an index patient to assess the effectiveness of the proposed PSM.

Methods

Data set

Data used in this study was extracted from the Electronic Medical Records (EMR) system of a tertiary hospital in Beijing, China, from 2014 to 2016, covering 104,482 patients with over 140,000 hospital admissions. Each record included demographics (age and gender), up to 11 disease diagnoses, and laboratory tests. In order to build predictive models for the diabetes status for a certain person, 5,000 patients with diabetes were randomly selected from the overall 27,803 patients with diabetes in the dataset. Together with another 5,000 randomly selected patients without diabetes, they composed the study sample set for the subsequent study.

Calculation of the patient similarity

Four patient features included in this study included age, gender, disease diagnosis and laboratory test. Similarities at the feature level were first calculated according to the feature's data type. Age similarity S_A was set as the ratio of the minimum to the maximum of two age, and gender similarity S_G was defined as 1 if the two patients have the same gender and 0 otherwise. Laboratory test similarity S_L was defined as one minus the Euclidean distance between two sets of laboratory tests.

$$S_D(P_i, P_j) = 1 - \frac{|A \cap B|}{|A \cup B|} \quad (1)$$

Disease diagnosis similarity S_D was computed by one minus the Jaccard distance (Eq. 1), where A and B were the disease diagnoses sets (represented by the ICD-10 codes) of patient P_i and P_j. Patient similarity was the weighted sum of those similarities at the feature level.

Feature combination scheme

We used the task-guided method to identify the optimal combination of four feature similarities. There were three main variants for the PSM calculation, including the code scheme for disease diagnosis which may impact the Jaccard similarity, the number of laboratory tests which may impact the Euclidean distance, and the weights assigned to each feature similarity.

- ICD-10 codes truncated by the first three or four letter and numbers (named ICD-T3 and ICD-T4, respectively) were used in this study. Additionally, Clinical Classification Software (CCS) code scheme was used in this study, where ICD-10 codes were grouped into 259 categories (encoded as 1–259) which may be more meaningful clinically.
- 77 most common and regular laboratory tests were selected as the full set of laboratory tests. Among them, 45 and 55 laboratory tests with significant difference between patients with and without diabetes ($P<0.01$ and $P<0.05$, respectively) were grouped into Lab subset A and B, respectively.
- Three typical weight allocation schemes for the feature similarities were chosen taking the clinical importance into account. Scheme Ⅰ hypothesized that all the four features supported the same contribution to the patient similarity, giving the equal weights of 0.25 for them. Schemes Ⅱ (weights of 0.1, 0.1, 0.4, and 0.4, respectively) and Ⅲ (weights of 0.1, 0.1, 0.6, and 0.2, respectively) paid more attention to the laboratory tests and disease diagnoses, which maybe more important for the clinical diagnoses.

In total, we designed 27 PSM calculation schemes, involving three disease code systems, three laboratory test sets, and three weight allocation schemes.

Application of the patient similarity measurement

PSM was used to build predictive models for diabetes status. The study samples were randomly split into three parts: i) an optimization set with 3,000 samples for determining the optimal patient similarity. They were further split randomly into a subset of 1,000 and 2,000 samples for seeking the optimal PSM; ii) a training set with 6,000 samples for building predictive models (logistic regression models in this study), and iii) a validation set with 1,000 samples for validating.

For a given patient in the validation set, k randomly selected training samples or k most similar training samples identified by the proposed PSM and the Euclidean distance based PSM were used to build the predictive model for that patient, respectively. The Euclidean distance based PSM was defined as one minus the Euclidean distance between two patients, represented by age, gender (1 for male and 0 for female), laboratory test (77 items in total), and disease was represented by an vector $X = \{x_d | x_d \in \{0,1\}, d = 1, \ldots, n\}$ where n was the number of all possible disease recorded in the dataset, and x_d=1 if the patient had the disease and 0 otherwise.

For logistic regression, log-likelihood loss function was used to measure the predictive error (Eq. 2). The predictive performance was evaluated by the area under the Receiver Operating Characteristic (ROC) curve (AUC), and the average of AUCs (AAUC) was used as the comprehensive index to compare the performance when k changed.

$$\mathcal{L}(\hat{y}, y) = -y * log\, \hat{y} - (1 - y) * \log(1 - \hat{y}) \qquad (2)$$

where y was the true value and ŷ was the predict value.

Results

The optimal scheme for calculating the patient similarity

Under all the possible combinations of disease code schemes (CCS, ICD-T3, and ICD-T4), laboratory test set (Lab subsets A, Lab subsets B and full set), and weights allocation schemes (Schemes , , and), the AAUC of predicting diabetes status for 1000 samples in the optimization set ranged from 0.7334 to 0.8521, and the optimal PSM scheme was the combination of ICD-T3 for disease diagnosis, Scheme for weights allocation and laboratory tests of Lab subset A (Figure 1).

Performance comparison

The predictive performance of the models built on k (from 60 to 1800 step by 60) training samples selected by different methods were shown in Figure 2. Models based on the proposed PSM could obtain higher performance with less training samples, and the corresponding AAUC was 0.86, which was higher than those (0.80 and 0.83, respectively) on training samples selected randomly and by Euclidean distance based PSM.

Discussion

There are increasing studies on patient similarity. The commonly used features for computing the similarity involved clinical data, diagnoses, medications, procedures, and lab results [1], and vital signs like heart rate and blood pressure [4]. Though the similarities were computed only with age, gender, laboratory test and disease diagnosis in this study, they were helpful in building and improving predictive models. For the specific predictive task in this study, the models built on the similar samples identified by the proposed PSM could get higher performance than those built on randomly selected samples. We also found the proposed PSM was most useful when there was little training data available.

In the proposed PSM, computation methods used for computing similarities varied from feature to feature, instead of a single measure like cosine similarity [4]. Our experimental results showed that predictive models built with the help of the proposed PSM had a higher performance than those built with a single Euclidean similarity, suggesting that a comprehensive scheme of similarity measurements was necessary.

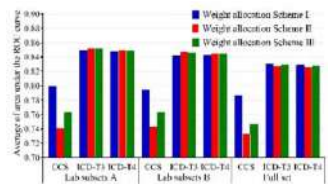

Figure 1 – Average areas under the ROC curve for all the 27 PSM calculation schemes. CCS: Clinical Classification Software; ICD-T3 or ICD-T4: ICD-10 code truncated by the first three or four letter and numbers.

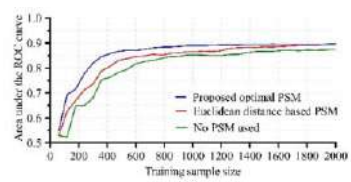

Figure 2 – Performance of predictive models built on training samples selected by using different methods.

However, other clinical features like bio signals, procedures, and diagnostic imaging were also important in similarity computation [1], which were not available in our current study. In addition, the proposed optimal task-guided PSM scheme may be limited in cross-domain applications.

Conclusions

This study proposed a patient similarity measurement scheme which the optimal combination of feature similarities was determined by experiments and the proposed patient similarity showed a higher performance than others. It could be expected that the proposed method will be helpful in EMR applications.

Successful Implementation of Terminology Binding in Hong Kong Hospital Authority

Karissa Hung, Maggie Lau, Vicky Fung

Health Informatics Section, Hospital Authority, Hong Kong Special Administrative Region

Abstract

Terminology binding has been adopted in Hong Kong Hospital Authority to link terminology component to clinical information models. This linkage facilitates structured data capturing and streamlines clinical workflow. With information models and data representation standards in place, data interoperability and data integration can be maintained for seamless patient care delivery.

Keywords:
Health Information Exchange, Interoperability, Terminology

Introduction

In Hong Kong Hospital Authority (HA), clinical information beyond diagnoses and procedures can be captured by electronic Generic Clinical Documentation (GCD) forms with customized questions and answers. The HA constructs Information Architecture (IA) with "Form", "Entity" (form questions), and "Data Value" (form answers) under clinical information model. The GCD forms are easy tools which were designed to fit clinical workflow for organized data capturing and reviewing. It helps to capture comprehensive cross-domain-data on one screen within a few clicks that enables flexible documentation. Clinicians can synthesize information at a glance for fast and precise decision [1].

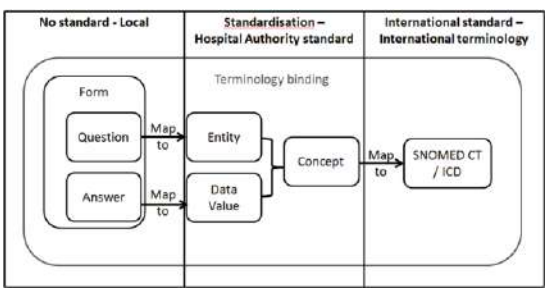

Figure 1– Illustration of terminology binding used in Hong Kong Hospital Authority

As advocated globally, HA has implemented standardization of clinical records using international standards to prepare for the data interoperability needs of the territory-wide electronic health record [2]. Thus, HA has adopted terminology binding for data standardization to facilitate clinical workflow by linking clinical information model and clinical terminology, and achieving semantic interoperability [3].

For the terminology component, HA uses Hong Kong Clinical Terminology Table (HKCTT), a medical dictionary developed for HK use, as a standard clinical terminology. It includes but not limited to diagnoses, procedures, substances, and pharmaceutical product concepts. Each concept was mapped to international terminologies, including SNOMED CT, International Statistical Classification of Diseases (ICD), etc.

Method

This paper demonstrates the initiation of applying terminology binding of diagnosis and procedure terms in HA corporate forms. Locally, we customized form questions and answers. Behind the scene, we implemented standardization by mapping the questions and answers to reusable and standardized "Entity" and "Data value" under IA (Figure 1).

With the application of terminology binding, the clinical terms captured by form questions and answers were mapped to structured HKCTT terms with international terminologies (see Table 1). Therefore, linkages were established between terminology component and information model artifact. This implementation achieved the real-time automation of clinical terminology binding from front-end to international standard without negative impact on clinical workflow. Furthermore, different questions and answers across the interface would generate the same concept as long as they mean the same.

Afterward, the form data were sent to other systems and healthcare organizations for patient care, for public health reporting including Hong Kong Department of Health then to the World Health Organisation (WHO), and for statistical analysis, resource planning, and research.

The screen in Figure 2 shows how structured procedure terms were mapped to clinical form. The forms, questions, and answers refer to the specified structured data mapping to international terminology.

Figure 2– Electrophysiology Study & Catheter Ablation Form

Result

The procedure capture rate from the mentioned form increased by 31.5% from 2017 to 2018 after terminology binding implementation in five months (see Table 2). Clinical

information was standardized with no negative impact on clinical workflow as reported by clinical users.

Table 1 – The journey from customized form question and answers to HKCTT concepts mapped to International Terminologies. Form name: EP Study & Catheter Ablation Form. Question / Entity description: Energy Source(s) / Energy source used in mapping and catheter ablation

Answer (Data Value)	HKCTT Concept	ICD9CM mapped by HKCTT Concept	SNOMED CT mapped by HKCTT Concept
Cryoablation	Transluminal cryoablation of heart lesion for arrhythmia	37.34 Excision or destruction of other lesion or tissue of heart, other approach	Is a = 233161001 Cryoablation operation for arrhythmia (procedure) Surgical approach = 261449002 Transluminal approach (qualifier value)
RFA	Radiofrequency ablation - heart lesion	37.34 Excision or destruction of other lesion or tissue of heart, other approach	Is a = 447954001 Radiofrequency ablation of lesion of heart (procedure)
RFA (irrigation)	Radiofrequency ablation of lesion of heart with saline irrigated electrode	37.34 Excision or destruction of other lesion or tissue of heart, other approach	Is a = 447954001 Radiofrequency ablation of lesion of heart (procedure), primitive

Despite the small sample size, standardization was achieved, and clinical documentation was facilitated by mapping structured HKCTT concepts to SNOMED CT from customized form questions and answers. Terminology binding facilitates clinical workflow, reinforces information models and data representation standards, and enhances data interoperability and data integration.

Clinical data, not limited to diagnoses and procedures data, could be captured in a faster way than inserting terms individually. In the binding model, the captured data were comprehensive since the data capturing became convenient. This implementation served as a prelude to clinical decision support by reviewing form data. With the improved clinical documentation, duplicated procedures on patients could be avoided, and the treatment given could be more precise. Moreover, structured and standardized terminologies could be captured, stored, and retrieved across forms with a user-friendly interface. Data sharing, retrieval, and analysis could be promoted. Furthermore, this linkage can contribute to clinical research and resource planning for better population health.

Table 2– Comparison of Procedure capture rate before and after implementation of terminology binding

	Procedure Reported Date (Year/Month)	The total number of the listed procedure reported	Average procedure captured per month
Before terminology binding implementation	2017-05	34	35.58
	2017-06	33	
	2017-07	39	
	2017-08	40	
	2017-09	50	
	2017-10	37	
	2017-11	31	
	2017-12	38	
	2018-01	27	
	2018-02	36	
	2018-03	35	
	2018-04	27	
After terminology binding implementation	2018-05	35	46.8 (↑31.52%)
	2018-06	39	
	2018-07	43	
	2018-08	64	
	2018-09	53	
	Total	330	

Conclusion

Terminology binding has been implemented in HA successfully that enabled standardized clinical data capturing and smoothened clinical workflow. Accurate data interpretation could be ensured no matter how data were being captured at front-end. Information models and data representation standards were maintained by linking the terminology component to our information model. Data interoperability and data integration were enhanced. This binding model helped to improve population health.

Extending Achilles Heel Data Quality Tool with New Rules Informed by Multi-Site Data Quality Comparison

Vojtech Huser[a], Xiaochun Li[b], Zuoyi Zhang[b], Sungjae Jung[c], Rae Woong Park[c], Juan Banda[d], Hanieh Razzaghi[e], Ajit Londhe[f], Karthik Natarajan[g]

Abstract

Large healthcare datasets of Electronic Health Record data became indispensable in clinical research. Data quality in such datasets recently became a focus of many distributed research networks. Despite the fact that data quality is specific to a given research question, many existing data quality platform prove that general data quality assessment on dataset level (given a spectrum of research questions) is possible and highly requested by researchers. We present comparison of 12 datasets and extension of Achilles Heel data quality software tool with new rules and data characterization measures.

Keywords: *data quality, observational study*

Introduction

Data quality is an important pre-requisite for research on Electronic Health Record (EHR) data. In recent years, several efforts and tools emerged that perform data quality assessment (DQA).[1] Another important trend is that research is increasingly conducted using distributed research networks. Such networks often provide tools to their data partners that lower the barrier to join or participate within the network and help with data preparation or analysis execution.

The Achilles tool from the Observational Health Data Sciences and Informatics Consortium (OHDSI) is one such tool that performs data characterization and includes an Achilles Heel part that contains rules for checking data quality (DQ). The Achilles tool has been first deployed in October 2014 (version 1.0) with several updates (versions 1.1 to 1.6) during a period from 2014 to 2018. Since 2016, the web-based user interface part of Achilles was incorporated into the OHDSI Atlas tool, which is a new interface that integrates into one interface several previously developed OHDSI tools.

In developing the Achilles tool, the OHDSI consortium actively encourages researchers to submit requests for new data quality checks or insightful data visualizations that would extend the tool's utility. The Achilles' software repository receives numerous inputs (in a form of Github issues) that identify such new DQ measures or checks. In addition to this ongoing feedback, European EMIF research network conducted a formal survey of the tool that indicated the need for new features.

This study describes a set of extensions of the Achilles tool based on a comparison of data quality indicators of several healthcare datasets.

Methods

The study had two goals. The first goal was to compare data quality characteristics across datasets. Informed by this comparison, the second goal was to extend Achilles with new features and new data quality rules that would improve the assessment of data quality generated by the tool. This study includes a larger set of exported dataset metadata compared with a previous study done by our team, that only focused on Achilles Heel output messages.

The Achilles tool currently generates over 170 measures. However, many healthcare dataset administrators are not permitted to share such comprehensive set of dataset indicators. To be able to conduct our comparison, we designed a smaller set of measures generated by Achilles pre-computations that includes only measures that were deemed acceptable by the dataset administrators.

To maintain a data aggregation privacy-preserving principle for our comparison, our study used a small-cell count threshold of 11+ patients per aggregated count. Achilles tool allows suppressing pre-computations that result in small counts of patients (or small counts of providers, or healthcare events). This filtering is done either when Achilles pre-computations are executed, but if it was not done during the Achilles pre-computation phase, our methodology enforced it again during when site data extract generation. The R package for our study (called DataQuality) is open source and available on the Github platform at https://github.com/OHDSI/StudyProtocolSandbox/tree/master/DataQuality.Actual input data for the study consisted of the following: (1) subset of Achilles analyses converted to ratios (for example, ratio of persons with at least one visit by visit type); (2) Achilles derived measures (for example, percentage of unmapped source data concepts by domain) and (3) an approximate size of the dataset (for example, <10k, 10-99k,100k-1M, 1-5M,5-9M and >10M; exact size of populations is masked into a dataset size category). Sample input data (for a synthetic SynPuf OMOP dataset) is available at Github.

Each dataset was assigned a meaningless identifier to facilitate the comparison. The purpose for this dataset masking is the fact that data quality comparisons can lead to withdrawal of a data partner from a research consortium (or an analysis project) if a particular partner's dataset is identified as having low quality data. Masking was done to avoid this outcome and to focus on advancing the methodologies for DQA. For the same reason, neither a list of individual datasets is provided. We plan to

destroy individual site aggregated data used as input at 6 months after the publication of the study results. To protect the sites, only masked and isolated combined comparisons are reported in this article. Non-aggregated, single dataset DQ data are never posted publically.

Determination of goodness of fit or "data fitness" is highly dependent on the research question being asked. This phenomenon was described earlier and is sometimes referred to a task-dependence nature of DQA.[2] A dataset that only contains inpatient events and data may not be appropriate for general research questions (e.g., descriptive study of a course of a disease); however, it may be sufficient for a subset of research questions (e.g., inpatient-only research questions).

One can conclude that without knowing the specific research question context, any data quality assessment is impossible to pre-empt. This requirement for specifying research question context up-front makes development of general DQA tools almost impossible. However, existing DQA tools and efforts indicate that some general DQA rules indeed exist.

To partially overcome this problem ("data fitness for what?"), we assumed that the dataset being assessed represents lifetime record of general population and the tool should perform DQA for a wide range of possible research questions ("*general* data fitness for a wide *range of research questions*"). Once a general DQA analysis is done, a researcher with a specific research analysis can simply ignore DQA messages that do not apply to his/her context. (e.g., ignore messages about lack of eye doctor's visit and eye care data if data about vision care are not essential for his/her research question).

Results

A total of 12 datasets were compared in the study; however due to use of prior Achilles versions by some sites, comparison of some newly implemented measures are made on data from datasets that implemented at least Achilles version 1.4 at the time of our study data extraction.

Version 1.6 of Achilles contains a total of 44 data quality rules (also called data quality checks). A total of 12 rules are *model conformance rules* that check adherence to the CDM specification. For example, a model conformance rule may require that provider specialty column contains only concepts that are indeed specialties. The remaining 22 rules are *data quality rules* that check for data completeness, data plausibility or other data quality problems. Such rules can be considered model-independent and should be portable to other data models, such as Sentinel model or PCORNet. The pooled dataset of all Achilles Heel messages from all datasets consisted of 546 messages. Median number of Heel messages for a single dataset was 51 with a median of 25 for errors, 22 for warnings and 4 for notification. Poster will show evaluation of severity of each rule violation by computing median record counts for each rule. The second goal of our study was to add new functionality (either new DQ rules or new DQ measures to Achilles) based on availability of data about multiple CDM datasets. The results are divided into multiple sections according to the data domain of the new rule and will be included in the poster.

(1) **Empirical rules:** Comparing selected dataset parameters and computing 90th or 10th percentile and using them as benchmark thresholds.

(2) **Data density rules:** We considered data density at three levels (*concepts per person* as a number of distinct measurements per person (e.g., count of 2 measurements per person, such as cholesterol and hematocrit). This comparison aims at "data breadth"; *records per person* as total number of all measurement records per person (e.g., count of 8 tests, such as 3 LDL cholesterol and 5 hematocrit measurements). This comparison aims at "data depth"; records per visit as a data density measure on a visit level. Because visits with no measurements occur, the per visit ratio measure can be below 1. However, for a ratio looking at clinical notes (if in scope for the dataset), it may be reasonable to expect at least one note per visit.

(3) **Minimum-data patients:** For many research question, at least one data point in a given clinical data domain (such as medications) is required for any meaningful analysis. For example, for analyzing event prevalence, using a proper denominator and determining the size of the relevant population can significantly affect the reported measure. We determined empiric thresholds for existing Achilles DQA measures that count number of patients with at least one event in a clinical data domain. (e.g., patients with at least one visit, patients with at least 1 diagnosis and 1 medication.

(4) **Unmapped data:** OMOP CDM allows storage of data that is not fully semantically mapped to standard concepts (for example, drug exposure data may include data rows that have a value of 0 ('No matching concept') in drug_concept_id while the yet-to-be-mapped local code is stored in drug_source_value). We introduced measures computing unmapped data and threshold rules for several domains, such as Conditions, Procedures or Drug Exposure.

Discussion and Conclusion

Our current method for picking an empiric threshold is using a fixed threshold (e.g., 10th percentile). Future methodology revision may alter this approach for each considered DQ measure. Another limitation is our primary focus on OMOP CDM sites. Our extension to Achilles rule knowledge base, however, point to what data measures are required by each rule and whether a rule is terminology dependent. We compared data quality indicators across several datasets. We arrived at empirical values that could be used as thresholds for several DQA measures. The study resulted in several new data quality checks being added to Achilles.

We would like to thank Ritu Khare, Taha Abdul, Chris Knoll and Martijn Schuemie. VH work was supported by the Intramural Research Program of the National Institutes of Health (NIH)/ National Library of Medicine (NLM)/ Lister Hill National Center for Biomedical Communications (LHNCBC).

Abstract

Statistical analysis of Medical Subject Headings (MeSH) descriptors to improve biomedical literature search is an active research area. Existing tools have limited interactive visualizations that are accessible to researchers investigating how their hypotheses compare to trends in the research literature. We present a web application that computes and provides an interactive visualization of basic frequencies and co-occurrence statistics of MeSH descriptors associated with a PubMed query.

Keywords:

Data Mining, Data Display, Medical Subject Headings

Introduction

Biomedical literature mining is an active area of research for enhancing information retrieval and knowledge discovery. The exponential growth [1] of publications available in PubMed/MEDLINE in the last decades fueled the development of many biomedical literature mining systems. Lu has presented a comprehensive survey [2] reviewing 28 such tools.

Of the 28 entries in Lu's review, only 14 continue to be available. A public list [4] of web applications for querying, mining, and visualizing results from PubMed has been created and made available as a complement to this study. From this list, it is apparent that most available frameworks focus on querying, with only a few having visualization capabilities.

The importance of providing visualizations to help literature exploration and understanding was leveraged in more recent work. Zhang *et al*. proposed PubMedMiner [3], a software package developed to mine and visualize associations of MeSH descriptors. In this study, a tool is presented that builds on the foundations developed in the original PubMedMiner package[3]. We enhance the methods with statistical measures and visualizations. The developed web-based tool follows best practices to provide visualizations that are interactive and require no software installation. The functionality is demonstrated through queries to identify mental health comorbidities for suicide.

Methods

Figure 1 provides a summary of the workflow and technology stack for the web-based tool. A user can access the tool from a web browser to explore sample studies or submit a new query. The query is sent to the backend server using a Representational State Transfer (REST) Application Programming Interface (API). The backend checks if the query has been performed before; if so, cached statistics are returned. Otherwise, the statistics are computed and returned. The results are presented as interactive visualizations.

Statistical Methods

Two types of statistical methods are presented to the user: *(1) Univariate statistics:* Total counts for the 50 most common MeSH descriptors related to the input query are provided; and *(2) Covariate statistics:* Pairwise statistics are based on occurrence or co-occurrence matrices. The tool includes three types of covariate statistics:

1. *Pearson's Correlation Coefficient:* Pearson's correlation coefficient is computed to investigate the statistical relation between the random variables (MeSH terms). In particular, the coefficient measures the strength and direction of the linear relationship of the two variables.
2. *Pointwise Mutual Information (PMI)*: This measure quantifies the distance between the joint probability of the variables and their individual distributions. If the variables are independent, then PMI is equal to zero.
3. *Association Rules and Frequent Itemsets:* An association rule is defined as a relation of the form X $\rightarrow$ Y, where X is a set of MeSH and Y is one MeSH. A frequent itemset is defined as X$\cup$Y. We use an implementation that is a variation of the Apriori and the Eclat algorithms [5,6].

Visualization Methods

Interactive Bar Plot: Univariate statistics are presented using an interactive bar plot that displays counts and names on hover.

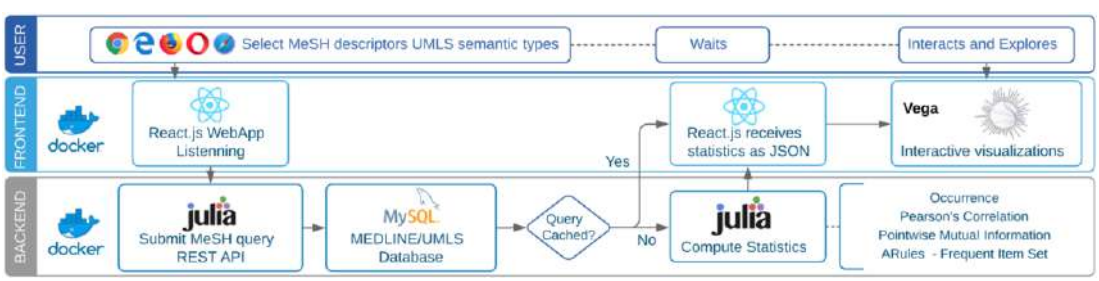

Figure 1 – Workflow and Technology Stack of the Web Application

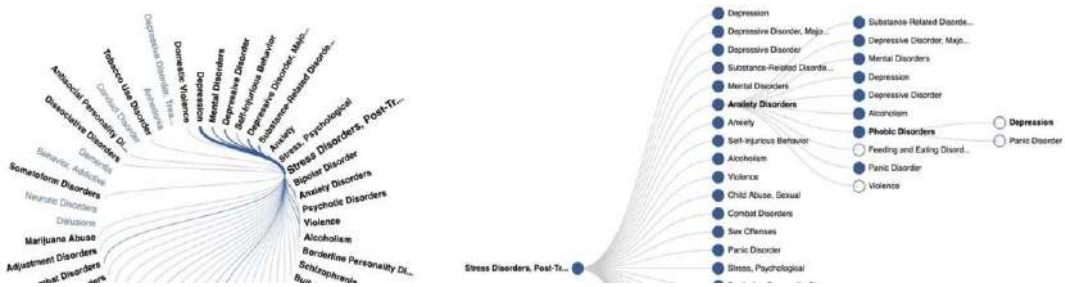

Figure 2 – Co-occurrence Chord Diagram and Expanded Tree of Frequent-Set Items for Case Study – MeSH: "Suicidal Ideation" and UMLS Semantic Type: Mental or Behavioral Dysfunction

Interactive Matrix View: Pearson's correlation coefficient and PMI are presented to the user as interactive matrices. The color ranges according to the strength and direction of the measure.

Co-Occurrence Chord Graph and Interactive Tree: The interactive chord graph displays co-occurrence as well as frequent itemsets in an intuitive and simple manner as shown in Figure 2. The conditional co-occurrence matrix is given in the interactive chord graph. On selection of a node, the adjacent tree displays the frequent itemsets. A button is provided to search PubMed/MEDLINE for these terms, turning the visualization into a novel way to query PubMed.

Technology Stack

Figure 1 illustrates the technology stack and how the technologies interact. Technologies used in this work, which were chosen to support maintenance and reproducibility, include: Julia [6], React.js [7], Vega [8], and Docker [9].

Results

Web App

The web app developed in this work is available at https://bcbi.brown.edu/pubmedminer. The results are presented within the context of a case study to demonstrate how the tool may support researchers and clinicians to explore relationships between concepts imputed from biomedical literature.

Case Study

Mental health (MH) conditions affect 1 in 5 people in the United States [10]. These conditions are among the factors contributing to suicide. Studies have identified specific MH conditions as risk factors; however, there is a need to better understand the interactions of MH comorbidities on suicidal thoughts and behaviors (STB) [11–13].

PubMed could be used to characterize and discover connections between risk factors such as MH comorbidities for STB. We explore the query for *"Suicidal Ideation"* filtered by the UMLS semantic type *"Mental or Behavioral Dysfunction"*.

Figure 2 shows the chord graph and expanded tree view corresponding to the frequent itemset {Stress Disorders, Post-Traumatic, Anxiety Disorders, Phobic Disorders, Depression} resulting from the query. To the best of our knowledge, this is the first time a chord diagram combined with an interactive tree is used to explore frequent itemsets.

Visualizations of the article counts of the 50 most frequent MeSH descriptors and Pearson's correlation and PMI matrices are available on the accompanying web site.

Conclusions

This study presents a web application that provides interactive visualizations of the univariate and covariate statistics of MeSH descriptors in biomedical literature. The technology stack used in this project is intended to be of high performance, composable, reproducible, open source, and be extendable.

Development of Patient State Model to Overview Clinical Registry Database

Masamichi Ishii[a], Kengo Miyo[a], Takehiro Sugiyama[b], Mitsuru Ohsugi[b], Kohjiro Ueki[b]

[a] Healthcare Intelligence Technology Center, NCGM (National Center for Global Health and Medicine), Shinjuku-ku, Tokyo, Japan,
[b] Diabetes Research Center, NCGM, Shinjuku-ku, Tokyo, Japan

Abstract

By applying the Bayesian network method to the clinical registry database J-DREAMS (Japan Diabetes compREhensive database project based on an Advanced electronic Medical record System), we have developed a reference model that summarizes the exploration of the patient group's state and facilitates a bird's-eye view. This visualization method would help registry researchers to screen the registry database.

Keywords:

Data Aggregation, Bayesian , Registries

Introduction

Our institution NCGM (National Center for Global Health and Medicine) is promoting J-DREAMS (Japan Diabetes compREhensive database project based on an Advanced electronic Medical record System) [1], which is a clinical registry database project in collaboration with the Japan Diabetes Society, aiming to register between 100,000 and 200,000 patients. The development of artificial-intelligence systems using clinical data collected by J-DREAMS is expected.

The J-DREAMS database consists of 50 tables (over 400 columns) and has over 50,000 patients' records, making it difficult to get an intuitive grasp of the patient group's state for each particular topic. Previously, if one wanted to discover a particular patient group's status one was researching, they were required to apply basic statistics on each clinical question. It was necessary to repeat the statistical analysis according to the increasing number of clinical questions [5].

Accordingly, as a solution we propose to apply the Bayesian network method [2-4] to summarize the registry database [6-9]. We believe that this visualization method would help registry researchers to screen the entire database easily without the need for a prior understanding of the database schema and mutual relations between its tables.

Methods

We propose a patient group's state model, expressed in terms of Bayesian networks, as a method to utilize accumulated multi-institutional clinical data for general purpose effectively. The features of the model are as follows:

1. Extraction of observation items: Extract observation items from the columns of J-DREAMS registry tables (Figure 1, left side).
2. Bayesian network node definition: Define observation items as nodes in Bayesian networks.
3. DAG (Directed Acyclic Graph) definition: Define hierarchical relationships between nodes in terms of DAG (Figure 1, right side).

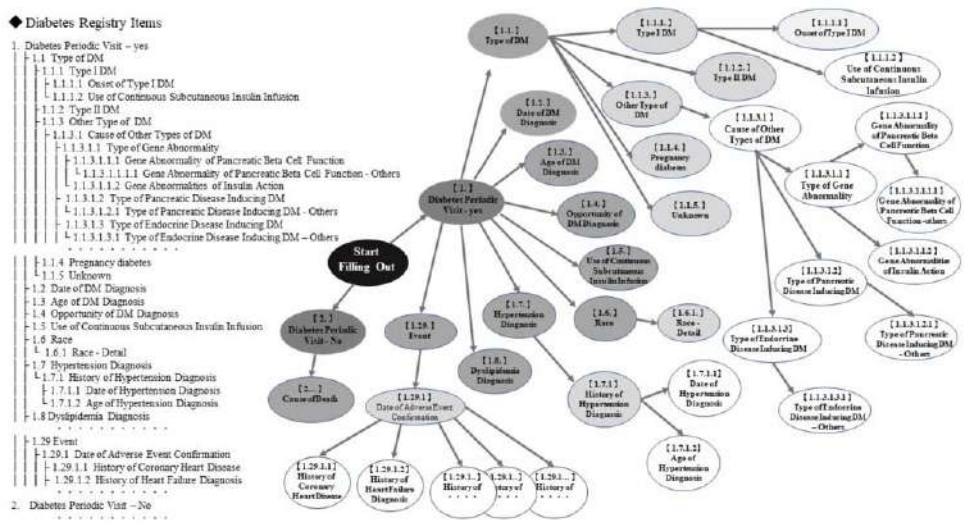

Figure 1. J-DREAMS observation items and Bayesian network DAG definition (example)

For example, the observation items of J-DREAMS are gradually detailed and they have up to nine-level hierarchy. In that case, define the direction of the arrow from the upper item node to the one-step lower one.

When calculating the posterior probability from the given conditional probability in Bayesian statistics, the direction of the arrow and the causal relationship between the nodes do not necessarily have to coincide, since it does not depend on the direction of the arrow.

4. Extraction of real data: Extract real data corresponding to the observation items from the clinical registry database.
5. Preparation of learning data: Prepare learning data from the extracted data by cleansing them (e.g., abnormal value judgment), calculating new feature quantity (phenotyping), and converting numerical data into categorical variables (discretization).

Link the lab test data that satisfies a specific time-series condition to each case record. For example, extract the latest result data of HbA1c (within the past one month), data after 90 days, data after 180 days, etc., when the case report date is taken as the reference date from the HbA1c of the timeline.

6. Modeling (Bayesian network generation): Calculation of conditional probability distribution
7. Evaluations by diabetes specialists: The generated model expresses the entire registry database.

If one gives conditional probabilities to the model and re-calculates the posterior probabilities, they could interpret a particular patient group's status. In this way, evaluations are carried out by diabetes specialists.

Results

A prototype of the patient group's state model is developed by using the Bayesian networks method. The relationships between the registry items are expressed with the DAG model, such as a parent-child relationship between two nodes. Accordingly, the entire clinical registry database can be visualized.

Comments from diabetes specialists:

- Compared to the previous basic descriptive statistics, the registry database schema can be visualized, and the registry data can be easily overviewed.
- Before analysis, it is possible to grasp the bias of collected data (e.g., missing values, abnormal values, etc.).
- By changing the conditional probability setting, we can search the registry database in an exploratory manner and screen the registry.

Discussion

An inference is possible by giving a prior probability distribution, executing the probability propagation method, and calculating the posterior probability.

Before considering the analysis axis for data analysis, it is possible for researchers to grasp the number of cases and trends for each search condition.

By facilitating database search, we have made it easy for experts to provide their awareness and feedback from their tacit knowledge.

Conclusions

We showed that a clinical registry database could be visualized by constructing a patient state model with Bayesian network architecture, and it could be helpful for constructing a clinical knowledge base.

Risk of Acute Myocardial Infarction in Patients with Rheumatic Arthritis: A National-Wide Population-Based Cohort Study

Md. Mohaimenul Islam[a,b], Taimina Nasrin Poly[a,b], Hsuan-Chia Yang[a,b], Yu-Chuan (Jack) Li[a,b]

Abstract

We performed a cohort study to quantify the association between rheumatic arthritis (RA) and acute myocardial infarction (AMI) risk. ICD-9 was used to identify AMI and RA patients, and the Cox proportional hazards model with adjusted confounding factors was used to quantify the risk. The overall risk of AMI for RA patients was an aHR of 1.05 (95% CI 1.01–1.09). We found RA was associated with an increased risk for AMI.

Keywords:

Acute Myocardial Infarction, Rheumatic Arthritis, Cohort Studies

Introduction

Rheumatic disease is characterized by chronic and abnormal inflammatory reactions of the immune system against body tissues which increases the chance of joint destruction and physical disability. Nowadays, the prevalence of Rheumatic disease has increased leading to higher substantial social costs like the increased risk of work-related disability. Contrarily, acute myocardial infarction (AMI) is one of the primary causes of frequent hospital admissions and mortality around the globe [1]. A patient with AMI and multiple diseases could affect both treatment and prognosis. Over the past several decades, acute myocardial infraction has become a significant public health problem worldwide.

Rheumatic arthritis (RA), in fact, has appeared as an independent risk factor for developing AMI. Several biological studies have shown that inflammatory mediators in RA patients are linked to prothrombotic factors and endothelial dysfunction which are associated with developing AMI. Moreover, the previous epidemiological studies have reported that rheumatic arthritis is associated with a higher risk of acute myocardial infarction.

However, the extent to which rheumatic arthritis may confer risk of acute myocardial infarction remains uncertain. We therefore performed a cohort study to quantify the magnitude of the association between rheumatic arthritis and acute myocardial infarction risk.

Method

This population-based cohort study was conducted within a cohort of patients registered with the National Health Insurance Bureau that contributes to the National Health Insurance Research and development Database (NHIRD). This is a large database which collects information on patient demographics (with encrypted patient identification numbers, birthdates, and sex), inpatients or outpatients claim data, and pharmacy records. The NHIRD database covers over 99% of the 23 million Taiwanese population who are registered with the National Health Insurance program [2,3]. Additionally, NHIRD records information on the medications prescribed, laboratory and diagnostic test data, dates of visits, lengths of hospitalization, and diagnoses based on the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM). The NHIRD database, however, has been widely used for research to make valuable clinical decisions and health care policies.

In our current study, a 3-year dataset was retrieved and analyzed which included all the patients that visited the hospital between January 1, 2009 and December 31, 2011. All participants who were aged 20 years and above, and visited for rheumatic arthritis, were considered for inclusion in this study. However, the index date is defined as the date a primary diagnosis of rheumatic arthritis was made between January 1, 2009 to December 31, 2011. The diagnoses of rheumatic arthritis in outpatients and inpatients were also identified by validated ICD-9 Codes (International Classification of Disease, Clinical Modification, Ninth Revision [ICD-9-CM] codes 714.xxx).

Four participants who received no diagnosis of rheumatic disease were randomly frequency matched according to sex, age, and baseline year to each patient diagnosed with rheumatic disease. Patients who developed AMI (ICD-9-CM code 410) during the study period were also identified. The patients with a diagnosis of AMI before the index date were excluded from our study. The only two demographic variables measured were sex and age.

Additionally, to reduce confounding factors, we also evaluated different comorbidities associated with AMI. Baseline pre-existing diagnoses of cardiovascular disease (CVD) prior to the Rheumatic disease comorbidities included CVDs, which was defined as patients who were assigned to any one of the procedural codes for coronary artery bypass grafts (ICD-9-CM code 361.xx), coronary stents (ICD-9-CM code 36.xx), chronic obstructive pulmonary disease (COPD) (ICD-9-CM codes 490–492, 494, 496, A324), diabetes (ICD-9-CM codes 250), hypertension (HTN) (ICD-9-CM codes: 401–405), and hyperlipidemia (ICD-9-CM codes: 272).

We performed a Chi-square test to determine categorical variables for assessing the distribution differences between the two cohorts. We also drew the Kaplan-Meier method to estimate cumulative incidence curves of AMI for the cohorts and the log-rank test was performed to estimate the difference between the curves. Furthermore, the Cox proportional hazards regression model with adjusted potential confounding factors was used to estimate the hazard ratios (HRs) and confidence

intervals (CIs). Data management and analysis were performed using SAS, and a value of $P<0.05$ was considered significant.

Results

A total of 2512 patients were included in the final analysis; a total of 394 cases of Atrial Fibrilation were used in the analysis. The mean age of rheumatic patients was 72.93 and non-rheumatic patients was 50.64. The age range of rheumatic, and non-rheumatic patients was 20 to above 80. A significant difference exists in the distribution between RA patients and controls in gender and age (Table 1).

However, several comorbidities were more prevalent among RA patients than controls, including hypertension (69.11% vs. 57.53%; $P<0.001$), diabetes (10.83% vs. 12.34%; $P=.23$), hyperlipidemia (5.65% vs. 10.34%; $P<0.001$), CHF (2.23% vs. 2.0%), and COPD (1.27% vs. 1.12%; $P=0.72$). After adjusting the covariates, the overall risk of AMI for RA patients was an aHR of 1.05 (95% CI 1.01–1.09). Women had a lower AMI incidence with an aHR of 0.84 (95% CI 0.66–1.07).

Table 1: Demographic characteristics and comorbidity in patients with or without rheumatic disease

	Rheumatic (n=1256)	**Non-Rheumatic (n=1256)**	**p-value**
Gender	Male=916 (72.93)	Male=632 (50.64)	<0.001
Age			
20-29	16 (1.28)	77 (6.9)	
30-39	39 (3.12)	133(10.86)	
40-49	110 (8.79)	202 (16.49)	
50-59	295 (23.58)	305 (24.90)	
60-69	348 (27.82)	248 (20.24)	
70-79	309 (24.70)	176 (14.37)	
80++	134 (10.71)	84 (6.84)	
Diabetics	136 (10.83)	154 (12.37)	0.23
CHF	28 (2.23)	25 (2.0)	0.69
Hypertension	868 (69.11)	718 (57.53)	<0.001
COPD	16 (1.27)	14 (1.12)	0.72
Hyperlipidemia	71 (5.65)	129 (10.34)	<0.001

Conclusion

In this population-based study, we found that rheumatic disease patients were not associated with an increased risk for acute myocardial infarction though AMI is strongly associated with hypertension and COPD patients. Although it is an observational study from a large database, our study was unable to prove causality. All of the findings only relied on the EMR database and did not examine categories related to the severity of the disease with AMI. Furthermore, the findings could be varied due to some confounding factors we did not include such as medication history, other comorbidities, duration of RA, etc. Therefore, additional studies with more variables are required to establish whether rheumatic disease is actually responsible for developing AMI or not. Physicians should routinely screen RA patients to avoid unwanted consequence effects.

Analysis of Usage of Term Weighting Algorithm for Mapping Health Procedures into the Unified Terminology of Supplemental Health (TUSS)

Eluizio H. Saraiva Barretto[a], Diogo F. da Costa Patrao[b], Márcia Ito[a,c]

[a] *Instituto de Pesquisa Tecnológica de São Paulo, São Paulo, SP, Brazil,*
[b] *A. C. Camargo Cancer Center, São Paulo, SP, Brazil,*
[c] *Informar Saude-Grupo Bem, São Paulo, SP, Brazil*

Abstract

TUSS is a Brazilian health procedure standard used by the supplementary health providers. Currently, there is no available mapping between TUSS and other standards. In this paper, we analyze performance of two term weighting algorithms when classifying TUSS procedure description. The TF-IDF classified 99% of chapters, 89% of groups, and 33% of subgroups; Doc2Vec classified 65%, 43%, and 33%, respectively, showing that those algorithms can support creation of an accurate mapping between those procedure standards.

Keywords:

Health Information Interoperability, Current Procedural Terminology, Natural Language Processing

Introduction

Healthcare interoperability is defined as enabling access to patient information independently of the system or location that holds the record. Several methods, such as text processing, full text search, association rules, ontologies and taxonomies, are used to achieve it. Some methods are based on term weighting, which detects the word relevance given a specific context [1]. The adoption of terminologies and standards facilitates the manipulation of electronic records across heterogeneous systems, enabling system interoperability.

In Brazil, the lack of standardization and the use of multiple terminologies among health systems hinders interoperability. The challenge is to develop methods to make new standards compatible with others. *Terminologia Unificada da Saúde Suplementar* (Unified Terminology of Supplemental Health - TUSS) [2], one of the most important Brazilian health procedures standards, is used by the supplementary health system, mainly for claims. However, there is no available mapping between this coding system and others, e.g. the SIA/SIH SUS coding, used by the public health system in Brazil, which hinders any effort in database integration. The public healthcare and legacy systems require ways to communicate with this standard, which calls for methods of conversion and classification to enable its adoption.

A systematic review was performed to describe the state of the art on this subject. Several of the selected papers involved usage of SNOMED [1,3-8], others the UMLS [1,4-6,8], proving great interest and importance of these terminologies. Some works propose automated methods [5,6,8,9], others are based on ontology mapping [1,3,4], use keywords in their methods [5-7], and only two use term weighting [8,9]. Despite the great diversity of works in the literature related to interoperability, however, the usage of ontologies or taxonomies associated with term weighting has not been reported to date.

We propose an approach for classifying TUSS' medical records using term weighting and taxonomy. We applied two term weighting algorithms, namely TF-IDF and Doc2Vec, and compare their accuracy when classifying TUSS' records.

Methods

TUSS' records are hierarchically organized in chapters, groups and subgroups, as a taxonomy. We used the OWL format to represent TUSS' codes and hierarchical organization. We evaluated the relevance of each description in the TUSS terminology procedures using the mentioned term-weighting techniques. We developed vector models, assigning weights for each identified term, considering their relevance within the hierarchy specified by the taxonomy. Each model uses distinct algorithms, such as TF-IDF, and Doc2Vec, to allow comparisons and analysis of their accuracy in predicting (ability of the method of hitting the conversion, expressed as a percentage). In order to validate the mechanism proposed, we used Table 22 of the TUSS standard, which includes 5,769 codes and description of health procedures and events for the December 2015 edition. These codes are divided into 6 chapters, 16 groups and 38 subgroups. Chapter, group, and subgroup identifications are used to classify each procedure description through the composition of the TUSS code. We created three models for each of the proposed algorithms, with 90%, 85%, and 66% of the total data mass (5,769 procedures) as the model training set and 10%, 15%, and 33% as the validation set. The first experiment randomly selected 90% of the procedures descriptions to be used in the training of the model. In this step of the Doc2Vec algorithm, each procedure is transformed into a vector according to its terms, being positioned by the algorithm according to its similarities and its chapters, groups and subgroups. Then, the remaining 10% of the data is classified according to the proximity of the vectors of the trained model. The classification obtained by the algorithm is compared with the current classification of the TUSS standard and, thus, the accuracy rate of the model is calculated. Similarly, for the TF-IDF algorithm, a portion of the procedures are randomly selected so that the algorithm calculates the repetition and weight of each word involved in the procedures, thus creating a term weighting model. The remaining portion of the data is used for model validation. Each procedure description is broken in tokens and according to the weighting model of these terms, a classification of the procedure is obtained and the accuracy rate of the calculated model.

Results

The results show that the model using the 90% / 10% ration between training set and validation set obtained the best hit rates for all classification levels of the Doc2Vec algorithm, matching 65.16% of the chapters using one hundred dimensions and 3,000 iterations. For the groups, the best accuracy rate was 43.32% with two hundred dimensions and 4,500 iterations. For subgroups, we obtained 33.44% of hits with the same group configuration. The algorithm TF-IDF obtained the best accuracy with the 85% / 15% division, with 99.08% of the chapters, 89.38% of the groups and 33.26% of the subgroups. Figure 1 presents the summary with the best results of each algorithm for different levels of taxonomy.

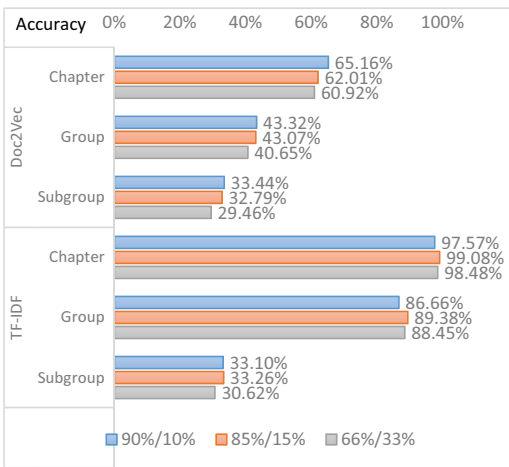

Figure 1 – Accuracy of Doc2Vec and TF-IDF Models

The TF-IDF performed better in classifying groups, yielding accuracy of 89%, while Doc2Vec scored 43%. However, for the classification of subgroups the two algorithms obtained lower accuracy rate, with the TF-IDF reaching the maximum 33.26% and the Doc2Vec slightly higher with 33.44%. In turn, Doc2Vec achieved its best performance for all levels of the taxonomy by dividing the data in the proportion of 90% for training and 10% for validation.

Discussion

The experiment results show that the greater the generalization of the level of taxonomy, the greater the accuracy. The classification of chapters obtained the best classification rates followed by groups and subgroups. Conversely, the more specific the hierarchy of taxonomy, the worse the algorithm performance. It is noted, at the more specific levels, that the proximity between the descriptions of the procedures is related to the decrease of the levels of accuracy for both algorithms. Although the mechanism of this work does not identify a TUSS code in its entirety, it can be concluded that the use of taxonomy associated to machine learning algorithms was effective in classifying a procedure. Since TUSS' codes have eight digits, composed by numerals of its chapter, group, subgroup and followed by a service sequence number and a checker digit, the first five elements of the code have been identified. The service number does not have a specific logic, it is only the sequence of creation of each procedure. A limitation of this work concerns the mass of data used, based exclusively on Table 22 of TUSS medical procedures. Other data sources can be used to obtain trained models with a wider variety of terms or in different domains of knowledge. This work was restricted to compare the TF-IDF and Doc2Vec algorithms. Both work with vector word mapping. As future work, other algorithms can be analyzed, integrated and compared, seeking to improve accuracy, especially at more specific levels of taxonomy where the results of these algorithms were not satisfactory.

Conclusions

We were able to discuss the challenges and importance of achieving interoperability between distinct health terminologies, and how machine learning and the weighting of terms can help achieve this goal. We showed that two algorithms with similar functionalities can present complexities and different results in their use. We also presented the relevance of the hierarchical structuring of the information, in the form of taxonomy, in order to facilitate its classification. Finally, we presented a mechanism for classifying TUSS terminology chapters and groups. We also demonstrated that, in this specific context, the TF-IDF algorithm was more efficient than the Doc2Vec algorithm and may be helpful when constructing mappings between two different code systems.

Abstract

We aimed to develop rhabdomyolysis (RB) phenotyping algorithms using machine learning techniques and to create subphenotyping algorithms to identify RB patients who lack RB diagnosis. Two pattern algorithms, one with a focus on improving predictive value and one focused on improving sensitivity, were finally created and had a high area under the curve value of 0.846. Although we were unable to create subphenotyping algorithms, an attempt to detect unknown RB patients is important for epidemiological studies.

Keywords:

Algorithms, Machine learning, Rhabdomyolysis

Introduction

Phenotyping algorithms that automatically identify patients diagnosed with a particular disease based on electronic health records (EHRs) have been gradually increasing [1][2]. The Medical Information Database Network (MID-NET) is a large-scale, anonymized database that contains more than 4 million (estimated to reach 10 million in the future) patients' structured EHRs. The MID-NET stores laboratory test values differently than other domestic large databases [3]. The MID-NET was constructed primarily by the Ministry of Health, Labour, and Welfare and Pharmaceuticals and Medical Devices Agency for the early detection of adverse drug events. With a nationwide use of the MID-NET that began in Japan in 2018, further development of phenotyping algorithms using various MID-NET data is required.

Rhabdomyolysis (RB) is a well-known drug-induced adverse event. However, there are no useful phenotyping algorithms that automatically detect RB patients via the MID-NET. Therefore, we aimed to develop RB phenotyping algorithms using machine learning (ML) techniques and to create sub-phenotyping algorithms to identify RB patients who lack RB diagnosis.

Methods

Population

We retrospectively analyzed 93,106 inpatient cases in Kyushu University Hospital between January 1, 2013 and December 31, 2016.

Development of the Phenotyping Algorithm for RB

We developed an algorithm to detect RB. This algorithm is described in the next three steps as shown in Figure 1.

Step 1: Creating the Main Phenotyping Algorithm

1-1. Creation of an initial RB phenotyping algorithm using International Classifications of Diseases 10th revision (ICD10) codes (M6289, G720-G722, and G729) **[RB algorithm A].**

> **RB algorithm A**
> (Rhabdomyolysis [M6289]) or (Myopathy [G720-G722 or G729])
> Index date: Diagnosed date based on a 30-day interval

1-2. Data extraction using from MID-NET and random sampling

1-3. Review by two physicians per case and calculation of the weighted kappa coefficient (κ-coefficient) as a summary of the coincidence degree between each pair of physicians

1-4. Modification and improvement of RB algorithm A using ML techniques
We estimated a predictive model for RB using the highest area under the curve (AUC), the predictive value, or the sensitivity using the gradient boosting decision tree (GBDT)
[mRB algorithm A'].

Step 2: Creating the Subphenotyping Algorithm

2-1. Creation of an initial phenotyping algorithm to detect RB cases without RB algorithm A and instead using creatine kinase (CK), creatine kinase-MB (CK-MB), and troponin-T values [**RB algorithm B]**.

The CK-MB or troponin-T value was established to exclude cardiovascular diseases with CK elevation, such as myocardial infarction.

> **RB algorithm B**: **a NOT b**
> **a.** CK over 10-fold increase from reference value[*1]
> **b.** ([CK-Mb over 10% increase in CK] or [Troponin-T more than 0.014 μg/dL[*2]]) during the same time period as **a**
> Index date: Abnormal laboratory results based on a 30-day interval
> *[1] Japanese Committee for Clinical Laboratory Standards (JCCLS)-based reference value. *[2] Hospital-based reference value

2-2. Data extraction (same as step 1)

2.3. Physician review (same as step 1)

2-4. Modification and improvement of RB algorithm B' (same as step 1) **[mRB algorithm B']**

Step 3: Creating the Final Phenotyping Algorithm

We integrated (mRB algorithm A' [step 1]) and (mRB algorithm B' [step 2]) to create the final phenotyping algorithm.

Results

Data Extraction and Random Sampling

The RB algorithm A identified 111 cases, and 3,231 cases were extracted by the RB algorithm B. We randomly sampled 100 cases per algorithm.

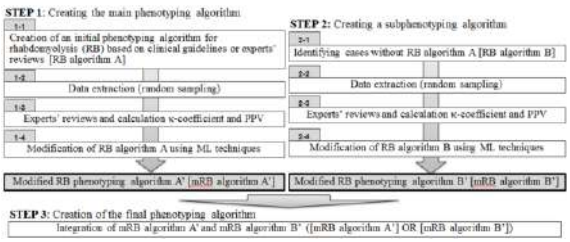

Figure 1. *Workflow of phenotyping algorithm development. Step 1 aimed to improve the phenotyping algorithm based on disease diagnosis data, and Step 2 aimed to identify RB patients who were not extracted in Step 1.*

Expert Review Results

The κ-coefficient for the review of 2 physicians was 0.50.

Results of RB algorithm A

Thirty-four cases were identified as true-positive, and the PPV was 34.0%. Few of the cases with a myopathy diagnosis code were true-positive. Thus, we excluded the myopathy diagnosis codes (G720-722 and G729) from the algorithm during the modification step.

Results of RB algorithm B

Eighteen true-positive cases were identified, and the PPV was 18.0%. Half of the true-negative cases (n = 55) caused temporary increases in CK values because of surgery. Thus, we excluded "surgery implementation within three days from the index date" during the next step.

Algorithm Modification

A total of 1,619 explanatory variables for the GBDT were extracted from 200 cases. These consisted of the following structured-data codes or values in the MID-NET: Disease diagnosis, hospitalization number, pharmaceutical products, laboratory test values, surgery implementation, medical intervention in Japanese administrative and claims, patient's age and gender.

Modification of RB algorithm A

The top 5 principle variables that contributed to the model, in order, were CK, aspartate aminotransferase, lactate dehydrogenase, M6289 (ICD10 code), and serum chloride (AUC = 0.846). According to the GBDT, all variables without CK was less than 20% of the gain rate. Thus, we focused on the CK value for algorithm modification considering PPV and sensitivity within 200 cases.

The modified phenotyping algorithm is shown below:

Modification of RB algorithm B

According to the GBDT, the AUC was 0.622. We could not improve the RB algorithm B. Eventually, (mRB algorithm A') was accepted as the final RB phenotyping algorithm.

mRB algorithm A'

An algorithm based on improving PPV

(PPV = 92.9%, Sensitivity[*1] = 4.6%)

[RB ICD10 code (M6289) on DPC] or ([RB ICD10 code (M6289) on HIS] and [CK value over five-fold increase compared to reference value])

An algorithm based on improving sensitivity

(PPV = 36.8%, Sensitivity[*1] = 83.7%)

(ICD10 code [M6289] on DPC) **OR** (ICD10 code [M6289] on HIS) **and** [CK more than reference value[*1]]) **OR** ([RB algorithm B] **not** [Surgery implementation within three days before the index date])

*[1] Sensitivity = estimated sensitivity in all possible cases

Discussion

We aimed to develop an RB phenotyping algorithm following a three-step procedure. Improvement of the initial phenotyping algorithm based on disease diagnosis was successful and resulted in a high AUC. However, we could not modify the initial algorithm based on the laboratory results because of the low AUC value. When creating the initial phenotyping algorithm, we should have reconsidered the following: the time interval for excluding myocardial disorders based on CK-MB or troponin-T values and the exclusion of cases that temporary increased CK caused by surgical procedures. However, we were able to identify previously unknown RB cases that were not diagnosed as RB. Eventually, we created two types of RB algorithms: one that focused on improving the PPV and one that focused on improving the sensitivity. These algorithms should be used differently depending on the study purpose.

Conclusions and Limitations

We created two types of new RB phenotyping algorithms. These algorithms should be used differently depending on the study purpose. Although these algorithms were created using small samples, we will validate these samples at other hospitals this year.

Evaluating a Clinical Decision Support System for Drug-Drug Interactions

Amin Jalali[a], Paul Johannesson[a], Erik Perjons[a], Ylva Askfors[b], Abdolazim Rezaei Kalladj[b], Tero Shemeikka[b], Anikó Vég[b]

Abstract

Janusmed is a clinical decision support system, developed by the Stockholm County Council that supports physicians in identifying drug-drug interactions. To determine how Janusmed is used in and affects the clinical practice, an evaluation study is currently being carried out that analyzes multiple data sources through descriptive statistics. The study focuses on how Janusmed affects the behavior of the physicians, in particular, to what extent physicians reconsider their prescription decisions based on warnings from Janusmed.

Keywords:

Drug Combinations, Drug Interactions, Prescriptions, Clinical Decision Support Systems, Medical Informatics

Introduction

Drug prescribing is becoming more complex due to the increasing number of drugs available as well as more information about their usage, effectiveness, and side effects. At the same time, patient safety is a major public concern emphasizing the importance of prescribing the right drug to the right patient in the right dose. Adverse drug reactions are a significant source of illness and also a cause of death [1], and drug-drug interactions represent a common cause of adverse drug reactions [2,3]. Thus, concise and up-to-date information about possible drug-drug interactions available at the point of drug prescription is vital for physicians [4, 5, 6, 7].

Janusmed Integrated (toolbar) is a clinical decision support system (CDSS) that includes several medication-related knowledge databases (modules) such as Janusmed Interactions, Janusmed Risk Profile, Janusmed Drugs and Birth Defects, Janusmed Drugs and Breast Feeding, Janusmed Drugs and Renal Function, and Janusmed Sex and Gender [5, 6]. The Janusmed system is designed especially for integration into electronic health record systems. It is available in most of the EHR systems in healthcare organizations in the Stockholm County Council in Sweden.

The Janusmed Interactions module warns for and provides information about (pharmacokinetic) drug-drug interactions based on 1) information in the drug-drug interaction knowledge base and 2) information in the electronic health record (EHR) system, such as the patient's present list of prescribed drugs. It will automatically alert for drug-to-drug interactions when physicians prescribe new drugs. The interactions are classified from A to D based on their clinical relevance and corresponding color codes have been developed to aid end users. A (green) is a minor interaction with no clinical relevance, B (white) means that the clinical outcome of the interaction is uncertain and/or may vary, C (yellow) is a clinically relevant interaction that can be handled, for example, by dose adjustments, and D (red) is a clinically relevant interaction that should be avoided [4].

Janusmed is widely available and used, but it is still unknown how the system is used and to what extent it actually affects the clinical practice, for example, if prescribing physicians do change their behavior due to warnings for drug-drug interactions. Filling this knowledge gap would support and guide the future development of Janusmed.

In order to address these issues, an evaluation project is being carried out between the Stockholm County Council responsible for developing the system and Stockholm University. The goal of the evaluation project is to determine how Janusmed is used in the clinical practice. More specifically, the project addresses three main research questions:

- How does the utilization of Janusmed Interactions change over time?
- How is the usage of Janusmed Interactions influenced by patient demography, especially age and gender?
- To what extent do physicians recognize and act on the drug-drug interaction warnings provided by Janusmed?

Method

A data survey was carried out to answer the three research questions. First, we operationalized the concepts used in the three research questions in order to understand which data to collect and analyze. Second, we identified data sources that contained relevant data. The first data source was the Janusmed log. In the log, a record is created every time a physician checks a patient's list of drugs, changes the list by adding another drug to it, or does a follow-up on a warning for a drug-drug interaction to obtain additional information from Janusmed. The second source was the Janusmed drug-drug interaction database that was used for reconstructing drug-drug interactions not included in the Janusmed Integrated log. The third source was Health Bank that contains all EHR records from the EHR systems in one of the major hospitals in Stockholm, Karolinska University Hospital. We needed this third source to determine whether the physician prescribes another drug instead of one of those causing the drug-drug interaction.

A major task in the project has been to address interoperability challenges. In particular, the information in the Janusmed log is anonymized in the sense that it does not identify any individual. Therefore, there is no way to directly map Janusmed log records to EHR records in Health Bank. Instead, we had to rely on combinations of patient attributes (for example, age and gender) and information on physician consultations (for example, place and time) to arrive at a mapping between the systems. Another

interoperability issue concerned different formats and identifiers for drugs.

The data analysis was primarily carried out by means of descriptive statistics. This allowed us to investigate the possibility to apply process mining techniques in the future. Process mining is a new paradigm of data science that offers AI techniques that support decision-making in process management. The techniques are based on analyzing event logs, that is, logs of the activities that users have carried out during a process [8, 9].

Results and Conclusions

The data is still being analyzed but an initial result is that the utilization of Janusmed Integrated (toolbar) has increased over time. To investigate the utilization, we measured the number of follow-ups the physicians did to obtain additional information. This measurement was based on all care units using Janusmed in the Stockholm County Council for a time period of 15 months. We are presently analyzing the usage patterns of the different modules in Janusmed, in particular, Janusmed Interactions.

We are also currently investigating whether the usage of Janusmed depends on demographic factors, in particular, the age and gender of the patients. We are also investigating how the warnings affect the behavior of the physicians, depending on the class of clinical relevance. In particular, to what extent physicians carry out follow-ups and reconsider their prescription decisions.

In order to better understand how the physicians are using Janusmed, a qualitative investigation is planned using observations at the point of prescription, followed by semi-structured interviews with the prescribing physicians.

Acknowledgements

The project is funded by the Stockholm County Council, Sweden.

Augmenting Medical Device Evaluation Using a Reusable Unique Device Identifier Interoperability Solution Based on the OHDSI Common Data Model

Guoqian Jiang[a], Yue Yu[a], Paul R. Kingsbury[a], Nilay Shah[a]

[a] Department of Health Sciences Research, Mayo Clinic, Rochester, MN, USA

Abstract

The objective of the study is to augment safety and effectiveness evaluation of medical devices through building a reusable unique device identifier (UDI) interoperability solution. We propose a framework for building a UDI research database for medical device evaluation using the OHDSI common data model (CDM). As a pilot study, we design, develop and evaluate a UDI vocabulary, which would enable tackling challenges of data islands and standardization for medical device evaluation.

Keywords:

Equipment Safety, Reference Standards, Controlled Vocabulary, Electronic Health Records.

Introduction

Reliable and timely data and information on the performance and safety of medical devices such as stents and artificial joints are critical to the success of postmarket surveillance of medical devices. In recent years, there are increasing needs for capturing Real World Evidence (RWE) from claims and electronic health records (EHR) data for evaluations of medical device safety and effectiveness [1]. In particular, the Food and Drug Administration (FDA) and medical device evaluation community have envisioned a system that can not only promote patient safety through earlier detection of safety signals, but also generate, synthesize and analyze evidence on real-world performance and patient outcomes [2].

However, valuable data for evaluating device exists largely as data islands with only limited connectivity. It has been well recognized that a standard is key for documentation and linking of medical device identification information to diverse data soures. Fortunately, FDA initiated the regulation of the Unique Device Identifier (UDI) implementation and established a Global Unique Device Identifier Database (GUDID) for making uniquely identify medical device possible [3]. By September 24, 2018, all Class III and Class II devices are required to bear a permanent UDI. Note that such a classification is risk based. Class I includes device with the lowest risk and Class II includes those with the great risk. Meanwhile, a number of demonstration projects have been conducted to demonstrate the feasibility of informatics technology on building a medical device evaluation system and to identify keys to success and challenges to achieving targeted goals [4]. These projects provided proof of concept that UDIs can be used as the index key to combine device and clinical data in a database useful for device evaluation. However, the community lacks of an open-source solution for community-based medical device evaluation.

The Observational Health Data Sciences and Informatics (OHDSI) Common Data Model (CDM) has been increasingly used to build a large-scale international data network in support of observational studies [5]. In this study, we propose a reusable UDI interoperability solution based on the OHDSI CDM that tackles the challenges of data islands and standardization. We aim to build a prototype device evaluation system with the capability to uniquely identify medical devices, implementing standardized clinical vocabularies and dictionaries, and linking diverse, strategically complementary data sources.

Methods

OHDSI CDM: The OHDSI CDM 5.0.1 version contains 39 database tables in 6 categories: standardized clinical data, standardized health system data, standardized health economics, standardized metadata, standardized vocabularies and standardized derived elements [5]. Of them, 10 tables are designed for handling standardized vocabularies, including tables describing CONCEPT, CONCEPT_RELATIONSHIP, CONCEPT_CLASS, DOMAIN, VOCABULARY. We installed an OHDSI virtual machine (VM) that is conformant to the OHDSI CDM 5.0.1 version. The VM contains the full OHDSI technology stack and is loaded with both standard vocabularies and sample data.

FDA GUDID: The database contains key device identification information submitted to the FDA about medical devices that have UDI [3]. As of September 1, 2018, a total of 1,765,653 UDIs have been recorded, comprising 45,011 UDIs for Class III devices, 1,456,524 UDIs for Class II devices and 264,128 UDIs for Class I devices. In this study, we used the UDI information for Class III devices for prototyping the UDI vocabulary.

System Architecture: We propose a framework for building a UDI research database for medical device evaluation using the OHDSI CDM (**Figure 1**). The framewrok comprises three modules: 1) UDI Vocabulary; 2) ETL for UDI-Enabled Device Data; and 3) Analytic methods for medical device evaluation.

Prototype Implementation: In this study, we prototyped a UDI vocabulary using the UDI information for Class III devices.

First, we downloaded the Class III device dataset from the GUDID website. The dataset contains 45,011 records for Class III device. The fields of the dataset are "DEVICE_ID|DEVICE_ID_ISSUING_AGENCY|BRAND_NAME|COMPANY_NAME|VERSION_MODEL_NUMBER|MRI_SAFETY_STATUS|LABELED_CONTAINS_NRL|GMDN_TERMS."

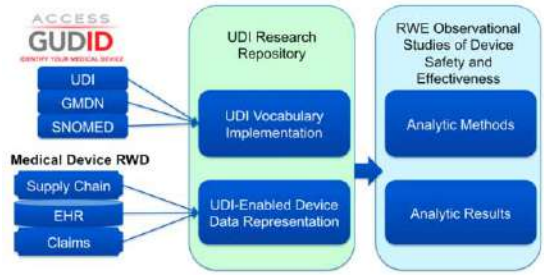

Figure 1. System architecure of our proposed framework. RWD: Real-World Data; RWE: Real-World Evidence.

Second, we retrieved the SNOMED CT information associated with each single device using the GUDID web service API called Device SNOMED. A device identifier and a UMLS single-use ticket are required to receive a response.

Third, we used the feature of custom structures of HAPI FHIR API [6] and generated Java-based data model for the OHDSI Standardized Vocabulary CDM which comprises 10 tables. With this advanced feature, vocabulary content can be readily represented in the FHIR-compliant XML or JSON format.

Fourth, we parsed the Class III device dataset and generated the concept_id from each single device. And then we populated the CONCEPT, CONCEPT_RELATIONSHIP, CONCEPT_CLASS, DOMAIN and VOCABULARY tables. The key design points here include 1) the concept_name is formed as a combination of BRAND_NAME, COMPANY_NAME, and VERSION_MODEL_NUMBER; 2) We tentatively set the status of STANDARD_CONCEPT as non-standard for each single device is linked to a SNOMED CT concept code which by default is used as standard concept in the OHDSI CDM. 3) The Global Medical Device Nomenclature (GMDN) term information is recorded in the CONCEPT_RELATIONSHIP table. The concept_id is also generated for each GMDN term. An intermidiary FHIR Bundle XML file is generated, which can be easily exported into standard OHDSI vocabulary release CSV files.

Preliminary Evaluation: We loaded the UDI vocabulary release files into a OHDSI VM and used its ATLAS tool to explore the utility of the vocabulary. We compared the string search vs. concept-based search.

Results

A total of 51,597 records were generated in the CONCEPT table, in which 45,011 records are for Class III devices and the rest are for the GMDN terms and a few of relationship concept ids. A total of 17,052 records were generated in the CONCEP_RELATIONSHIP table, in which half of records are for the relationships to SNOMED CT and the other half for the relationships to GMDN terms.

We successfully loaded the UDI vocabulary into an OHDSI VM platform. We used the ATLAS concept search tool for the string search of "Thermocool" and obtained 76 records. When we used the SNOMED CT concept code for "Cardiac mapping/radio-frequency ablation catheter, single use", we obtained 250 records (**Figure 2**). These results indicated that concept-based search may be more reliable if users would like to get comprehensive query results.

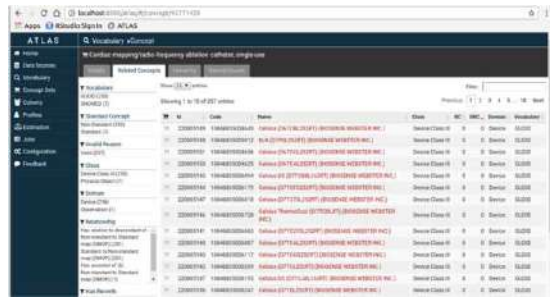

Figure 2. An ATLAS screenshot for concept-based search.

Discussion and Conclusions

In this study, we proposed a framework for building a OHDSI CDM-based UDI research database and prototyped a UDI vocabulary for Class III devices as a pilot study. Such a standard UDI vocabulary will serve as semantic foundation to enable both individual-level and class-level device data analyses and eventually augment safety and effectiveness evaluation of medical devices. We believe that the approach can be readily generalized for the devices in other classes. There are a number of design points that would need a community-based consensus. We plan to initiate a Working Group in the OHDSI community for the consensus development. In addition, more rigorous evaluation of the UDI vocabulary will be conducted in the near future after loading the real-world device data into the UDI research database driven by specific use cases.

Abstract

The study was done to validate the real time efficacy of a customised algorithm in detecting diabetic retinopathy (DR) among diabetic patients being examined at the vitreo retinal outpatient department (VR OPD) of a tertiary care hospital, Diabetic Retinopathy algorithm showed sensitivity of 79% and specificity of 57% which is an acceptable methodology to diagnose diabetic retinopathy and avoid unnecessary referrals.

Keywords:

Diabetic Retinopathy, Algorithm, Photograph

Introduction

Diabetic retinopathy (DR) is a microvascular complication of diabetes and is a potentially blinding disease, especially in its advanced stages[1]. In India, one of the several challenges faced in screening is inadequate man power, with only one ophthalmologist for every 107,000 people [2]. This scenario warranted an urgent need for alternative methods of screening. However, screening, timely referral, and intervention can lessen the likelihood of blindness and can reduce the health care costs[3].

Several studies have reported the effectiveness of computer-assisted screening tool for DR detection [4-8]. HTIC developed and reported an algorithm for the detection of presence of DR[9]. We reported that the algorithm can identify the presence or absence of DR in subjects with diabetes under mydriatic and non mydriatic conditions using retinal photographs.

Methods

Our DR image screening algorithm [9] includes modules for analyzing retinal images to identify normal retinal structures such as the optic disk, macular region, segmentation of blood vessels, detection of three classes of pathologic lesions in the retina: red lesions (such as blot and flame haemorrhages), bright lesions (hard exudates, circinates, cotton-wool spots, ischemic zones), and microaneurysms. Each of the modules derives parameters from the retinal image using image analysis techniques such as object detection and segmentation, and computes parameter values corresponding to the different features. The composite low level information of the locality, morphology, appearance and extent of the disease signs is considered and solved for the clinical decision (DR vs no-DR) using a multi-parametric machine learning based classification. The gradeability of the image, as well as presence of severe and proliferative DR signs are added as high-level information of gradeability and advanced late stage disease, and are combined to frame the final decision on DR referability, giving a value in the range of 0 to 1, with 1 indicating higher confidence score on the decision of 'DR-present'. The optimal operating point for the referability decision is chosen by doing a ROC analysis with multiple publicly available datasets, and a large retrospective dataset.

We validated the algorithm prospectively for real time use in an outpatient department of Sankara Nethralaya, a tertiary care hospital and compared the performance of the algorithm with that of vitreo-retinal surgeon (reference standard) and optometrist under non-mydriatic condition. This study was approved by Institutional Review Board of Vision Research Foundation, Chennai, India. Patients provided written informed consent. The study was conducted from Jan 2015 to May 2017. Patients with type 2 diabetes aged ≥35 years were included. Those with miotic pupil, nystagmus, history of other intraocular surgeries except cataract surgery and injections for diabetic macular edema were excluded.

848 eyes of 485 patients underwent 45-degree fundus photography (Forus3nethra Classic Non Mydriatic Fundus Camera, Bangalore, India) in both eyes after dark adaptation. The photo graders received a CD-ROM containing de-identified images in JPEG format. Information on the patients age, sex and duration of diabetes was shared with the reader and were masked to the rest of the demographic characteristics. The images were run through the automated system and were also graded by human graders (optometrist) and by an experienced vitreoretinal surgeon (gold standard). The patient was also examined by any one vitreoretinal surgeon in the outpatient department with the indirect ophthalmoscope who provided advise treatment/disposal of the patient, independent of the result of the algorithm.

Results

The effectiveness of the CAD to detect diabetic retinopathy lesions was examined in comparison to that by the human graders, optometrist and ophthalmologist ('reference standard'). The mean age of patients was 58.2±7.5 years and 68% were men. The mean duration of diabetes was 13.1±7.9 years (median=13 years, range=0.5 – 34 years) and the mean fasting blood sugar was 128±45mg% (median = 120mg%, range=70-250mg%). DR Diagnosis and gradeability were assessed as two separate tools for retinal photographs.

The algorithm successfully graded 634 out of 848 possible images (75%) and diagnosed presence of DR in 583 images. Compared to the ophthalmologist (Reference standard), 214 (25%) images were ungradable by the algorithm. Overall, the ophthalmologist found only 9 images to be ungradable compared to 214 images by the algorithm. There was only slight agreement in terms of image gradeability between the

ophthalmologist and algorithm, Kappa= 0.016 (95% CI = -0.013 – 0.044).

The sensitivity of the algorithm to detect DR for gradable images was found to be 79% and specificity was found to be 57% in detecting DR compared to ophthalmologist with an area under the receiver operator curve (AUC) was 0.67 (95%CI=0.63 to 0.71). With respect to vision threatening DR (VTDR), there were no significant differences in the image gradeability of the algorithm based on the VTDR status of the eye as graded by the ophthalmologist (P=0.32) by chi square test.

Compared to the optometrist, 25% images were ungradable by the algorithm. Overall, the optometrist found only 11 images to be ungradable compared to 214 images by the algorithm. There was slight or no agreement in terms of image gradeability between the ophthalmologist/ optometrist and algorithm, Kappa= 0.002 (95% CI = -0.024 – 0.028)

Conclusion

We found that the computer assisted algorithm developed by HTIC showed 78 - 79% sensitivity and 55 - 57% specificity in detecting DR. The algorithm appears to be highly sensitive at the expense of lower specificity for DR detection .. The strength of our study is that the algorithm was tested under physiological dilation and therefore more closely applicable to real-life situations. The main areas that require enhancement is the reduction in ungradable images and specifically improve agreement of gradeability and DR status with human graders.

Abstract

In this study, we built a multi-center integrated database platform of localized prostate cancer and developed biochemical recurrence (BCR) prediction system with Gradient Boosted Regression model using Korean Prostate Cancer Registry (KPCR) database. This platform will facilitate clinical management of patients with prostate cancer, and it will also help develop appropriate treatment of prostate cancer.

Keywords:

Prostatic Neoplasms, Biochemical Recurrence Prediction, Database Management Systems

Introduction

Prostate cancer is the fifth most common cancer in men in South Korea, and the incidence is increasing [1]. Prostate cancer is a high incidence of disease and it is important to prevent and manage recurrence after curative treatment. By managing the integrated data of prostate cancer and predicting biochemical recurrence (BCR), progress and pattern of prostate cancer is possible to analyze and may help to choose a treatment in the future. Currently, there are prostate cancer data portals for scientists and clinical doctors, but most of the studies were based on Americans and Europeans data. The cancer incidence rates are different among the countries [2], and there is also racial difference both in cancer incidence and survival rate [3]. Therefore, in order to analyze and predict the prostate cancer data of Koreans, Korean Prostate Cancer Database System is required. The purpose of this study is to construct a multi-center integrated database platform using the Korean Prostate Cancer Registry (KPCR) data and develop a biochemical recurrence (BCR) prediction system to facilitate clinical management of prostate cancer.

Methods

The KPCR Database has collected 7,394 prostate cancer data of Korean from six domestic EMR-based medical institutions. We implemented a system platform to visualize and manage this data. We implemented a web-based platform using Java language and Tomcat Server. In order to predict BCR, we extracted 5,119 analytic data from the KPCR database, generated train dataset for BCR prediction and trained the dataset. We used 15 statistical analysis models to predict BCR including decision tree, logistic regression, and neural networks.

Results

This platform has been implemented features of integrated data management and BCR prediction. The AUC (Area Under the Curve) of BCR prediction is shown in Table 1. 3 years post-surgery, the highest AUC of BCR prediction is achieved by Gradient Boosted Regression, and the value is 0.8419. 5 years after surgery, the highest AUC is achieved by Ridged regression with a value of 0.8071. Finally, we implemented a BCR prediction system using a Gradient Boosted Regression model which reaches the highest average of AUC.

The 3-year and 5-year BCR prediction system with Gradient Boosted Regression model was implemented using the Python language, and we used the GradientBoostingClassifier of the sklearn module in Python. In order to integrate the Web-based platform implemented in Java with the BCR prediction system implemented in Python, we used the Django framework, a Python web framework.

The variables used for BCR prediction include age, initial PSA, clinical stage, pathology Gleason score, pathology stage, surgical margin, perineural invasion, seminal vesicle, extracapsular extension, and lymphovascular invasion. We used the feature_importances_method of GradientBoostingClassifier to output the variable importance, and the result is shown in Table 2.

The result shows that age, initial PSA, and pathology Gleason score are important variables in predicting BCR with gradient boosting regression model.

We developed biochemical recurrence (BCR) prediction system using data of Korean prostate cancer patients. In the input screen, enter the value of age, initial PSA, clinical stage, pathology Gleason score, pathology stage, surgical margin,

perineural invasion, seminal vesicle, extracapsular extension, and lymphovascular invasion. The input value uses the predict_proba method of GradientBoostingClassifier to determine the probability of occurrence of BCR and the probability of non-occurrence of BCR after 3-year and 5-year of surgery. In the result screen, BCR prediction is implemented by outputting the probability of BCR occurrence after 3-year and 5-year of prostate cancer surgery using Gradient Boosting Regression model.

Table 1 – BCR Prediction AUC

Analysis	Method	3-year	5-year
Trees	Decision Tree	0.8186	0.7561
	Random Forest(ntrees=20)	0.8320	0.7956
	Random Forest(ntrees=50)	0.8349	0.8047
	Random Forest(ntrees=80)	0.8362	0.8050
Logistic Regression	Ridged Regression(L2)	0.8288	0.8071
	Lasso(L1)	0.8319	0.7993
	Gradient Boosted	0.8419	0.8031
Neural Networks	1hidden, dropout=0.3 at input	0.7939	0.7895
	1hidden dropout=0.1 at input	0.8027	0.7977
	1hidden dropout=0.1 at input, hidden	0.7984	0.7923
	2hidden, dropout=0.3 at input	0.7978	0.7941
	2hidden dropout=0.1 at input	0.7988	0.7967
	2hidden dropout=0.1 at input, hidden	0.8016	0.7943
Survival Regression	Cox PH	0.7944	0.7816
	Random survival forest	0.7645	0.6920

Table 2 – Variable Importance

Variable	3-year	5-year
Age	0.1601	0.1870
Initial PSA	0.2813	0.2284
Clinical T stage	0.1357	0.1343
Pathology Gleason Score Sum	0.1484	0.1546
Pathology T stage	0.0656	0.0445
Surgical margin	0.0321	0.0525
Perineral invasion	0.0380	0.0483
Seminal vesicle	0.0470	0.0247
Extracapsular extension	0.0055	0.0083
Lymphovascular invasion	0.0454	0.0360

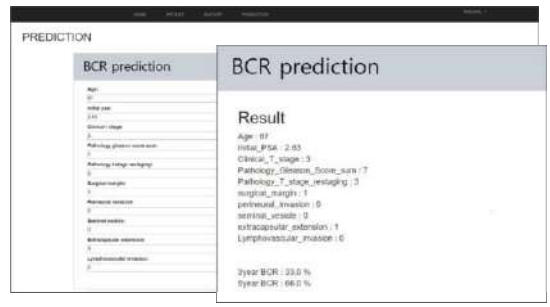

Figure1 – BCR Prediction System

Conclusions

In this study, we designed a management system platform for Korean prostate cancer patients. The platform was implemented on web-based to facilitate data access, management and BCR prediction. It will further facilitate clinical management of patients with prostate cancer and it will also help develop appropriate treatment of prostate cancer in future.

[d]*Medical Center for Information and Communication Technology, University Hospital Erlangen, Erlangen, Germany*

Abstract

The Demonstrator study aims to analyse comorbidities and rare diseases among patients from German university hospitals within the German Medical Informatics Initiative. This work aimed to design and determine the feasibility of a model to assess the quality of the claims data used in the study. Several data quality issues were identified affecting small amounts of cases in one of the participating sites. As a next step an extension to all participating sites is planned.

Keywords:

Data Accuracy; Electronic Health Records; Medical Informatics

Introduction

The German Medical Informatics Initiative (MII) is a long-term nationwide program established to improve research opportunities and patient care through Information Technology (IT) solutions, as well as to facilitate the exchange and use of data across German University Hospitals [1]. It involves four consortia implementing Data Integration Centers (DICs) in every participating university hospitals (MII sites) [1]. The Demonstrator Study was initiated with the intention of a continuous cross-consortia cooperation throughout the project duration. The study carries out a retrospective, descriptive and geo-regionalized exploration of comorbidities and rare diseases of patients in MII sites. The study leverages the standardized "§21" data format mandated by the German Diagnosis Related Group-based billing regulations [2], which enables multicentric analyses even before interoperable data structures and interfaces were fully developed and deployed across the MII sites. The §21-conformant datasets provide a narrow set of data elements for inpatient cases including demographics, diagnoses, procedures and further administrative data. The Demonstrator Study makes use of the Integrated Data Repository Toolkit (IDRT) to extract, transform and load the source §21-conformant data into local i2b2 data repositories (Informatics for Integrating Biology and the Bedside), including a pseudonymization step (see Figure 1). The Demonstrator Study carries out analyses on these repositories to calculate Comorbidity scores and to analyse rare diseases from ICD10 diagnosis data, under consideration of patient ages, encounter duration, hospital admission and discharge reasons, patient zip codes areas and the treating university hospital.

The use of routine clinical data (specifically: claims data) in the Demonstrator Study raises questions concerning the fitness for purpose of the data for the planned analyses. In this regard, the combination of data completeness, data conformance and data plausibility aspects of the data quality (DQ) may considerably determine the validity and veracity of analysis results [3].

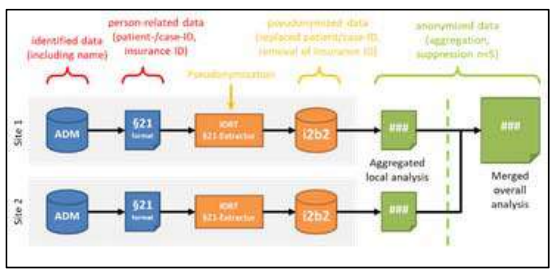

Figure 1 - Data processing pipeline of the MII Demonstrator study

Even though syntactic and coding aspects of the §21 source dataset quality is already tightly defined by billing regulations and controlled yearly by an independent institute in order to ensure their adequacy for billing purposes [2], aspects of data completeness and conformance taking account the aspects of the Demonstrator Study should be additionally addressed, as well as plausibility aspects of the variables in the datasets. The goal of the project was to evaluate the feasibility of constructing and implementing a DQ assessment framework based on a pretest of aggregated §21-conformant data from just one MII site taking part in the Demonstrator Study, before a large scale rollout to all the MII sites is conducted.

Methods

Quality ontology and analysis methods

According to the harmonized terminology of Kahn et al [3], the three quality dimensions completeness, conformance, and plausibility were choosen based on their relevance for the initial DQ approach. Operationalized quality indicators provided by the DQ Assessment guidelines from the German Technology and Method Platform for Networked Medical Research [4] were assigned to each dimensions, and quantitatively assessed using the verification method [3], through seven items formulated in consideration of longitudinal and cross-sectional aspects of the Demonstrator Study (see Table 1).

Implementation of the data quality queries

At the time of the submission, a pre-test was carried out based on the billing data of one of the participating MII sites based on an i2b2 database with data already loaded. We implemented

Table 1- Initial DQA-Framework

DQA-Dimensions	DQA-Indicators	Measurement Items
Completeness	Missing values for data elements (ID-1013)	**1-** Frequency of missing values in data elements
Conformance	Invalid values for qualitative data elements (ID-1021)	**2-** Frequency of invalid values contained in qualitative data elements
	Invalid values for quantitative data elements (ID-1024)	**3-** Frequency of invalid values contained in quantitative data elements
Plausibility	Freedom of Contradiction (ID-1003)	**4-** Men with malignant neoplasms of the female genital organs (C51-C58) as a hospital diagnosis **5-** Women with malignant neoplasms of the male genital organs (C60-C63) as a hospital diagnosis **6-** Men with in-patient delivery (birth) as admission reason **7-** Patients with a difference between the maximum and minimum age within the study period greater than 3 years (study duration)

SQL queries against the i2b2 database resulting in aggregated results. Data use within the project was approved by the ethics commissions of all involved MII sites lead by the Mannheim University Medicine Ethics Board (2018-864R-MA).

Results

Cohort description

The dataset consisted of 152,806 inpatient cases assigned to 94,570 patients. 25,238 patients (26.7%) had more than one case assigned to them (ranging from 1 to 66 cases assigned to a single patient during the observation period: 2015-2017).

Data quality analysis

The DQA results are displayed in

Table 2.

Table 2 - DQA results

DQA-Dimensions	Items	Results
Completeness	1	2532 missing values (1.6%) in the variable “Postal code” 37 missing values (0.02%) in the variable “ICD codes of the principal hospital diagnosis”
Conformance	2	178 invalid codes (0.12%) in the variable “Reason for the hospital admission”
	3	Range of patient ages at the hospital admission: 0-116
Plausibility	4	1 case
	5	5 cases
	6	0 cases
	7	2 patients

Conclusion

The results showed that a subset of 1.6% of cases did not contain a postal code, which, however, can be traced back to foreign patients or homeless patients for which zip codes are either unavailable or are excluded from documentation within the definition of the §21 dataset. In addition a small subset of cases did not contain a diagnosis (0.02%) or contained truncated or invalid codes not listed in the ICD10-GM classification (0.12%). The plausibility analysis revealed only a very small amount (single-digit) of inconsistent cases (see

Table 2). These first results address the feasibility of constructing and implementing a structured DQ analysis model focusing on quality aspects of data completeness, data conformance and data plausibility of the datasets used in the Demonstrator study. In the next steps we plan to implement a visualization of the DQ analysis using the R statistics software. The resulting scripts will be deployed to all MII sites participating in the MII Demonstrator study. This will allow us to carry out and compare DQ analysis based on the datasets from each of the participating MII locations. Further investigation will be perfomed to identify the reasons behind the formation of the problematic cases and to decide about how to handle the given cases before the datasets are used for statistical analysis.

An Adversorial Approach to Enable Re-Use of Machine Learning Models and Collaborative Research Efforts Using Synthetic Unstructured Free-Text Medical Data

Suranga N. Kasthurirathne[a,b], Gregory Dexter[a], Shaun J. Grannis[a,c]

[a] *Center for Biomedical Informatics, Regenstrief Institute, Indianapolis, Indiana, USA*
[b] *Richard M. Fairbanks School of Public Health, Indiana University, Indianapolis, Indiana, USA*

Abstract

We leverage Generative Adversarial Networks (GAN) to produce synthetic free-text medical data with low re-identification risk, and apply these to replicate machine learning solutions. We trained GAN models to generate free-text cancer pathology reports. Decision models were trained using synthetic datasets reported performance metrics that were statistically similar to models trained using original test data. Our results further the use of GANs to generate synthetic data for collaborative research and re-use of machine learning models.

***Keywords*:**

Neural Networks (Computer); Machine Learning; Dataset

Introduction

Large scale adoption of Health Information Systems (HIS), together with the rapid evolution of Artificial Intelligence (AI) and various analytical and machine learning toolkits have led to the widespread development of machine learning solutions to address various healthcare challenges using patient data. However, legislation on sharing of Patient Health Identifiers (PHI) restricts researchers from (a) re-using machine learning solutions across larger audiences, (b) fostering inter-organizational collaboration addressing various healthcare challenges, and (c) building generalized machine learning models targeting larger, diverse populations.

Current efforts to enable better data sharing focus on de-identification efforts, where PHI is scrubbed from patient data. However, de-identified free-text data may be vulnerable to re-identification based on clinical data elements. In contrast, alternate approaches to create synthetic data that mimic clinical patterns in data present considerably lower re-identification risk [1]. We leverage recent advances in Generative Adversarial Networks (GAN) [2] to produce synthetic unstructured free-text medical data, and assess (a) possibility of using these datasets to replicate machine learning results generated using original patient data, and (b) levels of re-identification risk posed by these synthetic datasets.

Methods

We leveraged a convenience sample of 7,000 free-text pathology reports on potential cancer cases from the Indiana Network for Patient Care (INPC) [3], a statewide Health Information Exchange (HIE) to build decision models capable of identifying positive cancer cases for public health reporting. Positive and negative report sets were extracted, and used to train SeqGAN [2] models of varying epoch sizes. We selected optimal GAN models for positive and negative cancer report sets by comparing synthetic data generated by these models with original test data using Bilingual Evaluation Understudy (BLEU) scores. We created vectors by counting presence of each stemmed feature in positive and negative contexts across each report in the report set. Next, we developed decision models to predict cancer cases using the Random Forest classification algorithm [4] and the top 5, 10, 20 and 50 features selected from the original test and synthetic feature sets using the Kullback-Leibler divergence (information gain) method [5].

We compared the performance of these models using sensitivity, specificity, F1-measure (harmonic mean between precision and recall) and area under the ROC curve values (AUC), together with their 95% confidence intervals. We assed re-identification risk for presence disclosure [6], where attackers in possession of a set of patient records can determine if any of them were used to train GAN models by comparing these records against the synthetic patient dataset using Hamming scores, a measure of variation between two binary strings.

Results

The 7,000 free-text cancer cases consisted of 1,950 (27.86%) positive reports and 5,050 (72.14%) negative reports [7]. Comparison of BLEU scores identified models trained for 70 epochs as the optimal synthetic data generation model for both positive and negative cancer reports. We extracted the top 50 features from each of the original and synthetic datasets using information gain scores (*Table 1*). Feature selection identified a 36% overlap between the top 50 features extracted from each dataset (*Table 2*).

Figure 1 presents variance of information gain scores across each of the top 50 feature sets. Decision models trained using the top 5, 10, 20 and 50 features extracted from the synthetic and original datasets reported performance metrics that were significantly high (sensitivity: 77-92%, specificity: 95.7-99.8%, F1-measure: 91-97%, AUC: 90-99%). Further, there was no statistically significant difference between many performance metrics reported by models trained using original or synthetic datasets. Presence disclosure tests performed using Hamming score comparisons indicated relatively low probability for re-identification across positive and negative synthetic reports.

Table 1 - List of top 20 stemmed features selected from the original and synthetic datasets using information gain scores.

Rank	Original dataset	Synthetic dataset
1	Tumor	consult
2	Carcinoma	slide
3	Invasion	node
4	Slide	lymph
5	Cell	malign
6	Metastat	grade
7	Lymph	right
8	Node	pathologist
9	Return	submit
10	adenocarcinoma	prostat
11	Margin	collect
12	involve	carcinoma
13	Consult	section
14	differenti	receiv
15	mass	left
16	cassett	specimen
17	phone	posterior
18	left	surgic
19	grade	identifi
20	microscop	tumor

Table 2 - Intersection of top 5, 10, 20 and 50 features selected from the original and synthetic datasets using information gain scores.

Feature subset size	# features overlap	List of features present in both datasets
5	1 (20%)	slide
10	3 (30%)	slide, lymph, node
20	8 (40%)	slide, consult, node, grade, tumor, lymph, left, carcinoma
50	18 (36%)	note, section, prostat, cassett, slide, malign, consult, node, grade, tumor, right, margin, phone, submit, case, lymph, carcinoma, left

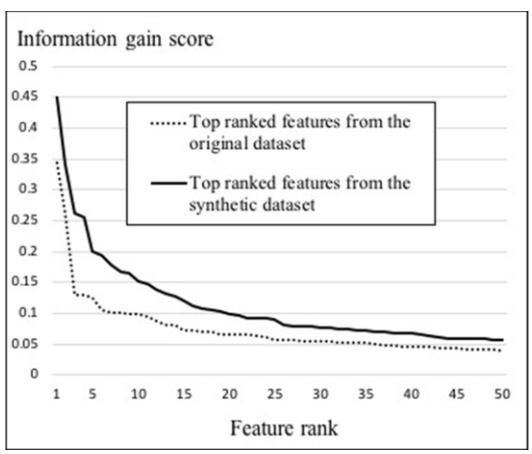

Figure 1 - Variance of information gain scores reported by the top 50 original and synthetic features.

Conclusions

Our results indicate that GAN methodologies can generate synthetic free-text medical data with limited re-identification risk, and that synthetic datasets can be used to develop machine learning models with statistically similar performance metrics to decision models trained using original test data. As such, they are of considerable importance for enabling cross-institutional collaboration and broader dissemination of machine learning models. Adoption of GAN models alone does not result in de-identified data. However, synthetic data generation reduces re-identification risk by creating new patient records with similar, but different data. It also removes any 1-to-1 mapping between test and synthetic reports. Our results demonstrate that synthetic datasets poise a significantly lower chance of re-identification based on clinical information. However, synthetic data produced by these efforts must undergo rigorous de-identification of PHI elements before they can be distributed for public use. Future research includes use of GAN models to create truly de-identified synthetic free-text data that does not require additional de-identification, and expansion of our work across other more challenging healthcare datasets.

We propose the following hypothetical scenario to demonstrate how our approach could be applied in a real-life setting. An organization that possesses rich free-text data sources, but lacks adequate machine learning expertise can leverage our approach to create synthetic data. They de-identify and share the synthetic data with experts who use it to build machine learning models. Once optimal models have been identified, they can be implemented across the original dataset with compatible performance measures.

Abstract

We present AutoScribe, a system for automatically extracting pertinent medical information from dialogues between clinicians and patients. AutoScribe parses the dialogue and extracts entities such as medications and symptoms, using context to predict which entities are relevant, and automatically generates a patient note and primary diagnosis.

Keywords:

Medical Records, Machine Learning, Medical Informatics

Introduction

Currently, clinicians spend up to 50% of their time entering information from patient interviews into electronic medical records (EMRs) [1]. This reliance on slow, laborious, and inconsistent data entry results in wide variability in the quality of EMR data [2], which presents a challenge to clinical data analytics [3]. Recent machine learning (ML) algorithms, such as recurrent neural networks and word embeddings [4], have been applied to tasks such as disease and mortality prediction from EMR data [5,6]. This suggests that a significant portion of clinical data entry can be automated by analyzing patient-clinician dialogues.

Here, we optimize an ML model, *AutoScribe,* to classify dialogue phrases from patient interviews as contextually pertinent to clinical documentation, which is the foundational step to generating EMR data from the analysis of patient-clinician dialogues. We extract medically relevant entities such as signs, symptoms, diagnoses, therapies, and referrals through natural language processing. Unlike systems which primarily use lexicon-based term matching, our system also uses linguistic context and time information.

Data

The data consists of 800 audio patient-clinician dialogues and their transcripts, purchased from Verilogue Inc[1], including primary diagnosis codes. The most frequent are *ADHD*, *COPD*, *depression*, and *influenza.*

We developed a new annotation tool and are doubly annotating all dyads for relevant medical entities. Of the 30 dialogues that have been completed, the annotations have .53 agreement (Krippendorff's alpha [8]) and .80 partial match F_1 score. We also have 302 dialogues with annotations from one physician at present. We present a synthetic patient-clinician dialogue in Figure 1 with the output of our system compared to human annotation.

Methods and Results

The AutoScribe system currently consists of several modules. The cumulative output of these models constitutes the initial AutoScribe system. We evaluate each component of the system using F_1 measure, considering tags that overlap with the human annotation as correct. For entity tagging, we also calculate inter-annotator agreement between the physicians and the automatic pipeline using Krippendorff's alpha [8]. All but the utterance type classification model are evaluated on 302 conversations.

Utterance type classification

Each utterance in the dialogue is automatically labeled as a *question, statement, positive answer, negative answer, backchannel* or *excluded.* We use a two-layer bidirectional gated recurrent unit (GRU) neural network [12], implemented in PyTorch. Each word is represented as a 200-dimensional vector using the freely available Wikipedia-PubMed word embedding model[2]. We evaluate the utterance type classifier on 20 conversations, annotated independently by 2 annotators with inter-annotator agreement of .77 (Cohen's kappa). For training, we use two external, publicly available datasets: the Switchboard corpus [10], and the AMI corpus[3]. Our model achieves .71 F_1 score on Verilogue data.

Time expression identification

Phrases in the dialogue that reference absolute and relative times and dates are automatically tagged and converted to standardized values using HeidelTime [11], a freely available temporal tagger. For example, in a document dated Jan 1, 2018, the phrase *tomorrow* would be normalized to *2018-01-02*.

Medical entity identification

AutoScribe currently identifies the following medical concepts: anatomical locations, signs and symptoms, diagnoses, medications, referrals, investigations and therapies, and reasons for visit. The identification uses lexicon look-up using terms from BioPortal[4], Consumer Health Vocabulary (CHV)[5], SNOMED-CT[6], and RxNorm[7], and achieves an average F_1 score of .63 and .55 Krippendorff's alpha. Entity identification is currently limited to the terms present in our reference lists, which are large but cannot cover all possible expressions of relevant entities. There may be many valid variations of these entities that we hope to be able to identify in the future.

*Figure 1 – Example dialogue - **(a)** Human annotation. **(b)** Automatic annotation. In both **1a** and **1b**, highlight indicates the annotated entities; darker highlights indicate overlap between human and automatic annotations. Subscripts indicate the entity type (TIMEX3 indicates time phrases).*

Attribute classification

Once the entities have been identified, the system should determine which are actually pertinent to the diagnosis. For instance, a physician or patient might mention a medication that they have never actually taken, so the system should not record that medication as part of the patient's history. Currently, we classify two attributes: *modality* and *pertinence*. The modality indicates whether the event actually occurred (actual, negative, possible), and pertinence indicates the condition to which the entity is medically relevant (i.e., *ADHD*, *COPD*, *depression*, *influenza*, other). The attribute classifier is a support vector machine (SVM) trained with stochastic gradient descent [9].

Each medical entity is represented as the average word embedding, concatenated with the word embeddings for the previous and next 5 words. We also include the speaker code of the utterance in which the entity appears. The system achieves .77 F_1 score for modality classification, and .62 for pertinence. Pertinence classification currently performs worse than modality, perhaps because it requires more global information.

Primary diagnosis classification

We classify the primary diagnosis on each patient-clinician conversation to be used for billing codes. We train and test the models on a 5-fold cross validation of the 800 dyads. We apply tf-idf on the cleaned text of each dyad and use logistic regression, SVMs, and random forest models. The F_1 scores of classification are calculated based on the human-assigned labels available in the transcription of the conversation's 'primary diagnosis' field. Diagnosis classification currently handles 6 classes only and does not account for conditions other than the primary diagnosis that may be discussed in the conversation.

F_1 scores (Linear SVM**):** *Influenza .93*±.04, *ADHD .83*±*.05*, *COPD .68*±*.14, Osteoporosis .78*±.04, *Type II diabetes .76*±.07*, Depression .71*±*.08,* and *Other .76*±*.05.*

Discussion & Conclusion

We have presented a novel approach to clinician-patient dialogue parsing, whose outputs are oriented toward pragmatic linguistic features, and the needs of clinicians. Specifically, we have developed machine learning models based on recurrent neural networks that extract medical linguistic entities and their time-based contextual partners, as well as primary diagnoses from dialogue. Future directions include extracting other key contextual entities within clinical dialogues that are pertinent to clinical documentation, such as quantity, quality, and severity words and phrases, as well as accounting for similar medical terms and spelling variations. Training will be expanded to include more entities, more conversations, more diagnoses, and multiple diagnoses per conversation.

Development of a Common Data Model Facilitating Clinical Decision-Making and Analyses

Eizen Kimura[a], Hideo Suzuki[b]

[a] *National Institute of Public Health, Wako, Saitama, Japan,*
[b] *MoDeL Corp., Yokohama, Kanagawa, Japan*

Abstract

Currently, the Common Data Model (CDM) for primary use (as distinct from models designed for secondary use) poorly supports clinical decision-making and medical process analyses. We designed a CDM featuring a search flow that identifies facts after defining the clinical process, and we make the data definition language of the CDM employed freely available as open source.

Keywords:

Data warehousing, clinical decision support systems, data mining

Introduction

To allow medical records to be used in clinical research, Common Data Models (CDMs) have been developed by several groups; the models include Informatics for Integrating Biology and the Bedside (i2b2) [1], Observational Health Data Sciences and Informatics (OHDSI) [2], and the Cancer Biomedical Informatics Grid (caGRID) [3]. The i2b2 allows the research community to find interesting patients by reviewing electronic records while preserving patient privacy. The OHDSI features an international network of real-world data facilitating collaborative observational studies. These CDMs feature tables with relatively few columns and shallow hierarchical star schemas; they embrace an Entity-Attribute-Value (EAV) philosophy allowing rapid exploratory interrogation. While CDMs for secondary use are widespread, few CDMs for primary use supporting clinical decision-making and analyses are available. CDMs for primary use should essentially be the good source of business intelligence tools, must be readable by clinicians, and allow facile interrogation.

It is first necessary to minimize the complexity of interrogation (thus enhancing usability) by ensuring that the database is appropriately denormalized. Usually, the normalization of relational databases is considered desirable. However, as the number of tables increases, querying becomes difficult. In addition, the CDM must feature extensive analyses axes, allowing analysis of various medical processes.

Arden Syntax etc. has been developed as Domain Specific Language (DSL) [4] for medical knowledge supporting clinical decision-making. However, the "curly brace problem" is in play; no standard data retrieval method is yet available [5]. Queries depend on the database structure and the terminology used by the system; it is difficult to port a given logic to another clinical decision-making system [6]. In addition, readability declines if system-specific descriptions become admixed, rendering it increasingly difficult for medical professionals who are not familiar with computers to read the query logic [7]. Although FHIR [8] uses a standard query method to explore routine information, and openCDS [9] attempts to standardize both the data and the API of the clinical support system, neither is easy to use and the data can be employed only to aid in clinical decision-making. Therefore, a CDM that can retrieve medical information after receipt of a simple query is required. A few previous CDMs sought to attain this goal; here, we present a CDM for primary use that is easy to use.

Methods

HL7 messages are associated with prescriptions, injections, radiographic procedures, and specimen examinations. During DWH construction, many ordered HL7 message tables must be created to allow full exploration of the clinical processes used. The number of tables increases as the clinical process of interest becomes more complex, negatively affecting query structure. We built a database that aggregates clinical processes, identifies medical procedures requiring analyses, and then outputs facts. As analyses of clinical decision-making and the associated financial implications require answers to many time-sensitive questions, we optimized the table index to facilitate time-series retrieval. To facilitate analyses of the business processes of an organization, we code names, places, organizations, and teams in a standardized manner; allowing searching based on organizational role and function. To optimize performance, we create specialized tables and indices for specific analysis without creating SQL views; we intentionally allow data duplication and schema denormalization. During the Extract-Transform-Load (ETL) process, we standardize the notation, units, and ranges; searching is consistent across different electronic medical record systems. In addition, traceability is ensured to prevent tampering.

Results

The CDM is currently managed by the Semantic Data Model (SDM) consortium [10]; all specifications are free to all consortium members. We have published the Data Definition Language (DDL) for the relational database systems SQLite, MySQL, PostgreSQL, Microsoft SQL Server, Oracle, and DB2, and the source code of the DDL generator at GitHub [11]. As of October 2018, SDM ver 1.09 features 91 tables, 2,833 unique columns, and 40 common columns allowing construction of dimensions.

Acts (including orders) are collected in the SDM_ORDER table. The SDM_CALENDAR table lists all events during hospitalization, with the dates of major events (including initial hospitalization, discharge, and surgery) being linked, in a simple manner, to specific events. The SDM_INDEX table lists all events and is key when analyzing medical processes. The SDM_KEYS table recodes the editing histories of medical records, ensuring authenticity (the table is an audit trail). Whenever the text of a medical record changes, a hash value is calculated and added to the SDM_KEYS table with 50 attributes such as document related attributes, creators, and modification dates. The SDM_REPORT table manages the links among reports allowing medical staff to view all relevant reports contemporaneously. Thus, tables associated with clinical processes are centralized and factual tables are placed at the periphery; the structure of the database is a shallow star schema (Fig. 1).

A single prescription/injection creates one record row in a table. However, common laboratory data are collectively stored in a single row. Since the results of the laboratory exams often evaluate multiple items at the same time, consideration is given so that a plurality of sample inspection results can be taken out collectively with one query.

The codes use standard terminologies such as the JAHIS Protocol for Clinical Laboratory Data Communication (equivalent to LOINC), the Standard Master for Pharmaceutical Products (equivalent to RxNorm), and the ICD10-based Standard Disease Code Master for the ETL process.

All tables feature 40 common columns storing data on actors, wards, dates, and times, facilitating multi-dimensional analyses. As of 2018, the SDM consortium cooperates with the electronic medical record vendors Canon, Fujitsu, Hitachi, IBM, NAIS, NEC, SSI, and Softmax.

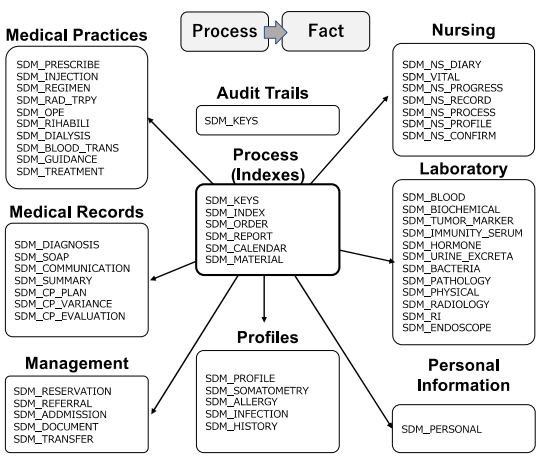

Fig1-The Overview of the Semantic Data Model ables

Discussion

Our CDM includes only information required in medical practice, thus not the items of standard information models such as the FHIR. As the data structure differs for each vendor of electronic medical records, we developed an independent ETL process featuring a trade-off between developmental cost and completion of all SDM tables. This study has limitations that it has no quantitative evaluation of the proposed model yet such like the time for building ETL, the concept coverage rate compared with another CDMs, the effectiveness of denormalization on the degree of contribution to simplifying the queries on CDM. We will harmonize the standard medical information models with the SDM tables. Thus, data conforming to the standard model for medical information is output by the electronic medical record system, the need for further ETL development is reduced, and the fulfillment of SDM items will increase.

Conclusions

In the future, we will seek to conform to the FHIR which is increasingly the accepted model of standard information.

Scientific Challenge in eHealth: MAPPATHON, a Metadata Mapping Challenge

Ann-Kristin Kock-Schoppenhauer[a], Philipp Bruland[b], Dennis Kadioglu[c], Dominik Brammen[d], Hannes Ulrich[a], Kerstin Kulbe [e], Petra Duhm-Harbeck[a], Josef Ingenerf[a,e]

[e] Institute of Medical Informatics, University of Lübeck, Germany

Abstract

Scientific challenges based on benchmark data enable the comparison and evaluation of different algorithms and take place regularly in scientific disciplines like medical image processing, text mining or genetics. The idea of a challenge is rarely applied within the eHealth community. Mappathon is a metadata mapping challenge that asks for methods to find corresponding data elements within similar datasets and to correlate data elements among each other.

Keywords:
Metadata, Telemedicine, Benchmarking

Introduction

To enable secondary use of routinely collected medical data, it is necessary to create a general understanding of given information. As a common practice, this understanding is achieved through metadata about data elements and the interconnections between data elements. Metadata can be stored in so-called metadata repositories (MDR). The functionalities of such an MDR include pure storage, administration and other specific metadata functionalities like matching and mapping. Mapping means transforming instance data using mapping rules. The technical term matching is used for searching corresponding, semantically similar data elements at the schema level. Matching and mapping rules are difficult to determine and often require manual effort. Therefore, there is a great need for advanced data analysis techniques promoting the definition of matchings and mappings, where matching refers to the discovery of related or equivalent metadata and mapping to the relationship between data elements such as conversion rules. We organized a scientific challenge enabling competition between approaches for determining automatically related data elements [1].

Methods

The challenge was organized in two phases: The training phase, where datasets have been published and a restful service for the evaluation of the results have been implemented, and the test phase, where the algorithms have been compared. Within the training phase, participants were invited to download the training dataset consisting of metadata about eCRFs and the included data elements as well as a gold standard mapping of related data elements created by medical experts. This allowed the validation and optimization of algorithms and methods. Any automatic method that predicts the valid mapping was asked for. There was no restriction on new, innovative or unpublished methods and no limitations on including external information like terminologies. Participants were explicitly invited to use of coding systems and terminology servers. The Mappathon Challenge provided two tasks, which were independently evaluated:

1. The first task, multilabel classification, is the problem of classifying source data elements to one or more target data elements.
2. The second task, multiclass classification, is the problem of classifying source data elements in specific relation to (multiple) target data elements.

Data

We provided no instance level data, but only metadata sets in the German language. Dealing with German metadata is one of the main reasons for this challenge because most existing and freely available datasets (e.g., MIMIC II) are in English. At the same time, most available lexical or text mining tools do not fully support the analysis of German medical texts.

All training datasets are at least partly annotated with UMLS CUIs, but there were no annotations in the test dataset. For the challenge, datasets of routine documentation and clinical research are provided by the Portal of Medical Data Models [2]. Curated training datasets have been made available for download in different formats like FHIR questionnaires or CDISC ODM. All eCRFs refer to the use of case Emergency Department Visit. We provided seven training datasets consisting of 950 data elements and three test datasets with 579 data elements.

	relatedto	equivalent	equal	wider	narrower	undefined

Figure 1 -- Evaluation matrix to calculated the Mappathon Score (left side: defined mapping, right side: gold standard mapping. Row names correspond to the equivalence classes referred to FHIR ConceptMaps.

Equivalence Classes

The Evaluation Classification of the Mappathon is based on the FHIR v3.0.1 ConceptMap [3], which uses the ConceptMapEquivalence value set. The number of classes has been significantly reduced and the classes are being utilized on data element level and not on the intended concept level.

Mapping

The validation was carried out on the basis of elaborately developed manual mappings (ground truth) in cooperation with clinical partners, see Fig. 2. The mappings are directional - from the source to the destination. Nevertheless, in many cases, reverse mappings are valid as well. Not all data sets were compared to each other, but suitable preselection took place. However, the manual mapping resulted in an overall of 104,207 possible mappings to consider in the training sets and 110,936 in the test sets. The quantitative output of valid mappings is less. The experts could identify 417 actual mappings in the training data and 419 in the test datasets.

Validator

The mapping results could be evaluated using the Online Mappathon Validator. The Mappathon challenge provided a RESTful interface for uploading mapping results under https://validate.mappathon.de and an additional client available on the ITCR GitHub repository [4]. The Mappathon Validator calculates the Zero-one Classification Loss and the Mappathon Score according to the published evaluation matrix, see Fig. 1.

Results

Six teams have registered to the challenge. During the on-site workshop held at the 63rd Annual Meeting of the German Association for Medical Informatics, Biometry and Epidemiology (GMDS) e. V. in Osnabrück, a set of test cases was released of which participants were asked to apply their

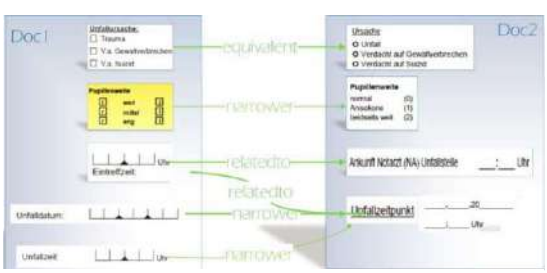

Figure 2 – Defined mapping according to the equivalence classes between several data elements of two datasets.

algorithm on and upload their mapping results. In the workshop, the teams finally had the opportunity to present and discuss their respective results and their methods in particular. Based on the evaluation matrix, which was also published at the beginning, the organizer selected the team whose results most closely corresponded to the gold standard. Both metrics have been calculated for each test dataset. The results are shown in Tab. 1. In addition, the workshop participants had the opportunity to vote on which of the shown solutions they considered to be the most innovative and original. The award for the best mapping went to the team "MDRCupid" consisting of Noemi Deppenwiese and Hannes Ulrich from the University of Lübeck and the prize for the most innovative solution to the team "Marvelous Mappers" consisting of Michael Storck, Philipp Neuhaus and Stefan Hegselmann from the University of Münster.

Table 1– Overvie of best Mappathon results in 2018.

Datase	Zero-One-	M-
TEST1	0,18	-8,7
TEST2	0,16	2,4
TEST3	0,0	-1,0

Discussion

Various datasets and the related heterogeneity make it nearly impossible to compare different approaches in a fair way. By providing a high-quality dataset publicly as well as pre-defined evaluation rules, this challenge aims to overcome these limitations and to create a common framework for a comprehensible and adequate comparison of results. Before a repetition of the challenge Mappathon, further detailed rules about the aims of the mapping (concept versus data element level) should be developed.

Conclusions

The Mappathon and the contributed solutions are the first steps towards to enable routine data for the secondary use in clinical research. We are planning another Mappathon and are already looking forward to furthering input, interesting solutions, and exciting discussions.

Acknowledgements

We would like to thank the GMDS for making the workshop at the annual conference possible as well as all the professional societies and data stewards to provide us with excellent data sets.

Abstract

Laboratory tests results have potential secondary usage. Each healthcare facility has a laboratory test code. Hence, test code mapping is required to support laboratory technicians. An automatic code mapping can reduce the burden of manual mapping during data preparation. The authors developed a semi-automatic mapping support system that uses the newest test results generated in the electronic health record.

Keywords:
Clinical Laboratory Information Systems, Electronic Health Records

Introduction

Recently, researchers applied various data analysis methods and artificial intelligence algorithms to process and analyze medical data. However, the lack of massive and properly structured can affect the performance of computer-aided data analysis. Several countries implemented Electronic Health Records (EHR) [1,2]. Healthcare facilities might implement various laboratory test coding systems where the same laboratory test might have different codes numbers. The EHR vendors have to maintain and map the laboratory test to each facility coding system that uses their EHR instead of delegating this task to the healthcare facility itself to ensure the correctness of the mapping between the EHR codes and the local coding system. Mapping the local codes that different healthcare facilities use can be valuable for secondary usage and data exchange. Hence automating the mapping of laboratory tests codes can reduce the manual efforts, and each healthcare facility can oversee and manitain the coding to ensure the correctness of the mapping. This study proposes a laboratory codes mapping support system that can reduce the manual mapping process.

Conventionally, the authors defined a common laboratory test code standard due to the lack of pervasiveness of LOINC and JLAC10 in many hospitals [3]. The original code has three segments. The first segment is an accounting system code, which the Ministry of Health and Welfare in Japan defines. The accounting system code reflects the clinical aspect of the test from the physician perspective rather than the technician perspective, which provide over precise classification. The second segment, subcode1, represents the classification of specimens and items. The third segment represents subcode2, the laboratory test characteristics such as standard and unit.

There are two significant factors for the efficiency of the mapping. The first is retrieving the newest facility code, that facility manager prepares and sends it to the EHR manager. Hence, manual mapping time depends on the facility manager. The second factor is different management of mapped facility code. The selection of the expired code, the mapped code, and the new code are the main tasks to generate the specific code that the managers assign to the original unique code.

Therefore, the mapping system has two functions. The system can automatically identify the different unregistered code in the original unique code master. The system can manage all the facility code, including active, rejected, and expired code, to track the mapping history.

Methods

This study applies two steps to create the continuous maintenance of the original unique code master. The first step classifies the facility code using the accounting code in the code master that the facility manager provides. Hence, the maintener can focus on the two subcodes mapping. In the second step, an extraction function in the EHR detects all test results items in the data received from all facilities by daily batch processing. The daily test result items include the newest 100 values. The proposed mapping support system identifies the new items of facilities using the retrieved list.

Consequently, a maintener can proceed with the mapping task using the following three steps;

1. The initial test code mapping: The facility code master is imported to the mapping support system. The mapping system proposes the unique code, which is the candidate of the mapping to the facility codes.
2. Difference detection: The newest test result items list are extracted from the EHR, then the different codes are registered for mapping task waitlist when the test item list are imported into the proposed system.
3. The maintener workflow: After insurance organizations announce a new test item, the maintener waits until the item appears on the EHR test result list. Afterwards, the EHR test result listis imported to the proposed system so that the maintener can start the mapping the subcode without any other preparation.

The proposed system described above is a continuous subcode mapping as a stational process after the initial master code mapping.

Definition of Laboratory test code master

Table 1 shows the definition of the original unique code structure. Accounting code, two subcodes and item name are defined.

Table 1 – Examples of the original unique code definition

Accounting code	Subcode1	Subcode2	Item name
160010010	000	00	HbA1c (NGSP)
160010010	000	01	HbA1c (JDS)
160022510	000	00	AST/GOT
160022610	000	00	ALT/GPT
…	…	…	…

Table 2 shows the definition of the EHR test result item list. OID indicates the hospital that reports the test result. Labtest OID indicates the laboratory that runs the test.

Table 2 – The EHR test result item list definiton

No	Item	Example
1	Organization ID	1.2.840.114319.5.1000.1.50.1
2	Labtest OID	1.2.840.114319.5.1000.1.50.1
3	Facility test code	68001
4	Item name	WBC
5	Reference value	3500—9200
6	Unit	x10^3/muL
7	Report date	2017/1/5 15:48
8	Value	5.8
9	Registered date	2017/1/5 23:59
10	New/Exist flag	New

Mapping Support System

Figure 1 illustrates the structure of the EHR, Electronic Medical Record (EMR) and the proposed system. Daily submitted test results from EMR are accumulated as a list in the EHR. The maintener imports the list into the proposed system.

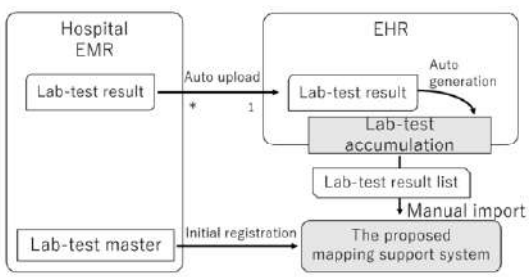

Figure 1- The mapping support system and the relation with EHR and EMR

Results

We compared the manual mapping workflow to the proposed system workflow. We described the manual mapping workflow in seven steps; 1. Comment code omission, 2. Sort by the accounting code to compare the code, 3. List the accounting code classification of the facility code, 4. Subcode mapping, 5. Retreive new master data from the facility manager, 6. Omit flag setup for the mapped code on the newest facility master, 7. Process step 2 to step 4 for the new code.

The proposed system workflow has four steps; 1. Comment code omission, 2. Format the facility code master for import, 3. Import EHR data and facility code master, 4. subcode mapping.

System operation performed all processes on the proposed system workflow. The proposed system reduced the additional wait time such as step 5 on the manual mapping workflow. The maintener only needed to import several files to the system before starting the actual mapping task. Hence, the proposed system drastically reduced mapping preparation tasks.

Conclusions

This study proposes a mapping support system for laboratory test code. The method leverages the EHR to retrieve the newest test item that is not in the original facility code master. The system reduced the burden of manually mapping the target code as well as parallelizing the workflow with several mainteners according to the active, rejected, and expired code management.

An Ontology for Assessing Health Information Needed During Pregnancy

Joo Yun Lee[a]

[a] *College of Nursing, Gachon University, Incheon, Korea*

Abstract

In this study we developed an ontology for accessing online health information related to pregnancy. Social media data and the categories in the literature on pregnancy information were used to collect terms for identifying class and class hierarchy. The developed ontology included 241 classes and 788 synonyms, with six superclasses. This ontology can be used to provide appropriate information based on a needs assessment.

Keywords:

Consumer health informatics, pregnant women, social networking,

Introduction

Patients and consumers actively use online social media, including online communities, to obtain health-related information and to share experiences and opinions. According to the Pew Internet Report [1], the health information shared most frequently online was information on food, drug use, and pregnancy-related health. Although pregnancy is a normal life-cycle process, and not a disease, many pregnant women seek information during pregnancy in order to relieve anxiety and to help with decisions related to pregnancy [2].

Despite the high information needs, the reliability of online information tends to be underestimated compared with information provided by professional caregivers. In addition, pregnant women were found to judge the reliability of online information by their own standards [3].

Detailed information on the kind of health information a pregnant woman requires is necessary in order to provide reliable, high-quality information. Studies that have assessed the information needs of pregnant women have mainly used questionnaires or focus group interviews. As a result, most of the information needed involves broad topic levels, such as fetal growth, symptoms of pregnancy or its complications, and nutrition during pregnancy. An analysis of social media data should provide additional details on the diverse topics pregnant women want to learn about.

Recently, an analysis of social media data based on ontology has been used for effective data collection and extraction [4].

Therefore, in this study we developed an ontology for health information needs during pregnancy to be used for collecting and analyzing social data.

Methods

This study consisted of six steps [4, 5]. First, we determined the scope of the ontology. We collect termsed for identifying classes and the class hierarchy: , social media data written by pregnant women in online communities were used as a source of terms for class identification, and categories in the pregnancy literature, including textbooks and guidelines, were used as the source of class hierarchy. In Step 2, we enumerated terms for the ontology. Over the full month of July 2017, we used a web crawler to collect 11,290 pregnancy-related text posts from online communities running in the largest two web portal sites in Korea. Approximately 90 search keywords containing term information were used (e.g., 24 weeks pregnant or first trimester pregnancy). We used text mining to extract pregnancy-related terms. These collection and text mining processes were carried out in collaboration with a leading Korean telecommunications company. We then identified the classes and synonyms for the classes using collected terms. In Step 4, we defined the class hierarchy based on the categories in the pregnancy literature. In Step 5, additional terms were assessed as a second data collection from same online communities using a crawler from August 1, 2017, to July 31, 2018. Newly identified terms were added as classes or synonyms based on the developed ontology. Finally, in Step 6, the adequacy of the class hierarchy of the developed ontology was validated by interviewing three domain experts.

Results

In total, 578 terms were extracted from 11,290 pregnancy-related text posts using a text-mining technique. Of these, 212 terms were identified as classes and another 366 terms were identified as synonyms. Based on the categories in the pregnancy literature, class relationships and hierarchies were defined. The classes had three- or four-level hierarchies, with six superclasses: “pregnancy stages”, “fetal health”, “maternal health”, “medical care”, “support”, and “preparing for birth (supplies)” (See Figure 1). The “maternal health” superclass comprised physiology, psychology, and lifestyle. The “lifestyle” subclass included classes such as “diet”, “activity”, “beauty” and “travelling”. The “support” superclass was classified into “family”, “work”, and “community”. The “Work” subclass included classes such as “maternity leave”, “flextime” and “working mom”. The second round of data collection added 29 classes and 422 synonyms. For example, a “fine dust levels” class was added to “maternal health” and an “mobile application” class was added to “support”. Information related closely to health was included in four classes: “pregnancy stages”, “fetal health”, “maternal health”, and “medical care”. After reviewing the ontology, domain experts recommended that the “pregnancy stages” class be placed in a crossed relationship with the other classes. In this way, one can analyze the change in health information needs according to pregnancy stage.

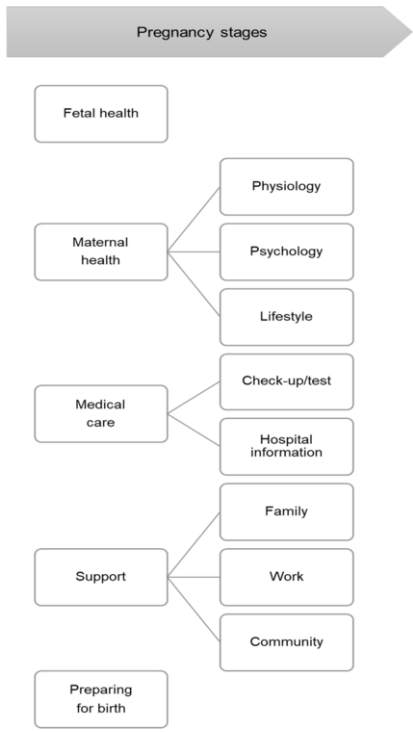

Figure 1. Superclasses in the Developed Ontology

Conclusions

The ontology developed in this study can be used to assess the detailed information needed by pregnant women. Based on the results from this needs assessment, health professionals can determine the reliable information to provide to pregnant women.

Machine Learning Approaches for Extracting Stage from Pathology Reports in Prostate Cancer

Raphael Lenain[a], Martin G. Seneviratne[a], Selen Bozkurt[a,b], Douglas W. Blayney[c], James D. Brooks[d], Tina Hernandez-Boussard[a,b]

Abstract

Clinical and pathological stage are defining parameters in oncology, which direct a patient's treatment options and prognosis. Pathology reports contain a wealth of staging information that is not stored in structured form in most electronic health records (EHRs). Therefore, we evaluated three supervised machine learning methods (Support Vector Machine, Decision Trees, Gradient Boosting) to classify free-text pathology reports for prostate cancer into T, N and M stage groups.

Keywords:

Prostate Cancer, Neoplasm Staging, Natural Language Processing

Introduction

Prostate cancer is the commonest non-cutaneous malignancies in men, with over 260,000 new cases annually in the United States [1]. The staging of these newly diagnosed cancer patients is one of the most important factors in determining treatment options and predicting patient survival [3]. Free-text pathology reports contain a wealth of staging information that is not captured in structured form in most electronic health records (EHRs). The ability to automatically extract stage from pathology reports would facilitate the creation of research cohorts from the EHR (e.g. pragmatic trials), provide a framework for quality assurance over time (e.g. assess bone scan adherence), and assist with harmonizing data across sites (e.g. evaulate population-level trends).

Natural language processing (NLP) has emerged as a promising tool for extracting stage from clinical texts. There have been various attempts to apply NLP to automatically extract stage from progress clnical notes and pathology reports across a range of tumor types including lung, breast, colorectal and prostate [4-9]. The majority of these studies have used a rule-based approach, relying on regular expressions associated with stage descriptions or smart text forms. However, rule-based approaches often have limited generalizability between tumor types and across institutions. Therefore, in this study, we aimed to evaluate the performance of different machine learning approaches for extracting staging information from pathology reports in prostate cancer using a more generalizable machine learning approach. This may help to inform the strategy of automated stage extraction from unstructured clinical text.

Methods

The Stanford prostate cancer research database was used for analysis, which is described in detail elsewhere [10]. We identified a cohort of prostate cancer subjects with at least one pathology report. This study was made possible due to linkage of the EHR with an institutional cancer registry, which contained ground-truth stage labels manually abstracted from the clinical notes. Stage annotations were defined at the time of diagnosis using the T, N, M classification (i.e. each document had a separate T, N and M annotation).

We included only reports within one year of the diagnosis date. As we are a teritary cancer center, one year post-diagnosis was used to ensure patients on active surveillance seeking secondary opinions were included. In the case where multiple reports appeared within one year of diagnosis, we treated each report as a separate training sample. In an effort to simplify the classification task, stage labels from the cancer registry were clustered intro groups under the guidance of clinical advisors (e.g. 7 separate T stage labels were grouped into 3). The cohort contained only tumors of T stage 2 and above, as lower-stage tumors were not biopsied.

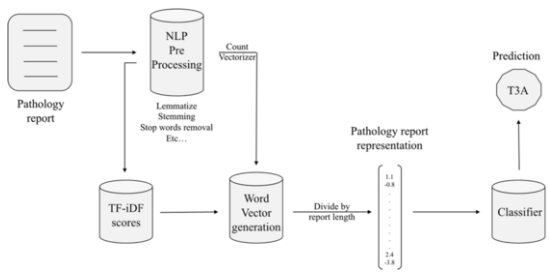

Figure 1 - Architecture of the NLP pipeline for classifying pathology reports into T, N, M stage categories

The pipeline was built with Python (version 3.6) using the Natural Language Toolkit (NLTK) for preprocessing, and scikit-learn for feature extraction and classification. Each report was put through a pre-processing pipeline consisting of stemming, lemmatizing, stop-word and punctuation removal. Subsequently, term frequency-inverse document frequency (TF-iDF) scores were generated for each term-document pair [11].

A bag-of-words representation for each document was generated, with word weighting by TF-iDF scores. A vocabulary was constructed using the entire document corpus. This vocabulary was used to generate document-level word vectors. Neural embeddings were not used because of the limited size of the corpus, and the fact that pre-trained embeddings such as GloVe (GLobal Vectors for Word Representation) were not well suited to the vocabulary of pathology reports. The NLP pipeline is illustrated in Figure 1.

For each of T, N and M stage classifications, we used the document-level vector representations to train a classifier against the ground-truth pooled stage labels from the cancer registry. We used an 80/10/10% split for training/validation/test sets. The following classifiers were trialed: support vector machines (SVM), random forest (RF), and extreme gradient boosting (XGB). With F1-score as our target metric, we used random hyperparameter search to tune our classifiers.

Results

This study cohort included 4,470 prostate cancer subjects with at least one pathology report, yielding a total of 13,595 unique reports. Table 1 shows the results of each classifier for the T, N, M classification tasks. The optimal F1-score achieved was 0.80 on pooled T stage (3 labels), 0.71 on unpooled T stage (7 labels), 0.98 on N stage and 0.99 on M stage.

Table 1 - Evaluation Results

Classifier	Model	Precision	Recall	F-Score
T	SVM	0.77	0.79	0.77
(3 labels)	Decision Trees	0.76	0.75	0.76
	Gradient Boosting	0.80	0.81	0.80
T	SVM	0.61	0.64	0.61
(7 labels)	Decision Trees	0.63	0.62	0.62
	Gradient Boosting	0.71	0.71	0.71
N	SVM	0.98	0.98	0.97
(2 labels)	Gradient Boosting	0.99	0.98	0.98
M	SVM	0. 99	0. 99	0. 99
(2 labels)	Gradient Boosting	0.99	0. 99	0. 99

This study is limited in analyzing pathology reports from a single institution, albeit one with a very diverse clinician and patient population over an extended timeframe. Further work is warranted to apply the pipeline to pathology reports from other sites in order to validate the putative generalizability of this machine learning approach relative to rule-based methods. In addition, the classification tasks were affected by the class imbalances in the dataset, especially between prostate M0 and M1, and breast M0 and M1. We have also made assumptions that a pathology report within one year of diagnosis date reflects the stage at the time of diagnosis - it is conceivable that the stage listed by the registry is not accurate at the time of the report.

Conclusions

Our NLP pipeline is able to efficiently classify pathology reports into T, N, and M stage categories, with strongest performance for N and M stage. This may be a more scalable method than rule-based systems for extracting staging data from unstructured text, which has implications for auto-populating registries and identifying observational research cohorts from EHRs.

Named Entity Recognition in Chinese Electronic Medical Records Based on the Model of Bidirectional Long Short-Term Memory with a Conditional Random Field Layer

Luqi Li [a], Li Hou [a]

[a] *Institute of Medical Information and Library, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China*

Abstract

Named entity recognition in electronic medical records is of great significance to the construction of medical knowledge maps. This paper proposes a model of bidirectional Long Short-Term Memory with a conditional random field layer(BiLSTM-CRF). In terms of simultaneously identifying 5 types of clinical entities from CCKS2018 Chinese EHRs corpus, the BiLSTM-CRF model finally achieved better performance than the baseline CRF model (F-score of 84.23% vs 82.49%).

Keywords:
Data Mining; Electronic Health Records; Natural Language Processing

Introduction

Electronic medical record (EMRs) contain diagnoses, examinations, medications and other important clinical evidence that are helpful to support clinical decision-making and health management. However, a large number of unstructured texts hinder the key information extraction and deep utilization of EHRs. Therefore, it is urgent to explore auto-information extraction methods to transform the natural language in EHRs into structured data that is easy for computers to understand and use.

Named entity recognition (NER) has received much attention recently as an important step for text mining, which aims to automatically detect the target concepts from given texts. In previous works, clinical named entity recognition systems ofen used rule-based NER approaches to match strings by rule templates and dictionaries. They could get good results and high efficiency in the recognition of small sample data, but relied too much on domain knowledge by experts and professional dictionaries. However, state-of-the-art CRF-based NER methods depend on effective feature engineering, i.e. the design of effective features using various NLP tools and knowledge resources, which is still a labor-intensive and skill-dependent task. Recently, deep learning has become prevalent in the machine learning research community. This method can automatically learn and predict the features of texts by using neural network models based on word embedding. In particular, the model of bidirectional Long ShortTerm Memory with a conditional random field layer (BiLSTM-CRF) has been widely used in NER tasks and has achieved excellent performance in various fields. Zeng et al. made outstanding achievements in the drug name recognition tasks of DDIExtrction2011 (DDI2011) and DDIExtrction2013 (DDI2013) by proposing a method combining bidirectional long short-term memory and CRF (BiLSTM-CRF) to explore word and character characteristics [1]. Therefore, in this paper, we propose the BiLSTM-CRF model to improve NER performance in Chinese EHRs, while the BiLSTM layer is used to solve the problem of artificial feature extraction and the CRF layer is used to capture sentence-level tag information.

Methods

In this section, embedded features used in our neural network model are introduced. Then, we employ a CRF model as the baseline for performance comparison. Last, the BiLSTM-CRF model is presented.

Recently, distributed feature representation or word embedding has been widely used in the field of NLP, especially for deep learning methods. It can capture both the semantic and syntactic information of words from a large unlabeled corpus, and has attracted considerable attention from many researchers [2]. Compared with the bag-of-words (BOW) representation, word embedding is low-dimensional and dense. In recent years, word2vec and GloVe have been widely used in the field of NLP. In order to avoid clinical word segmentation interference caused by common word segmentation tools, we employ character embedding as a basic feature. To achieve high-quality character embedding, we collected a total of 2,605 clinical texts from the China Conference on Knowledge Graph and Semantic Computing (CCKS) 2017 challenge. Then these 2,605 texts and another 1,000 texts from the CCKS 2018 NER task were used to train 100-dimensional character embedding by the word2vec tool as pre-trained character embedding.

CRF is a probabilistic undirected graphical model which can take into account the joint probability distribution of the output sequence of labels. The CRF-based model has been widely used for sequence labeling tasks like NER. In this study, we use the CRF++ package for the implementation of CRF model and fix the content window size at 5, then build 18 Unigram templates to extract context characters. As an additional feature, part of speech (POS) tags are generated by the Jieba segmentation system [3].

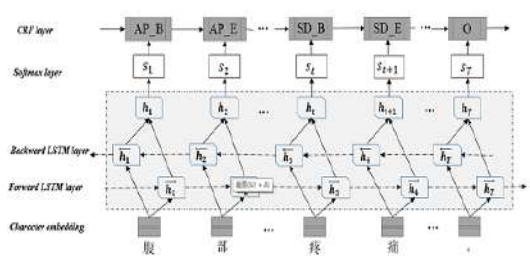

Figure 1–Structure of The BiLSTM-CRF Model

The architecture of a BiLSTM-CRF model is illustrated in Figure 1 [4]. In this paper, each tagged entity in the corpus was encoded in a BIESO (Begin, Internal, End, Single, Other) tagging scheme. We divide the EMR corpus into sentences by periods. The model will predict a label corresponding to each of the input tokens in the sentence. The first layer of the model is the embedding layer. Through the pre-trained character embedding table lookup operation, the input sentence is represented as a sequence of vectors $[X]_1^T = (X_1, X_2, X_3, \dots, X_T)$, where T is the length of the sentence. Next, the vectors are input to the BiLSTM layer. The output $[h]_1^T$ is obtained by connecting the output of the forward LSTM $h_f = < h_{f1}, h_{f2}, h_{f3}, \dots, h_{fT} >$ and the output of the backward LSTM $h_b =< h_{b1}, h_{b2}, h_{b3}, \dots, h_{bT} >$,the meaning of h_t is the deep characteristic representation of X_t. Then, through the softmax function, the decision probability of h_t mapping to the annotated result is expressed as $P_{ht,yt} = softmax(h_t)$. Finally, instead of modeling tagging decisions independently, the CRF layer is added to decode the best of all possible tag paths. In the CRF layer, the current input is predicted by the past input and the state to which the input belongs; the score by moving from state i to state j is represented by the probability transfer matrix $T_{i,j}$; $[O]_1^n$ is defined as an output state sequence; therefore the entire network and the output state sequence have a transition score of

$$\mathrm{S}([X]_1^T, [O]_1^T, \theta, \mathrm{T}) = \sum_{t-1}^{T}(P_{ht,yt} + T_{t-1,t}) \qquad (1)$$

In order to optimize the parameters of the model, the loss function is defined $£(\theta, \mathrm{T})$, which regularizes all possible state sequences $[j]_1^T$ with log likelihood to avoid overfitting:

$$£(\theta, \mathrm{T}) = \mathrm{S}([X]_1^T, [O]_1^T, \theta, \mathrm{T}) - \log \sum_{\forall [j]_1^T} e^{\mathrm{S}([X]_1^T, [j]_1^T, \theta, \mathrm{T})} \quad (2)$$

During the training phase, the objective of the model is to maximize the log-probability of the correct tag sequence. This can be computed using dynamic programming. In the prediction phase, the Viterbi algorithm always is used to discover the state sequence with the highest transition score as the prediction result.

The dataset used for performance evaluation in this study is derived from the NER task in CCKS2018. This study focuses on the identification of three major types of entities-"Symptom", "Drug", and "Surgery". Considering the "Symptom" type of entities are more structured, they are further classified into three categories: "Anatomical Position" (e.g., "***腹***痛 ***abdominal*** pain"), "Symptomatic Description" (e.g.,"腹***痛*** abdominal ***pain***") and "Independent Symptom"(e.g.,"***咳嗽 cough***"). The training set involves 600 annotated clinical texts and another 400 are served as test data. Precision, Recall and F-score are used to evaluate the performance.

Results

The distribution of entities in the training set and the test set is shown in Table 1.

Table 1–Distribution of Entities Among the Training Set and the Test Set

Data set	AP	SD	IS	Drug	Surgery
Training set	52%	14%	20%	7%	7%
Test set	63%	9%	13%	8%	7%

AP: *Anatomical Position;* ***SD:*** *Symptomatic Description;* ***IS****: Independent Symptom*

Figure 2 shows the recognition performances of the BiLSTM-CRF model and the CRF model for five different entities. The BiLSTM-CRF model with character embedding achieves better F-score performance (84.23%) than the CRF model with POS feature (82.49%). The BiLSTM-CRF model is superior in four types of clinical entity recognition but slightly inferior in "Symptomatic Description" because of the small training set and the complexity of Chinese NERs. In view of the unsatisfactory performance of "Drug," caused by a large number of new words and acronyms, we will consider using drug dictionaries and other features (such as chunk and stroke) to improve the ability of the model to discover new words. At the same time, tagging inconsistency of the document-level was found. Furthermore, the BiLSTM-CRF model combined with attention mechanism solved the problem of label inconsistency.

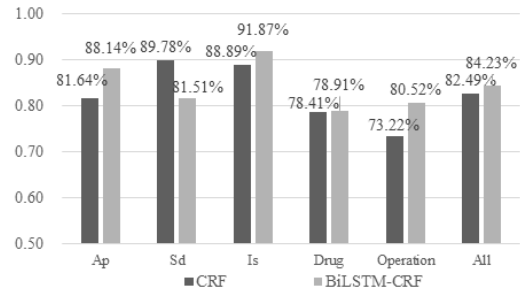

Figure 2–Comparision of F-scores Between Two Models Among 5 Entity Types

Conclusions

We have developed an automatic method of NER in Chinese EMRs and achieved a good overall recognition performance. This BiLSTM-CRF model with character embedding lays a good foundation for future work.

Exploring Hidden In-Hospital Fall Clusters from Incident Reports Using Text Analytics

Jiaxing Liu[a], Zoie Shui-Yee Wong[b], Kwok-Leung Tsui[a], Hing-Yu So[c], Angela Kwok[c]

[c]New Territories East Cluster (NTEC), Quality and Safety Division Prince of Wales Hospital, New Territories, Hong Kong, China

Abstract

Retrospective analysing of fall incident reports can uncover hidden information, identify potential risk factors, and improve healthcare quality. This study explores potential fall incident clusters using word embeddings and hierarchical clustering. Fall incident reports from 7 local hospitals in Hong Kong were catalogued into 5 potential clusters with significantly different fall severity, gender, reporting department, and keywords. This study demonstrates the feasibility of using text clustering methods on real-world fall incident reports mining.

Keywords:
Unsupervised machine learning, natural language processing, patient safety

Introduction

In-hospital patient fall is one of the most commonly found incidents in hospitals. Falls can cause patients to suffer, prolong the length of stays and increase hospital resources. It is essential to identify fall risk factors through post-fall analysis and learn lessons from these incidents to provide better clinical care. And it would be more efficient if this can be achieved by automatic text mining reviews. Existing studies mainly target effectively mining the narrative text of patient safety reports that contain fall incidents. Some of the studies successfully identified fall incident reports from other types of patient safety incident reports using text classification or text clustering methods [1-3]. However, the nature, cause and mechanism of in-hospital falls are not studied specifically using text mining. We envision the potential to use recent advances in natural language processing and modelling techniques for automatic fall incident report classification, retrieval, and analysis.

Methods

We retrospectively analysed a cohort of in-hospital fall incidents from AIRS system in Hong Kong from January 2011 to September 2014. The workflow of the text analysis is shown in Figure 1. Narrative text including a brief description and immediate action taken was retrieved and preprocessed. Next, the word2vec method is used to map words to vector representations of words that capture the syntactic and semantic information. Word2vec has two basic architectures: Continuous Bag of Words (CBOW) and Skip-gram. The CBOW architecture was chosen because of its fast computation time. CBOW targets to predict the current word based on the context. Our strategy is to train the word vectors on the whole corpus of the fall incident report narratives under CBOW architecture using negative sampling. Other hyperparameters were selected based on the optimal choice set from Google news [4]. Then we take an average of word embeddings of all the words appearing in the given document as the document's representation. Finally, we applied Ward's agglomerative hierarchical clustering algorithm with Euclidean distance to cluster the reports. The optimal number of clusters was determined by majority vote of indices in R package NbClust [5].

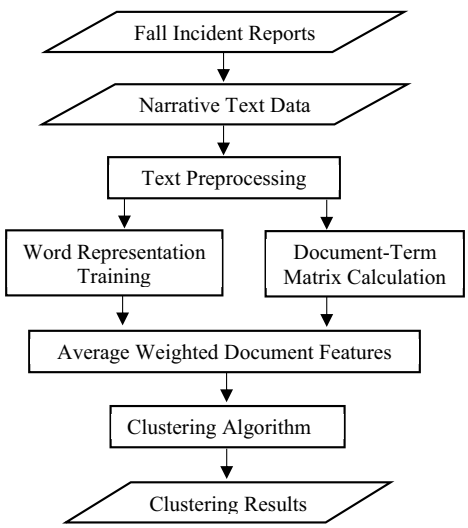

Figure 1– Text clustering procedure

Results

To evaluate our cluster results statistically, we compared the characteristics of the incidents in each cluster and the result is shown in Table 1. The patient sex, reporting departments, and severity levels in different groups are significantly different under the 0.05 significance level. Furthermore, we selected the top 15 TF-IDF words in each cluster's corpus as the characteristic words to represent the content. These keywords are presented in Table 2. From the top TF-IDF terms, it is more likely to reveal the action taken and type of injuries from the plain description text. Based on the current clustering outcome, we cannot make a conclusive catalogue over other pre-specific fall types frameworks. This may be due to the fact that the nature and mechanism of fall are still hidden under our current level of text analysis.

Table 1– Characteristic Words in Different Clusters

Cluster 1	wife, bridg(e), carri(ed), houseoffic(er), lobe, rehabilit(ation), lacer(ated), befor(e), accid(dentally), bone, ent(erance), similar
Cluster 2	Furnitur(e), LT(OT), resid(ent), educ(ate), circumstanti(al), ground, appar(ant), temp, nil, arm, elbow, madam, hrs, befor(e), ca, qud, toe, miss
Cluster 3	Hemorrhag(e), educ(ate), dress(ed), lacer(ated), CA, neurosurger(y), event, haemorrhag(e), shown, gc(s), hematoma, NS, shift, multipl(e), ST, befor(e), film, remind, effect, gauz(e), pleural, stitch
Cluster 4	Radiograp(h), cot, wait, therapist, nil, DMO, ISS, read, geriatr(ic), sustain, rehab, appar(ant), intend, stretcher, final, mang(ement), tri, bus, HDU, lift, occup(y)
Cluster 5	row, april, leg, rib, transfus(ion), bedpan, wait, film, necessar(y), physiotherapi(st), husband, Rt(right), wrist, current, react, sever(e)

Conclusion

This work contributes to quantitative research using text mining methods on the fall incident reports analysis and demonstrates a way to partition a large pool of incident reports based on the semantic use and identify characteristic groups automatically for the retrospective study. We plan to further explore improvement by pre-training word representation on other large open source fall incident related text sources, using other unsupervised machine learning methods, and trying different parts of text datasets as our corpus. The reports of resulting groups will be further reviewed by clinical experts to confirm the meaningful patterns in the group of falls.

Abstract

Secondary use of electronic health record (EHR) data requires a detailed description of metadata, especially when data collection and data re-use are organizationally and technically far apart. This paper describes the concept of the SMITH consortium that includes conventions, processes, and tools for describing and managing metadata using common standards for semantic interoperability. It deals in particular with the chain of processing steps of data from existing information systems and provides an overview of the planned use of metadata, medical terminologies, and semantic services in the consortium.

Keywords:

Metadata, Information Systems, Health Information Interoperability

Introduction

The re-use of clinical data for research purposes has been an active field of medical informatics for a long time [1-2], but recent developments such as Fast Healthcare Interoperability Resources (FHIR) and machine learning enable new levels of interoperability between sites and more sophisticated ways of phenotyping. In 2018, Germany launched a major project called the Medical Informatics Initiative to make such data available for research [3]. To this end, all university hospitals have joined one of the four consortia that want to meet this goal with different technical approaches. The main objective of the initiative is to make patient data from clinical care available for biomedical research in new organizational units to be set up called Data Integration Center (DIC) in every participating site. One of the consortia is *SMITH* [4].

Methods

In the area of data exchange, SMITH focuses on the HL7 Clinical Document Architecture (CDA) standard for clinical documents and FHIR for individual medical data points as well as appropriate profiles from Integrating the Healthcare Enterprise (IHE). Information systems supporting these standards are referred to as type A data sources (see Figure 1). However, many existing systems in hospitals cannot directly support these standards and their data need to be transformed. Type B sources export data in standard formats such as HL7, DICOM etc., but need data transformations for a unified data exchange. Finally, type C sources are proprietary such as data provided by CSV files or arbitrary SQL databases. Metadata Services that can semantically describe captured medical data are therefore essential for data curation, analysis, and sharing.

Results

The SMITH Consortium will provide Metadata Services to promote secondary use of clinical and research data not only between the DICs but also with other data providers. First, barriers between “data consumers” and “data providers” will be lowered by promoting user-friendly services to discover, interpret, and provide access to data. Second, consortium members will be provided with means to improve metadata quality and reusability of shared data. In line with the FAIR (Findable, Accessible, Interoperable, Reusable) data principles [5] developed for sharing research data, the services provided will guide DIC and external data providers to generate metadata, annotate the shared data, define access rights and protocols, integrate heterogeneous data models, and eventually support discoverability and reusability of data. Following subsections will outline required infrastructure and processes to comply with the FAIR principles, including metadata capturing and management, quality-driven metadata improvements through curation on every site in the consortium as well as metadata harmonization (e.g., naming, coding scheme) across different sites.

Metadata Capturing and Management

A Metadata Repository (MDR) is a system that describes the syntax and semantics of each data element representing the clinical facts (data points). In SMITH, we will establish a MDR at each site, i.e., in Aachen, Jena, and Leipzig. Each local MDR will manage metadata according to the clinical information systems available at each site. Additionally, a consortia-level MDR will be established to facilitate central metadata interoperability. The consortia-level MDR will provide persistent identifier (PI) services for identifiable data and metadata, as well as cross-site metadata harmonization and query services (API). Figure 1 illustrates the set-up and metadata-related components relevant to each site and across all the sites, and their relationship to the planned national metadata services. A major step before metadata are uniformly managed by a dedicated MDR is to capture relevant metadata and import them into the MDR. While some clinical information systems store metadata inherently so that they can

be extracted automatically, transformed, and then loaded to the MDR, in other cases only a portion or none of the necessary metadata are electronically available. The proposed connectors will read available metadata wherever possible. For all other cases, standardized manual metadata capturing processes will be established. The Raw Metadata component stores all the metadata as submitted by the Metadata Capturing Service within the DIC. In order to enable querying and subscription services, the metadata need to be mapped and aligned, after which they are stored in the Aligned Metadata component taking provenance aspects into account. Currently, querying and subscription services use this aligned metadata storage. In the Consortium-Level MDR, this step is replaced by a Metadata Harmonization component, which ensures that metadata are compatible across sites.

Metadata Curation

The SMITH metadata curation and harmonization services will define a process to harmonize common metadata elements from each site by creating descriptive metadata at both document and data element levels including semantic, technical, and provenance metadata. Varying coding schemes and vocabularies will be semantically annotated, mapped, and harmonized using the tools and algorithms developed. A quality management process will be set up to ensure better metadata quality at the metadata entry stage by applying terminology management and semantic data validity checks.

Terminology and Ontology Service

We will set up terminology services to provide detailed representation of conceptual entities. This includes browsing using terminologies, displaying concepts, facetted searching in terminologies, and exporting. We will import standard terminologies for coded medical data such as ICD-10-GM (diagnoses), OPS (procedures, modified version of ICPM), LOINC (laboratory), ATC/DDD (pharmaceutical agents); UCUM (measurement units); terminologies and ontologies used for text mining and phenotyping such as MeSH, UMLS, or HPO; and also local vocabularies used in a DIC. The use of SNOMED-CT is being prepared as this terminology would cover many topics (e.g., pathogen/microbiology), but its use depends on acquisition of a license. Furthermore, new vocabularies and concepts can be created and mapped to terminologies to facilitate use of core data sets. The terminology services will be accessible through a graphical user interface as well as via a ReST API.

Conclusions

We expect that the concept outlined here will be powerful enough to map the heterogeneous health information technology landscape and processes in university hospitals in Germany, along with the integration of other partners such as non-university hospitals, general practitioners, data from epidemiological studies, health insurance companies, and patient-reported outcomes.

Characterizing the Scope of Exposome Research Through Topic Modeling and Ontology Analysis

Guillermo Lopez-Campos[a,b], Philip Kiossoglou[b], Ann Borda[b], Christopher Hawthorne[a], Kathleen Gray[b,c], Karin Verspoor[b,c]

[c] *School of Computing and Information Systems, The University of Melbourne, Parkville, Victoria, Australia*

Abstract

Exposomics is a field of research which is receiving growing attention. In this work, we characterize the exposome research landscape and update our previous study of formal knowledge representation approaches to this field. We applied a deductive analysis using the National Center for Biomedical Ontology Recommender for comparability of the results generated from a literature dataset and newly available ontologies with our previously published work. We highlight the changes in ontology recommendations.

Keywords:

Biomedical Ontologies, Data Mining, Environmental Exposure, Publications

Introduction

Environmental factors and exposures remain the major risk factors for most diseases and certainly for those that are a major burden for the health system. The concept of the *exposome* was introduced in 2005 when C.P. Wild coined the term, defining it as an exposure-oriented analogue of the genome [1]. The concept has since gained significant attention, particularly with the recent establishment of several large research collaborations and because of the demonstrated relevance to the new paradigm of "precision medicine" [2].

The increasing corpus of literature focused on the exposome provides opportunities to characterize the breadth of the field. As an interdisciplinary and evolving field, exposome research covers a broad range of topics and methodologies that could be related to different areas such as public health and biomarker detection.

Formal knowledge representation is an important tool for organization of information in many different areas and disciplines. The exposome poses complex challenges for biomedical informatics and requires the adaptation and development of suitable methods and tools [3]. Knowledge representation methods, such as ontologies, have also significantly supported "omics" research; examples of well-adopted informatics tools include the Gene Ontology [4] and the Human Phenotype Ontology, both of which provide formal vocabularies and represent relationships among concepts within these vocabularies.

In an associated work on which we base this study [5], we proposed a methodology to characterize this evolving exposome landscape.

The deductive analysis approach of the prior work used the National Center for Biomedical Ontology (NCBO) Recommender [6], which allowed for contextualization of current formal knowledge representation of the exposome. However, only a small portion of the overall recommended ontologies could be deemed as broadly useful in the field of exposome research at that point. Importantly, the results showed that none of the frequently recommended ontologies had major associations with the science of environment or exposures, suggesting that there was a need to bridge interdisciplinary research gaps to build knowledge in this field.

This study seeks to re-apply our previously developed deductive analysis to analyze the evolution of knowledge representation tools covering exposome research, as well as to ensure comparability with new publication results, indicated by the growth of the corpus of exposome literature, which has more than doubled in the last two years (2017-2018).

Methods

We analyzed the recommended ontologies using an expanded dataset of papers up to October 2018. The new dataset used a similar search strategy to our previous work [5]. Briefly, we considered papers published between January 2005 and October 2018 with the term "exposom*" in the title, abstract or keyword fields.

The abstracts from the retrieved documents were subsequently submitted for ontology recommendation using the NCBO Ontology Recommender tool API. Default parameters were used to ensure the comparability of the results generated using the literature dataset up to 2018 and the new ontologies, with those previously published.

For topic modeling, we used the R package "text2vec" (v0.5.1) on the subset of documents that contain the word exposome in their abstract.

Results

The results from the ontology analyses using NCBO's Ontology Recommender for the search 2005-2018 resulted in the identification of 171 ontologies for 2018 and 165 for 2016. Of those just 20 ontologies were present in more than 50% of the documents (50 ORF – ontology recommended fraction). The comparison of these ontologies with the results previously published shows that there is a significant overlap among the ontologies recommended for the three datasets in Table 1.

To identify the number of topics we used the R library "LDATuning" determining the presence of 25 topics, based on a balance among different criteria.

Table 1 – List of Ontologies Recommended with ORF >50 in 2016 and in 2018.

Shared 2016 & 2018		Found in 2018	Found in 2016
NCIT	EFO	IOBC	SNMI
SNOMEDCT	CRISP	CHEAR	RH-MESH
MESH	HL7	GO-EXT	
LOINC	NDFRT	MEDDRA	
HUPSON	EDAM	NBO	
ONTOAD	GO		
NIFSTD	RCD		
MEDLINEPLUS			

Discussion

Deductive analyses using the knowledge representation tools led to the identification of 171 recommended ontologies for the 2018 dataset of documents, in comparison with 165 ontologies identified in 2016. The differences between the 2016 and 2018 recommendations are slightly reduced after applying the ORF >50 threshold.

However, there are five differences in the ontologies that fulfill the requirement of being recommended for at least 50% of the documents that appear as significant in the 2018 analyses. Among these five newly identified ontologies it is important to note that three of them, NBO (Neurobehaviour Ontology), MEDDRA (Medical Dictionary for Regulatory Activities Terminology) and GO-EXT (Gene Ontology Extension), were present in the 2016 results but did not reach the significance threshold of ORF >50 at that time. In the most recent analysis, these three have jumped to be recommended for around 60% of the documents. This change was more relevant for NBO which experienced a nearly 50% increase in its recommendations (from 41% to 62% of the documents). In terms of the recommendation ranking, MEDDRA did not change its average recommendation position (a corrected average of 20.5) whereas in the case of GO-EXT it improved its ranking in three positions, from an average corrected rank of 20.7 to 18.7. Similarly NBO's rank improved from 22.3 to 19.5.

These changes in the recommended ontologies can be explained by the update of existing technologies and by an expansion of the exposome research in areas already covered by the ontologies that led them to be deemed as significant.

The other two newly recommended ontologies CHEAR (Children's Health Exposure Analysis Resource) [7] and IOBC (Interlinking Ontology for Biological Concepts) are recently developed and cover important aspects related to the exposome. CHEAR has been recommended for 64% of the documents. This resource was developed for the analysis of environmental exposures in an "exposome context" and therefore it could be considered as an "authentic" exposome ontology. IOBC is a recently developed ontology containing both biological concepts and earth and environmental sciences concepts.

Conclusions

Exposomics research and literature have doubled over the last two years. This increment reflects the increasing relevance of the field. Analysis of the recommended ontologies that could potentially be used to annotate or model exposome research still shows that broad and general tools such as National Cancer Institute Thesaurus (NCIT), Systematized Nomenclature of Medicine - Clinical Terms (SNOMED CT), Medical Subject Headings (MESH), and Logical Observation Identifiers Names and Codes (LOINC) would cover aspects of all the documents. However, in the last couple of years, CHEAR and IOBC have emerged as two new and promising tools to describe the knowledge around the exposome more formally.

Using Enriched Samples for Semi-Automated Vocabulary Expansion to Identify Rare Events in Clinical Text: Sexual Orientation as a Use Case

Kristine E Lynch[a,b], Patrick Alba[a,b], Benjamin Viernes[a,b], Scott L DuVall[a,b]

[a]*VA Informatics and Computing Infrastructure, Department of Veterans Affairs, Salt Lake City, UT, USA,*
[b]*Department of Internal Medicine, Division of Epidemiology, University of Utah, Salt Lake City, UT, USA*

Abstract

We demonstrate the utility of concept lexicon expansion and evaluation using enriched samples of patients and documents with sexual orientation as a use case for rare event detection in electronic medical records. Using this approach, we found 7 additional words and 21 misspellings beyond our initial set of five seed words. We can use the expanded vocabulary to further develop a full natural language processing system to identify instances where sexual orientation is documented.

Keywords:

Natural Language Processing, Electronic Health Records

Introduction

Finding instances of rare events in medical notes with natural language processing (NLP) can be challenging. When the goal of a study is to identify all patients who have experienced an event, a concept lexicon with contextual diversity and widespread coverage is sine qua non. Survey research often deliberately oversamples racial, ethnic and other minority groups to attain adequate numbers to make meaningful comparisons [1]. In a similar fashion, sampling from document groups that, based on a priori knowledge are likely to have a higher proportion of mentions than other groups, can help discover and evaluate terms that may have otherwise been overlooked. We explore sexual orientation documentation in the Department of Veterans Affairs' (VA) electronic health record (EHR) as a motivating example.

Sexual orientation documentation is expected to be a rare occurrence in VA. Based on estimates of active military (2.8% of all military personnel are homosexual [2]) and estimates of Veteran disclosure rates (30% [3] to 80% [4]), we expect to discover 71,400 to 190,400 of the 8,500,000 total Veterans with an outpatient visit in VA in the last 18 years to have at least one mention of lesbian, gay, or bisexual (LGB) status in the EHR. Documentation of sexual orientation is not representative of all LGB Veterans nor all who have disclosed to a provider. Rather, documentation is evidence that information about sexual orientation was exchanged either through patient or provider initiated communication and the provider felt it relevant enough to the patient's health to record it in the EHR. Failure to assess and document sexual orientation status of patients can contribute to the perpetuation of health inequalities that LGB Veterans may face compared to their heterosexual counterparts. Understanding the extent to which documentation occurs is therefore important, but unlike age and race, sexual orientation is not formally incorporated into the EHR of most healthcare systems as a structured demographic field. Consequentially, the only place to find documentation of sexual orientation is in providers' medical notes.

A common way that NLP is used in EHR research is to supplement variables for a study population that has been formerly defined using structured data, such as administrative codes. Correspondingly, only a small subset of potentially relevant documents is required to be processed. Administrative codes do not exist for sexual orientation as they do for gender identity disorder, for example, which can be used to identify a subset of transgender patients and aid in the search of transgender words or phrases [5], so an NLP assisted approach was needed to build our vocabulary. In this study, we describe our strategy for developing a representative sexual orientation lexicon among unstructured text of clinical notes of the VA EHR. This work forms the bedrock for a future, validated NLP system to be used in health disparity research.

Methods

Data Source

The VA is the largest integrated healthcare delivery network in the United States, capturing healthcare information from patients across all medical specialities with broad geographical coverage. The VA's Corporate Data Warehouse (CDW) is a nationwide repository with historical data dating back to October 1, 1999, including patient encounters, pharmacy, lab/chemistry, microbiology, vital sign, and radiology related data. For the present study, we evaluated clinical notes from the CDW from 2000-2017 for patients enrolled in VA after 2000 with a record of at least one outpatient visit (~8.5 million Veterans). This study was approved by the University of Utah's Institutional Review Board.

Vocabulary Expansion

Our LGB vocabulary started with an initial set of five seed terms (lesbian, gay, homosexual, LGBT, and bisexual). We used a combination of four approaches to expand our word set. First, we manually reviewed LGBT health literature and added any words thought to be relevant. Second, we used a full text index built in the Microsoft SQL Server instance storing clinical notes to find terms within an edit distance of 3 from any of the five initial terms that had at least 100 instances. Third, we conducted an analysis of bigrams and trigrams that surrounded the original 5 terms to determine frequently occurring terms in the same immediate context [6]. A search was done using these terms to see if any other similar terms existed in the same context. Lastly, we used a lexicon discovery tool [7] implemented with an Ipython Jupyter Notebook to automatically find semantically and lexically similar words from a corpus to words from the initial term set. The tool uses a combination of word embeddings, a mathematical representation of the context in which a string is used and edit distance. The settings for the tool were set to a cosine similarity threshold of 0.75 and a maximum edit distance threshold of 3.

Terms at or above the threshold were reviewed for inclusion in our vocabulary.

We applied the lexicon discovery tool to a random set of documents and from patients hypothesized to have a high volume of sexual orientation documentation relative to other groups (i.e., enriched samples). We evaluated documents from patients diagnosed with Human Immunodeficiency Virus (HIV,) according to International Classification of Disease diagnostic codes. It is estimated that 68% of newly diagnosed HIV patients are homosexuals.

From each of the two cohorts, 1,000 random documents containing each of the five initial terms were processed (5,000 documents per cohort). We manually reviewed the output from the four different approaches for additional potentially relevant terms. We processed every document from all patients in our sample and the entire HIV cohort separately. We used cumulative binomial probabilities $\sum_{k=0}^{n} \binom{n}{k} x^k p^{n-k}$, to determine the probability of getting x or more patients without documentation given a hypothesized background rate of no documentation. In this equation n = number of HIV patients, k = number of patients without documentation, and p = estimated background documentation rate. In other words, we compared the proportion of observed patients without keywords to the proportion expected in to determine if additional keywords were potentially needed. Expected background rate in this context refers to the number of patients that would have sexual orientation documented had the rates of sexual orientation and disclosure been equal to documented prevalence. For example, if we assumed that 68% of HIV patients are homosexual, 60% disclose and 90% that disclose are documented we expect to see ≥36% of the HIV cohort with ≥1 keyword (64% without a keyword). Vocabulary expansion is the first of multiple steps needed to develop and deploy an accurate NLP system. As we formally incorporate exclusionary rules that consider surrounding context the number of relative instances of LGB will decrease. Assuming an accurate background rate, observing more patients without documentation than expected, may indicate that our vocabulary is inadequate and additional work is needed.

Results

Our initial set of five keywords was found among 441,870 of the 8.5 million patients across 1,100,737 documents. The literature review added 6 terms (His husband, Her wife, His boyfriend, Her girlfriend, Queer, and Same-sex). The full text index search identified 8 misspellings and 1 additional term. We assessed five bigrams/trigrams ("sexuality:", "sexual preference:", "orientation:", "identifies as", "came out as") and no additional terms were found. The lexicon discovery tool identified 11 misspellings and 5 new terms, of which one was also found in the literature review (same-sex) and the full text index search (lesbianism). Our final vocabulary consisted of 28 distinct words including misspellings. A sample list of the most common terms is presented in Table 1.

We found 28,437 patients with a diagnosis of HIV. Before including additional terms found through our four approaches we found 11,550 patients (126,559 documents) of the HIV cohort with at least one instance of any of the five initial keywords. After re-processing using our expanded list of new and misspelled terms, the number of HIV patients with a keyword increased to 12,051 patients (42%) across 146,689 documents. Assuming 64% Veterans diagnosed with HIV will not have LGB documentation, the probability of getting 58% of HIV patients without documentation in a sample of 28,437 is 0.98, suggesting that our vocabulary is an adequate starting point.

After all documents from the 8.5 million Veterans were passed through the entire expanded vocabulary, we identified an additional 19,543 (+4.4%) and 49,716 (+4.5%) potentially relevant patients and documents, respectively, beyond what was found with the initial five term set.

Conclusions

We demonstrate that using enriched cohorts is advantageous for two reasons. First, the approach resulted in an expanded vocabulary that identifies additional patients and documents that may be relevant but otherwise been overlooked. Second, enriched cohorts can lend insight into whether the vocabulary will capture all instances of the event by comparing observed rates to expected rates. We will use the expanded vocabulary to further develop a validated NLP system to identify instances where sexual orientation is documented. We demonstrated our approach using sexual orientation documentation, but it can be tailored to any scenario in which instances are expected to be rare and precise structured data is unavailable to aid the construction of a comprehensive concept lexicon.

Table 1. Keywords by document and patient count

Rank	Keyword	Document count	Patient count
1	Gay	708,341	292,726
2	Bisexual	270,866	167,589
3	Homosexual	240,585	139,970
4	Lesbian	151,151	87,939
5	LGBT	58,734	15,274
6	Same-sex	37,637	12,622
7	LGB	26,789	12,476
8	Queer	8,584	3,992
9	Homosexual-lesbian	3,668	8,014
10	Homosexual-gay	684	759

A Cross-Lingual Effort Towards Managing English-Chinese Cancer Education Resources

Hetong Ma[a], Jiansong Ren[b], Xuwen Wang[a], An Fang[a], Jiao Li[a], Qing Qian[a]

[a] *Institute of Medical Information/Library, Chinese Academy of Medical Sciences/Peking Union Medical College, Beijing, China*
[b] *National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences/Peking Union Medical College, Beijing, China*

Abstract

As translated education resource plays an important role in healthcare providers' training and medical knowledge dissemination, we proposed a method to manage cross-lingual education resources with the goal of facilitating the medical education and physician training. We created an English-Chinese cancer knowledge base including bilingual description on cancer diagnosis, prevention, screening, treatments, etc. We developed a workflow to create the bilingual corpus, and applied it to six cancer monographs in PDQ (Physician Data Query).

Keywords:

Cancer education resource, Cross language, Parallel corpus

Introduction

Multi-lingual resources promote knowledge dissemination and communication. Many efforts have been made for the construction from expert translation, machine translation, crowd-sourcing (e.g., Wikipedia [1]), etc. In this field, literatures are still mainly recorded in English, however, health professionals often need to learn those written in native languages. Local languages are most common with least difficulty, which will naturally lead to the highly requirement of processing and transformation among various languages. Since manual translation will not meet the requirements of mass data, automatic machine translation will be an irresistible trend.

Based on multi-languages similarities and ambiguities, an acceptable translation is supposed to be both correct with analyzing and generating, and to be humanlike where a great amount of processing and understanding are completed [2]. Still, medical field can be much different for its own professional knowledge, which may lead to higher-level difficulty, and may require a better quality of translation where high-quality parallel corpus are intensely needed. A good parallel corpus has high demand for content, either in specific realm or aligned pattern.

In this paper, we constructed an English-Chinese cancer parallel corpus using Physician Data Query (PDQ). Up to now, no English-Chinese parallel corpus of cancer subject in the same type has been established yet, which is quite substantial for data collection, analysis, and dissemination. We used the Physician Data Query (PDQ) as the original corpus, which was NCI's comprehensive source of cancer information, for its authoritativeness, specialty and leading role in cancer information. For better reuse and redistribution of PDQ information, NCI encourages the translation in different language. As Chinese translated version of PDQ was rigorously translated by experienced clinicians and experts in both Chinese and English in a recognized cancer hospital, responsible for cancer patients, the dataset was greatly precious for its golden standard. The format of original data is XML, which is open accessible. PDQ English version (PDQ_{EN}) describes information ranged from cancer, drug, genetic terms, and other related knowledge [3] with its own presence entrance, so is the Chinese version (PDQ_{CH}) [4]. Since the corpora was translated at different time, in this paper, The PDQ_{EN} and PDQ_{CH} we use were from 2013 edited in XML.

We selected education monographs related to six cancers as our data set, including liver cancer, colorectal cancer, breast cancer, lung cancer, stomach cancer and esophageal cancer. Inside these cancers, there were various themes including prevention, screening, diagnosis and treatment. In this corpus, there were 22 pairs of file, each containing different content from others, either in cancer type or in cancer theme. Every file in PDQ was stored in XML format structure, which had many elements embedded in other elements. The total numbers of English sentences, Chinese sentences, English words, Chinese words are respectively 22091, 12365, 291095, and 170688.

Despite PDQ_{CH} came from manual translation of PDQ_{EN}, layers, elements and even the whole structure were not always the same. Some of translation were lost, some paragraphs had not yet been translated, and some elements had been deleted from PDQ_{CH}, which led to a major difficulty when trying to make the corpus parallel. Nesting elements are quite common in original corpus, while there was only one element possessing ID that can help with the alignment and location of two corpus. The other great difficulty was that appearance times of the same element can be quite different, thus, we could not make sure which two paragraphs or sentences should be aligned.

Methods

Following the framework shown in Figure 1, the construction contained three stages: cancer resource parsing, data processing and parallel corpus release. In the first stage, we examined the similarities and differences of the two PDQ corpora in structure features and possible alignment anchors. Next come to the

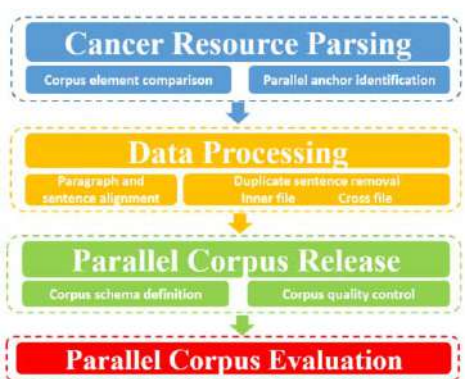

Figure 1 – The Workflow of Parallel Corpus Construction.

second stage where extraction of content in elements that occur in both corpora were completed, which brought a large amount of paragraphs. It was followed by the alignment strategies setting, alignment of paragraphs and sentences, and duplicate sentence removal. Then it enters into the third stage where we defined the corpus schema, controlled the corpus quality and evaluated the corpus.

We set a rule that text should be classified into words, phrases, and sentences. Words were mostly professional terms that could help us just like a dictionary. Phrases were not same with sentences, they had smaller numbers of words and may not expressed an integrated meaning. The rule could be summarized through length, those with 1-2 words should be sorted into 'Word', those with 3-7 words should be sorted to 'Phrase', and those over 7 words should be sorted to 'Sentence'.

We used the sentence alignment ratio as a metric to evaluate the parallel corpus quality. To ensure the quality of our corpus, we mannualy assessed the corpus sentence by sentence. The criteria could be categorized as: correct, incorrect and partially correct, where partially correct means one sentence was partially aligned to the counterpart but still there was some part unaligned. The evaluation formula is as follows, where α, β, and γ respectively represent the numbers of correct, partially correct, and incorrect alignments:

$$\text{Ratio} = 100\% * \frac{\alpha + 0.5 * \beta + 0 * \gamma}{\alpha + \beta + \gamma}$$

Results

We constructed the parallel corpus where PDQ_{EN} and PDQ_{CH} were separated apart but combined with the same ID. It formed a 23-pair parallel corpus focused on medical cancer information with words, phrases and sentences. Finally, we constructed a parallel corpus of 7188 pairs consisting of 514 words, 1236 phrases and 5438 sentences involving information of six cancers and 23 detailed groups including the newly-created group. The whole corpus contained 7026 one-to-one corpus pairs, 160 one-to-many corpus pairs and two many-to-many corpus pairs. The statistics was shown in Figure 2. After checking, the number of partially correct alignments is 47 and the number of incorrect alignments is 23, where we could get the alignment ratio 99.35%.

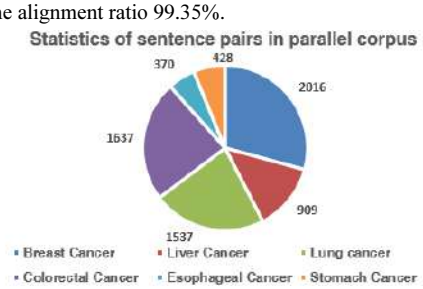

Figure 2 – Statistics of Sentence Pairs in English-Chinese PDQ Parallel Corpus.

Discussion

This corpus was constructed to provide the original prerequisite resouce data for real medical needs not limited to as follows:

Decision Making

Staff like medical researchers and doctors need an updated, authorized, and reliable medical knowledge base on cancer to efficiently assist them with decision making and problem solving.

Knowledge Dissemination

More people and patients are eager to learn professional knowledge about cancer, a knowledge base with cancer theme can satisfy these needs, and can help public education.

Cross-lingual Scenario

Parallel corpus, as a prerequisite resource, can help with machine reading, machine translation and machine understanding, which exactly matches the crucial requirement of those using different languages such as Chinese.

Conclusion

To help medical domain machine reading, understanding, and generating for possible smart question and answering systems, we have created a cancer focused multilingual parallel corpus of 7,188 pairs using the peculiar XML corpus, containing 5,438 pairs of English-Chinese sentences, 1,236 pairs of phrases and 514 pairs of words involving information of six cancers and 23 detailed groups through steps of corpus research, data processing, and corpus construction, which can be clarified into comparison between elements, analysis on parallel anchor, element alignment, sentence splitting, sentence alignment, design and analysis on data processing steps, design of parallel corpus construction strategy, and the final evaluation for the whole corpus.

In summary, the corpus we constructed is a deep-level knowledge Chinese-English corpus on medical domain, specifically, cancer information. General corpus is mostly sentence-level, we decided to make it a hybrid. To our knowledge, there is no similar or comparable resource like the corpus we presented in this paper. Our future work will keep on deeper research of better applications including machine translation on cancer knowledge, automatic information retrieval to achieve automatic update, automatic question and answer system based on this corpus.

eHOP Clinical Data Warehouse: From a Prototype to the Creation of an Inter-Regional Clinical Data Centers Network

Julia Madec, Guillaume Bouzillé, Christine Riou, Pascal Van Hille, Christian Merour, Marie-Lisen Artigny, Denis Delamarre, Veronique Raimbert, Pierre Lemordant , Marc Cuggia

Univ Rennes, CHU Rennes, Inserm, LTSI – UMR 1099, F-35000 Rennes, France

Abstract

Creation of networks such as clinical data centers within the hospital enables efficient exploitation of clinical data from a local to an inter-regional scope. This work present the structuration of the French Western Clinical Data Center Network (FWCDCN) conducted between 2016 and 2018. As of November 2018, FWCDCD is compounded with 7 institutions. CDW of the combinded Clinical Data Centers (CDC) contains the data of over 4 million patients followed since 2000.

Keywords:
Clinical Data Warehouse, Health Information System, Health Big Data

Introduction

Among strategic data sets, those produced at the hospital during patient care are already bringing new knowledge and technological innovations, from whom society and patients will benefit [1].

A CDC is an organization dedicated to exploit health bigdata for the hospital. The main IT infrastructure of a CDC relies on a cutting edge Clinical Data Warehouse technology called eHOP, developed by the academic hospital of Rennes.

The deployment of a such system in hospital institutions supposes to set up 3 main works: technical, functional and organizational.

Methods

Technical work

eHOP is an indoor development of Rennes University Hospital, using up-to-date technologies and compatible to the open-source platforms such as i2b2 and SHRINE

The system encompasses:

- Libraries : R
- Database management system : Oracle & MySQL
- Web servers used : Apache PHP (application server) and Java (database server)
- ETL : ENOVACOM Suite V2
- Interoperability standards : HL7, HPRIM, PN13, RSS
- Reference terminologies and mapping managed from UMLS

Functional work

Data flows have been chosen by each institution among all the data sources provided by the hospital (biology, drugs…). Data flows regarding the patient master index and hospital structures were mandatory to enable any clinical data flows .

Data integration procedures were the following :

- Real-time data integration : batches of dataset
- Takeover of the existing system

Every center has set up the request circuit with user and profile management. eHOP is only accessible on the center internal network from a web browser. Access is secured using the HTTPS protocol and traceability of requests and studies is ensured.

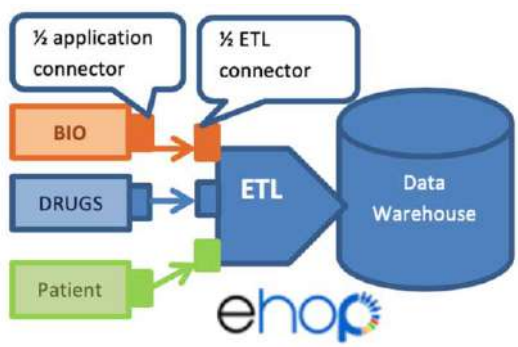

Figure 1 - eHOP data integration process

Organizational work

This work contents :

- CNIL (the French supervisory authority) formalities
- Reglementary procedure : patient information, patient opposition, user charters…
- Human resources assignation for project
- Creation of the corresponding structures :
- An administrative structure to set up strategic orientations of the CDC

- A regulatory structure to validate the access and exploitation policy of the CDW
- An operational structure for data processing. It undertakes to respect the following principles:
- Neutrality: No particular interest in the exploitation of data
- Confidentiality - Security: Exclusive and secure access to all (sensitive) data entrusted to it.
- Transparency: Carries out processing operations only if they are subject to agreement with the organizations and actors providing the data.
- Multidisciplinary medical (Methodological, IT and statistical), regulatory (Data Protection) and technical expertise.

eHOP CDW projects typologies

- **Non-interventional data research**: ex : epidemiological studies
- **Vigilance studies:** ex: therapeutic follow-up in real life
- **Support to health professionals**: ex: assistance in signal interpretation
- **Evaluation of practices**: ex: analysis of health trajectories

Results

The FWCDCN is now compounded with the following institutions : Angers University Hospital, Brest Regional University Hospital, West Cancerology Institute, Nantes University Hospital, Poitiers University Hospital, Rennes University Hospital, Tours University Hospital.

These institutions represent almost 4 million hospitalizations and consultations per year, with a total of 13 000 beds and a budget of almost 4 m€.

Table 1– eHOP documents by flows (mn) with historical depth-example of Rennes University Hospital (as of November 14, 2018)

Type of data flow	2010	2015	2018
medical surveys	-	1.1	3.5
PMSI	2.7	6.3	7.1
emergency report	0.3	0.7	1.8
medical report & doc	0.6	2.6	6.1
biology	0.4	4.9	8.3
anapath	0.1	0.2	0.3
drugs	-	1.2	22.1
Total	4.1	17	49.2

Conclusions

The FWCDCN structuring network makes it possible to share both an organizational model and good practices for the exploitation of data, and innovative tools designed to accelerate research. It creates the conditions to integrate and securely exploit other data sources such as registers epidemiological, administrative database data, and connected objects.

The main objective for the network for 2019 will be to position itself as a local node for the French national Health Data Hub.

Table 2– aggregated content of FWCDCN (as of November 14, 2018)

Historical Depth	Number of patients (mn)	Number of documents (mn)	Number of structured data (mn)
2000	0.1	-	-
2006	0.7	3	16
2009	1.4	12	109
2015	3.1	57	610
2018	4.3	102	1067

Medical Equipment Replacement Prioritisation: A Comparison Between Linear and Fuzzy System Models

Norbert Maggi[a], Antonella Adornetto[a], Stefano Scillieri[a], Ezio Nicholas Bruno Urbina[b], Carmelina Ruggiero[a], Mauro Giacomini[a]

[a] Department of Informatics, Bioengineering, Robotics and Systems engineering, DIBRIS, University of Genoa, Italy
[b] S.C. RUP - Nuovo Galliera, EO Ospedali Galliera, Genoa, Italy;

Abstract

In hospital management, health technology assessment techniques are being increasingly developed. This paper presents a comparison of the results obtained using two models for replacement priority value calculation applied to the Galliera hospital in Genoa (Italy). One the models was developed at the Galliera Hospital along the lines of the model by Fennigkoh and addresses four primary replacement issues: equipment service and support, equipment function, cost benefits and clinical efficacy, by a "yes-no" scheme. This model is compared with a model based on fuzzy logic. The comparison between the two models shows a conservative behaviour by the Galliera model, according to which 77.4% of the analysed instrumentation is maintained, whereas the classification by the fuzzy model allows for a better discrimination among the devices.

Keywords:
Fuzzy Logic, Health technology assessment model

Introduction

In the last few years, very fast health technology changes have taken place, but they have not been paralleled by progress in management. Medical equipment requires very time-consuming and costly maintenance, which makes it crucial to introduce innovative technology management strategies focused on appropriateness, efficiency and cost effectiveness. Many health technology assessment (HTA) procedure have been proposed, often identifying mathematical models which require mostly subjective parameters. Many hospitals are carrying out research on models that objectively express obsolescence.

A linear multiparametric model for medical equipment replacement has been proposed by Fennigkoh [3]. This model can be adapted to each specific hospital by changes in the parameters and has often been used. A model based on this approach has been developed for the Busto Arsizio hospital (Northern Italy) [2] and has subsequently been adapted to meet the needs of the Galliera hospital in Genoa (Italy). Subsequently, a model based on fuzzy logic has been developed. A comparison of the two models is presented.

Methods

The model based on the Fennigkoh approach follows the one which has been adopted by Caimmi et al. [2] for the Busto Arsizio hospital, but it is simpler. In the first place some difficulties deriving from the retrieval of data such as maintenance cost for individual devices have been avoided. Secondly, the model by Fennigkoh requires choices as to which parameters should be regarded as relevant for decisions about substitutions. In this respect, some of these choices may not be generally valid and may not be the most appropriate in different contexts. Moreover, obtaining subjective opinion of medical users about the equipment in use and/or to be purchased is difficult. Therefore, the procedure for calculating the replacement priority value (RPV) has been divided into two phases. In the first phase (RPV1) only objective parameters are considered – and only if they exceed a threshold. Subjective data are considered in the second phase (RPV2). This allows to reduce the overall workload and the dependence on subjective factors. RPV2 is calculated only if RPV1 is above a predetermined threshold.

The following parameters have been taken into account.

- Age (x_1) – It is calculated by the following

$$x_1 = \begin{cases} 0, & if \ \dfrac{\text{current year} - \text{year of purchase}}{\text{functional age}} < 0 \\ 1, & otherwise \end{cases} \quad (1)$$

identifying if a device is over its functional age. The functional age is indicated by the manufacturer of the equipment and may also vary among devices belonging to the same group.
- Downtime (x_2) – A threshold value of 6 days was set up as indicated by the hospital. x_2 takes the value of 0 if it is below the threshold and 1 if it is above the threshold.
- Equipment function (x_3) – Same as in BA model (1 to 4).
- Manufacturer support, maintenance service, and availability of parts (x_4) – As in Fennigkoh's model, $x_4 = 0$ if parts, consumables, maintenance service, or manufacturer support are available or adequate (availability is guaranteed by law for 10 years after purchase); otherwise $x_4 = 1$.

RVP1 has been calculated as linear combination of these parameters according to the following

$$RPV_1 = 9(x_1 + x_2) + 7.5x_3 + 25x_4 \quad (2)$$

Ranking of the result is the same as in BA Model. Specifically: RPV1 < 40 → good conditions, no need to proceed, 40 ≤ RPV1 ≤ 60 → critical device, enter the second step, RPV1 > 60 → very critical device, replacement suggested as soon as possible. If RPV1 is between 40 and 60, it enters the second assessment phase, as in the BA model.

Fuzzy logic-based systems have been developed in hospital management only recently even though for analogue qualitative reasoning approaches has already been applied many years ago in bioengineering [1; 4; 5; 7; 8], where the problem of uncertain values of variables has similar effects. The limited availability of financial resources and of qualified personnel are among the

causes of improper and incorrect management of biomedical instrumentation. This has inspired some work [9] and the set up a fuzzy model for the classification of biomedical instrumentation according to the risk level [10]. Moreover, an inferential fuzzy model has been proposed [6].

Biomedical equipment can be classified by type of device (life support, therapeutics, diagnostics and others). Moreover, all instruments in the same class of equipment may not have the same functional age. In this respect, different fuzzy models have been produced which differ as relates to two features: rules (which allow a stricter assessment for life support or therapeutic equipment than for diagnostic or other devices) and age-related membership function. The variables that have been chosen are the same as for the GA model.

The model that has been developed is a fuzzy *mamdani* model in which preamble and conclusions are linguistic concepts (model with set of inferential rules). The model has the four variables (corresponding to the variables used in RPV1) and provides an output that suggests whether a device should be replaced. Specifically, the variable can give four suggestions: maintain, maintain over the functional age, re-evaluate (second phase), replace. The Fuzzy model presented here aims to replace the first phase of the GA model. The model has been implemented using the MATLAB Fuzzy Logic Toolbox.

For each input and output variable, the corresponding membership functions have been created. The membership functions define how each input (or output) value is mapped between 0 and 1. For each input, the degree of membership in fuzzy sets has been calculated by the application of IF-THEN type rules which have been set up on the basis of the suggestions by the Galliera Hospital. The fuzzified inputs have been applied to the antecedents: since the rules used have more than one antecedent, the AND intersection operator has been used to obtain the result of the antecedents. This operator provides the minimum degree of belonging among those present. The result of the antecedents has been applied to the function of membership of the consequent one according to the Clipping method, which simply cuts the consequent at the level of membership of the antecedent. The aggregation has allowed the unification of the consequent of all rules. The fuzzy set for the output variable has been obtained from this process. The last step is defuzzification, transforming the aggregates fuzzy set into RPV1.

Results and discussion

This work focuses on the analysis of six categories of instrumentation: electro-controlled bed for intensive care (BED), patient monitors (MON), biological refrigerators (BIR), surgical lights (SUL), ultrasound machines (USM), armchairs for therapy and blood samples (ARC). Both the GA model and the fuzzy model have been tested on the same equipment classes. Although most of the instrumentation has been analysed, for each class there is a number of biomedical equipment "not found" or for which it has not been possible to find the data necessary to calculate the RPV. The reasons for this are a number of factors, including problems in the outsourced service of management and monitoring of the technological park, difficulties in obtaining direct feedback from suppliers and/or technicians and equipment ageing.

The two models have been defined on the basis of different logics, but they do not differ greatly as relates to identification of the instrument RPV classes. The GA model has a tendency towards a more conservative behaviour, about 78.2% of the analysed instrumentation is maintained, 22% pass to the second phase of evaluation and suggests replacement only for 0.6%. The Fuzzy model suggests maintenance of the devices analysed for 70.8%. It also further specifies that 58.3% of the instruments are certainly to be maintained and that 12.6% of the instruments at this time are not a source of concern, but that their age or functional state could cause a significant increase in RPV in the future. This model also identifies the need for re-evaluation for 25.1% of the instrumentation analysed and 4% of the total recommends replacement without further evaluation.

The two largest differences between the models are found for ultrasound machines (USMs) and patient monitors (MON). Specifically, it is suggested to maintain 83.3% of the total USMs analysed according to the GA model and 58.3% according to the Fuzzy model, while for MON, the GA model identifies 36.7% of instruments to be maintained, 57.6% to be revalued and no instruments to be replaced immediately. The Fuzzy model identifies 15.1% of MON to be replaced.

At this initial stage, both models have been validated on a limited number of equipment classes. This is the basis of a much broader analysis. The Galliera Hospital showed interest in the Fuzzy model, whose results have been regarded as more satisfactory than those obtained by the GA model. Exploiting the uncertainty elements, as allowed by the fuzzy model, could be an advantage for the evaluation of the future availability of spare parts for each specific instrument.

In this respect, the Galliera Hospital intends to extend the application of the fuzzy model to the its entire technology park.

Recovery Medication from Free Text to a Structured Form

Humberto Fernán Mandirola Brieux[a], Santiago Orozco[a], Marisa Lanfranconi[a], Jorge De All[a], Nahin Chedresse[b], Sebastián Guillen[c], Alejandro Deporte[c]

[a]Sanatorio Otamendi, Buenos Aires, Argentina,
[b]Hospital Naval Puerto Belgrano (HNPB), Argentina,
[c]BIOCOM Sistemas, Argentina

Abstract

We studied methods to convert medical prescriptions in free text to a structured form for pharmacy insructions and planning nursing activities in hospitalized patients. We compared Natural Language Processing (NLP) with Parsing Process (PP), both for the Spanish language. We studied 87,750 and processed 65,000 prescriptions and recovered 62% and 65% with NLP and PP to a structured format respectively. The difference between the methods is significant ($p < 0.001$) and further work is needed to determine if combining them will have higher performance.

Keywords:

Natural Language Processing, Prescriptions, Medical Order Entry Systems

Introduction

Physicians usually prescribe medications in free text, however, computer systems need this information in a structured way to organize the data so that the pharmacy can deliver the medications and nurses can organize their tasks [1]. Computerized Provider Order Entry (CPOE) can reduce medication errors; but, its benefits are only achieved when data is entered in a structured format and entries are properly coded [2].

To process the information by computer, the system extracts the data from many fields. The system analyzes the following information: generic drug name, dose, strength, posology, route of administration, care and recommendations that are required to comply with the medication.[3].

FHIR standard (Fast Healthcare Interoperability Resources) has resources to manage pharmaceutical orders but it needs this information to be structured. Thus it is fundamental to perform the data extraction in different fields to match the FHIR interoperability standard [4].

Automated dispensing cabinets for pharmacies use HL7 and the information to construct the messages needed in a structured way [5] [6] .

A prescription is an order for medication which is dispensed to a patient. The medical prescription is not enough for the pharmacy to deliver the medication of the day to different departments. It requires prior processing so that the pharmacist knows the daily amount of each drug to deliver [7]. The pharmacist verifies the legality, safety and appropriateness of the prescription order, checks the patient medication record before dispensing the prescription (when such records are kept in the pharmacy), ensures that the quantities of medication are dispensed accurately and decides whether the medication should be handed to the patient, with appropriate counselling, by a pharmacist [8].

Even if doctors are becoming more accustomed to entering data in a structured way using CPOE, there are prescriptions in free text form that need to be processed.

Our question is: “How good can the medical prescription extraction process be when using a free text input for Spanish language?”

We studied Natural Language Processing (NLP) and Parsing Process (PP) as two possible methods to process unstructured text.

Methods

The objective of this work is to demonstrate that it is possible to recover information about medications in a structured format. Passing the narrative medical prescription through NLP is a helpful tool for doctors to better transform it in structured format for hospitalized patients.

We build the NLP routine for this study in C# .net using the Stanford CoreNLP technology tools.

The PP routine was developed by our programmers. Since the data we have uses a fixed pattern, we use the regular expression technique to extract and control its elements.

A retrospective,,observational, cross-sectional, descriptive study was designed. The sample consisted of 87,750 medical prescriptions collected consecutively during March 1th, 2017 and March 1th, 2018. The medical prescriptions were made by the institution's staff and independent external physicians who assist patients within the institution.

We used the following criteria for the study inclusion:

- Adults pharmacological prescriptions
- Singular generic drugs (for example, Losacor®", that has only one drug (Losartan) but not "Losacor D®" that has two drugs Losartan and Hydrochlorothiazide)
- Commercial names where used (for example, "Losacor®" is acceptable for Losartan)
- One prescription (100 characters per line or field) and one drug per line
- Spelling mistakes and different ways of writing each prescription elements that we analyzed

We used the following criteria for the study exclusion:

- Non-pharmacological prescriptions such as prescription for nutrition, vital signs, studies or any other type of indication that is not pharmacological.
- Pediatric medication

- Parenteral hydration plans
- Medications with more than one drug
- Multiple line medications

We included 65,000 and excluded 22,750 medical prescriptions collected consecutively with this process.The medical prescriptions that met the inclusion criteria were processed by the two algorithms.

The average age of the study population of the samples was 67 years old, with the maximum age of 96 and the minimum age of 22 years. The percentage of males participating in the study was 45.3% and the female participation was 54.7%.

In this study we tested two algorithms:

1. The PP method
2. The NLP algorithm

We considered it a success when the algorithm could complete the five fields and the pharmacist confirmed that it was correct.

Results

The results were the following: we were able to recover 62% and 65% with the NLP and the PP method respectively to a structured format that could be processed by computer systems. Please see tables 1 and 2.

The difference between the two methods was statistically significant when calculated using the Z-test with $p < 0.001$.

Table 1 – Results in Absolute Values

	NLP	PP
Correct	40,300	42,250
Incorrect	24,700	22,750

Table 2 – Results in Percentage

	NLP	PP
Correct	62%	65%
Incorrect	38%	35%

Discussion

The PP routine used the regular expression technique to extract data (i.e., narrative text or speech data) in the context of a specific task. Our results have shown that both algorithms are capable of detecting more than 60% of the medical prescriptions made with free text. However, there is a significant difference between the two methods.

The NLP method has the possibility to learn and improve over time, while the PP cannot improve by itself. It requires more expressions to be loaded by manual programming.

Conclusions

It remains to be seen if these methods can achieve higher performance in future. It is possible to make the system learn from medical prescriptions through a knowledge thesaurus. We will work to incorporate these challenges in future work.

Disseminating Research Findings: The Crowdhealth Paradigm

Andriana Magdalinou[a], John Mantas[a], Parisis Gallos [a], Lydia Montandon[b]

[a]European Federation for Medical Informatics, Lausanne, Switzerland,
[b]ATOS, Spain

Abstract

The CrowdHEALTH project intends to integrate high volumes of health-related heterogeneous data from multiple sources with the aim of supporting policy making decisions. The European Federation of Medical Informatics supports the development of an effective Communication and Collaboration Plan.A dissemination strategy has been applied for this purpose considering appropriate messages, target audience, tools, and channels to achieve the highest impact and the first results of social media dissemination are presented here.

Keywords:
Social Media, Policy Making, Intention

Introduction

The CrowdHEALTH project intends to integrate high volumes of health-related heterogeneous data from multiple sources with the aim of supporting policy-making decisions. The CrowdHEALTH is delivering a secure ICT platform that seamlessly integrates Big Data technologies, providing Data as a Service (DaaS) and a Data Analysis Toolkit. The transition from patient health records towards the Holistic Health Records (HHRs) and Social HHR is also proposed.

The European Federation of Medical Informatics (EFMI) supports the development of an effective Communication and Collaboration Plan identifying the messages and the tools and channels in disseminating the project and its outcomes to the target audience based on the McGuire approach. The main objective of the strategy envisioned is to engage and inform the target audience about the CrowdHEALTH project and its outcomes [1]. It is important that a large number of audience is addressed through appropriate means in order to be engaged with the progress of the project and raise its awareness about the project and the deliverable outcomes. Each applied tool has different strengths and weaknesses in reaching the audience and therefore by using more than one tool, they complement one another to produce a strong dissemination plan [2]. Social media can play a significant role in all phases of the research lifecycle, from identifying research opportunities to disseminating findings. Scientific journals, conferences, and edited books remain the core traditional means of disseminating research, but social media has become an important channel for disseminating research [3].

In the CrowdHEALTH project a cyclical process was developed. In the cyclical models, individual components are linked, and the process is depicted as interactive and ongoing. This is the case with Graham et al's knowledge to action model where aspects of the research, context, knowledge transfer intervention, and evaluation lead to the identification of new opportunities [4]. Researchers need to adopt a theory-informed approach to their research dissemination [5].

Methods

Dissemination strategy is defined through a cyclical process. The McGuire Persuasive communication approach was implemented for the development of an effective Collaboration and Communication plan, figuring out the dissemination objective, the message to be communicated, the tools and channels of communication, and the target audience. The statistics of the CrowdHEALTH Facebook page are monitored to give first evidence of audience engagement in social media and the published material.

Results

Defining a Dissemination Strategy Through a Cyclic Process

Defining the CrowdHEALTH dissemination strategy is an ongoing cyclic process as shown in Figure1. Past or published ongoing dissemination efforts are reviewed, the available resources are identified, the momentum and opportunities are considered and the four dimensions of the dissemination strategy consisting of the objective of the dissemination, the key messages to be communicated, the appropriate dissemination tools and channels, and the target audience are defined (Figure2). KPIs are monitored in order to evaluate dissemination efforts.

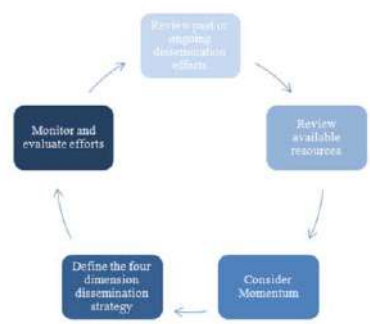

Figure 1 – The Cyclical Process of a Dissemination Strategy

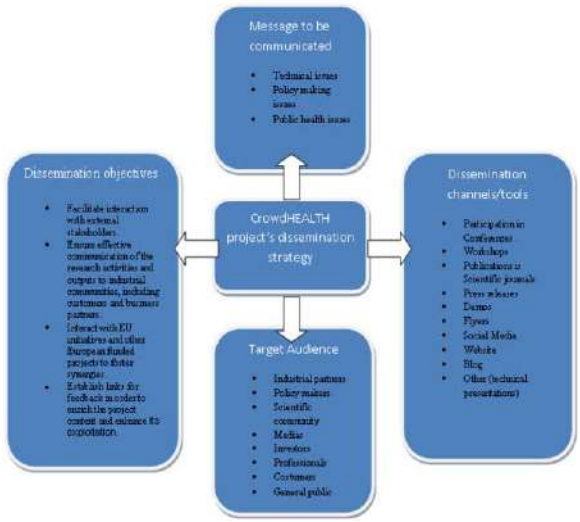

Figure 2 – The Four Dimensions of the Dissemination Strategy

Monitoring Efforts of Social Media Dissemination

Data regarding the people reached, the post clicks, and reactions (shares, likes, comments) are collected from 28 December 2017 to 24 November 2018 from the CrowdHEALTH Facebook page as illustrated in Figure 3.

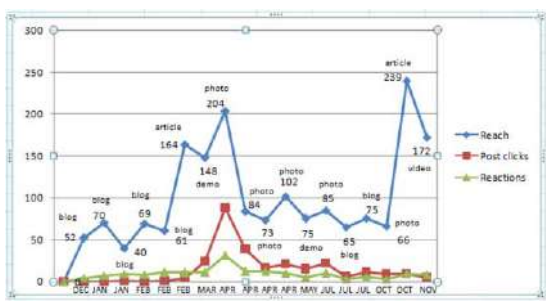

Figure 3 – The Impact of Blog Posts and Other Published Material on the CrowdHEALTH Facebook Page

Discussion

The CrowdHEALTH project implemented a cyclical process for defining the dissemination strategy consisting of five steps. Taking into consideration this framework , the four pillars of the dissemination strategy were described, defining the dissemination objective, the message to be communicated, the tools and channels of communication, and the target audience. Early evidence from the CrowdHEALTH social page on Facebook suggests that audience is more engaged to articles, demos, videos, and photos from events and conferences and less on blog posts.

Conclusions

The implemented framework identified a dissemination strategy to better communicate project's findings. Optimal communication and dissemination would also facilitate interaction with the target groups. It is important that a large number of audience be addressed through appropriate means in order to be engaged with the progress of the project and raise their awareness about the project and its deliverable outcomes. Social media can play a significant role in all phases of the research lifecycle indluding the dissemination of research findings. Scientific journals, conferences, and edited books remain the core traditional means of disseminating research, although social media has become an important channel for disseminating research. Each applied tool has different strengths and weaknesses in reaching the audience and therefore by using more than one tool, they complement one another. First evidence of the CrowdHEALTH project suggests that press releases connected with social media pages of the project can engage audience in social media. Visual materials such as demos, videos, pictures, and photos can highly engage audience in social media.

Acknowledgements

The CrowdHEALTH project is co-funded by the Horizon 2020 Programme of the European Commission Grant Agreement number: 727560 – Collective wisdom driving public health policies.

The Opportunities and Challenges of Pragmatic Randomized Trials Using a Specialized Software: CloudTrials Project

Santiago Márquez Fosser [a], Andrey Kamozin [b], Emily Gibson McDonald [b], Robyn Tamblyn [a,c], Todd Campbell Lee[a,b,c]

[a] Clinical and Health Informatics Research Group, McGill University, Montréal, Canada

[c] Department of Epidemiology, Biostatistics, and Occupational Health, McGill University, Montréal, Canada

Abstract

Pragmatic randomized trials are essential to improve knowledge of real world clinical practice. Pragmatic trials design reflect routine clinical care, which have advantages to initiate and conduct, compared to classical clinical trials. Trials help to: engage bedside clinicians, increase efficiency of patient recruitment and follow up, minimize loss to follow up and include technological patient reported outcomes. The objective is to describe the opportunities and challenges designing a specialized software to administrate pragmatic randomized trials.

Keywords:
Research Design, Patient Selection, Software Design

Introduction

A randomized controlled trial (RCT) is considered the best method to evaluate therapeutic efficacy. In a RCT, one or more groups of patients receive different treatments in order to compare the results across the different groups with minimal bias. Ideally, RCTs should apply interventions that resemble actual clinical practice and enroll representative samples of clinicians and patients. However, they are generally very expensive, time consuming, and are complex to carry out [1]; consequently, they are not accessible to most physicians and patients.

The objective of these trials (also known as explanatory trials) is to test the superiority, equivalence, or non-inferiority of the new treatment being tested [2]. Clinical trials also commonly require the collection of highly detailed patient data. This necessitates onsite staff training regarding data collection and management, which presents a burden to study sites, interferes with usual care, and presents a barrier which often excludes research-native practitioners and sites from participation [3-4].

A different type of trial, known as a pragmatic trial, aims to identify the best choice between clinical decisions which are usually made in real practice or which answer important questions about whether a practice is beneficial. Pragmatic trials need to closely align all study-related interventions with routine clinical practice so as to minimize interference with routine care and enhance the generalizability of the results to the real-word setting [5].

Our objective was to create an application to serve as a clinical trials platform which overcomes many of the barriers and methodological challenges to designing, administering, conducting, monitoring, and analyzing pragmatic clinical trials. This platform was designed to be independent from the EMR to allow participation in many centers independent of their underlying system and to include, from the beginning, a patient voice in terms of patient reported outcomes. The software seeks to do all of this while maintaining the highest methodological rigor for the study and minimizing the administrative and human resource costs of participation.

Methods

This article uses a methodology that assesses and describes obstacles in the conduct of pragmatic randomized trials as well as avenues for future developments of software-based solutions.

Setting

The McGill Clinical and Health Informatics (MCHI) is a research group in the Faculty of Medicine whose research activities focus on the development and evaluation of health software and the analysis of data generated by these systems.

Challenge

When interference with usual care or the administrative and/or data collection burden for physicians is too high, many physicians will not participate. By contrast, if the data collection is incomplete or not standardized, the entire methodology of the study can be called into question. A strategy that aims to collect information through an EHR has the advantage of not interfering with routine clinical care, however, it may not have the data quality needed [6].

Results

CloudTrials components

Establishing common structures across different clinical trials allows for the design of a scalable software which could facilitate multiple trials.

User administration

The development of methods of user registration and validation was essential. A user signs up by filling in their basic professional information with a system verification of their email account, and, in this case, a manual verification by an administrator who confirms identity with provincial provider databases and again via direct communication and the

completion of any legal contracts and agreements necessary in that jurisdiction.

Patient enrollment

Each doctor is responsible for the recruitment and enrollment of their patients in the system. For that a 5-step wizard was designed, with the minimum requirements to incorporate a patient in the study: *Patient profile, Eligibility by Clinical Information, Verbal Consent. Follow Up, Summary.*

Randomization

At the end of patient enrollment, the system assigns the patient to an intervention group using a pre-prepared lookup table which has been previously produced for the study in question using proper statistical methods for the question being investigated.

Patient list

To allow for management of their enrolled patients and to identify tasks remaining to be performed, a list of patients had to be developed.

Follow up

Following a pre-designed schedule which is customized for each trial, this module allows for documentation of follow up visits and tests during the period of observation.

Data monitoring

An administrator view is necessary for the supervision of any RCT. This user is required to oversee the study progress to apply corrections early on when the study is deviating from the planned course.

Privacy and security

The biggest concern while developing the application was the safety of patients' identities. Outside of important security features employed at the server levels, several additional measures were put in place:

Ethical and regulatory challenges

While somewhat outside of the scope of a document discussing the software development of a clinical trials platform, it is relevant to consider the challenges of performing crowd sourced clinical trials. Namely, such studies need to be mindfully designed such that they allow clinicians to enroll patients ethically within their own practice drawing upon the pre-existing informed consent process and professional code of conduct.

Discussion

This article describes the issues and challenges we faced in the design of our software which allows for the administration of PRTs. The incorporation or creation of a module for the generation of new structured clinical trials by end users is a key step in our future to allow for maximal reuse of existing code prior to launching a new trial. We are excited to see our first two trials, involving hundreds of patients, enrolled in 2019.

Conclusions

This article describes the design of a software which allows for the administration of PRTs.

Abstract

In this study, we aim to develop an automatic pipeline to identify clinical findings in the unstructured text of radiology reports that necessitate communications between radiologists and referring physicians. Our approach identified 20 distinct clinical concepts and highlighted statistically significant concepts with strong associations to cases that require prompt communication.

Keywords:

Natural language processing, communication, radiology.

Introduction

It is well understood in clinical practice that lapses in communication, either due to delays or a lack of communication altogether, increase the likelihood of adverse patient outcomes. In radiology, high case volumes and the expectation of timely clinical interpretation present challenges in identifying and communicating cases that require urgent management on the part of the referring physician. In this study, we developed a pipeline for the identification of critical clinical concepts that are the most likely to appear in patient cases requiring prompt communication between a radiologist and a referring physician.

Related Work

There are many examples of previous uses of automatic information extraction from medical records, particularly with radiology report text analysis [1]. MetaMap has been developed and utilized to map radiology reports and other clinical note texts to concepts in the Unified Medical Language System (UMLS) Metathesaurus [2]. Apache clinical Text Analysis and Knowledge Extraction System (cTAKES) is a system to analyze clinical notes and annotate UMLS concepts in free text [3], which is utilized in this project and will be further discussed in the following sections. Of note, this study is built on our previous work to use machine learning to identify urgent cases for prompt communication in radiology reporting [4].

Methods

We developed a natural language processing (NLP) pipeline to extract clinical findings from a corpus of free-text radiology reports at our institution that required prompt communication between radiologists and referring physicians. We then compared these clinical findings to the extracted findings from regular radiology reports. We used a statistical test of significance to identify critical findings in these reports that are associated with prompt communication. The overview of our pipeline is shown in Figure 1.

Dataset

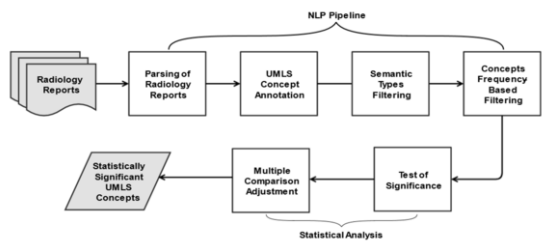

Figure 1– An Overview of Our Framework to Identify Statistically Significant Clinical Findings Requiring Prompt Communication with Referring Physicians Based on Radiology Reports

We took a retrospective approach in this research, starting with 1,460 radiology reports extracted from electronic medical records within the years of 2010 – 2018 from Dartmouth-Hitchcock Medical Center (DHMC). These reports came from a mixture of three imaging modalities: (1) computed tomography (CT); (2) magnetic resonance imaging (MRI); and (3) X-ray. Two radiologists manually annotated each of these reports, adding a binary label, either "this report requires prompt communication to referring physician" or "this report does not require prompt communication." In order to minimize the errors, reports that received the same label from both radiologists were included in the analysis and those that did not were excluded. Our final data set included 1,389 radiology reports. 1,057 of these were interpreted by both radiologists as requiring urgent communication to a referring physician, while 332 were interpreted as not requiring urgent communication.

NLP Pipeline

Parsing of Radiology Reports

We focused only on analyzing the text that appears in the "impression" sections of radiology reports. This is because the impression section contains information about diagnosis and follow-up recommendations.

UMLS Concept Annotation

We applied Apache clinical Text Analysis and Knowledge Extraction System (cTAKES), which identifies nouns and noun phrases in clinical text that correspond to UMLS concepts. Using cTAKES, we identified the concepts in radiology reports that are classified in 5 high level classes based on a subset of UMLS semantic types: (1) disorders/diseases, (2) signs/symptoms, (3) procedures, (4) anatomy, and (5) drugs. cTAKES also provides preferred names from UMLS for extracted concepts to facilitate a standard representation. In

addition, this pipeline incorporates NegEx [5] to identify the concepts that are used in a negative context in the radiology report. We mapped all the medical terms and phrases that appeared in the impression section to UMLS concepts, excluding those that were negated.

Semantic Types Filtering

The identified UMLS concepts were aggregated according to the five high level semantic type classes. Using the full list of concepts identified by cTAKES, we found that the aggregated concepts helped to narrow down a list of potential concepts associated with the need for prompt communication with referring physicians. After consultation with the domain-expert clinicians involved in our study, we focused solely on UMLS concepts belonging to the diseases/disorders class in our analysis from the five aforementioned UMLS classes returned by cTAKES.

Concepts Identified by Frequency-Based Filtering

The identified UMLS concepts found in the reports were also filtered by frequency, including those that were only found in 2% or greater of reports. This frequency-based filtering reduced the noise in our analysis and directed our focus to reasonably common findings in radiology reports that encompass the majority of cases requiring prompt communication. The concept frequencies were further analyzed in the following statistical analysis steps to differentiate reports requiring prompt communication from those not requiring prompt communication.

Statistical Analysis

We used Fisher's exact test to find statistically significant associations between identified UMLS concepts and the radiology reports that require prompt communication. The concepts with a P-value < 0.05 are considered strongly associated with necessary prompt communication with referring physicians.

We addressed the multiple comparisons problem in evaluating the significance of extracted UMLS concepts. The false discovery rate provides a complementary measure to positive predictive value, which indicates the probability of a positive test result being accurate. In order to identify truly significant UMLS concepts while still maintaining a low false positive rate, we adjusted the P-values calculated by Fisher's exact test. To adjust the P-values, we utilized the Benjamini-Hochberg method, which is a powerful method to address the multiple comparisons problem through false discovery rate.

Results

The described NLP pipeline identified 580 UMLS concepts. Table 1 shows the extracted concepts with adjusted P-values less than 0.5 from radiology reports that are associated with reports requiring prompt communication. The most commonly identified UMLS concepts in radiology reports that required prompt communication with referring physicians are shown in Table 2.

Table 1– Frequency of Selected UMLS Concepts in Radiology Reports that Require Prompt Communication
P = Occurrences with Prompt Communication
N = Occurrences without Prompt Communication

UMLS Concept	*Semantic Type*	*P*	*N*	*Odds Ratio*	*P-value*	*Adjusted P-value*
Pneumothorax	Disease or Syndrome	33	0	∞	2.25E-04	4.19E-02
Malignant Neoplasms	Neoplastic Process	73	3	8.05	2.66E-06	7.72E-04
Fracture	Injury or Poisoning	127	7	6.27	3.34E-09	1.94E-06
Nodule	Acquired Abnormality	107	13	2.73	2.89E-04	4.19E-02

Conclusions

We developed an automatic pipeline to identify clinical concepts that are statistically significant for radiology reports requiring prompt communication with referring physicians. However, our imbalanced dataset containing urgent and non-urgent cases for prompt communication is a potential limitation of this study. We plan to address this limitation by extending our dataset in our future work.

Table 2– Most Frequency UMLS Concepts in Impression Sections of Radiology Reports that Require Prompt Communication

P = Positive for Occurrences，N = Negative for Occurrences

UMLS Concept	*Semantic Type*	*P*	*N*
Fracture	Injury or Poisoning	127	7
Nodule	Acquired Abnormality	107	13
Malignant Neoplasms	Neoplastic Process	73	3
Communicable Diseases	Disease or Syndrome	62	6
Neoplasms	Neoplastic Process	53	8
Pleural effusion disorder	Disease or Syndrome	50	5
Traumatic injury	Injury or Poisoning	49	5
Cyst	Disease or Syndrome	43	6
Disorder of skeletal system	Disease or Syndrome	42	16

Enabling West African Herbal-Based Traditional Medicine Digitizing: The WATRIMed Knowledge Graph

Borlli Michel Jonas Somé[a], Georgeta Bordea[b], Frantz Thiessard[b], Gayo Diallo[b]

[a] Ecole Supérieure d'Informatique, Université Nazi Boni, Bobo Dioulasso, Burkina Faso

Abstract

The purpose of this study is to describe the design and development of the first release of the West African Herbal based Traditional Medicine Knowledge Graph (WATRIMed). It is a resource containing Traditional Medicine (TM) related entities and linked with publicly available knowledge bases in order to facilitate bringing West African TM into the digital world. The core model comprises currently 556 concepts including 143 identified West African medicinal plants and 108 recipes used by tradi-practitioners to treat 110 diseases and symptoms which are commonly encountered in this part of the world.

Keywords:
African Traditional Medicine, Knowledge Bases; Phytotherapy

Introduction

For many people in Africa, Traditional Medicine (TM) is either the first line of treatment or is used as a last resort when all the available possibilities in the conventional medicine are exploited. Although its affordability, it comes with various issues, in particular due to the oral transmission of knowledge and lack of digitized resources that could contributed to making gathered experiences sustainable.

The high usage of TM is often driven by the inaccessibility, unaffordability or unavailability of conventional health care services and medicines in socioeconomic settings that are characterised by a high rate of poverty and a lack of suitable and affordable conventional medicine services and drugs, like in West Africa. That underserved and mostly illiterate, rural people account for the majority of the population, is an additional barrier to access healthcare. In response to the growing recognition of the potential of TM, the supra-national West African Health Organisation (WAHO)[1] has given priority to TM in 2007, with the objective of supporting the institutionalization of African Traditional Medicine (ATM) in member countries' health systems, followed up by WAHO's 2016-2020 Strategic Plan. Within this plan, an important action item is the standardisation of descriptions of herbal and TM. Together with the lack of computable TM data, it is difficult to take benefit from them for primary and secondary use cases including patient follow-up and public health statistics or phytovigilance about available herbal medications. An important step was the launch of the first edition of the West African pharmacopeia in 2013, with inputs from ATM experts coming from different member states [1]. This step is a good asset towards the West African TM standardisation.

In this study, we aim at relying on this endeavor in order to design and develop the first release of the West African Herbal Traditional Medicine (WATRIMed) Knowledge Graph (KG), with the objective of helping to preserve TM knowledge and for bringing West Africa TM to the digital world using a state-of-the-art, flexible and shareable knowledge representation approach. Further, helping to establish bridges with conventional medicine, similarly to previous attempts of digitizing Chinese TM [2] and more general African TM [3,4].

Methods

The West African Herbal Pharmacopeia (aka WAHO herbal pharmacopeia) gathers information on medicinal plants used in West Africa, building on a first African Pharmacopeia including 105 plants created in 1985, followed by a book on medicinal plant analysis in 1986 [1]. It describes every plant by the following features: a summary description of the plant, its ethno-medicinal usage, related clinical information and safety, its chemical constitution, contraindications, the regions where the plant grows, a photograph, information on biological and pharmacological activity, and possible dosages and mode of administration.

The workflow to build the WATRIMed KG comprises three main components:

1. Designing and feeding the TM relational database (TradiMed) from the WAHO Herbal Pharmacopeia resources;
2. Designing the Herbal-based TM (HTM) Ontology, and establish links between TM and conventional medicine entities. This is particularly relevant for supporting phytovigilance activities and taking benefit from the advances in terms of pharmacovigilance and drug usage assessment in conventional medicine;
3. Mapping TradiMed and HTM Ontology and linking them to the external publicly available Knowledge Bases (KB) relevant to the domain.

We identified a set of publicly available KBs, which allow to enrich the core information of West African TM and to widen its scope while opening up the perspective of wide-scale integration: Therefore, the following KBs are considered:

[1] http://www.wahooas.org/index3.php?lang=en

DBpedia[2] for plants and diseases; STITCH[3] and PubChem for chemical compounds; IPNI for plants names and bibliographic references; GeoNames for information about countries and regions; Wikidata and Yago for local dialects and vernacular names of plants and recipes.

The OpenRefine tool[4] is used to query these external KBs and to perform the mapping with the core WATRIMed model.

Results

The TradiMed Database

The database comprises of 25 relational tables which total 3544 tuples. It is hosted in a PostGreSQL server and the schema is available online[5]. Table 1 indicates the statistics about the main entities of TradiMed. As can be seen, 143 plants are identified and documented from the WA countries members.

The Herbal based Traditional Medicine Knowledge Model

The Herbal-based TM knowledge model, referred as HTM comprises 556 main Concepts and 75 Properties. The latter are subdivided into 18 Datatype Properties and 57 Object Properties. The main component is *MedicinalPlant*. It is linked with the *ChemicalCompound* entity by the object property *HasChemicalComponent*. A *MedicinalPlant* has a *BotanicalName* (which is a Datatype Property). The *PlantInRecipe* entity illustrates the n-ary relationship pattern. A *PlantInRecipe* defines the plant part components which constitute a given Recipe. Thus, two property restrictions are used to link *PlantInRecipe* respectively to Recipe and Plant-Part. For example, let's take as an illustration the *1.Rx* recipe of TradiMed, which is a treatment for Malaria. For 100g dosage, it is composed of 40g of the root of the *Cryotolepsis sanguinolenta*, 20g of *Moringa oleifera leaves*, 20g of *Cymbopogon citratus leaves* and 20g of *Khaya senegalensis stem barks*.

Table 1. Current Statistics of the Main Entities of the TradiMed Database

Component	Size (#tuples)
West African Plants	143
Countries	16
Therapeutic Indications	110
Contraindications	148
Local Dialects	122
Traditional Medicine Recipes	108
Chemical Compounds	179
Plant Parts	34

The WATRIMed Knowledge Graph

The following entities of the HTM Ontology have been linked to external resources identified among the publicly available external KBs: *MedicinalPlant*, *TheurapeuticIndication*, *ContraIndication*, *ChemicalComponent* and *Dialect*.

There are 143 *MedicinalPlant* respectively linked to 143 DBpedia entities and 143 IPNI resources. With setting up these external links we were able to enrich the description of the plants, because the information provided by the two KBs is complementary. IPNI references the bibliographic information about the first scientific publication that references a given plant; while DBpedia provides, among others, information including species, fat and fibre content of a given plant. For *TherapeuticIndication*, about 40% of them are linked to DBpedia entities (42 out of 110). However, only 6 out of 110 could be linked to some Yago entity.

Eighteen *ContraIndication* entities have been linked to Yago (12%). All the *ChemicalComponent* entities have been linked to external resources by fetching URLs from STITCH and PubChem. We ensured that any *ChemicalCompound* is consistent and correctly labelled.

For *Dialect*, we have identified 13 out of 122 links with Yago entities and 46% (56 out of 122) links with Wikidata.

Conclusion

We have briefly described the West African Herbal-based TM KG, which is made available to the community at www.watrimed.org together with a SPARQL endpoint. It could therefore be processed both by human and machines. It comprises 556 Concepts and 75 Properties. It is further mapped to a set of external KBs including DBpedia, PubChem and GeoNames. It has been built from the core component of the WAHO's Herbal Pharmacopeia resource and linked to publicly available KBs about plants, diseases and drugs. It is ongoing work which describes 143 plants and 108 traditional recipes identified as treatments of common diseases in West Africa. Future work includes further validation of WATRIMed with ATM experts and enriching the current graph with resources from additional external KBs.

Unsupervised Phrase-Level Query Rewriting for Assisting Search in Clinical Free Text

Hans Moen[a], Laura Peltonen[b], Henry Suhonen[b], Mikko Koivumäki[b], Tapio Salakoski[a], Sanna Salanterä[b]

[a] *Department of Future Technologies, University of Turku, Turku, Finland,*
[b] *Department of Nursing Science, University of Turku, Turku, Finland*

Abstract

We report on the pilot evaluation of an experimental query-based search functionality that enables phrase-level query rewriting in an unsupervised way. It is intended for supporting search in clinical text. Qualitative evaluation is done by three clinicans using a prototype search tool. They report that they find the tested search functionality to be beneficial for making query-based searching in clinical text more efficient.

Keywords:

Natural Language Processing, Information Storage and Retrieval, Electronic Health Records.

Introduction

Query-based searching for information in clinical free text, such as information about a specific health-related phenomena or concept, can be challenging as the same concept can be described in many different ways. An important job for a search engine is to try to bridge the gap between user queries and how associated phrases of similar meaning (semantics) are documented in the targeted text. The aim of the presented work is to test an experimental search functionality that aims to find, suggest and highlight phrases which have similar meaning and length as queries provided by the user. Intended users of a search engine with this functionality are clinicans who are looking for previously documented information in a patient's electronic health record (EHR). One example could be a clinician who is interested in reading what, if any, information concerning *confusion symptoms* has been documented by searching with queries similar to how he/she would typically document such symptoms.

Unlike traditional information retrieval that focuses on retrieving relevant documents, paragraphs or sentences, we are focusing on phrase-level matching and highlighting. Labeled training data, e.g. in the form of search history logs (see e.g. [1]) for enabling supervised query rewriting and expansion techniques, is typically not readily available from EHR systems. Thus, our approach relies primarily on un-labeled free text for training. We are not aware of related works that have proposed suitable, unsupervised approaches/methods for enabling the search functionality that we are aiming for.

The two main challenges in the identified scenario are: 1) Individual words may have several synonyms, near synonyms, and/or closely related words which refers to the same or similar underlying concept (e.g., "oxygen" vs. "SaO2" (oxygen saturation)); 2) When using multiple words, more complex concepts may be expressed and there are typically a greater number of ways to describe a single concept with variations in the choice of words, compositionality and length (e.g., "DM II" vs. "type 2 diabetes mellitus," see also Table 1).

Our approach/method is based on unsupervised machine learning and uses primarily three components: A statistical language model (KenLM toolkit [2]); an off-the-shelf search engine (Apache Solr search platform); and a semantic model of word n-gram vectors (or embeddings) trained with the Word2Vec toolkit [3] – which learns semantics from word co-occurrence statistics in a large text corpora in an unsupervised way. Such models of distributional semantics have been shown to capture word synonymy and relatedness. Similar to Zhao et al. [4], we combine co-occurrence statistics from word n-grams of two different sizes: unigrams (single words) and bigrams (word pairs) when training a single semantic model. One motivation for doing this is that we want to be able to map from unigrams to semantically similar bigrams and vice versa. Another motivation is that Zhao et al. [4] found this to produce improved word representations compared to only using unigram co-occurrence statistics.

We hypothesize that the proposed search functionality (described in the Methods section) can be beneficial to clinicians for saving time and effort when seeking for information of interest in clinical free text. Evaluation of the search functionality is enabled and tested through a prototype query-based search tool/interface. We report on a pilot evaluation performed by three domain experts. The evaluation provides qualitative feedback on how the search functionality performs, and highlights strengths and weaknesses as seen by the evaluators.

Methods

The data set we use is a relatively large corpus of clinical text consisting of physician notes and nursing shift notes from patients admitted to a Finnish hospital. It consists of 136 million tokens (1.5 million unique tokens). For training the semantic model, we first preprocess a version of the corpus with lowercasing, tokenization and stemming (Snowball stemmer for Finnish). We decided to use stemming primarily to reduce the vocabulary size. Next, the text is converted into uni- and bi-grams. As an example, the sentence "a nice flower" becomes: "a a_nice nice nice_flower flower". We train the semantic model with Word2Vec using the SkipGram architecture and hierarchical softmax. We use a dimensionality of 300 and a window size of 6. To train the statistical langauge, we use a version of the corpus only containing stemmed and lowercased unigrams.

Briefly explained, the way we generate rewritten candidate suggestions for a given query is as follows. First, we create two query vectors by splitting the query into uni- and bi-grams before summing the associated vectors (normalized) from the semantic model. If, let us say, the query is: "this is a query", we create two query vectors as follows:

$\text{qvec}_{\text{unigram}} = \overrightarrow{this} + \vec{is} + \vec{a} + \overrightarrow{query}$
$\text{qvec}_{\text{bigram}} = \overrightarrow{this\_is} + \overrightarrow{is\_a} + \overrightarrow{a\_query}$

Next, these are both used to extract the semantically most similar unigrams and bigrams using the semantic model and cosine similarty (sim) as vector distance measure. In addition to forming individual candidate suggestions, we use them to generate multi-word phrase candidates. For bigrams, this is done by iteratively combining bigrams that have one overlapping word in order to create longer phrases (e.g., "is_a" and "a_solution" is combined to "is_a_solution"). To reduce the number of nonsensical phrases being generated, we use the statistical language model to iteratively assess whether or not a potential phrase candidate is likely to exist in the corpus. If no additional n-grams can be added to any of the phrase candidates, the process stops. Another stopping criteria we introduce is a max length relative to the length of the query. Next, we again use the semantic model, this time to create phrase vectors ($p_i\text{vec}$) for each phrase candidate in the same way as we did with the query (i.e., $p_i\text{vec}_{\text{unigram}}$ and $p_i\text{vec}_{\text{bigram}}$). Then, we calculate a similarity score between the query and each of the phrases before sorting them according to their similarity score. As similarity function between a query (q) and a phrase candidate (p_i) we use:

$$\text{sim}(q, p_i) = \text{avg}(\text{sim}(\text{qvec}_{\text{unigram}}, p_i\text{vec}_{\text{unigram}}), \text{sim}(\text{qvec}_{\text{unigram}}, p_i\text{vec}_{\text{bigram}}), \text{sim}(\text{qvec}_{\text{bigram}}, p_i\text{vec}_{\text{unigram}}), \text{sim}(\text{qvec}_{\text{unigram}}, p_i\text{vec}_{\text{bigram}}))$$

As a final step, we use the search engine (Apache Solr search platform) where we have indexed the clinical notes in the care episodes to search in. We use a filter that enables matching stemmed queries with their inflected forms in the indexed text. Finally, the search engine is used to find and highlight the top *n* phrase candidates that actually occur in the targeted care episode. Candidates not found are discarded.

Prototype Search tool and Experimental Setup

We asked three domain experts with a background as a hospital nurse to test the search functionality through a prototype query-based search tool/interface. The purpose was to have them evaluate how well the (rewrite) suggestions by the tool helps them to better find the information that they are searching for (if it exist at all), compared to only the exact matches of the query. When searching with a query, the tool highlights in the clinical notes/documents exact matches (if any) and additional rewritten phrase suggestions found with unique colors. Each unique match/suggestion are also listed in a separate table showing their similarity score to the query and occurrence count in the targeted care episode. The evaluators were given a set of patient phenomena to search for, including *state of mind*, *smoking status*, *secretion* and *activity level*. They were also encouraged to search for other phenomena of interest. We also encouraged them to use multi-word queries when searching. 20 different care episodes (i.e. all physician and nursing notes from 20 patients' hospital stays) were indexed and searchable (one at a time). The evaluators were given a set of questions to consider and comment on while they were doing the testing. These were questions about whether or not the tool made it easier and faster to find the information they were looking for (compared to only relying on the exact matches), weaknesses, strengths, problems and suggestions for improvements. Finally, their answers and comments formed the basis of a joint feedback meeting.

Results

All three evaluators reported that the suggestions provided by the tool makes it easier and faster to search for and find information in clinical text. Since the way clinicans document various phenomena can vary greatly, the rewrite suggestions help to identify potential words and phrases that are semantically related to the search query but written with different words. Even though some of the suggestions by the tool were not relevant, they reported that it was easy to simply ignore these. As problems, they reported that it can be difficult to know that something is not present in a care episode even if it is not found by the tool (false negatives). Also, they noticed that the use of stemming was not optimal as different inflections of the same word were not always connected and found. Examples of rewrite suggestions provided by the tool for a few queries can be seen in Table 1.

Table 1– Example of Query Rewrite Suggestions Found by the Tool. Translated from Finnish to English.

Query	Rewrite suggestions
"runs daily"	"exercise a lot"
"speaks funny things"	"speaks nonsense" "speaks delirious" "speaks by himself"
"patient sees small green men"	"sees a lot of things" "sees things that are not there" "sees illusions"

Conclusions

We present our ongoing work toward enabling unsupervised phrase-level query rewriting to support searching in clinical text. The evaluators report that they find the prototype search tool, with the underlying query rewrite functionality, to be beneficial for making searching and finding information in clinical text faster and easier compared to only exact query matching. As future work we plan to perform a quantitative evaluation. We also aim to test using this search functionality to supporting manual annotation of clinical text. Additional plans include looking into alternatives to stemming, the inclusion of trigrams in the semantic model(s), other similarity measures, query segmentation and algorithm optimization.

Automatic Mapping Between Brazilian Portuguese Clinical Terms and International Classification for Nursing Practice

Lucas Brehm Ronnau[a], Fernanda Broering Gomes Torres[a], Lucas Emanuel Silva e Oliveira[a], Denilsen Carvalho Gomes[a], Marcia Regina Cubas[a], Claudia Moro[a]

[a] Health Technology Program, Pontifícia Universidade Católica do Paraná, Brazil

Abstract

This study describes MappICNP, an automatic method for mapping between Brazilian Portuguese clinical narratives in free text and International Classification for Nursing Practice (ICNP) concepts. It's composed of six natural language processing rules, related to terms comparison. A set of 2,638 terms extracted from hospitals nursing notes was mapped. MappICNP helps to map 1,607 terms, 113 less than a manual approach. The results demostrate its advantages in minimizing the time spent and reducing the scope of analysis through candidate terms of ICNP.

Keywords:
Standardized Nursing Terminology; Natural Language Processing; Health Information Interoperability.

Introduction

Most of Electronic Health Record (EHR)'s data is represented as free text. It's necessary to map natural language text to a standard terminology, i.e., terminological mapping, to improve their reusability[1; 2]. International Classification for Nursing Practice (ICNP) is one of the clinical standard terminologies which allows nominating and documenting the elements of nursing practice. It is used for nursing diagnosis, outcomes, and, interventions standardization [3]. It's developed by International Council of Nurses, and has a translation to Brazilian Portuguese (pt-br). The 2017 version of the ICNP contains 4,326 concepts and 2,401 of them are primitive.

There are previous studies focusing on cross-mapping from clinical narrative terms to ICNP [4]. However, no existing studies or tools to automatically map terms in pt-br to ICNP concepts were identified. The objective of this study was to propose an automatic method, MappICNP, to support mapping between pt-br terms in free text and ICNP concepts.

Method

MappICNP method was developed by applying natural language processing (NLP) techniques and focuses on ICNP primitive concepts. It was structured in two phases.

The first phase performs normalization of terms in nurse notes and ICNP (2.401 primitive) concepts: accentuation, special characters and stopwords removal; and lowercasing. In the second phase, six NLP rules were created to perform terms comparison between an input term (nurse note term) and ICNP concepts. Except for the first rule, all input and ICNP terms are modified to cover orthographic variants possibilities. For each rule, the comparison between terms is carried out through Levenshtein's distance-editing algorithm.

Terms Comparison is the first rule. Each input term is compared to all ICNP terms until 100% of similarity is met. If the similarity is above 90%, the ICNP term is added to a list of candidate terms that represented the input term. Even if a candidate term is identified, the input term is compared to the next term of ICNP, until the end of ICNP list. So, in the end this rule is possible to have an ICNP term with 100% of similarity with the input term or a list of candidate terms. When this rule achieved 100% of similarity, the other rules are not executed. Otherwise, it goes to the second rule, trying to find more candidate terms.

In the second to sixth rules, all similar ICNP terms (from 90% to 100%) are registered in a list of candidate terms. These all five rules are executed even many candidate terms were met before. Stemming is applied as the second rule. Input terms are transformed into its orthographic root. The third rule applies a pt-br lemmatizer that transforms each input term and ICNP term into their motto, before comparing them. The fourth rule uses an orthographic synonyms dictionary to find a set of different terms that may represent the input term. Then, these synonyms are compared to ICNP terms applying the previous rules. The fifth rule aims to find an ICNP term with a semantic meaning encompassed by the input term. If this occurs, the concept is added to the list of candidate terms. Terms are separated into words and using the first 3 rules is checked if the ICNP concepts content all the words of the input term. The goal of Rule 6 is to find an ICNP concept with a semantic meaning that encompasses the input term, which are separated into words, and applied the first 3 rules to verify if all the words of the ICNP concept are present in the input term, adding the concept to the list of candidate terms.

A set of 2,638 most frequent terms extracted from 148,299 pt-br nursing notes created as free text generated in a period of 2 years, from a university hospital in south of Brazil. This set was also used to a manual mapping describes by Cubas et. al [5].

Results

MappICNP enable to identify ICNP candidates' concepts for the 1,607 input terms (≈62%). From these, 556 (≈ 21% of input terms) were associated with a single ICNP concept by rule 1 (100% of similarity). The rest of the terms (1,051) were mapped by rules 2 to 6, generating a set of candidate concepts. Figure 1 shows examples of all six rules results.

RULES	ICNP Example
1. Direct Comparison	tronco -> tronco|10020180
2. Stemming	responsivo -> responsividade|10017091
3. Lemmatization	dores -> dor|10013950
4. Orthographic Synonyms	higienizar-> limpar|10004444
5. Specific term	acidose -> acidose metabolica|10032010
6. Comprehensive term	acesso intravenoso -> acesso|10000340

Figure 1– MappICNP rules results examples.

Discussion

The results applying MappICNP are similar to manual mapping described by Cubas et al. [5], MappICNP mapped 1607 input terms and in Cubas et al. were identified 1720 (4% of difference). The difference of 113 terms between the results can be explained by the fact that in manual approach 443 terms were found in the definition of another term, a strategy that could be considered as future work. Where found 556 terms identical to the ICNP concepts, in the manual mapping 655 were considered identical. Rule 1 presented the best results, as it does not make changes in the structure of the terms, improving the accuracy of the mapping. It may introduce some errors when similarity is below 100%. Rules 2 and 3 results need analysis, as often they do not represent the correct semantic meaning of the term. The fourth rule can approximate the semantic equivalence of the mapped terms or indicate semantically distinct terms. It may be improved by using a synonyms dictionary specific to clinical or health domain. The fifth and sixth rules do not find equivalent concepts for the input terms, their goal, however, is to find terms with near meaning.

Conclusions

The method proposed in this study helps to map the terms of nursing notes to a standardized terminology; minimizing the time spent searching for identical terms and reducing the scope of analysis through candidate terms.

Table 1-- Mapping rules results

Terms covered	Candidate Terms	Rule	Similarity
568	556	1	100%
	13	1	>90% e <100%
122	129	2	100%
	10	2	>90% e <100%
140	144	3	100%
	4	3	>90% e <100%
598	593	4	100%
	14	4	>90% e <100%
540	1867	5	100%
	59	5	>90% e <100%
90	109	6	100%
	10	6	>90% e <100%

Mining Pharmaceutical Product Data Related to Payment Pattern from the CMS Open Payments Data: A Case Study in Thoracic Surgery

Xu Na, Haihong Guo, Sizhu Wu, Jiao Li

Institute of Medical Information / Library, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China

Abstract

This study used descriptive statistical analyses to investigate the payment characteristics and to discuss the regularity of highest paying industries. Payments by 4.70% of highest paying industries (N=446) accounted for 85% of the total (US $72,458,304) in 2014-2016. A tiny minority of highest paying industries control the majority of payments. Large payments from these industries are highly associated with few specific products. Furthermore, payment patterns among the industries include concentration and diversification.

Keywords:
Health expenditures, drug industry, medical informatics.

Introduction

Industry transactions to surgeons have become transparent and publicly accessible under the Open Payments program (OPP), a national financial disclosure program in healthcare systems in the U.S. OPP has been viewed as the most potent antidote for potential conflicts of interest engendered by financial interactions between industry and the health care delivery enterprise. Therefore, speaking with authority on the regularity from these transactions recorded in the OPP database becomes important in the open data science and medical informatics studies. Several studies have been conducted for analyzing the open payment. Piller found a pattern of after-the-fact compensation by industry to those advising the US government on drug approvals [1]. Na *et al.* discovered the massive transfer from industries to thoracic surgeons has a strong "apical dominance" and excludability [2].

In the case of thoracic surgery, we aimed to investigate the product associated payment pattern and discuss the regularity of industries who transfer large payments to surgeons.

Methods

We accessed the general payments in 2014-2016 focusing on the non-research and non-ownership payments, which are publicly accessible. We limited physician specialty to thoracic surgery (cardiothoracic vascular surgery) and excluded payments for *current or prospective ownership* or *investment interest* or *valued $0*. The final cohort included 197,592 payments transferred by 446 industries to 4552 surgeons in three-year period.

All analyses were performed with R 3.4.1. The pareto distribution was used to show the distribution of payments transferred by pharmaceutical industries in three years. Descriptive statistics were calculated to analyze the distribution of the highest annual payment associated with a specific product made by the tiny minority of highest paying industries.

Results

Distribution of payments transferred by pharmaceutical industries

Payments transferred by 4.70% (n=21) of highest paying pharmaceutical industries accounted for 85% of the total payments (72,458,304) in thoracic surgery in 2014-2016. The cumulative percentage of payments transferred by 10% of highest paying industries was 94.44%. Specifically, the highest paying industry transferred cumulative payments totaling $20662039, accounting for 28.52% of the total. 14 industries transferred cumulative payments more than one million in 3 years (see Figure 1). The result illustrated that distribution of payments shows a great discrepancy in pharmaceutical industries.

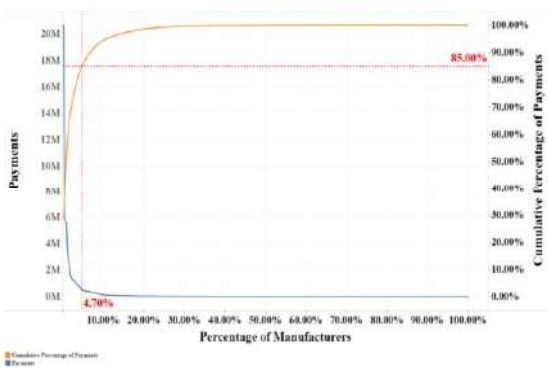

Figure 1– Pareto Distribution of Payments Transferred by Pharmaceutical Industries in 2014-2016

Distribution of the highest annual payment associated with specific product by the 21 highest paying industries

The percentage of the highest paying product transferred by 15, 15 and 13 manufacturers were more than 50% of total, among which 9,9 and 7 were approximately 90% in the three-year period, respectively. Furthermore, the highest annual payment transferred by 16 industries were associated with certain product in each of 3 years; meanwhile, 6 transferred more than 80% of the total (see Figure 2). The result reflected that payments transferred by these highest paying industries are specifically targeted to certain products. The payments pattern vary greatly in different industries.

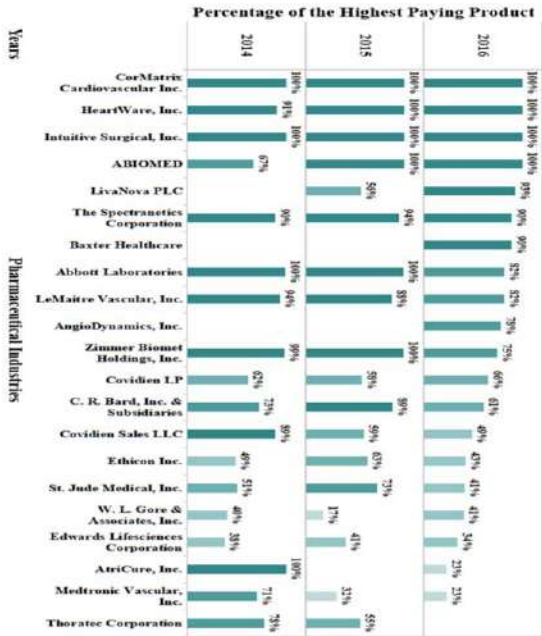

Figure 2– Proportion of the Highest Annual Payment Made by Industries Associated with Specific Product in 2014-2016

Discussion

The tiny minority of highest paying industries controlling the vast majority of payment

Our study indicated that there was significant difference in the distribution of payment made by pharmaceutical industries, with only 4.70% of highest paying industries controlling as high as 85.00% of the total payment. The pareto distribution is a power-law probability distribution that is originally applied to describing the distribution of wealth in a society, fitting the trend that a large portion of wealth is held by a small fraction of the population. This distribution gave the inequality of payment a very comprehensible and visible display that the tiny minority of industries determine the vast majority of payment in our research. In addition, we found that 3.14% of total industries transferred cumulative payments more than one million in 3 years, among which the highest paying industry accounted for approximately 30% of the total. The highly skew distribution of payments remain signification among the critical minority. Therefore, we focused on analyzing the payments pattern made by the tiny minority of highest paying industries.

Characteristic of payments pattern among the tiny minority of highest paying industries

Our research showed that the most majority of annual payment transferred by the tiny minority of highest paying industries were highly associated with their specific products. Nearly half of these highest paying industries transferred more than 50% of the total targeting to certain product in each of 3 years. Moreover, 28.57% of the industries transferred as high as four-fifths of the total. It indicated that these industries are strongly inclined to centralize the annual payment to one specific product. Conversely, others are more likely to pay for diversification. The implication is that there exists a great discrepancy in the payments patterns among the tiny minority of industries.

Modern portfolio theory assumes that investors are risk averse, meaning that when given two portfolios that offer the same expected return, investors will prefer the less risky one to lower the uncertainty. For this reason, an investor will only take on increased risk in return for higher expected returns. Industries will evaluate the trade-off differently in order to make the decision of benefit maximization, based on their individual risk aversion characteristics.

For the centralized paying industries, concentration means they may receive the maximum expected returns by using minimum payment in the certain period. In the meantime, these industries have to accept the high-risk that come with the high returns. Therefore, industries transferred almost all of the annual payments targeted to the potentially most valuable product after the analysis and assessment of potential risks and benefits. For the diversified paying industries, diversification may allow for the same expected returns with reduced risk. Due to the unpredictability of the market, industries can decrease the exposure to individual product risk by paying a diversified portfolio of the most valuable products.

Conclusions

There exists a great discrepancy in the distribution of payments transferred by pharmaceutical industries to healthcare professionals. The tiny minority of highest paying industries controlling the vast majority of payment. The largest majority of payments from these top-paying industries are mainly associated with few specific products. Furthermore, payments pattern among the tiny minority of industries include concentration and diversification. In future, we will attempt to investigate the driving factors of the concentration of certain pharmaceutical products via integrating more open datasets such as clinical trials and FDA approval documents.

Abstract

The demand for AI to improve patients outcome has been increased; we, therefore, aim to establish the diagnostic values of AI in diabetic retinopathy by pooling the published studies of deep learning on this subject. A total of eight studies included which evaluated deep learning in a total of 706,922 retinal images. The overall pooled area under receiver operating curve (AUROC) was 98.93% (95%CI:98.37%-99.49%). However, the overall pooled sensitivity and specificity for detecting referable diabetic retinopathy (RDR) was 74% (95% CI: 73%-74%), and 95% (95% CI: 95%-95%). The findings of this study show that deep learning had high sensitivity and specificity for identifying diabetic retinopathy.

Keywords:

artificial intelligence, deep learning, diabetic retinopathy

Introduction

Artificial intelligence (AI) is a machine intelligence that is meant to mimic human cognitive functions [1]. A deep learning system (DLS) is an advanced form of artificial intelligence allow an algorithm to program itself by learning from a large set of data. With rapid advances in technology, AI has recently been applied to many areas in healthcare due to paramount significant to enable early disease detection, and diagnosis decision. AI has already been created an opportunity to improve productivity in several areas of the economy, whereas in the healthcare need AI to improve efficiency, affordability, and accessibility [2].

The prevalence of diabetic retinopathy (DR) has been increasing. It is estimated that the number will be approximately 600 million by 2040 with one-third expected to have DR [2]. Retinopathy remains a leading cause of blindness globally. Therefore, timely screening for DR has accepted strategy for blindness prevention and proper treatment. However, there are several challenges to delivery of care: (1) clinical diagnosis is highly subjective; (2) lack of human assessors; and (3) long-term financial sustainability. Automated grading of DR indeed has potential benefits of increasing efficiency, reproducibility, and large-scale screening program. AI system would help to improve the quality of care by providing early diagnosis and treatment. Deep learning has had a profound impact on detecting DR from retinal photographs. We, therefore, evaluated the performance of deep learning in detecting DR by pooling the published literature.

Methods

This systematic review and meta-analysis were conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA). A review written protocol was not drafted.

We performed a comprehensive search of electronic databases, such as PubMed, Embase, Web of Science, Scopus, Google Scholar, Cochrane, and IEEE between 2000 and 2018. These databases provide a useful source of relevant and potential information as the subject of this study encompassed with two contexts including artificial intelligence and diabetic retinopathy. We used various keywords to search for most potential relevant studies. Keywords, synonyms of keywords, specific characters, and the Boolean operators are used in the search strategies as follows: “deep learning”, OR “artificial intelligence”, OR “automated computerized system”, OR “DL”, OR “CBIA”, AND “diabetic retinopathy”.

We carefully screened all the studies in the initial search and checked their relevant titles and abstracts. Two authors (MMI, TNP) examined these studies independently. To be included, all the studies had to fulfill the following criteria: (1) articles published in English and be peer-reviewed, (2) articles that provided an outcome diabetic retinopathy, (3) articles that provided information regarding evaluation measurements like receiver operating curve (ROC), accuracy, sensitivity, specificity, (4) articles that provided total number of DR patients (5) provided clear definition of DR, (6) articles that clearly described deep learning models and full information of dataset, (7) articles that provided explicit overview of DR image information. We excluded studies if they published in the form of editorials, letter to editor, review. All disagreement between two authors for selecting potential studies were then resolved by the chief investigator (YC, L).

Data extraction was conducted by the same two authors who used a predefined, standardized protocol, and data collection instrument. However, data were entered into Review Manager software (RevMan-5) and checked for accuracy. All information regarding extracted data were (a) title (b) method: study design, data source, number of image, number of study centers, and location, study setting, date of data analysis, process of data analysis, (c) participants: number of patients with diabetes, patients’ age, patients’ gender, age range, percentage of gender, diagnostic criteria, (d) outcome: primary and secondary outcome. We used the Quality Assessment of Diagnostic Accuracy Studies (QUADAS) tool-2 to assess the quality of the included studies in terms of risk of bias and concerns regarding applicability over four domains.

We calculated the sensitivity, specificity, and ROC value with 95% confidence interval (CI) for detecting diabetic retinopathy. A ROC curve is plotted the true positive rate (TPR) against the false positive rate (FPR) at various threshold settings. The values of the ROC curve 0.9-1, 0.8-0.9, 0.7-0.8, 0.6-0.7, 0.5-0.6 are defined as excellent, good, fair, poor and fail, respectively. The values of ROC, sensitivity, and specificity were measured with 95% CI in the final analysis. Every analysis was carried out in the random effect model. However, We used MetaDiSc (version 1.4) for the pooled estimate of AUROC, sensitivity, specificity, and diagnostic odds ratio.

Results

Through the initial searches of the electronic bibliographic databases, we identified 125 original articles. One author (HC, -Y) carried out additional searches of trial registers, commercial websites, conference proceedings, and reference lists of included studies; we identified one further study for inclusion. Therefore, the total number of records identified was 135. We then removed 87 duplicate studies. Furthermore, two authors (MMI, TNP) assessed 48 unique abstracts and eliminated obviously irrelevant studies from the titles and abstract alone. Of which, 12 articles went through full-text evaluation. Finally, 8 unique articles were eligible for the final meta-analysis [3-10].

Eight studies measured the performance of deep learning algorithms to detect referable diabetic retinopathy correctly and accurately from the retinal fundus photograph. The pooled AUROC of the deep learning model for diabetic retinopathy was 98.93% (95%CI:98.37%-99.49%), sensitivity was 74% (95%CI: 73%-74%), and specificity was 95% (95%CI:95%-95%). However, the diagnostic odds ratio was 250.83 (95%CI: 77.72-809.49). Three studies evaluated the performance of the deep learning algorithms to detect vision threating diabetic retinopathy. The overall pooled AUROC was 99.46% (95%CI: 99.27%-99.65%). However, sensitivity and specificity was 98% (95%CI: 97%-99%), 92% (95%CI: 92%-92%) respectively. In addition, positive likelihood ratio, negative likelihood ratio, and the diagnostic odds ratio was 25.08(95%CI: 11.36-55.39), 0.02(95%CI: 0.00-0.43), and 1316.41(95%CI:110.91-1562.29), respectively.

Conclusion

This systematic review and meta-analysis demonstrated that deep learning algorithms are highly accurate for the detection of referable diabetic retinopathy, with 74% sensitivity and 95% specificity. These results may change the way diabetic retinopathy is being diagnosed and would be helpful to implement AI in low resource areas. However, one of the key findings is that a deep learning system can detect DR with comparable or better performance than experts. The deep learning algorithm outperformed not only the most expert but also other traditional systems used previously. Overall, our study demonstrated that deep learning model has an acceptable degree of sensitivity and specificity for detecting diabetic retinopathy. The excellent likelihood and diagnostic odds ratio suggest that deep learning may be useful in the real-world clinical setting. However, deep learning algorithms would diagnose diabetic retinopathy better than human experts. In fact, it has potential applications in disease detection, monitoring, and prognosis in patients at risk of diabetic retinopathy.

Abstract

We explore the impact of data source on word representations for different NLP tasks in the clinical domain in French (natural language understanding and text classification). We compared word embeddings (Fasttext) and language models (ELMo), learned either on the general domain (Wikipedia) or on specialized data (electronic health records, EHR). The best results were obtained with ELMo representations learned on EHR data for one of the two tasks(+7% and +8% of gain in F1-score).

Keywords:
Natural language processing, electronic health records.

Introduction

State of the art methods in natural language processing (NLP) usually include learning a statistical representation of the vocabulary such as word embedding (e.g., word2vec, Glove, Fasttext [1]) or language models (e.g. ELMo [2]). One of the advantages of these approaches is that they are unsupervised: they do not require the learning datasets to be manually annotated with a ground truth. However, in the biomedical domain, the vocabulary is very specific. Would the representations learned from general domain corpus be usable for NLP tasks in the biomedical domain? Wang *et al.* [3] showed that learning embeddings using clinical notes from EHRs increased the performances. Nonetheless, it may be challenging to have access to the large number of documents requested (*e.g.,* more than 100k patients in the study of Wang *et al.*) or even have access to embedding matrices learned on such corpus, due to privacy issues.

This work explores the impact of the method and data source of embeddings on different tasks. We compared the performances of two types of word representations: Fasttext and ELMo. We also compared two different learning sets in French: Wikipedia or a set of 1M clinical notes from our local EHR. We evaluated the performances of these approaches on two different NLP tasks in French: natural language understanding and text classification.

Methods

Embeddings

We compared two types of embeddings: 1) continuous skip-gram model with sub-word information (*i.e.,* each word is represented as a bag of character n-grams), as implemented in fastText[1] and 2) embeddings from language models (ELMo) where the vectors are learned from the internal states of a deep bidirectional language model as described in [2]. As a baseline, we use a continuous skip-gram model learned only on the training set (no external dataset). We also compared the performances of these methods when learned on either a general domain dataset (French Wikipedia, Wiki) or a specialized dataset (1m clinical notes from a French AP-HP childrens hospital in Paris, EHR).

Tasks

Natural language understanding in a virtual assistant (VA task) This task aims to provide natural language understanding (NLU) in a virtual assistant for clinicians to explore biological tests results information in the patient's record in natural language (e.g., Donne moi le dernier résultat de créatinine 'Give me the last result of creatinin', Comment a évolué l'hémoglobine depuis 2 ans 'How has the hemoglobin evolved for the last 2 years'). The set of queries that a physician may have about characteristics and results of a patient is broad and diverse. Therefore, enabling queries in natural language may help access information more efficiently.

Given that no public dataset is available for this task in French, we generated a training set of 16,000 questions from templates, terminologies and paraphrases as described in a previous work [4]. This dataset contains 144k words (mean length of a question is 9). We also generated a development set of 4,000 questions for the tuning of the models. For the evaluation, we collected from physicians in our hospital, a set of 178 questions that they would like to ask in such a system.

For this study, we focused on the slot filling task (VA-sequence) consisting of a sequence labeling task aiming at

identifying whithin the question the lab test mention (e.g., *créatinine* 'creatinin') and the date-related information (e.g., *22/04/2012*, *depuis 4 semaines* 'for 4 weeks'). In the training set, the number of distinct lab mentions was 336 with a length ranging from 1 to 11 tokens and a median length of 2.

Text classification of absconding behaviour in nurses' notes (ABS-task) Absconding, where a patient leaves the **hospital without informing staff, is a rare but serious adverse event that can affect the safety of both the patient and people outside the hospital. Identifying hospital encounters with absconding patients can be challenging in most hospital information systems, given that those events are not systematically collected in a structured format.**

We collected nurses' notes from the clinical data warehouse of the European Hospital Georges Pompidou, an AP-HP hospital located in Paris. We collected a set of 2,605 notes that were manually classified by two experts by whether it mentions an actual absconding or not.

Models

As we aim to evaluate the impact of embeddings methods and data sources, we fixed the model used for the tasks and only let vary the embeddings.

We evaluated 5 different configurations of embeddings: a continuous skip-gram model of 300 dimensions learned on the training set; a fasttext embedding of 300 dimensions learned on the Wiki; a fasttext embedding of 300 dimensions learned on EHR; a ELMo embedding of 1024 dimensions learned on Wiki; and a ELMo embedding of 1024 dimensions learned on EHR.

Sequence Labeling task (VA-sequence) For the sequence labeling task (VA-sequence), we used a recurrent neural network (RNN) based on long short term memory units (LSTM). The architecture is based on a 2 layers bidirectional LSTM of 256 units.

CNN for Text Classification (ABS-task) For the classification tasks we used a convolutional neural network (CNN). After the embedding layer, the model contains a 1 dimensional convolutional layer of 250 units, kernel size of 3, ReLU activation, followed by a max pooling layer and a dense fully connected layer with softmax or sigmoid activation depending on the number of classes to predict.

We used a weighted F1-score to evaluate the results of the different models with 5 fold cross-validation.

Results

Sequence labeling task (VA-sequence) All the results for this task are presented in Table 1. The best results are obtained with ELMo learned on EHR with a F1-score of 0.76 (95%CI [0.74-77]) compared to Fasttext on EHR (0.67, 95%CI [0.61-0.73]). Interestingly, we show similar results between ELMo on Wiki (0.69, 95%CI [0.67-0.70]) and Fasttext on EHR (0.67, 95%CI [0.61-0.73]).

Text classification On this task, all the models give similar results with a low variation around the baseline (F1-score of 0.89 (95%CI [0.88-0.90])) as shown in Table 2.

Table 1 – Results for the NLU task for the virtual assistant: sequence labeling (Bi-LSTM)

Method	F1-score [95%CI]
Baseline (only training set)	0.62 [0.61-0.64]
Fasttext on Wiki	0.69 [0.67-0.70]
Fasttext on EHR	0.67 [0.61-0.73]
ELMo on Wiki	0.69 [0.67-0.70]
ELMo on EHR	**0.76 [0.74-0.77]**

Table 2 – Results for the classification of absconding in nurses' notes (CNN)

Method	F1-score [95%CI]
Baseline (only training set)	0.88 [0.87-0.89]
Fasttext on Wiki	0.85 [0.84-0.86]
Fasttext on EHR	0.87 [0.86-0.88]
ELMo on Wiki	**0.89 [0.88-0.90]**
ELMo on EHR	0.84 [0.83-0.85]

Conclusions

Depending on the task, embeddings learned on large corpora can have a significant impact on NLP tasks in the biomedical domain in French. Moreover, learning these embeddings on clinical notes will increase the performances compared to general domain. As it may not be feasible to access a large corpus of clinical notes, it is still profitable to use advanced methods such as ELMo learned on general domain and obtain reasonable results. When the task does not rely on a large specialized vocabulary, the impact of external embeddings might be reduced.

Rapid-Cycle Implementation of a Multi-Organization Registry for Heart Failure with Preserved Ejection Fraction Using Health Information Exchange Standards

Abstract

Constructing multi-site specialty registries typically proves time-consuming. Electronic health record (EHR) data collected during clinical care affords a pragmatic approach to accelerating registry implementation. Heart failure with preserved ejection fraction (HFpEF) is an increasingly common and morbid condition. Building a multi-site registry for HFpEF proved feasible using EHR data coded in standard terminologies (SNOMED CT, LOINC) and shared via Health Information Exchanges.

Keywords:

Registries; Health Information Exchange; Heart Failure, Diastolic

Introduction

After the major investment in migration to electronic health records in the U.S. [1], how can we leverage now-adopted EHR terminology standards for practical clinical benefit? Identifying and following patients with a specialized and/or rare condition across multiple centers/sites can help in better understanding the natural history of the condition, developing optimized diagnostic and management algorithms, and improving care. However, setting up multi-site specialty registries typically proves laborious and time-consuming. Agile development of EHR-based specialty registries leveraging data collected during clinical care shortens the development cycle time[2]. Additionally, shared definitions of conditions across multiple sites are now practical using standard terminologies for exchange of EHR data, such as SNOMED CT (Systematized Nomenclature of Medicine-Clinical Terms). SNOMED CT enables more focused condition definitions than possible with ICD (International Classification of Diseases) alone[3].

Heart failure with preserved ejection fraction (HFpEF, also termed "diastolic heart failure") is common, increasing in prevalence, and associated with a high burden of morbidity, mortality, and healthcare system expense[4]. Several cardioprotective pharmacotherapies have failed to improve clinical outcomes in patients with HFpEF largely due to the underlying heterogeneity in the disease pathophysiology, lack of uniform diagnostic criteria, and existence of clinically diverse phenotypes of the disease. Thus, there is an unmet need to better characterize patients with clinical HFpEF and develop targeted therapeutic strategies for their management. However, this information is not collected in standard cardiovascular registries. Accordingly, our institutions—an urban academic medical center, a large community hospital network, and an affiliated network of primary care physicians on disparate EHRs—wanted to create a pragmatic shared EHR-based registry of HFpEF patients for population health, quality improvement, and clinical research. Given that standard terminologies enable semantic interoperability between certified EHRs, we wanted to validate that leveraging those standards, specifically SNOMED CT and LOINC (Logical Observation Identifiers Names and Codes), would be helpful.

Methods

Software

The authors' institutions each separately employ Epic (Verona, WI, USA) as their EHR. Community physicians in our network are on a variety of EHRs (Allscripts, eClinicalWorks, NextGen, others). EHR diagnoses are recorded with clinical terms pre-mapped to SNOMED CT. Continuity of Care Documents (CCDs) conforming to U.S. standards were exchanged among EHRs via several health information exchanges (HIEs), both public and private: Carequality, eHealth Exchange, Epic's Care Everywhere, and our network's HIE (dbMotion, Pittsburgh, PA, USA). Diagnoses received via HIE are stored as "external problems." In 2017, UT Southwestern exchanged 7.3 million patient documents with other institutions' EHRs via HIEs.

Procedures

The HFpEF registry was constructed during two-week iterations, as previously described[2]. Both a broad (sensitive) and a narrower (specific) inclusion rule were constructed. The full registry was based on the broad rule, with the narrower definition applied as a report filter. Both inclusion rules were articulated initially during conference calls with cardiologists, captured as textual Boolean logic statements, then created within the EHR. Following medical record review of a sample of included patients by an expert clinician, the inclusion rules were further refined. Diagnosis groupers (value sets) for both HFpEF and co-morbid conditions were constructed using SNOMED CT concept hierarchies combined with boolean logic, and clinically vetted[2,3]. Existing SNOMED CT groupers for co-morbid conditions were re-used. LOINC codes were identified using the LOINC search browser.

Results

The broad (case-finding) registry inclusion rule employed five SNOMED CT condition-defining groupers (value sets) as inclusion or exclusion criteria. Two LOINC value sets were used, for left ventricular ejection fraction (LVEF) and estimated glomeular filtration rate (eGFR). The more specific inclusion rule added six SNOMED CT groupers defining exclusionary conditions (Table 1). An additional fifteen co-morbid conditions (e.g. diabetes, atrial fibrillation, etc.) employ SNOMED CT condition definitions (not shown).

Table 1 – Conditions Evaluated in Registry Inclusion Rules, Defined with SNOMED CT Concept Hierarchies

Role	Condition	Broad	Narrow
Inclusion	HFpEF-Diastolic Heart Failure	Yes	Yes
Inclusion	Congestive Heart Failure (with LVEF >=50%)	Yes	Yes
Exclusion	Systolic Heart Failure	Yes	Yes
Exclusion	CKD-5 (chronic kidney disease – stage 5)	Yes	Yes
Exclusion	On Renal Dialysis	Yes	Yes
Exclusion	CKD-4	No	Yes
Exclusion	Amyloidosis	No	Yes
Exclusion	Carcinoid Heart Disease	No	Yes
Exclusion	Cardiac Sarcoidosis	No	Yes
Exclusion	Hemochromatosis	No	Yes
Exclusion	Mitral Valve Replacement	No	Yes

SNOMED CT-defined conditions and LOINC-defined results were combined by boolean logic to form the registry inclusion rule, following the decision tree vetted with cardiologists (Figure 1).

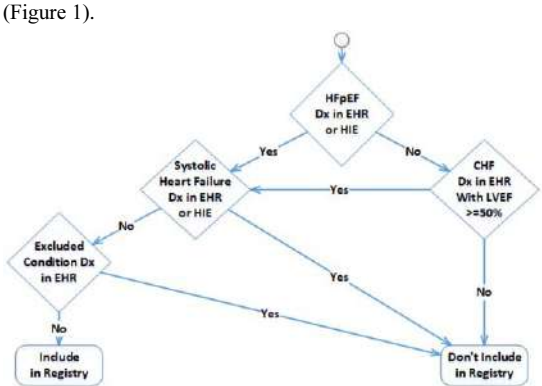

Figure 1 – Decision Tree for HFpEF Registry Inclusion Rule (Dx: diagnosis; CHF: congestive heart failure)

Registry Patient Characteristics

3,758 living patients are currently in the broad registry. 83% (3,111) also meet the more specific "primary" HFpEF inclusion rule. The population was primarily elderly, with the largest 10-year age band 70-79 (Figure 2). Female preponderance was seen in all age bands (overall 64% female, 36% male).

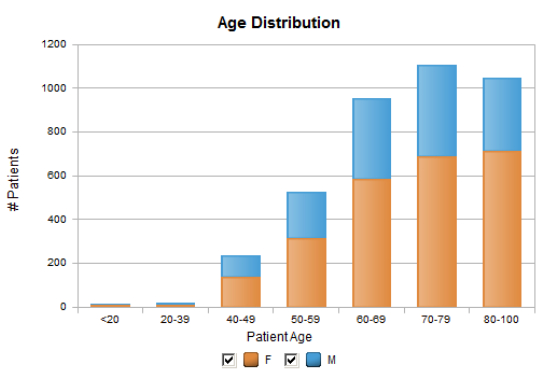

Figure 2 – Age-Sex Distribution of HFpEF Registry Patients

40% of registry patients had HFpEF on their external problem list data received via a CCD. Most of these (36% of registry patients) were included on the broad registry solely based on external data received via an HIE (Figure 3).

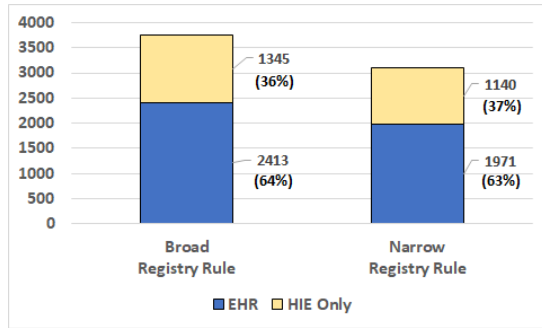

Figure 3 – Source of Information Placing Patient on Registry

Conclusions

Some specialized conditions such as heart failure with preserved ejection fraction (HFpEF) require complex inclusion rules evaluating both diagnosis and test result data. Even so, construction of a pragmatic multi-site EHR-based registry for HFpEF proved feasible using EHR data coded in standard terminologies. 36% of registry members were identified solely by clinical data received via an HIE. Sharing SNOMED CT rule-based value sets for computable clinical phenotype definitions, e.g. via the U.S. National Library of Medicine's Value Set Authority Center, would further expedite construction of such registries across multiple organizations using disparate EHRs. For specialized and/or rare conditions, using SNOMED CT-encoded EHR data has particular potential to help advance collaborative population health initiatives and to conduct multi-site pragmatic clinical research.

Abstract

Data standardiztion an important aspect to ensure data quality for utilizing large-scale, medical information databases such as the Medical Information Database Network (MID-NET) Project in Japan. We established a governance center to assess the consistency of standard codes across MID-NET-cooperating medical institutions. Moreover, we developed a real-time validation tool and determined its effect in improving data quality in medical institutions by providing a central feedback on the detected differences in standard disease-name codes.

Keywords:

Medical Information Database; Governance; Standardization

Introduction

The Medical Information Database Network (MID-NET) project (previously known as the "Japanese Sentinel Project") is establishing new "real-world data" (RWD) from multiple medical institutions in Japan. This project was established by the Ministry of Health, Labor, and Welfare, Japan, as a scientific approach to opt safety measures for adverse drug reactions to pharmaceuticals. The full-scale operation of the project was inititaed in FY2018 by the Pharmaceuticals and Medical Devices Agency (PMDA). The MID-NET database comprises RWD collected from approximately 4 million patients and consists of 10 medical institutions, including 23 hospitals in Japan. The project aimed to promote effective safety measures for drugs through pharmacoepidemiological methods using RWD. One of the most important factors for appropriately conducting pharmacoepidemiological research using medical information from multiple medical institutions is to systematically evaluate the quality of the data provided. However, the MID-NET Validation Project observed that, prioritized the management of medical institutions local codes associated to medical services, resulting in delays in clinical coding or omissions in standardized data [1]. As these factors are temporary, and continuously and unexpectedly occur at each institution, integrated management is extremely difficult and results in poor data quality. Therefore, our research group received support from the Japan Agency for Medical Research and Development (AMED) to establish an experimental "Governance Center" at the Kyushu University Hospital for the maintanence and management of the standard codes of the MID-NET project-cooperating medical institutions. Moreover, we developed a "real-time validation tool (Version 1)" for the management of standard codes and introduced this tool in two MID-NET project-cooperating medical institutions. Thus, the present study aimed to evaluate the standardization of codes across cooperating medical institutions and analyze the effect of this real-time validation tool in data standardization.

Methods

In this project, medical information from cooperating medical institutions was stored in the MID-NET integrated data source system from the Hospital Information System (HIS) via the Standardized Structured Medical Information eXchange Version 2 (SS-MIX2) [2]. This integrated data source system is used to network and comprises standardized database systems retrieved from electronic health records of cooperating institutions for the analysis and evaluation of adverse drug reactions. The MID-NET integrated data source system includes 11 types of currently available standard codes, such as the International Classification of Diseases 10th Revision (ICD10), Pharmaceutical Standard Code (HOT, YJ) and Laboratory Test Standard Code based (JLAC10) on SS-MIX2 standard storage. The table that was used while saving to a MID-NET integrated data source system was referred to as the "mapping table." The consistency of the standard codes from each cooperating medical institution that as extracted from the database of the Governance Center of the Kyushu University Hospital was evaluated using the mapping table (Fig. 1).

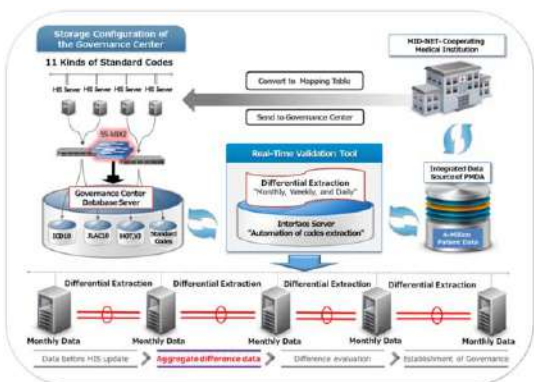

Figure 1–Configuration of the storage and real-time validation tool of the Governance Center

We evaluated the impact of the initial introduction of the real-time validation tool in two medical institutions for identifying differences in the standard disease-name codes from June 2018 to September 2018. The real-time validation tool automatically provided differential information on a monthly, weekly, and daily basis for 11 types of standard codes. Here, differential implies the addition of or change in the standard disease-management number and the standard disease name that matched with

the standard disease-name code in ICD10 as per the local code unique to that particular medical institution. We used the table for standard disease-name codes (v4.95 6/1 revised version) developed by the Medical Information System Development Center (MEDIS) as the key table (Fig. 2) to evaluate the accuracy of the difference detected by the real-time validation tool. Moreover, in an effort to determine the factors affecting the difference, we conducted an interview survey on the registration status of the standard disease names in the Electronic Health Records Management Department of medical institution A.

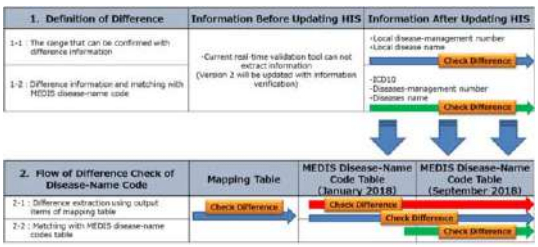

Figure 2–Flow of the procedure to detect differences in standard disease-name codes

Results

In total, 83 differences were detected by the real-time validation tool in medical institution A. Of these 83 differences, medical institution A showed a variation in the matching rate of the standard disease-name codes corresponding to 19 records in terms of consistency with the MEDIS key table. In medical institution B, 68 differences detected, which were consistent in the MEDIS key table (Table 1). Moreover, we confirmed three issues that were identified by an interview survey that assessed the flow of the registration of disease-name codes in the medical record management department.

1. 1. Medical records management department requested the registered, changed, and deleted disease-name codes from the medical information management department and were reflected in HIS.
2. 2. When registering the disease-name code in HIS, the codes were not evaluated for consistency with those in the MEDIS key table.
3. 3. When registering a disease-name code in HIS, the medical information department registered the medical institution unique disease-name code to the HIS when no suitable corresponding code was available in the MEDIS key table.

Table 1–Results of differential aggregation using MEDIS standard disease-name code

Time of Extraction	Medical Institution A (n=83)		Medical Institution B (n=68)	
Month	**Match**	**Mismatch**	**Match**	**Mismatch**
2018/6	0	4	20	0
2018/7	0	5	48	0
2018/8	0	5	0	0
2018/9	64	5	0	0
Total	**64**	**19**	**68**	**0**

Conclusions

The results of the present study indicate that the consistency between standard disease-name codes in the mapping table differed across medical institutions. At the clinical site, as only the institution unique code can be used, it is necessary to have a system that simultaneously, automatically, and correctly assigns corresponding standard codes. Moreover, using the real-time validation tool, we were able to visualize situations where large differences were noted in standard disease-name codes; these corresponded to differences detected by additions and changes at the clinical site. This may be attributed to the update of the MEDIS key table, which is conducted twice a year. Thus, it is presumed that the consistency may be affected following the update. Conversely, medical institution B showed a high consistency between and accuracy of disease-name codes regardless of the timing of the update of the MEDIS key table. Thus, these results indicate the following three reasons for the differences obseved in disease-name codes. First, while registering disease-name codes in HIS, if no code corresponded to those in the MEDIS key table, there was a high tendency to register a disease-name code unique to the medical institution. Second, when codes were stored in the mapping table in the SS-MIX2-standardized storage device, there was no real-time validation with the MEDIS key table. Third, coding errors and mistakes of the medical records management department were not evaluated when registering disease-name code in HIS. This study shows that consistency in standard disease-name codes by governance was effective in improving the data quality management system by detecting and unifying the mapping situation of standard disease-name codes in the MID-NET project. Taken together, our findings reinforce the importance of real-time management of standardized data and show that it is possible and feasible to improve data quality management by integrating and managing standard codes using a central governance method. While data inconsistencies were observed in the initial stage, the data quality dramatically improved following collaborative efforts between hospitals and PMDA. The MID-NET project is thus successfully progressing for full-scale implementation in FY2018.

An Information Retrieval Approach to ICD-10 Classification

Hee Park, José Castaño, Pilar Ávila, David Pérez, Hernán Berinsky, Laura Gambarte, Daniel Luna, Carlos Otero

Departamento de Informática en Salud, Hospital Italiano de Buenos Aires, Argentina

Abstract

ICD-10 (International Classification of Diseases 10th revision) is a classification code for diseases, signs and symptoms, abnormal findings, complaints, social circumstances, and external causes of injury or diseases. This paper describes an automatic information retrieval approach to map free-text disease descriptions to ICD-10 codes. We use the Hospital Italiano de Buenos Aires (HIBA) terminology data mapped to ICD-10 codes as indexed data to find an appropriate ICD-10 code using search engine similarity metrics.

Keywords:

Clinical Coding, International Classification of Diseases, Natural Language Processing

Introduction

The International Classification of Diseases code [1] is a very useful tool in a wide range of medical processes including statistical analysis of morbidity rate and mortality rate, medical reimbursement and resource allocation [2]. The registry by medical practitioners needs additional training time and manual encoding is not a simple task because not every health professional records in the same way [3].

Automated coding of ICD-10 is not an easy string matching work due to patient context's dependency [4]. There are two approaches to automated coding of medical texts to ICD-10: dictionary projection and supervised machine learning methods or the combination of both [3,4,5,7,8,9,10]. Dictionary projection methods use string matching techniques: n-grams, edit-distance, synonyms and abbreviations expansion, stop-word elimination, frequency of use, spell checkers and stemming. Machine learning methods include Support Vector Machine (SVM), Naive Bayes, Maximum Entropy Modeling (MaxEnt) and Gradient Boosting (XGBoost) [6].

The Hospital Italiano de Buenos Aires (HIBA) has a Spanish interface vocabulary where each term is mapped to SNOMED CT as its reference vocabulary. It has 207,000 post-coordinated concepts in its terminology system. This system provides services to the Hospital Italiano healthcare facilities as well as other healthcare institutions in Argentina, Uruguay, and Chile.

A major benefit of the local interface vocabulary is its size and coverage. Two previous works at HIBA are relevant to the work presented here. First, string similarity approaches [6] are used to map new description terms to existing terms in the interface vocabulary. Second, a terminology search-engine server was implemented [12]. We used a similar information retrieval approach to map a description term to the corresponding ICD-10 code. We constructed an ICD-10 search-engine that given a description term as a query, it finds the most similar existing term with an ICD-10 code and reports the corresponding ICD-10 code. We used the HIBA terminology data mapped to ICD-10 and the Spanish 2014 version of ICD-10 data. We also used HIBA terms frequency, stopwords, synonyms, collocations, abbreviations and frequent typographical errors term expansion. The ICD-10 data has 14,359 codes but HIBA mapping has 343,072 distinct terms that match only 8,537 codes (59.45%). We also added all the description terms corresponding to ICD-10 codes. We discovered a performance of 66.35% of recall @1, as an automated process [11,12]. We also evaluated recall @3, @5, @10. It should be noted that we obtained more than 80% with recall @5. These values are relevant for interactive approaches, where a health-care professional uses keywords or description terms to find the appropriate ICD-10 code for a given situation.

Methods

In this study, we constructed several indices using Elasticsearch to evaluate several alternative configurations. We used a dataset consisting of 6,787 distinct terms provided by an external institution that has been encoded by HIBA terminologists. Each electronic health record term can be codified to one or more ICD-10 codes, for example: "insuficiencia respiratoria con requerimiento alto de oxígeno" ("respiratory failure with high oxygen requirement") codes are J969 and R068.

Index Construction

The following parameters were used in each index construction with Elasticsearch:

1. Each data-set was indexed using Elasticsearch search engine using both n-gram and word analyzers.
2. For each concept in the HIBA terminology, we used its frequency to rank relevant concepts for a given mapping.
3. Mapping from HIBA terminology to ICD-10 concepts is a many-to-many mapping. We implemented these strategies using concept frequency:
   a) Maximum frequency of a HIBA concept mapped to an ICD-10 code.
   b) Minimum frequency of a HIBA concept.
   c) Average frequency of all HIBA concepts mapped to an ICD-10 code.
4. If a description term is mapped to more than one ICD-10 codes, if there is a more general term it is preferred (e.g. Z88 vs. Z889). At evaluation time, more general matches were considered correct.

5. Synonyms, collocations, abbreviations and frequent typographical errors term replacement. [6].

To construct the index, we evaluated 3 alternative data-sets:

I. The Spanish 2014 version of ICD-10 data.
II. The HIBA terminology.
III. The combination of both.

Results

We used several alternative configurations to construct the search-engine index. We used n-grams combined with word analyzers (1) and the term expansion (5) as the baseline approach. We used first only the Spanish 2014 version of ICD-10 data as the dictionary corpus (I), HIBA terminology frequency, and a general response as a valid match. This configuration resulted in 41.12 % recall @1.

Using the HIBA terminology as the dictionary corpus (II), we obtained a recall @1 of 62.84% improving the performance, without considering HIBA concept weights in ICD-10 codes. Using the two-dictionary corpus (III) provides a similar result, recall @1 62.9%.

The best result, recall @1 of 66.35, was obtained using minimum frequency strategy (3.b) stopwords and considering general codes as valid compared to a more specific one.

To be sure that the results returned by the search engine have better quality, a threshold can be used. We are considering a valid match only when the score is greater than the threshold. In other words, the search engine will not return a result under the confidence value. Using the score threshold of 6,000 we have a good balance, providing a better precision without losing too much recall. In Figure 1, we show the results of recall at more than one result for interactive choose.

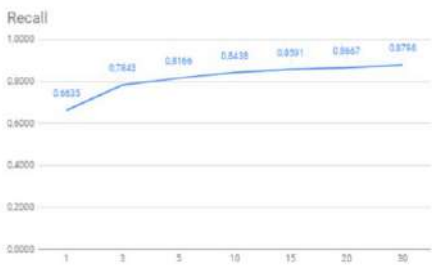

Figure 1. Recall @1, @3, @5, @10, @15, @20, @30

Discussion

We can see that the HIBA terminology to ICD-10 code mapping terms corpus, provides the best performance. The HIBA terminology covers only 59.45% of the ICD-10 codes but the richness in synonyms and frequent typographical errors enable a good result. We are using a combination of HIBA mapping to ICD-10 and the ICD-10 to complete all the ICD-10 codes but this addition doesn't provide a significant improvement.

The selection of the strategy (3.b) above, which uses the minimal frequency produces a better result than using the maximal, or the average frequency, which is somewhat surprising.

In the context of a health-care professional recording using an EHR, the system can provide the possibility of choosing the appropriate ICD-10 code from the list that returns the search engine, and as we have shown, recall @5 and @10 are very good, in the mid-80s.

Conclusions

In this work we showed several alternatives to construct an index for automatic ICD-10 term codification. We obtained a very reasonable performance. Some limitations of the current approach may be related to the differences on the corpus of the HIBA terminology data compared to the external institution data. Our approach is a dictionary projection method. A hybrid approach using supervised machine learning techniques may improve the performance.

Abstract

With the vast increase of digital healthcare data, there is an opportunity to mine the data for understanding inherent health patterns. Although machine-learning techniques demonstrated their applications in healthcare to answer several questions, there is still room for improvement in every aspect. In this paper, we are demonstrating a method that improves the performance of a delirium prediction model using random forest in combination with logistic regression.

Keywords:
Algorithms, Delirium, Logistic Models

Introduction

With the increase in the rate of generation and collection of digital healthcare data, there is the need to mine the data for the extraction of knowledge. In the context of secondary use of health care data, the question arises if the large set of health care data can prevent some unwanted events during the health care process [1].

Predicting Delirium in Hospitalized Patients

Delirium is a neuro psychiatric syndrome which is very common in the elderly and is prevalent in the hospital setting. ~Up to 60% of elderly patients develop delirium during hospitalization and are often under diagnosed [2]. ~30-40% of such cases can be prevented with an intervention [2]. Delirium can cause further morbidities and may lead to death [2]. Thus, delirium is being recognized as a hospital quality measure [3]. Recent publications dealing with delirium prediction were based on delirium assessment tests and some selected features [2]. The idea was to identify patients who are at risk of developing delirium during their stay at the point of hospitalization using electronic medical records (EMR). Related work has been presented in previous publications, in which we have selected Random Forest (RF) to predict delirium as it is transparent to explain the decisions when compared to its counterparts [4].

Classification with Random Forest

Predicting delirium is a binary classification problem (either delirium or not). The present work was motivated to find ways to further improve the performance of classification, by combining RF with other algorithms.

RF is an ensemble of a set of decision trees, where each decision tree is a weak learner as only a subset of the data is used. Figure 1 shows a forest of n decision trees where the labeled nodes are the leaves where the decisions of the observations of the data took place. In prediction step, for an observation of the test set, data traverses through the tree and lands in only one of the leaves in each tree of the forest (red node). The corresponding decision of the selected leaf is considered for the prediction.

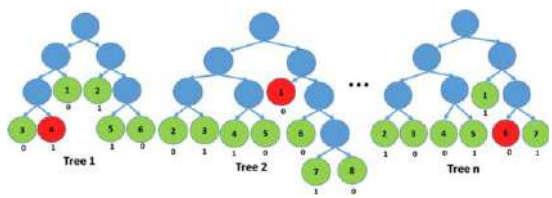

Figure 1– For prediction, each observation lands in one of the leaves (Decision leaf is red coloured node) in each tree of RF.

Objectives

The aim of this work was to present a method that would assign weights to each leaf (terminal node) in each tree of the RF, which would, subsequently improve the performance of the delirium prediction model and provide a transparent way of explaining the decisions.

Methods

Data, Sample Selection and Featureset

The data includes patients' demographical data, diagnoses, procedures, laboratory results, nursing assessment, etc. These data are partly based on international standards such as ICD - 10, ICPM, LOINC, etc. (see [4]). The data was provided by Steiermärkische Krankenanstaltengesellschaft m.b.H (KAGes).

After administering a set of criteria (see [4]), the delirium cohort consisted of 4,596 patients. 25,000 patients were selected randomly as control group in which 24,972 patients were considered for the analysis. After a systematic feature selection and engineering (see [4]), the final featureset consisted of 500 features with purely numerical values.

Algorithm

The algorithm described in this paper is based on an example published by Tim Head [5]. Initially, the given dataset was divided into three subsets with a ratio of 35%, 35%, and 30%. These datasets were used for training RF, Logistic Regression (LR), and evaluation, respectively. Figure 2 shows training set one, training set two and test set along with corresponding response variables y_{tr_1} , y_{tr_2} and y_{test} respectively (ground truth).

Step 1: Training the RF (turquoise): The training set one along with the corresponding response were used to train RF model. The leaves of individual weak learners of the RF model were transformed into a new feature matrix using One Hot Encoding [5].

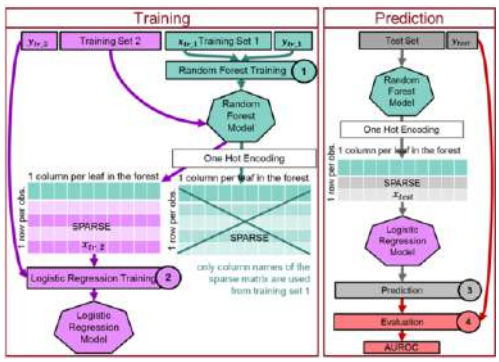

Figure 2– Overview of the algorithm, consisting of 1) training a random forest from training set one, two) deriving a new feature matrix, and 3) testing the final model with the test set.

Step 2: Training the LR model (purple): The training set two was applied to the RF model. Each observation in training set two leads to one leaf in each tree of the forest. The leaf indentifiers (IDs) of the corresponding decision leaves of each tree were fitted to the columns of the new feature matrix. The purple new feature matrix x_{tr_2} was considered as a training set along with a corresponding response variable $\{(x_{tr_2}, y_{tr_2})\}$ to train a LR, with regularisation. Step 3: Evaluation: the test set was fed into the RF model; the leaves of the decisions in the forest were fitted to the columns of the new feature matrix, which was used for prediction by the LR model. The predictions were then compared with the response variable y_{test} for evaluation. In this algorithm, we consider the IDs of decision leaves instead of the decision itself.

The length (number of columns) of the new feature matrix is denoted by $l = \sum_{i=1}^{n} N_i$, where, n is number of trees and N_i is number of leaves of the i^{th} tree. The coefficients (β_{ij}) that are derived from learning LR act as the weights of corresponding leaves in the trees of RF. The estimated outcome $\widehat{y_p}$ is derived from the formula given below.

$$\widehat{y_p} = \beta_0 + \sum_{i=1}^{n} \sum_{j=1}^{Ni} \beta_{ij} . x_{pij} \qquad (1)$$

Where $x_{pij} = 1$ when the decision for patient p lands in j^{th} node of the i^{th} tree, otherwise $x_{pij} = 0$. The classification will be obtained based on the selected threshold over the $\widehat{y_p}$.

Evaluation

We evaluated our approach by comparing the area under the receiver operating characteristic (AUROC) with that of LR, RF with majority voting and RF with weighted averaging. The results presented were obtained from built in functions of MATLAB for RF weighted average and LR. We have implemented proposed feature transformation method and RF Majority voting as described in evaluation in MATLAB. All RFs were trained with 1,000 trees, classification method with out of bag (OOB) prediction 'on' and without pruning and minimum leaf size selection.

Results

Figure 3 shows the AUROC of the four methods listed above. The AUROC of RF alone was 90.20%. With introduction of logistic regression, the performance increased by 1.17%.

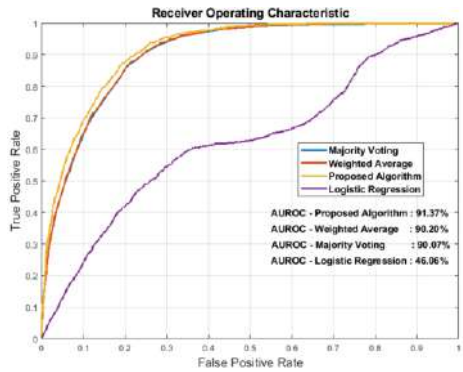

Figure 3 – AUROC of proposed method along with RF weighted average, majority voting and LR

Conclusions

The proposed method has outperformed the classical selected algorithms. However, there is a need for detailed investigation for real time health care applications. The merger of RF and LR has potential to find a reasonable way to explain the decisions.

Abstract

In this study, we sought to develop an automatic parser tool for unstructured free-text electronic prescriptions, focusing specifically on defining the daily dose. We manually coded a set of electronic discharge prescriptions and established the most reliable rules to structure the medication data. A named-entity recognition (NER) parser tool was implemented, which was capable of identifying 90% of the doses and 86% of the frequencies from 255 dosage instructions.

Keywords:

Electronic Prescribing, Natural Language Processing, Prescription Drugs

Introduction

Electronic prescription technology is a digital health solution that seeks to improve the productivity of prescription filling, reduce the number of prescription errors in traditional prescription script writing, and optimize the appropriate use of drugs. Currently, in Quebec, electronic prescribing systems within electronic medical records normally allow prescribers to input either structured or free-text drug dosage instructions, the latter which precludes the systematic application of computer algorithms for further analysis (e.g., for pharmacoepidemiology studies or clinical decision tools). In order to maximize the potential of electronic prescription technologies, it is essential to have access to structured and standard drug dosage instructions. This study seeks to develop an automatic parser for unstructured electronic instructions.

Several studies have presented methods to extract medication data. Most notably in the literature, the third i2b2 Workshop on Natural Language Processing promoted research in medication data extraction from discharge summary [1]. For example, Xu et al. developed a natural language processing (NLP)-based parser to capture signature information (e.g., strength, route, frequency) and discussed the potential of NLP technologies to extract contextual information ("start", "stop", "increase") [2]. Based on previous designed models, we decided to build a parser adapted to Quebec's prescribing practice using real-life e-prescriptions.

In this study, we developed an NLP-based parser for structuring the dose and frequency data from free-text electronic discharge prescriptions in Quebec, and compared its performance with a baseline using only regular expression.

Methods

Data Sources, Data Analysis, and Semantic Categories

The hospital discharge data originated from a previous study on medication reconciliation at the MUHC [3]. Between October 2014 and November 2016, the study collected 131,336 hospital discharge prescriptions written in English by 202 physicians. We manually structured the dose and frequency data to establish the reference standard.

Opioids (oral form) were targeted given their high level of risk, variability in dose and frequency instructions, which are prone to parsing errors. ATC codes were used to identify and filter the opioid therapeutic class of drugs (ATC code starting with N02A), resulting in a total of 925 free-text opioid prescriptions.

Based on the available data for the input fields (Table 1), we established our desired output fields (Table 2) to determine the daily dose (daily drug exposure). For reference standard, the dose and frequency could either be fixed (one value) or variable (dose range per day with one minimum and one maximum value). To provide a better context of the daily drug exposure, we defined contextual tags (e.g., if the drug is "taken if needed", a "combination drug" or "variable dose over time"). The ultimate goal of this study is to define the daily dose, which could then be used to evaluate patient drug exposure on a daily basis and then applied to population-level data. We manually entered the dosage instruction in the appropriate fields according to our established reference standard, which was later compared with the results generated by the parser tool.

Implementation of a Natural Language Processing Tool

We compared two approaches to structuring the prescription data: regular expressions and an NLP-based approach. Although relatively simple to implement, regular expressions can only detect specific words or pattern of letters in a fairly rigid framework. Consequently, they could fail at any little divergence from the specific patterns defined. To produce a more robust parser, we used named-entity recognition (NER), an advanced natural language processing technique, for a

more generalized pattern recognition. NER is applied to detect different parts of a prescription such as the dosage or frequency. We implemented this method in SpaCy, a open-source NLP library that does NER [4]. The results were compared with the manually coded reference standard. Errors (e.g., not a perfect match) were then manually reviewed by the pharmacy intern (MQL), who analyzed their cause and provided feedback.

Table 1- Data source available for input for the parser tool

Input source	Examples
Generated by the prescriber	
Generic name	HYDROMORPHONE
Free text posology	1–2mg po q4-6h PRN for 2 weeks
DIN	885444
Generated through a look-up table with Vigilance (via DIN)	
Pharmaceutical form	TABLET
Strength	1MG
ATC code	N02AA03

Table 2- Desired output source for the parser tool

Example: 1–2mg po q4-6h PRN for 2 weeks	
Output field	**Desired output**
Dose information	
Dose range tag	1
Fixed dose	
Minimum dose	1
Maximum dose	2
Dose unit	mg
Frequency information	
Variable frequency	1
Fixed frequency	
Minimum frequency	4
Maximum frequency	6
Other qualifiers	
If needed (PRN)	1
Variable dose over time	0
Combination medication	0
Daily dose	
Minimum daily dose	4
Maximum daily dose	12

ResultsOverall, the NLP-based parser achieved a similar recognition success rate as the regular expression baseline. Both methods had similar frequency detection rate (91%). The dosage detection was better in the SpaCy-based parser (90%) than the baseline (86%) (Table 3). However, regular expressions had a better perfect match rate (84%) than NER-based approach (79%). The errors were analyzed to determine the cause. The main cause of errors was associated with combination medications (e.g., two or more active ingredients contained in a single pharmaceutical form), as the parsers had not been trained to detect those patterns yet. During parsing, the dose obtained was expressed in unit (e.g., number of tabs) instead of the dose per intake (in mg), which mislead the calculation of the daily dose. The daily dose was calculated according to the strength of each ingredient contained in the combined medication multiplied by the unit. Alternate doses in a single instruction also caused confusion during parsing. Lastly, the prescriber could prescribe either by product strength (e.g. tablets of 5mg) or dose (2.5 mg). When prescribed by product strength the parser had difficulty recognizing the difference between the dose per intake and the dose per tablet.

Table 3- Success rate for the extraction of unstructured dosage instructions

Match Type	Regular expressions (230 samples)	NLP-based parser (225 samples)
Fixed dose	86.5%	89.8%
Dose range	N/A	86.3%
Dose units	N/A	85.5%
Number of tabs	N/A	79.2%
Number of tabs range	N/A	81.2%
Strength	N/A	74.9%
Fixed frequency	91.7%	90.2%
Frequency range	N/A	80.8%
Taken if needed	N/A	94.1%
Variable dose over time	N/A	58.4%
Perfect match	83.9%	79.6%

Conclusions

In this study, we demonstrated that unstructured dosage instructions can be accurately extracted from hospital opioid prescriptions using standard NLP techniques. With promising results at an early development stage, it is reasonable to assume that the parser will have the potential to detect particular context cues and calculate the appropriate daily drug exposure. We can hope that future pharmacoepidemiology studies can benefit from this tool by extracting a variety of dosage instruction information, including the unstructured data without proper standardized fields. The ability to structure free-text opioid dosage instructions can be used to detect particular prescribing behaviors and resulting consequences, which are particularly relevant in the current context of opioid epidemic and misusage.

Abstract

Advanced chronic kidney disease (CKD) requires routine renal replacement therapy (RRT) that involves hemodialysis (HD) which may cause increased risk of muscle spasms, cardiovascular events, and death. We used Artificial Neural Network (ANN) method to predict clinical events during the HD sessions. The vital signs, captured using a non-contact bed-sensor, and demographic information from the electronic medical records for 109 patients enrolled in the study was used. Weka Workbench software was used to train and validate the ANN model. The prediction model was built using a Multilayer perceptron (MLP) algorithm as part of the ANN with 10-fold cross-validation. The model showed mean precision and recall of 93.45% and AUC of 96.7%. Age was the most important variable for static feature and heart rate for dynamic feature. This model can be used to predict the risk of clinical events among HD patients and can support decision-making for healthcare professionals.

Keywords:
Renal dialysis, neural networks, electronic health records

Introduction

Taiwan reached peak incidence of chronic kidney disease (CKD) in 2014. CKD could advance into end stage renal disease (ESRD) which can be mentally and financially burdening. ESRD requires renal replacement therapy (RRT) to maintain quality of life and extend life expectancy among ESRD patients [1]. Hemodialysis is considered as treatment of choice for renal CKD and ESRD [2]. Despite its benefits, the procedure comes with risk of muscle spasms, cardiovascular events, and even death [3].

Artificial neural networks (ANN) have been known to provide state-of-the-art results for most of the classification tasks [4]. Despite its limitation to handle imbalanced data, recent oversampling method could overcome the problem correctly [5]. In this study, we aimed to predict clinical events during hemodialysis session using Multilayer Perceptron (MLP) algorithm.

Methods

In this study, the vital parameters were monitored and recorded for 109 patients during their HD session at Taipei Medical Hospital, Taipei, Taiwan. The data were collected using non-contact piezoelectric sensor which can be placed under the mattress. Total 3,237 HD sessions were observed in 23 weeks. During each session the data captured included: heart rates (HR), respiration rates (RR) and movement data (MD). In addition, the demographic details of patients such as gender, age, height, and weight, were also obtained. Following data collection, data cleaning and preparation procedures were conducted, using the synthetic minority over-sampling technique (SMOTE) [6] to handle unbalanced data between classes. Patients who reported emergency visit (ER), muscle spasm (MS), inpatient (IP), emergency visit and inpatient (ERIP) or sudden death (SD) during observation were classified in the class-event, and not reported clinical events as no-event. Weka Workbench software was used to train and validate the ANN model [7]. We performed 10-fold cross validation to evalute the model.

Results

The performance of the model developed in this study as shown in Table 1, showed an ROC of 0.96 (Figure 1) with False Positive Rate (FPR) and True Positive Rate (TPR).

Table 1 – Weighted Average Performance Model Result

	Precision	Recall	ROC
MLP	0.93	0.93	0.96

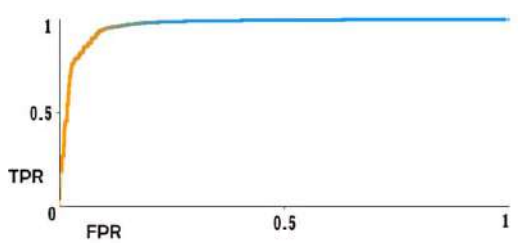

Figure 1 – ROC Curve
(TPR: True Positive Rate, FPR: False Positive Rate)

6 nodes in hidden layer MLP model showed top 5 significant variables (Table 2) as following: Heart Rate First Five Minutes (HR_FFM), Respiration Rate First Five Minutes (RR_FFM), Age, Respiration Rate Last Five Minutes (RR_LFM), and Heart Rate Last Five Minutes (HR_LFM) (Table 2).

Table 2 – Total weight variable in hidden layer MLP

No	Variable	Total Weight
1	HR_FFM	51.65743
2	RR_FFM	27.29772
3	Age	18.02295
4	RR_LFM	9.87849
5	HR_LFM	6.46442

Discussion

Our study indicated that ANN approach when applied to the classification task, performed with an ROC curve of 0.96 %. A study conducted by Barbieri et. al used AI to improve anaemia management during HD [8]. Our previous study [9] applied commonly known statistical learning methods such as k-Nearest Neighbour (kNN) and Support Vector Machine (SVM). In our study, MLP, as a feature selection algorithm, extracted HR_FFM as the most important variable for static feature and age for dynamic feature, which indicated that the model used the non-contact sensor to come up for clinical suggestions determine event or non-event patient. These suggestions could be sent to physicians to assist with their clinical decision making. Feedback about the suggestions (correct or wrong) would be collected, and as feedback into the AI system so that it can keep improving accuracy.

Conclusions

Our study demonstrated a new approach using non-contact sensor data and demographic data of HD patients, MLP being the proposed prediction model. MLP algorithm shows better performance than commonly known statistical learning methods. Our model could be used to predict the risk of clinical events among HD patients to support decision for healthcare professionals.

Design of a System of Systems (SoS) for the Interoperability of Non-Invasive Sensors for the Care of Older People

Carla Taramasco[a,b], Fabián Riquelme[a,b]

[a] *Escuela de Ingeniería Civil Informática, Universidad de Valparaíso, Chile,*
[b] *Centro de Investigación y Desarrollo en Ingeniería en Salud, Universidad de Valparaíso, Chile*

Abstract

We propose the design of a system of systems (SoS) called Seniors Guardian as an integrated environment for healthcare monitoring, in which several non-invasive sensors coexist to monitor falls, nocturia, perseverant behaviors, air quality (carbon monoxide), humidity, and temperature in real time. The modular architecture also allows the integration of new components. This research adheres to the use of Internet of Things to develop ambient assisted living in smart homes.

Keywords:

Frail elderly, Homes for the Aged, Environment, Internet

Introduction

A permanent risk in older adults is falls. Around one-third of adults older than 65 suffer a fall each year, and only half can get back on their own after they fall [1]. This can lead to fear, pressure ulcers, osteopenia, loss of muscle mass, dehydration, hypothermia, pneumonia, and even death [2]. The financial costs that countries pay to cover injuries caused by falls in adults over 65 are substantial and sometimes unsustainable over time [3]. Other risky event that may occur inside homes of the elderly is nocturia – the need to wake up at night many times to go to the bathroom. Nocturia is associated with sleep disorders that can lead to reduced concentration, cognitive decline, poor levels of energy, and overall, negative effects on the quality of life [4].

To deal with these issues, a patient-centered care model is recommended, where not only emergency cases are accepted, but also patients are actively committed to their care and therapeutic processes [5]. The advances in information technology (IT) and the reduction in hardware costs favor a preventive and proactive healthcare experience. Non-invasive monitoring of elderly allows for this experience and takes care of early symptoms of neurodegenerative diseases and the generation of treatments, plans, and programs geared towards the needs of this age group. In this context, *smart homes* quip homes with technology elements (such as sensors, microcontrollers) to monitor actions or events of the residents, as well as environmental conditions at the location, in order to detect emergencies early and reduce the times in making subsequent decisions [6,7].

There are several recent advances in low-cost devices to detect falls [7,8] and nocturia [9] in older people. It is known that people with nocturia are exposed to falls, due to the state of drowsiness at night [10]. However, there are no long-term measures to determine what percentage of falls in older adults are caused by nocturia. To solve this problem, the interoperability of monitoring systems would be necessary.

Methods

The goal is to develop a platform for continuous monitoring of the adult's daily activities to detect risk events both *inside* and *outside* of home. The key is to provide them with tools while safeguarding their autonomy and independence. The System of Systems (SoS) should contain software and hardware (sensor network) components. The monitoring systems considered are the following:

Actimetry (M1): To classify the daily activities of the elderly through infrared sensors of low resolution (for privacy). This will allow generating patterns of daily behavior. After the elderly activity profile is created, a probabilistic model based on Markov chains can determine abnormal behaviors. This module will be used to detect falls with an accuracy of 90%, by means of AI algorithms already in use [8].

Harmful gases detector (M2): To detect abnormal concentrations in environment and thus prevent accidents (such as explosions, inhalation of carbon monoxide) from sources of emission of gases (such as kitchen, stove, heater).

Temperature and humidity sensors (M3): To measure environment indicators that could negatively affect the health of the elderly.

Alert module (M4): To receive alerts generated by the elderly out of home through a 3G key chain with a panic button. Alerts are sent together with the elderly location to his/her contacts and emergencies.

Wandering analysis module (M5): To detect the wandering of the elderly. A mathematical model on the key chain of M4 monitor elderly trajectory and determines if she/he is lost.

With the data collected by the sensors, daily, monthly, and annual reports on the activities of the patient will be made. By unifying information from several patients, it will be possible to perform advanced analysis through data mining, to find non-trivial patterns: characteristics of the evolution of old age, disability, dependency, and more in order to guide treatments, plans, programs, and policies.

Results

We propose *Seniors Guardian*, an integrated environment for healthcare monitoring (Figure 1). The modularity approach allows the integration of new components. If one module stops

working, the others can continue to work. Data access will be given by two types of interfaces: a web application, for healthcare staff and decision makers that displays data about follow-up of the elderly, alerts issued, and descriptive statistics of their evolution; and a mobile application that receives the alerts and displays them in the cell phones of the contacts (user's family/caregiver) and the physician in charge.

The hardware drivers consist of a Local Processing Unit (LPU) to process the signals captured by the sensors, and a Remote Supervision Unir (RSU) to receive and manage the information sent from the LPU or the 3G key chain. The thermal sensor-actimetry is an AMG8833 (Figure 2) with 8x8 resolution pixels (viewing angle of 60°x60°). Information is processed by an ODROID-C1+ minicomputer connected to the sensors by an ATMEGA328P microcontroller (Figure 3). The key chain 3G uses a wireless button with 3G connection, 3.7V 800mAh battery, GPS and will allow calls. A DHT22 sensor detects humidity between 0-100% RH with 5% accuracy and temperature from -40°C to 125°C with 0.5°C of precision. It has a sampling rate of 0.5 [Hz] (it measures every 2 seconds). The MQ-9 sensor can detect concentrations of harmful gases from 100-10000ppm.

Figure 1 – The Proposed Solution

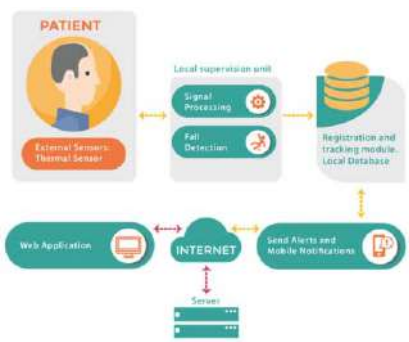

Figure 2 – Thermal Sensor Diagram

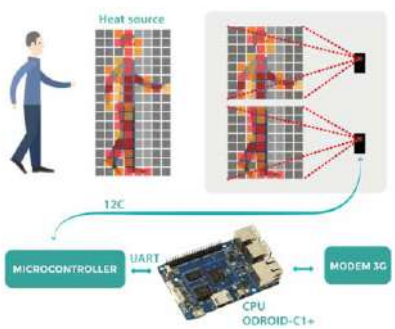

Figure 3 – Older Adult Detection and Sensor Coverage Area

Conclusions

Nowadays, the patient-centered care model is fundamental to improve the quality of life of the elderly people. In this work, we proposed a SoS that allows the interoperability of all these systems in a modular way, favoring the crossing of information to improve patient care, detect emerging risks more quickly, and respond more efficiently when a fall or some other problem occurs. Once the system is implemented, it will be validated by patients in a real-world environment.

Comparing Two Standardized Value Sets of Infectious Agents: Implications for Semantic Interoperability

Julian Sass[a], Moritz Lehne[a], Sylvia Thun[a, b, c]

[a] *Berlin Institute of Health (BIH),10178 Berlin, Germany,*
[b] *Charité – Universitätsmedizin Berlin, 10117 Berlin, Germany*
[c] *Hochschule Niederrhein – University of Applied Sciences, 47805 Krefeld, Germany*

Abstract

Infections are a global public health concern. For coordinated actions against infectious diseases, semantic interoperability between infection control systems is crucial. This requires a consistent use of standard terminologies such as SNOMED CT. Here, we compare two value sets of infectious agents annotated with SNOMED CT (WHONET 2018 vs. pathogens reported under the German Protection against Infection Act). Our comparison revealed several inconsistencies, highlighting the importance of the consistent and coordinated use of standard terminologies.

Keywords:

Infection control, SNOMED CT, Standardization

Introduction

Infections are among the leading causes of death worldwide [1]. As communicable diseases, infections can lead to dangerous outbreaks, claiming a high number of victims (recall, for example, the 2013-2016 Ebola epidemic in West Africa, which killed over 60% of the patients infected [2]). Multidrug-resistant organisms exacerbate the danger of infectious diseases and are especially challenging for hospitals, in which the total burden of hospital-acquired infections largely exceeds other communicable diseases [3]. Improving our understanding of infections and developing effective surveillance, treatment and prevention programs are therefore high-priority public health concerns, which can save lives and mitigate the risk of local and global epidemics.

Establishing effective infection control programs requires a common language—a standard terminology—for infectious organisms. Such a standard terminology can ensure that, once detected, infectious agents are documented in a systematic way so that different institutions or systems can easily exchange information. This semantic interoperability can enable large-scale analyses across different hospitals, institutions and countries leading to better prediction, early intervention and, ultimately, prevention of infectious diseases.

SNOMED CT (www.snomed.org) is a powerful terminology of medical concepts that provides a possible solution for developing standardized value sets of infectious agents. The top-level concept "Organism" that is part of SNOMED CT includes 34,405 subconcepts, among them a multitude of bacteria, viruses, prions, fungi, nematodes and others. This makes SNOMED CT a suitable terminology for defining comprehensive value sets of infectious agents.

The clinical concepts included in SNOMED CT have been used to generate standardized value sets for infectious organisms. For example, WHONET 2018 [4], a microbiology laboratory database software developed for the surveillance of infectious diseases, includes a list of 2,551 infectious agents annotated with SNOMED CT. Similarly, a German project annotated a list of infectious organisms with SNOMED CT to improve the communication between laboratories and public health authorities [5]. This list comprises the notifiable infectious organisms that have to be reported to the Robert Koch Institut (RKI) under the German Protection against Infection Act (Infektionsschutzgesetz, IfSG) [6].

However, to ensure semantic interoperability between different value sets (such as the two described above), standard terminologies have to be applied consistently. If different value sets use different codes for the same organism—even if they originate from the same terminology—interoperability is not eventually achieved.

This study aims to evaluate the consistency between two value sets that use SNOMED CT as a standard terminology for infectious agents. Using the value sets from WHONET 2018 and the RKI list of infectious agents annotated with SNOMED CT, we compare the agreement between concepts in the two value sets.

Table 1 – Example of infectious organisms reported under the German Protection against Infection Act (FSN: Fully specified name).

Organism	SNOMED CT identifier	SNOMED CT FSN
Adenovirus	74871001	Human adenovirus (organism)
Bacillus anthracis	21927003	Bacillus anthracis (organism)
Bordetella parapertussis	26183002	Bordetella parapertussis (organism)
Bordetella pertussis	5247005	Bordetella pertussis (organism)
Borrelia recurrentis	34726005	Borrelia recurrentis (organism)
Brucella sp.	26250004	Genus Brucella (organism)
Campylobacter	35408001	Genus Campylobacter (organism)
Chlamydia psittaci	14590003	Chlamydiophila psittaci (organism)

Methods

The starting point of this analysis is the list of microorganisms included in the WHONET 2018 software [4], which additionally contains a map to SNOMED CT identifiers for each of its organisms. A second list of 55 organisms is provided by the Robert Koch Institut (RKI) under the German Protection against Infection Act [6]. This set of notifiable pathogens was annotated with SNOMED CT as part of a project in the German federal state of North Rhine-Westphalia aimed at modernizing the reporting system between laboratories and health authorities [5]. Table 1 shows an excerpt of the organisms included in the RKI list. Initially, this analysis tested, how many of the 55 microorganisms from the RKI set were included in the WHONET set. In a second step, as illustrated in table 2, we compared if SNOMED CT identifiers for organisms in one set matched the identifiers of equivalent organisms in the other set.

Table 2 – Example comparison of agreement between organisms mapped to SNOMED CT from WHONET and RKI

WHO organism	SNOMED CT identifier	RKI organism	SNOMED CT identifier
Adenovirus	74871001	Adenovirus	74871001
Campylo-bacter sp.	116457002 (deprecated)	Campylo-bacter	35408001
Varicella zoster virus	80298008	Varicella-Zoster Virus	19551004

Results

Of the 55 pathogens listed in the RKI value set, 49 (89.1%) could also be identified in the WHONET value set. Of these, 32 (58.2%) were annotated with the same SNOMED CT identifier; 12 (21.8%) were annotated with different, sometimes more specific SNOMED CT identifiers; 2 (3.6%) were annotated with inactive identifiers; 3 (5.5%) did not have identifiers in the WHONET list (Figure 1).

Conclusions

The comparison between both sets of microorganisms annotated with SNOMED CT presented several inconsistencies. For example, semantically equal concepts did not have identical identifiers or matched just narrowly in subtype relationships. Note that with 2,551 organisms, the WHONET value set is much larger than the RKI value set and therefore can use a more fine-grained classification of organisms. This could explain why, for some organisms in the RKI value set, no direct matches were found in the WHONET value set. Furthermore, WHONET contains some deprecated codes, which by now have been replaced by active SNOMED CT concepts. This analysis highlights that, to achieve semantic interoperability between systems, coordinated efforts with regular updates, consistency checks and quality assurance are necessary. For terminology services it should be considerd to cluster subspecies of organisms, if reasonable, for example through SNOMED Expression Constraint Language (ECL). Algorithms for infection control systems may then be able to detect outbreaks where hospital information systems report organisms in varying granularity.

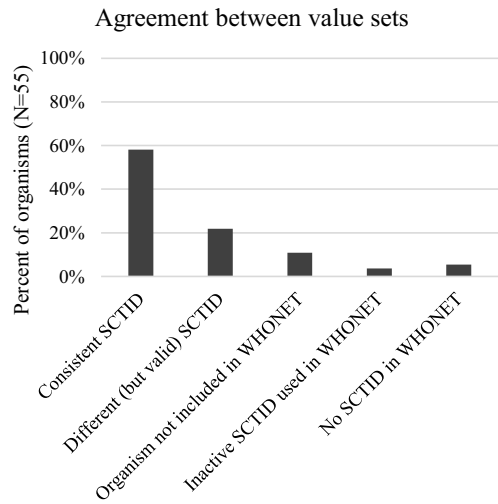

Figure 1 – Agreement between the infectious organisms reported under the German Protection against Infection Act compared with the WHONET 2018 value set (SCTID: SNOMED CT identifier).

Abstract

Cerebrovascular and hypertensive diseases are among the leading causes of death in the world. This study was developed in two stages: the development of a dashboard with specific reports of cerebrovascular diseases and applied a preliminary predictive analysis model for cerebrovascular diseases. The results demonstrate the abitity to predict a citizen's chance acquiring a cerebrovascular disease.

Data Mining, Primary Health Care, Cerebrovascular Diseases.

Introduction

The Ministry of Health (MS) is working on the guidelines on e-Health, inline with the principles of the Unified Health System (SUS) and the e-Government policies (e-Gov). The e-Health Strategy document for Brazil is targeting 2020 in order to increase the quality and the access for health care, as well as consolidate e-Health as a relevant State Policy for SUS [1].

Health organizations around the world are generating large amounts of data. Thus, organizations throughout the world face dilemmas due to the growth and volume of health data. Making decisions based on facts is not dependent on the amount of data you have. According to the SAS Institute [2], working with so much data can be scary. In this sense, success in decision making will depend on how quickly information is discovered and how this information are used to generate best practices in the organization. The SAS Institute also emphasizes that data visualization showing important metrics and indicators can help facilitate the understanding of health information via dashboards. Predictive analysis, data mining, machine learning and decision management will be key to assessing and predicting some behavior based of that data. Thus using it to transform data into proactive ideas with actions that are used in operational processes. This is a key interest of this study. The ability to store this data enhances both learning and the ability to develop knowledge that promotes improvements in health outcomes. In this way, it is fundamental to understanding the behavior of a disease and improving its clinical outcomes [3]. The objectives of this study were to develop a georeferenced map of cerebrovascular diseases in primary health care as support for decision-making to sensitive health conditions from integrated e-SUS AB data in Brazil; and to present a preliminary model predictive report of citizens at risk of cerebrovascular diseases for possible integration with e-SUS primary care in Brazil.

Methods

The study was divided into two stages. The first was the development of a dashboard with specific reports of cerebrovascular diseases in primary health care, presenting individual citizens who either had or have a cerebrovascular disease. Another report presented the indicators of each ICD10 in the cerebrovascular disease group, with the number of cases, grouped by sex, mean age and distribution per period. Also, in the dashboard, the cases of citizens who have already been affected by this disease were presented georeferenced on a map. The second stage was the development of a preliminary predictive analysis model, based on logistic regression, where an algorithm learns from historical data on characteristics and risk factors for cerebrovascular diseases with people who already have a group disease and predicts a citizen's chance to have, for example, a stroke.

The predictive model used in the study was a regression optimized by an optimization algorithm, Stochastic Descending Gradient (SGD) in which the stochastic downward gradient does not use all the data but a fraction of the data. For the tool developed, data was randomly generated from 170,567 citizens. These people served as reference for the algorithm to learn the patterns and relationships in which the citizen develops a cerebrovascular disease. The variables that served as analysis for this preliminary model were age, sex, race-color, obese, ex-obese, smoker and ex-smoker, hypertension, diabetes, pregnant women, alcohol and ex-alcohol, drugs and ex-drugs, among others. The results of this predictive analysis model are presented in the dashboard in the form of a report.

The tool has been developed according to software engineering tools, from prototyping, database modeling, migration process, tool construction and predictive analytics using free technologies.

The distribution of Cerebrovascular Disease functionality was divided into three tabs: a general Dashboard, a Heat Map and a Georeferenced Map. The georeferenced map shows the residences of people with cerebrovascular diseases identified by a point on the map (Figures 1).

To view or apply the preliminary model, the tool has a screen to show the chance of an individual getting a cerebrovascular disease in percent. The name of the functionality in the system is Risk of Cerebrovascular Diseases (Predictive) Analyze. (Figure 2)

Figure 1: Distribution of Cerebrovascular Diseases – Heat Map.

Figure 2: Risk of Cerebrovascular Diseases (Predictive Analysis)

Results

After structuring the database in PostgreSQL®, 5.3 the data and consolidated information is presented ina dashboard built with JAVA using Spring. Next, the data and information is analyzed on a map with geoprocessing technique from the Google® Geocoding API tool, and the database addresses were converted by geographic coordinates in a process called geocoding. Thus the citizens who have had or have cerebrovascular diseases for monitoring and management of health care are identified. Another important report was the presentation of the indicators of cerebrovascular diseases.

For the preliminary predictive analysis with citizens who have risks of developing cerebrovascular diseases to health professionals, an algorithm using Python v3.7.0 was applied. Initially, we exported the prediction table that was based off data from the e-SUS (system) basic care for cerebrovascular diseases. In the preparation to receive the source data, the input columns were defined, that is, the variables that the prediction algorithm would use to learn the pattern and to generate the probabilities. It was necessary to normalize age using Fuzzy Sets. For the execution of the algorithm, the prepared data were converted to X_train and X_test and executed using logistic regression optimized by an optimization algorithm, Stochastic Descending Gradient (SGD). It was possible to observe the correlation between the training and test variables to discover data failures, because if they differ greatly, it would be a problem for the algorithm, but in this case, they are similar. Heat maps of this correlation in algorithm model learning (Figure 3) showed the negative relationship between males and females, which validates that the data has no error in relation to these columns. On the other hand, cerebrovascular disease showed a positive correlation with hypertension, so it is expected that these two variables will similarly affect the outcome for both males and females.

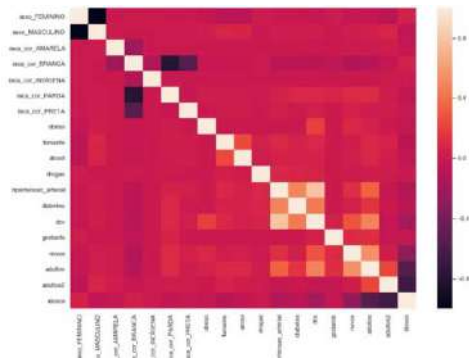

Figure 3: Heat map of correlation in learning

Finally, the trained algorithm was prepared to execute on the whole set of data and obtain the probability result. The report of Cerebral Vascular Diseases (Predictive Analysis) shows a list of all citizens of the base, after applying the preliminary predictive algorithm, ordered by the highest probability of acquiring the disease.

Conclusions

The development of the present study offered to the health professionals and health managers' geo-referenced demographic reports to visualize the health conditions in the territory, as well as to have follow-up reports of citizens with diseases and visualize indicators of each disease in your health region. The report of Risk of Cerebrovascular Diseases by the predictive analysis, although still preliminary, presents to the citizen the chance of the person being surprised by the disease according to its parameters of health risks. In addition, a risk assessment of cerebrovascular diseases will enable preventive actions to be performed before the clinical condition occurs, with the purpose of reducing costs of hospital admission, providing subsidies for health professionals to take decision-making and planning.

Abstract

Medical insurance claims are useful data to offer a big-picture view and insight of a nation-wide healthcare system. Yet, formal description of the logic to analyze the claims has not been established. So far, we proposed a description scheme of analytics logic over claims database. In this paper, we propose a novel analytics framework based on the description scheme. By showing a case study, we demonstrate the effectiveness of the framework.

Keywords:
Analytic Data, Insurance Claims Analysis, Logic.

Introduction

Japan's Ministry of Health, Labour and Welfare (MHLW) has continuously collected anonymized insurance claims data from all the insurers throughout Japan since April 2009 to build National Database of Health Insurance Claims and Specific Health Checkups of Japan (a.k.a. NDB) [1]. All medical services in Japan are basically covered under the universal health insurance system. The database potentially offers great opportunities to analyze all the medical services provided in the country. The database holds more than 14.8 billion claims as of March 2018 [1], which is one of the largest big data in the field of healthcare. To facilitate the intensive and extensive utilization of this database, we have formed a research team comprising researchers from both healthcare and informatics and built a home-grown analytics platform that accommodates 6-year claims data (provided by MHLW) to offer analytics services to healthcare researchers and practitioners [2].

So far, several analytics tools were developed to specific purposes [3]. Similar to big data analytics in other fields, most of the analytics on insurance claims database are basically *ad-hoc* and *wide-range*. Yet, a method to formally describe the analytics logic of insurance claims has not been established. Healthcare researchers and practitioners often have difficulties to discuss and share their analytics ideas since they have no common language or scheme to clearly describe the analytics logic. To solve this problem, we proposed a description scheme of analytics logic for claims data in our previous study [4]. In this paper, we present a novel analytics framework that we developed based on the description scheme. By presenting a typical case study that we observed on the prototype system, we demonstrate the effectiveness of the framework.

Methods

Scheme for describing analytics logics

So far, we have defined domain-specific data types and functional operator types that are typically utilized for insurance claims data processing. One can formally define an analytics logic as a functional operator or its combination by instantiating the defined data types and functional operator types. Suppose a typical analytics logic composed of three steps: (1) selecting claims from the database based on a certain condition, (2) performing a certain arithmetic calculation on the claim attributes, and (3) summarizing them in a spreadsheet. For such a specific logic, we have defined $f_{rez\_to\_tup}$ that inputs a claim set, applies selection, conversion and extraction operations and then outputs the results into a spreadsheet. In this way, we have finally defined six different functional operator types indicated in Figure 1, which are good enough for describing most of analytics logics that the healthcare reasearchers and practitioners need in our experience.

$$f_{rez\_to\_tup} : \mathbf{C} \xrightarrow{selection} \mathbf{C} \xrightarrow{conversion} \mathbf{C} \xrightarrow{extraction} \mathbf{R}$$
$$f_{rez\_to\_ep} : \mathbf{C} \xrightarrow{selection} \mathbf{C} \xrightarrow{conversion} \mathbf{C} \xrightarrow{sessionization} \mathbf{E}$$
$$f_{rezs\_to\_rez} : \mathbf{C} \times \mathbf{C} \xrightarrow{reduction} \mathbf{C}$$
$$f_{ep\_to\_tup} : \mathbf{E} \xrightarrow{selection} \mathbf{E} \xrightarrow{conversion} \mathbf{E} \xrightarrow{summarization} \mathbf{R}$$
$$f_{eps\_to\_ep} : \mathbf{E} \times \mathbf{E} \xrightarrow{reduction} \mathbf{E}$$
$$f_{tup\_to\_tup} : \mathbf{R} \xrightarrow{selection} \mathbf{R} \xrightarrow{sql-based-conversion} \mathbf{R}$$

Figure 1 – Typical fucntional operator types

Implementation of analytics framework

We have newly prototyped an analytics framework, which is capable of accepting an analytics logic that a user describes based on the above noted description scheme, compiling the logic into database queries, executing the queries and then answering an execution result to the user. The framework offers a visual user interface (UI) to help the user to easily and intuitively describe an analytics logic and interprete the execution result (Figure 2).

Case Study

We have demonstrated dozens of analytics on the framework. In this paper, we present one representative case (nation-wide medical expenditure analysis).

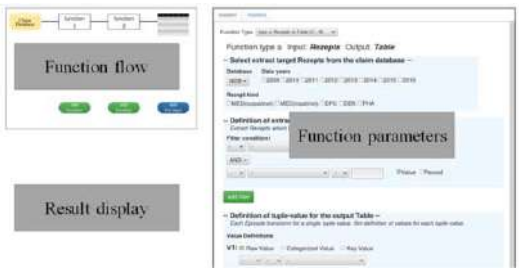

Figure 2 – User interface

Results

Figure 3 denotes an analytics logic defined for the study. Insurance claims are to be categorized by their medical service types: fee-for-service (MED_out-patinet, MED_in-patinet), diagnosis procedure combination (DPC), dental clinic (DEN) and pharmacy (PHA). The analytics logic is composed of two functional operator types: $f_{rez\_to\_tup}$ and $f_{tup\_to\_tup}$. (1) $f_{rez\_to\_tup}$ is defined to select only claims that were generated in 2014 and later (fiscal year based), extract patient ID, medical service type, patient age category, gender and medical expenditures and then summarize them into a spreadsheet. (2) $f_{tup\_to\_tup}$ is defined to aggregate average medical expenditures per capita for each age group, gender and medical service type. Figure 4 illustrates how a user can input the analytics logic into the framework and confirm its execution result. Figure 5 presents the analytics result of nation-scale medical expenditure breakdowns. This case study indicates that the proposed framework allows the user to perform a nation-scale analytics only by specifying the logic on the visual user interface without writing any programming language.

Function flow definition:

$$input \xrightarrow{f_{rez\_to\_tup}} R_1 \xrightarrow{f_{tup\_to\_tup}} output$$

Parameters of $f_{rez\_to\_tup}$**:**

selection:

$$e \mid (e \in C)(FiscalYear(e.RE_{<intervention\_year\_and\_month>}) = 2014)$$

conversion: *none*

extraction:

$$t.V_1 = e.RE_{<patient\_id>} \qquad t.V_2 = e.RE_{<age\_category>} \qquad t.V_3 = e.RE_{<gender>}$$

$$t.V_4 = \begin{cases} \text{'MED out-patient'} & \text{if } e.RE_{<receipt\_type>} = \text{'MED'} \\ & \quad \text{AND } e.RE_{<receipt\_kind>} \%2 = 0 \\ \text{'MED in-patient'} & \text{if } e.RE_{<receipt\_type>} = \text{'MED'} \\ & \quad \text{AND } e.RE_{<receipt\_kind>} \%2 = 1 \\ e.RE_{<receipt\_type>} & otherwise \end{cases}$$

$$t.V_5 = \sum_{r \in e.HO[]} \begin{cases} r_{<total\_points>} & \text{if } e.RE_{<receipt\_type>} \\ & \quad \in \{\text{'MED', 'DEN', 'PHA'}\} \\ & \quad \text{OR } (e.RE_{<receipt\_type>} = \text{'DPC'} \\ & \quad \text{AND } r_{<total\_point\_record\_flag>} = 1) \\ 0 & otherwise \end{cases}$$

Parameters of $f_{tup\_to\_tup}$**:**

selection: *none*

sql-based-conversion:

SELECT V_2, V_3, V_4, **SUM**(V_5)/**COUNT(DISTINCT** V_1**)**
GROUP BY V_2, V_3, V_4

Figure 3 – Example analytics logic

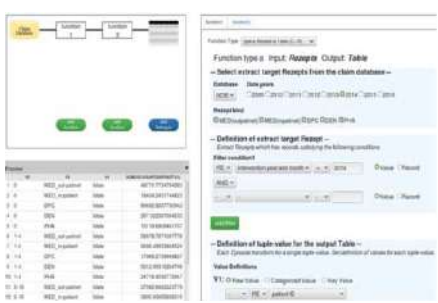

Figure 4 – User input and output

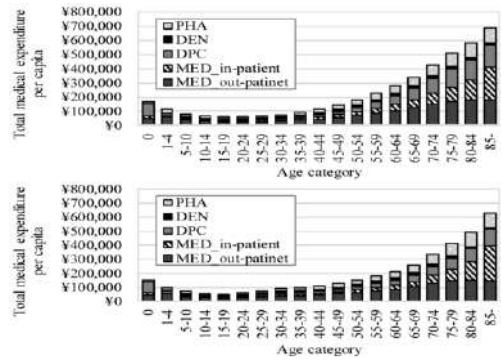

Figure 5 – Analytics result: male (upper), female (lower)

Conclusions

We have developed a novel analytics framework based on the formal description scheme that is useful to analyze nation-scale medical insurance claims database. The presented case study indicates that the framework helps the user to easily and intuitively describe an analytics logic and interprete the execution result.

Abstract

Clinical Decision Support Systems (CDSS) are promising to support physicians in finding the right diagnosis of patients with rare diseases (RD). The MIRACUM consortium, which includes ten university hospitals in Germany, will establish a diagnosis support system for RD. This system conducts a similarity analysis on distributed clinical data with the aim to identify similar patient cases at each MIRACUM site to offer the physician a hint to a possible diagnosis.

Keywords:

Rare Diseases, Clinical Decision Support, Data Science

Introduction

A big challenge with rare diseases (RD) is to find the correct diagnosis for a patient. A study by the EU showed that 25 % of the patients waited between 5 and 30 years for the correct diagnosis. In Europe, a disease is declared as “rare" if less than 5 out of 10.000 people are affected [1]. To tackle the problem of undiagnosed patients with RD, Clinical Decision Support Systems (CDSS) are promising. CDSSs provide clinically prepared and filtered information with the aim of achieving better health processes [2]. This paper focuses on a CDSS for RD based on distributed clinical data from ten university hospitals in Germany. The concept and the development of this system are part of the Medical Informatics for Research and Care for University Medicine consortium (MIRACUM), which is funded within the Medical Informatics Funding Scheme by the German Federal Ministry of Education and Research (BMBF) [3,4]. Within MIRACUM the university hospitals will establish Data Integration Centers (DIC) with the goal to improve collaborative research as well as clinical processes. A DIC will be established in the IT-infrastructure of each hospital which enables to exchange data among the partners in MIRACUM based on the principle of data federation. For query and analysis, the data of each hospital remains at the respective locations. To demonstrate the benefit of the evolving IT infrastructure, different use cases will be developed, including a use case about the diagnosis support for patients with RD [4]. In this use case, a similarity analysis on distributed clinical data is performed with the aim to identify similar patient cases at each hospital, which in turn can give the physician a hint to a possible diagnosis. In this paper we present a software-architecture based on distributed clinical data that can be devised in a CDSS for RD. The functionality of how similar patients are found in the data is not covered in this paper.

Methods

To perform a data analysis at each MIRACUM site, the data of each site needs to be harmonized. Harmonizing a very large amount of data from different previously established resources is a significant challenge [5]. To formally describe all data elements used for a similarity analysis, a meta data repository (MDR) is used, which is based on the international meta data standard ISO 11179 [6]. The description of data elements is moderated by clinical researchers and clinicians to define medical concepts based on meta data. All data in the DIC will be described at each site with their MDR. Used data elements will be mapped to a common dataset, which is available in the local databases [5]. The common dataset will be based on Common Data Models (CDM) such as the OMOP CDM, which includes a standard representation of common vocabularies for coding clinical concepts and allows to perform comparable analysis via different databases [7]. OMOP includes standardized vocabularies for representing data in the CDM

(e.g. SNOMED-CT) [8]. For data exchange between sites, HL7-FHIR-is used [9].

Results

The result of this work is a system architecture for a CDSS based on distributed clinical data (seen in Figure 1).

A physician formulates a query for similarity analysis to find similar patients. The web application DISERDIS (Diagnosis Support in Rare Diseases) will be available at each site. The application makes it possible to view the data of the undiagnosed patient and to perform a similarity analysis based on local data or other MIRACUM locations at one once. The patient data is stored in a OMOP database which is periodically updated with data from the respective hospital information system of the site. This involves the establishment of ETL-processes for mapping the data to the OMOP-CDM. When a similarity analysis is triggered at one site, a request is sent to the central MIRACUM search-broker which provides the request to the respective local FHIR server. The clinical hospital IT networks usually block external access to the data. Therefore, the search-broker is designed as a central request point allowing to forward the search request to the FHIR-Server which manages access to the data. The FHIR-Server is a REST API that can retrieve requests via corresponding FHIR resources. It retrieves the query from the search-broker and submits it to the similarity engine which performs the similarity analysis on the database. The data is available in the OMOP-CDM and must be transformed to the FHIR resources. The result is returned to the FHIR-Server which sends the result of the similarity analysis to the search-broker.

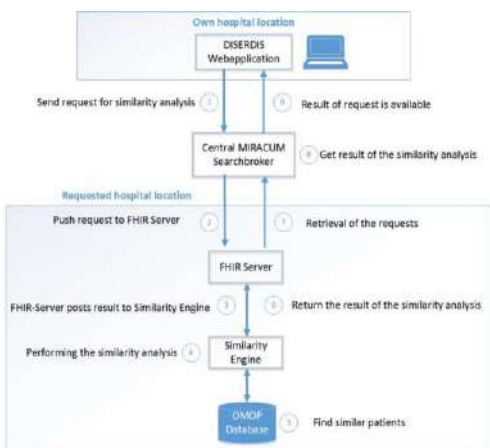

*Figure 1 – Detailed **A**rchitecture of **D**iagnosis **S**upport*

Conclusions

This paper demonstrates a concept of a system-architecture establishing a diagnosis support system for RD based on distributed clinical data.

Use of Nursing Interventions as an Indicator to Assess the Workload of Nurses in a Tertiary Care Surgical Ward Setting in Sri Lanka

S.N Silva[a], K.M. Mulleriyawa[b], S.R. Tissera[c], P.L. Jayawardene[d], K.A.P.T. Karunarathne[e]

[d]*School of Nursing, International Institute of Health Sciences, Sri Lanka*
[e]*School of Nursing, International Institute of Health Sciences, Sri Lanka*

Abstract

This research looked into the possibility of using the number of Nursing Interventions as a measure of Nurses workload in a Surgical ward setting. The quantification of the number of interventions was done using the Nursing Interventions Classification (NIC). This strategy could generate the average number of interventions required per patient and per shift as well as could assess the variation of the number of interventions under different factors.

Keywords:

Nursing Informatics, NIC Terminology, Workload

Introduction

Assessment of Nurses workload has been a challenging task in Sri Lanka as well as in hospitals worldwide. Nurses often complain of being overworked and declair work-related dissatisfaction. However, allocating nurses to wards as well as the assessmsnet of workload are done using indirect and crude measurements in Sri Lanka. The proper assessment of workload can have an added advantage of being able to quantify the need of physical resources necessary to carry out Nursing duties, in addition to better Human Resource Management.

The main share of work done by nurses in patient care is via Nursing Interventions. Therefore it is interesting to see how Nursing Interventions could be used as a direct scientific measure of quantifying the Nurses workload [1]. A standard approach in this regard would be to use the International Classification of Nursing Practices (ICNP), where Nursing Interventions are classified as NIC – Nursing Interventions Classification, along with the North American Nursing Diagnosis Association (NANDA) and Nursing Outcomes Classifications (NOC) [2].

However the use of a system such as ICNP is quite challenging in a setting like Sri Lanka, where the standard Nursing process or the use of care plans are not practiced in routine patient care. Therefore firstly the use of nursing care plans has to be established, where Nursing Interventions would then be a standard part of patient care. This should be done without disturbing the routine patientcare in a hospital setting [3]. For this purpose a General Surgical ward would be ideal out of the main specialities, because it is less complicated than a Medical or a Pediatric setup and will have a better variety than an Obstetrics and Gynaecology setting.

The main research question in this study was therefore to assess whether quantification of Nursing Interventions could be used as an indicator of Nurses workload.

The objectives of this study was therefore to assess the number of Nursing Interventions required per patient in a Surigal ward at the National Hospital of Sri Lanka and to describe the variability of it depending on some selected factors.

Methods

The project was carried out in the Surgical section of the National Hospital of Sri Lanka, the largest teaching hospital in the country. The hospital gets direct admissions as well as referals from all over the country. Therefore it has the widest range of General Surgical cases in a given ward in Sri Lanka. As the first phase of the study, Nursing care plans were implemented in 6 typical surgical wards over a period of 4 weeks in January 2018. The nurses were given a training by experienced tutors 2 weeks before the implementation. Special documentation files were provided with stuctured templates for care plans. Additional data such as medical complications and duration of stay were also collected. Reference documents were also provided to each ward. Third year Nursing students who are in their Surgical placement were used to assist the nurses during busy shifts.

Out of the 6 wards where the first phases were completed, two were selected where the implementation was most successful. Out of the 4 weeks, the best week was selected where nearly all of the presented patients had a care plan prepared for them. This resulted in a total of 131 care plans. The care plans were then coded according to the North American Nursing Diagnosis Association (NANDA) Taxonomy 1, Nursing Interventions Classification (NIC), and Nursing Outcomes Classifications (NOC) by 3 trained nurses who weren't involved in data collection. The paper based coded data were analysed using descriptive and inferential statistics.

Results

There were 131 completed and coded care plans for 131 patients. The mean age of a patient was 48.02 years. 45 had Diabetes, 38 had Hypertension and 14 had Ischemic Heart Disease. 81 were Emergency (Casualty) admissions and 49 were Elective admissions. These 131 patients had a total of 93 Nursing Diagnoses, 103 Nursing Observations and 1822 Nursing interventions.

The average number of Nursing Interventions performed per patient were 13.87 (SD 4.52). The table below shows the number of interventions categorized in to 5 groups and the number of patients who belonged to those categories.

Table 1– Number of patients under each Interventions group

Number of Interventions Group	Number of Patients	Percentage
Less than 5	3	2.3%
6-10	29	22.1%
11-15	55	42%
16-20	33	25.2%
More than 21	11	8.4%

The Average number of Nursing Interventions were most for those who had Diabetes at 15.25 on average and were 14.5 for those with Hypertension and 14.43 for those with Ischaemic Heart Disease. Those with Diabetes had a statistically significantly different mean number of Nursing Interventions than for those who did not (p=0.009). There seemed to be no statistically significant difference in the number of Interventions required by those with Hypertension compared to those without (p=0.31) and for those with Ischaemic Heart Disease, compared to those without (p=0,627).

Further, there seemed to be no statistically significant difference between the number of Nursing Interventions required by those admitted as Emergency admissions compared to the Elective admissions (p=0.121).

Increased length of stay does not necessarily seem to increase the average number of interventions required.

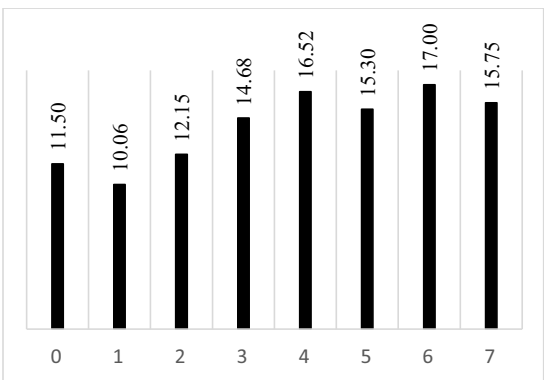

Figure 1– Average Number of Nursing Interventions required ccording to the Length of Stay in the Hospital

In total, there were 1822 Nursing Interventions practiced in these two wards during these two days. A rough assessment of the workload per nurse per shift could be made using this number. A ward would typically have 13 six hour shifts per day (6 in the morning, 5 in the afternoon and 2 in the night). Therefore the total number of shifts would be 182. This means per 6 hour shift a nurse would have to perform approximately at least 10 Nursing Interventions.

Discussion

The results seem to indicate that the Nursing Interventions Classification could be used well for approximating the Nursing work load under various situations.

Out of the Medical conditions concerned, Diabetes Mellitus seems to have a significant impact on the Number of Interventions required for a Surgical Patient rather than Hypertension or Ischaemic Heart Disease. However this situation is probably applicable only to a Surgical ward setting.

In a Medical ward, other co-morbidities could increase the number of Nursing Interventions required. Emergency admissions doesn't seem to require more number of interventions than routine elective admissions. Therefore these results bring to question some of the parameters used when deciding the number of shifts and when allocating staff in Surgical wards. Further evaluation of other factors using 'the Number of Nursing Interventions required' as the decisive indicator, could therefore reveal useful inteligence for Nurse Managers to allocate their staff in a more productive manner.

Similar studies could be done in all main sections of a Hospital such as Medical, Obstetrics and Gynecology, Pediatrics and Psychiatry. Unique patterns and factors that influence the number of Nursing Interventions required could then be identified. Such factors then should be considered alongside the different patient presentation patterns and seasonal variations before optimal staffing and shift allocations can be decided.

There are a few limitations of this study. The period concerned is not adequate to cover some patients who are in Surgical Wards. Therefore data collected over at least 4 weeks would produce far more accurate results. This study did not consider the number of Nursing Interventions according to the medical diagnosis, under a standard nomenclature or a classification. Such an addition would provide a more direct predictive ability of the work load required as per the seasonal pattners of patient presentations.

Conclusions

The study provides a very promising insight to scientifically validating and predicting the Nursing Work load using Nursing Interventions Classification. The use of "Number of Nursing Interventions Required" as the main indicator, with the consideration of its variation according to other confounding factors could provide a more scientific guideline to allocate Nursing Staff to meet the varying demands of each Surgical ward.

Acknowledgements

The Authors would like to Acknowledge the assistance provided by the Nursing staff and the Administration of the Surgical wards of the National Hospital of Sri Lanka and the School of Nursing of the International Institute of Health Sciences, Sri Lanka.

Abstract

This paper described the implementation of a terminology server performed at a health institution in Uruguay, whose architecture is based on SNOMED CT using graph databases (NoSQL). The aim of this development was to create an intuitive terminological service, making the most of SNOMED CT's ontology, and which can be used from a clinical, statistical, management, decision support and research point of view, among others, with good performance.

Keywords:
Systematized Nomenclature of Medicine; Vocabulary, Controlled; Databases, Factual

Introduction

Terminological services (TS) are essential components in the development of an Electronic Health Record (EHR), since their implementation strengthens the semantic quality of the data recorded during the care act. These services are fundamental tools for the management of controlled vocabularies in different instances of clinical events, whether for use in statistical data, management, decision support and research, or other areas. SNOMED CT is a global clinical terminology that covers a wide range of specialties, disciplines, and medical and care requirements. With SNOMED CT, clinical information is recorded with identifiers that refer to formally defined concepts as part of the terminology [1]. SNOMED CT allows the recording of clinical information with appropriate levels of detail through the use of relevant clinical concepts. This terminology structure allows information to be entered using synonyms that adapt to local preferences, while recording information in a consistent and comparable manner. SNOMED CT is also an ontology, which contains a poly-hierarchy model, meaning that a code can be grouped into different categories, forming directed acyclic graphs (DAG). Nonetheless, these graphs are difficult to implement in their entirety using relational or object-oriented databases, resulting in a loss of a wealth of information. SNOMED CT's continued expansion will make it more complex and model consistency will be more difficult to assure. Moreover, consumers of data will increasingly demand improvements to query functionality to accommodate additional granularity of clinical concepts without sacrificing speed. The above information and comparative retrieval characteristics of relational databases, triplestores, and general graph databases [9] determined the use of a graph database.

The emergence of Big Data has spurred development of new technologies and platforms, for example, Neo4j [2] which is a high-performance NoSQL database. We chose Neo4j because it had the best score of the graph databases [8]. This platform has already been used in different industries such as financial [3], social networks [4], in health [5], among others. Neo4j is a graphics database whose basic structure is composed of nodes, relationships and attributes. The nodes are designated as starting nodes and termination nodes, and two such nodes are connected by a relationship (edge). This database allows the representation of the SNOMED CT ontology, without loss of information, which makes it one of the most suitable platforms for this type of work. SNOMED CT has already been used in different works in conjunction with Neo4j [6] [7], but it has never been used as a terminology server to support clinical history in real time. Concretely, the objective of this work is the implementation of a terminology server in a health institution in Uruguay, using SNOMED CT on a graph-oriented database, in order to create an intuitive TS, making maximum use of the characteristics of the SNOMED CT ontology, and also to ensure usability from a clinical point of view.

Methods

In the first step, a graph database containing the SNOMED CT concept model was created. The implementation of the TS was done using the RF2 files of the International Release, Spanish Edition and the Uruguay extension. Currently, the TS is running with the Release International 2018-04-34. In terms of the graph database, the Neo4j Desktop Version 1.0.22 is used. Neo4j is a graph database platform based on Java that supports transactions with ACID (atomicity, coherence, isolation, and durability) properties. The content of SNOMED CT was extracted from the RF2 files and loaded into Neo4j using a series of scripts that were written in Python. The scripts extracted the following information from the RF2 files to create the nodes: "id", "term", and descType. For the creation of relationships, the following data is used: "sourceId", "destinationId", "relLabel", "typeId", "term", "descType." The nodes were created for all the basic SNOMED CT concepts, and the edges were created for all IS_A relationships, which is a relationship from a child concept to a parent concept. All nodes contain every aspect of a SNOMED CT concept such as concept ID, status, and the description of the concept. Queries on the terminology server are made using the declarative language of Neo4j (Cypher). In this language the query defined makes a lexicographical search using the descriptions (without accents and in minuscule) stored in the nodes, then a recursive search is made through the edges, using the IS_A relations (see Figure 1) but in the opposite direction (from parent to child). Finally, as a result of the query, the description and the ID of the obtained concepts is returned.

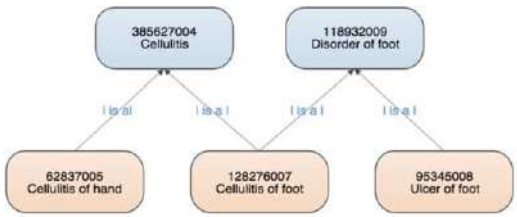

Figure 1 - (SNOMED IS_A Relationship) Obtained from https://confluence.ihtsdotools.org/

The Terminology Server is accessed by clients through a Glassfish application server that uses SOAP or REST protocols depending on the web services invoked. The server consults a Lexicon (under development) in the first instance (a linguistic tool with the morphological variations and grammatical uses of words), subsequently accessing the Terminology Server the Bolt protocol (see Figure 2).

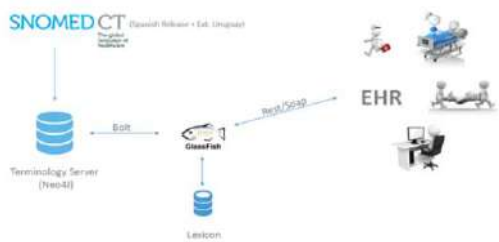

Figure 2 - Architecture

Figure 3 below shows the record form of the EHR, in which the TS is accessed through a web service to obtain terms associated with findings that will be linked to the patient as personal or family background. At present the TS is in production for use by internal medicine physicians.

Figure 3 - Background Record Form of the EHR

Terminology Server Features

In the present example (Figure 3), the query to the TS is made from the EHR and includes the following features:

- Analysis of the text entered (diabetes mellitus) by the lexicon.
- Search the set obtained from the lexicon in the database.
- Return of the found terms and the associated coding that was requested when making the query.

Conclusions

The development of a TS with a graph database architecture using SNOMED CT as the basis of the data model allows more comprehensive queries navigating through the database in a hierarchical manner than a relational database. We can navigate through the ontology choosing the levels of specificity in the terms retrievals, and the integration of extensions for use in a particular country can be included thanks to the characteristics of SNOMED CT. It is also noteworthy that the response times to the information are adequate, with an average of 500 milliseconds for the visualization of the collection of terms in the user interface of the EHR.

Abstract

Natural language processing (NLP) methods would improve outcomes in the area of prehospital Emergency Medical Services (EMS) data collection and abstraction. This study evaluated off-the-shelf solutions for automating labelling of clinically relevant data from EMS reports. A qualitative approach for choosing the best possible ensemble of pretrained NLP systems was developed and validated along with a feature using word embeddings to test phrase synonymy. The ensemble showed increased performance over individual systems.

Keywords:

Emergency medical services, Labeling, Natural language processing

Introduction

More people die each year from trauma (10% of all deaths) than from malaria, tuberculosis and HIV/AIDs combined [1]. Inappropriate prehospital care is one of the largest contributors to preventable trauma mortality in the United States [2]. The use of natural language processing (NLP) named entity (NE) recognition (NER) for performance monitoring and quality improvement is a novel approach to bridge this gap. Early studies published in 2019 have begun utilizing NLP for prehospital stroke notes [3]. However, NLP for prehospital trauma notes represents a new domain of inquiry.

NLP techniques hold promise for circumventing current limitations of discrete element documentation of EMS reports by reducing the effort of manual data abstraction [4]. The efficacy of how existing systems can best be utilized for notes with specific sublanguage characteristics of prehospital trauma is not well characterized and is the subject of this study.

We leveraged a small corpus of EMS reports of motor vehicle collisions (MVC) to develop an objective measure for creating an optimized NLP ensemble as discussed by Finley, et al. [5]. We also used word embeddings as a feature, as discussed by Turian, et al. [6]; and applied methods as discussed by Pakhomov, et al. [7], and Meng and Morioka [8] to use this feature as a test for phrase synonymy.

Methods

This study was a pilot to classify clinically relevant phrases related to prehospital trauma care using NER. Results were derived through an evaluation of four clinical NLP annotation systems, on their own, and as an optimized ensemble.

Data Sources

This study utilized de-identified North Memorial Health Hospital prehospital EMS MVC reports.

Creation of a Gold Standard Corpus

The development of a gold standard corpus consisted of two main parts: (1) schema creation, and (2) manual text annotation. 37 entities were identified based on clinical guidelines and the NEMSIS 3 standards [9] and iteratively incorporated into an annotation schema. Three trained annotators individually annotated 25 reports to establish inter-rater agreement (0.89 kappa, 99% agreement). Following this step, the remaining reports used for this study were manually annotated.

Creation of System Generated Annotations

Given the paucity of manual annotations for use in supervised training of a statistical model, we utilized the Artifact Discovery and Preparation Toolkit (NLP-ADAPT) [10], which included the clinical NLP annotator systems: cTAKES, CLAMP, BioMediCUS and MetaMap [11:14], to annotate our corpus of EMS MVC reports.

Evaluation Methods

We partitioned the gold standard annotations into a set of 10 reports to determine the best-at-task system annotation types. The remaining 112 reports were used for evaluation of the selected best-at-task system annotation types.

Matches between manual and system annotated reports were determined using a relaxed rule as noted by Finley, et al. [7]. Precision, recall, and F_1 score for each entity and system annotation pairing were calculated based on matches.

Best-at-task Evaluation

To compare NLP systems with respect to NE capture, we ranked each system annotation types for each entity using the three measures of NER performance shown in Figure 1. The geometric mean of the rankings was calculated to classify the best-at-task system annotation type. The annotation type with the lowest geometric mean (GM) was deemed best-at-task.

$$\frac{TP}{FN} \qquad F_1 score \qquad \frac{TP}{\sqrt{n_{sys}}}$$

Figure 1– NER Performance Measures; Abbreviations: TP, true positive; FN, false negative; n_{sys}, total system annotations

For validation of best-at-task systems, we analyzed the entity Procedure Indication using the remaining 112 EMS reports by comparing them to their corresponding manually annotated reports. We then combined best-at-task systems as an ensemble

to evaluate performance and further test how a word2phrase model as an additional feature affected recall [6:8].

A threshold of cosine distance of 0.5 was chosen after qualitatively evaluating several terms (e.g., "unresponsive," "unconscious," "agonal," and "tachycardic") and their resultant set when processed through the word2vec distance function [7]. Using string alignment methods [8], we used the Levenshtein edit distance (LD) to estimate degree of synonymy by identifying system and manual annotation match pairs on the resultant set with the lowest LD value.

Results

42 manual annotations pertained to the Procedure Indication entity in the set of 10 notes. Three best-at-task system annotation types were identified for this entity (Table 1).

Table 1-Best-at-task Annotation Types for Procedure Indication; Abbreviation: GM, Geometric Mean

System/Type	F_1	Precision	Recall	GM
CLAMP/Sentence	0.03	0.01	0.50	1.59
cTAKES/Sentence	0.02	0.01	0.52	2.15
MetaMap/Phrase	0.01	0.00	0.60	2.30

931 manual annotations pertaining to Procedure Indication were noted in the 112 notes. Individually, the three systems performed similarly with respect to recall and precision compared to the gold standard. The union ensemble resulted in significant improved coverage (87%) (Table 2).

Table 2- Best-at-task Validation for Procedure Indication Compared to Gold Standard with Final Rank

System/Type	F_1	Precision	Recall	Rank
CLAMP/Sentence	0.04	0.02	0.53	1
cTAKES/Sentence	0.03	0.02	0.54	2
MetaMap/Phrase	0.02	0.01	0.54	4
Ensemble	0.11	0.06	0.87	

The top 2 best-at-task rankings were consistent during validation (Rank). As anticipated, the ensemble performed very well with respect to recall, but precision was still poor due to a high false positive rate. Also, the ensemble did not account for matching on synonymous phrases. For example, patients that are unconscious and have agonal respirations meet the procedural indication for intubation. Using our word2phrase resultant set, phrases identified in system and manual annotations were matched for synonymy (Table 3). We were able to identify 93% (104 of 112 notes) coverage (match) with mean LD value of 2.5 (range 0-19).

Table 3- Word2phrase and System Annotations; Abbreviation: w2p, word2phrase

Note	w2p phrases	w2p common token	Synonymous best-at-task annotation
1	agonal	shallow	tachypnic shallow
2	tachycardic	sbp	80's sbp.
3	tachycardic	lungs	lungs clear bilat
4	unconscious	scene	alert on-scene

Conclusions

The present work represents one of the earliest NLP studies conducted in the prehospital trauma domain. Here we describe an approach to create an optimized NLP ensemble that when supplemented with a word2phrase model allows for over 90% NE capture. While these results are encouraging, the development of an extensive prehospital trauma corpus is paramount to facilitate development of models with improved precision, and further validation and extension of our methods.

Predicting Disease-Free Lung Cancer Survival Using Patient Reported Outcome (PRO) Measurements with Comparisons of Five Machine Learning Techniques (MLT)

Jin-ah Sim[a], Young Ho Yun*[b]

[a] *Cancer Research Institute, Seoul National University College of Medicine, Seoul, Korea*
[b] *Department of Biomedical Informatics, Seoul National University College of Medicine, Seoul, Korea*

Abstract

The study was to develop the lung cancer patients' prediction model for predicting 5-year survival after completion of treatment by using Machine Learning Technology (MLT), adding patient reporting (PRO) measurements of lung cancer survivors to a variety of clinical parameters. Finally, the survival prediction models with the addition of lung cancer survivors' PRO measurements to the well-known clinical variables, based on diverse MLT, improved the predictive performance that explains 5-year disease-free lung cancer survival.

Keywords:

Machine Learning, Cancer Survivors, Lung Neoplasms

Introduction

As the number of cancer survivor increases [1, 2], one of the major challenges in surviving lung cancer is to predict the survival of lung cancer after the completion of treatment based on diverse patients' information.

In general, statistical approaches focused on inferring the characteristics of a population from sample data[3], MLTs are more suitable to develop the prediction model with dozens of parameters when more prognostic variables are included because standard statistics do not generally work in this situation [4].

In fact, many recent studies have suggested that patient-reported outcome (PRO) measurements can provide distinct prognostic information [5, 6], PROs may be utilized as predictive tools for cancer survival. Even a variety of prediction models for cancer mortality have been developed in the clinical setting based on the MLTs [7-9], there were fewer studies developing survival prediction model with PRO factors based on MLTs.

Therefore, we evaluated the predictive performances of the developed mathematical models, multiple survival prediction models with the combination of lung cancer survivors' well-known clinical variables and PRO measurements, based on diverse MLTs compared with the well-known traditional prediction model only constructed based on the clinical and demographic variables.

Methods

Data Acquisition

For this supervised learning, regular follow-ups were undertaken for the patients based on each hospital's registry after the completion of treatment after surgery. Among finally contacted 836 patients, excluded 27 subjects whose survival status was censored until December 31, 2011. Thus, a total of 809 patients were included in this study.

Candidate Variables for Predictive Model

The candidate variables for our model included demographics (age and sex), socio-economic status (marital status, educational level, monthly family income), and clinical data (cancer stage, local invasion of a tumor, regional lymph node metastasis, recurrence, number of comorbidities, treatment type, time since diagnosis). In addition, patient lifestyle such as Body Mass Index (BMI), and metabolic equivalents of task (MET)-hours per week for Physical activity (PA) were included. Baseline PRO measurements were taken in this modeling process.

Data Preprocessing

As most machine learning algorithms strictly induce knowledge from data, the quality of the knowledge extracted is largely determined by the quality of the underlying data[10]. Therefore, we first attempted to apply the missing values imputation based on some important candidate information available in the data set.

Then, we grouped the candidate prognostic factors (variables form socio-demographic, clinical factors and PRO factors) for the modeling process. Before the model construction, we elected over-sampling producer to reduce the error costs for the whole imbalanced data.[11] Therefore, we balanced the number of 'dead' and 'alive' cases by over-sampling 617 'dead' cases to make equivalent 713 'alive' and 'dead' cases.

Finally, data splitting was employed to avoid over-fitting in the model and to derive reliable estimates of the model performance.[12, 13] The holdout method randomly splits the whole data sample into two mutually exclusive training (80%) and testing (20%) sets. The training set was utilized to generate the prediction model and the remaining data was employed as a testing set to evaluate the model's predictive performance. We compared demographic and clinical characteristics between train and test set using Chi-square and t-test.

Machine Learning Algorithms

Five supervised MLTs based classification model were employed to build each multivariate model to predict 5-year survival rates for Korean lung cancer survivors in training set. Decision Tree (DT), Logistic Regression (LR), Random Forest (RF) and Ensemble learnings such as Bagging or AdaBoost were selected for the prediction modeling process. The performance of the derived predictive models based on MLTs were also internally validated by 5-fold cross-validation.

Model Validation and Comparison

Each of predictive performance was assessed by the area (AUC) under the receiver operating characteristic curve (ROC). AUCs with 95% Confidence Interval (CI) were calculated for performance comparison between proposed five MLT based models.

Results

Data proportions after data up-sampling, splitting

After missing imputation was conducted, not statistically significant difference between the training and test data set were found.

Comparisons of MLT based models' performance

Among the overall model performances, DT showed the lowest performance, RF showed the highest in accuracy (76.30% and 82.30%, respectively), while DT showed the lowest AUC and RF showed the highest AUC in models (0.800 and 0.918 respectively).

Conclusions

In conclusion, we found that the same proposed feature set can be applied into ensemble MLT algorithms (particularly random forest or Adaboost algorithms) to predict disease-free lung cancer survival.

Table 1. Performance comparison of data mining algorithms based on the MLTs (cross-validation)

Feature Set	Machine learning algorithm	Train Accuracy (N=912)	Test Accuracy (M=286)
1	DT	0.625	0.692
	LR	0.657	0.632
	Bagging	0.655	0.706
	RF	0.675	0.692
	AdaBoost	0.642	0.713
2	DT	0.758	0.745
	LR	0.814	0.825
	Bagging	0.783	0.773
	RF	0.918	0.941
	AdaBoost	0.932	0.948

Abstract

Epilepsy is a serious neurological disorder that affects nearly 60 million individuals worldwide and it is characterized by repeated seizures. Graph theoretic approaches have been developed to analyze functional brain networks that underpin epileptogenic network. We have developed a Web-based application that enables neuroscientists to process high resolution Stereotactic Electroencephalogram (SEEG) signal data and compute various kinds of signal coupling measures using an intuitive user interface for study of epilepsy seizure networks. Results of a systematic evaluation of this new application show that it scales with increasing volume of signal data.

Keywords:
Electroencephalography, Workflow, Epilepsy

Introduction

Epilepsy is a serious neurological disorder marked by repeated seizures and it affects nearly 60 million individuals worldwide across racial, gender, and geographic boundaries [1]. More than 20% of these patients are refractory to anti-epileptic medication [2]. These patients are often considered for surgery for seizure freedom, which involves analysis of electroencephalogram (EEG) data for accurate characterization of the epileptogenic zone. Various measures for brain connectivity measures have been developed to provide new insights into the mechanism that underpins seizure onset and propagation. Many of these brain functional connectivity measures are derived from high-resolution EEG data, for example, signal data recorded from intracranial electrodes implanted using stereotactic techniques (also called SEEG signal data). The increasing availability of digital-era SEEG signal data from multi-institutional research studies requires the development of efficient data processing and analysis techniques that can effectively leverage the large volume of signal data for advancing brain connectivity research.

The European Data Format (EDF) is a widely used signal data format that was originally designed for recording of polysomnography signal data [3]. However, there are several challenges that impede the use of EDF for large-scale signal data analysis especially in the context of brain functional connectivity studies. In our previous work, we had developed a new model for signal data called the Cloudwave Signal Format (CSF) that addressed many of the limitations of EDF model [4], including the support for random read access to specific channels. In this abstract, we describe our work that builds on the CSF model to implement a Web-based workflow platform that allows users to process and analyze SEEG data to compute multiple measures of brain functional connectivity.

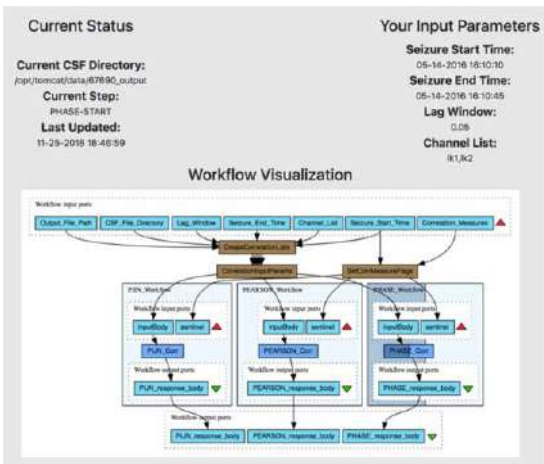

Figure 1 – User interface with visualization of the workflow module status. Light blue boxes are inputs, dark blue are REST calls, and brown are BeanShell scripts.

Related work. There has been a significant amount of work in the domain of brain connectivity [5]. Complex network analysis focus on computing graph theory-based measures, such as centrality and the detection of subgraph motifs, from network models of brain connectivity. For example, brain structural connectivity is used to study anatomical connectivity representing physical connections between brain regions whereas functional connectivity measures are used to determine functional coupling between brain regions [6]. These measures are used to analyze brain connectivity networks in healthy as well as persons suffering from neurological disorders such as epilepsy.

Method

There are three core components of our software tool, including: (1) a Representational State Transfer (REST) Application Programming Interface (API) for data processing; (2) a scientific workflow to integrate the API components as well as record metadata information; and (3) an intuitive Web-based user interface.

Component 1: RESTful Web Services

We developed a Java-based RESTful API for the conversion of EDF files to CSF files and computation of functional

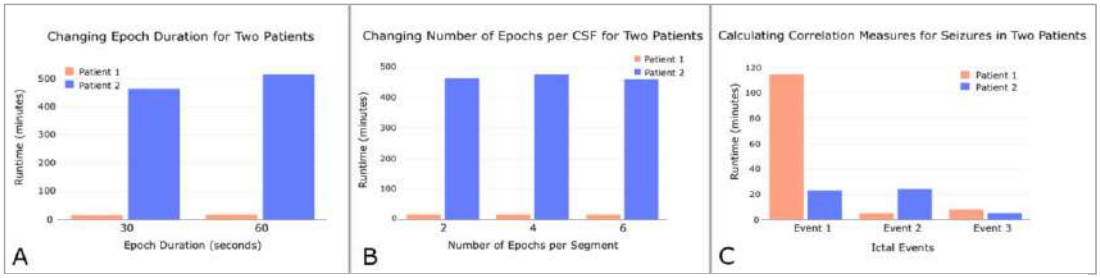

Figure 2 – Performance evaluation of data processing (Fig. 2a, 2b) and data analysis modules (Fig. 2c) using SEEG signal data

connectivity measures. Once CSF files are created, users are able to calculate channel-wise correlation values. Three correlation measures that have demonstrated efficacy in determining functional connectivity between brain regions have been implemented: Pearson's linear regression coefficient [7], a non-linear regression coefficient by Pijn [8], and a non-linear frequency-based measure called mean phase coherence [9]. The produced correlation matrices can be used to create adjacency matrices that describe a network graph.

Component 2: Scientific Workflow Tool

We used the open-source Taverna scientific workflow system to support large scale signal processing task and also allow users to visually track the entire signal processing pipeline [10]. Using the Taverna Workbench, we defined two workflow modules that take parameters as user inputs, which are invoked by the workflow module as REST calls. Figure 1 shows a screenshot of the user interface with a visualization of the workflow execution in the Taverna Workbench. We also use Taverna to record workflow provenance, including inputs, outputs, and intermediate results to support reproducibility of the data processing as well as analysis tasks.

Component 3: Intuitive User Interface

The user interface (UI) is designed using Python Django and Bootstrap. The UI has been designed to be intuitive and allow users to execute, validate, and monitor their workflow tasks. The UI consists of two forms to record user input for both data processing and data analysis. For example, the EDF-to-CSF data processing form allows users to specify input as well as output directories, epoch duration, and the number of epochs. On the backend, the server makes API calls to the various Taverna Server endpoints to start the workflow, and takes the user to a status page, with a real-time updating image of the workflow (Figure 1).

Results

In order to evaluate the scalability of the tool, we conducted a comparative analysis of the execution of the workflow on datasets with different sizes of signal data. We used de-identified data from two patients. The size of data from Patient 1 was 4.4 gigabytes (GB), and 122GB from Patient 2. The results of the comparative analysis are shown in Figure 2a and 2b for different input parameters to the data processing module, such as epoch duration and number of epochs per CSF file. Figure 2c shows the time taken to compute all three functional connectivity measures for different parameter values, including the length of the ictal event and number of channels analyzed.

Conclusions

In this paper, we describe the development of a Web-based user friendly software tool for large-scale signal analysis in epilepsy cohort studies to analyze functional brain networks. In future work, we plan to visualize network graphs and integrate computation of additional network connectivity measures, such as degree distribution and global as well as local efficiency measures.

Korean Pharmacovigilance System Based on EHR-CDM

Nayeong Son[a], Bonggi Kim[a], Sooyoun Chung[a], Soonyoung Han[a]

[a] *Korea Institute of Drug Safety & Risk Management, Anyang-si, Gyeonggi-do 14051*

Abstract

An electronic health record (EHR) contains various clinical information for pharmacovigilance studies, but they remain difficult to use.. From 2016 to 2018, the ministry of food and drug safety and Korea institute of drug safety & risk management (KIDS) converted the EHRs of more than 9 million patients to a MOA common data model (CDM). KIDS developed the Medical record observation and assessment for drug safety network (MOA-Net), a web portal site to build a network between CDM data partners. Through MOA-Net, hospitals participated in pharmacovigilance studies and confirmed the usability and adequacy of the CDM.

Keywords:

Electronic health record, pharmacoepidemiology, pharmacovigilance

Introduction

Recent advances in health informatics has led to an increased interest in a new type of distributed database system known as a common data model (CDM). CDM is a database model with a standardized schema and vocabulary system. By using CDM, it became possible to perform simultaneous multi-center analysis using a reusable, parametrized query tool without exposing any kind of private information out of the medical institutes. In the Republic of Korea, the Ministry of Food and Drug Safety (MFDS) and the Korea Institute of Drug Safety & Risk Management (KIDS) developed an active pharmacovigilance system using CDM based on electronic health records (EHRs) since 2016. KIDS named this customized Korean model MOA (Medical record observation and assessment for drug safety)-CDM. During 2016-2017, MFDS constructed MOA-CDM at 9 hospitals in Korea. In 2018, KIDS selected five major hospitals including local representative drug safety centers as an attempt to expand the CDM. Also, KIDS developed MOA-Net, a web-based, multi-directional portal service to network government and data partners. Through MOA-Net, hospitals participated in pharmaco-vigilance studies and confirmed the usability and adequacy of the CDM.

Methods

Building MOA-CDM requires several steps such as extracting raw data from EHR, transforming the database schema and vocabularies into a common format, and loading. The standard schema of MOA-CDM includes essential parts of Sentinel CDM from the United States Food and Drug Administration (U.S. FDA)[1; 2] and the observational medical outcomes partnership (OMOP) CDM from observational health data science and informatics (OHDSI)[3; 4]. Since Korean hospitals mostly use Korean electronic data interchange (EDI) code and Korean standard classification of diseases (KCD) code in the National health insurance system, we mapped the local vocabularies into standard vocabularies. Local vocabularies are saved as source_value in OMOP CDM tables [4]. The standard vocabularies that we selected are as shown below [5; 6; 7; 8]:

Table 1. Vocabulary Mapping

Category	Local vocabulary (before mapping)	Standard vocabulary (after mapping)
Drug	EDI code	RxNorm
Condition	KCD-7	SNOMED-CT
Procedure	EDI code	EDI code
Measurement	Vary by hospital	LOINC

* SNOMED-CT: Systematized nomenclature of medicine-clinical terms, EDI: Korean electronic data interchange, LOINC: Logical observation identifiers names and codes

We designed the workflow of the Korean active pharmacovigilance system based on the CDM as follows: first, MFDS requests the analysis of domestic status to KIDS when a drug safety issue occurs. KIDS designs the analysisby referring to the literature review and experts advice. Next, KIDS distributes the analysis module through the MOA-Net and invites data partners to research. Participated data partners run the module using their own data and provide results to KIDS through the portal. Finally, KIDS integrates the results from the data partners and suggests answers for MFDS' safety concern.

We checked the adequacy and efficiency of the pharmaco-vigilance system based on CDM as follows. First, we performed abnormality detection and logical error test to enhance the quality of CDM data. We applied the Achilles heel rules from OMOP CDM [3; 4] as a standard of logical error test. We also checked the rate of concepts that are mapped into standardized vocabularies successfully. Second, we designed three nested, case-control studies about current pharmaco-vigilance issues in Korea - (1) Diclofenac beta di-methyl-aminoethanol & angioedema, (2) Clazpine & pleurisy, and (3) Allopurinol & thyroid stimulating hormone (TSH) increase. For every case, we randomly selected four controls by incidence density sampling method. We matched them for age, sex, and cohort-in-date. We aimed to calculate descriptive statistics of subjects, and unadjusted odds ratio (crude OR) as a signal statistics of adverse drug reaction. We developed analysis tools using structured query language (SQL) and R. Then, we distributed the tools and collected analysis of results from data partners through MOA-Net.

Results

In Korea, more than 9 million patient information records from 14 national representative hospitals were acquired to construct

a CDM database. The database converting EHR to CDM includes more than 127 kinds of clinical laboratory tests, and more than 5,000 drugs available in Korea. Every database entered the logical error test by the Achilles heel rule successfully. In the mapping rate test, we found some unusual concepts were not mapped into standard vocabularies. Most of the unmapped concepts turned out to be old drugs that are not currently used, or very new drugs in clinical trials. Continuous review and examination in mapping are still in progress to improve the quality of vocabularies by experts.

A total of 6 hospitals participated in three phamacovigilance studies. Among the three studies, we found two significant adverse drug reaction signals – clozpine & pleurisy, and allopurinol & TSH increase. For clozapine and pleurisy, we identified 81 cases of pleurisy and 308 matched controls. When all non-users were compared with users of clozapine, the risk of pleurisy (unadjusted OR) was increased by 8.46 fold (95% CI: 1.4-51.28). For allopurinol and TSH increase, we identified 10,663 cases of TSH increase and 42,631 matched controls. When all non-users were compared with users of allopurinol, the risk of TSH increase (unadjusted OR) was increased 3.52 fold (95% CI: 2.96-4.20). Although these statistics are not enough to conclude the relationship between drug use and adverse effect in the way that it is an unadjusted result, it still implies considerable association as a signal statistics. For diclofenac dimethylaminoethanol and angioedema, we couldn't assess the relationship because diclofenac use was considerably rare in our subjects. However, we identified significant differences in Non Steriod Anti Infammatory Drugs (NSAIDs), antibiotics use and history of urticaria which are all well-known risk factors in angioedema. The analysis result is as follow:

Table 2. Pharmacovigilance Results

Subject	Case (N)	Control (N)	OR	95% C.I.
Diclofenac-angioedema	1,719	6,876	1.33	0.14-12.85
Clozapine-pleurisy	81	308	8.46	1.4-51.28
Allopurinol-TSH increase	10,663	42,631	3.52	2.96-4.20

Conclusions

The Korean pharmacovigilance system based on MOA-CDM promises for active drug safety surveillance. As a result of performing several projects via MOA-CDM pharmacovigilance system, we found that the CDM system is faster and more efficient than analyzing health claims data to answer drug safety concerns. Also, it was possible to elaborate on research designs for adverse drug reaction using clinical information such as laboratory test results.

However, we need to overcome some difficulties in using CDM. First, we should consistently improve quality of data and vocabulary mapping. Also, hospitals should update their data periodically to assess the safety of new drugs. Therefore, automatic, real-time ETL (extraction-transformation-loading) and mapping engines should be developed by hospitals. Second, there is a risk of serious underestimation in pharmacovigilance studies using CDM because interhospital data sharing is impossible. For example, if a patient was prescribed medication elsewhere first and visited the hospital after they noticed an adverse drug reaction, an algorithm would classify him as a non-exposed case. On the other hand, if a patient was prescribed medication in a hospital and visited the hospital again when they noticed adverse drug reaction, an algorithm would classify him as an exposed control. Thus, researchers should be aware of the risk of bias and carefully interpret analysis result from CDM. Also, more medical institutional participation is requisite to enhance the effectiveness of this network.

An Approach of Integrating Domain Knowledge into Data-Driven Diagnostic Model

Guanxu Su, Jianghui Wen, Zhaowei Zhu, Zhuo Liu, Wei Zhao, Xingzhi Sun, Gang Hu, Guotong Xie

Ping An Health Technology, Beijing, China

Abstract

A diagnostic model of general diseases could help general practitioners to decrease misdiagnoses and reduce workload. In this paper, we developed a neural network model that can classify potential diagnoses among 100 selected common diseases based on ambulatory health care data. We propose a novel approach to integrate domain knowledge into neural network training. The evaluation results show our model outperforming the baseline model in terms of knowledge consistency and model generalization.

Keywords:
Neural networks (computer), diagnosis

Introduction

Community hospital centers (CHCs) are primary clinical institutions in which general practitioners (GPs) provide services to people nearby. Diagnosing patients with various types of diseases requires GPs to grasp a wide range of clinical knowledge. However, CHCs in China are facing a severe shortage of skilled GPs, resulting in a considerable number of misdiagnoses [1,2]. To reduce the misdiagnoses and workload for GPs, a practical solution is to provide an auxiliary diagnosis service. There are two main types of diagnostic models in clinical practice: knowledge-driven models and data-driven models. Knowledge-driven models depend on domain knowledge and usually provide reliable recommendations. However, medical knowledge is hard to acquire and often too general to address individual cases. Alternately, data-driven models can extract finer hidden patterns or relationships from many patients' records and achieve a wide coverage of diseases. However, due to the overall optimization goal in the model building process, diagnoses provided by data-driven models could be unreasonable for some individual cases.

In this paper, we developed a diagnostic model that consists of both data and knowledge to address the specificity of individual patients and the use of general diagnoses. We build a data-driven neural network model as the baseline model based on the Centers for Disease Control and Prevention's (CDC) ambulatory health care data [3]. Then we integrate domain knowledge including a knowledge graph, hierarchy information, and symptom frequency into the neural network training by applying an iterative training method, doing multitask learning, and modifying neural network structures.

Methods

We extracted ambulatory health care data from the National Hospital Ambulatory Medical Care Survey (NHAMCS) and the National Ambulatory Medical Care Survey (NAMCS) provided by the CDC. We obtained over 2 million records from 1995 to 2015. The dataset contained patient information such as demographics (sex, age), medical history, symptoms, and diagnoses. Table 1 shows the feature vector of patient information extracted from the dataset. Diagnoses are indicated by international classification of disease 9th version (ICD-9) codes in the dataset. We filtered the diagnosis list and selected the top 100 common diseases as our target diseases.

Table 1- Input features.

Feature	Description
age	age of patient, integer
sex	sex of patient, dummy variable
Symptom (1-798)	the symptoms that the patient report, corresponding to 798 columns, with each being a dummy variable
past medical history (1-72)	24 kinds of disease history of the patient. Each disease history corresponds to 3 columns, with each represents 'yes', 'no', and 'NA', respectively

We considered the following types of domain knowledge.

1. Knowledge graph: The typical symptoms of diseases. We collect information on relations between diseases and symptoms from sources like OMAHA (http://www.omaha.org. cn/),Wanfang (http://www.wanfangdata.com.cn/index. html), and SNOMED CT (http://www.snomed.org/) to construct our knowledge graph.
2. Hierarchy information: The additional labels of diseases from different dimensions. We obtain the clinical departments of the target diseases by consulting qualified physicians.
3. Symptom frequency: Conditional probabilities of each symptom given diseases.

Figure 1 shows the final model on which we applied all domain knowledge including knowledge graph, department information, and symptom frequency to the baseline model. For the baseline model, inputs are feature vectors of patient information. The output gives confidence for each potential disease. The input layer and output layer are connected by two fully connected hidden layers. Hyperbolic tangent is used as the activation function for all the connections. Cross entropy loss is used for optimization.

To add knowledge to our data-based models, we first added the knowledge graph to the training procedure using an iterative training method. We defined two types of training steps. The first one is training steps on the training dataset. The second one is training steps on the knowledge graph. During the first type of training steps, all parameters would be optimized. During the

second type of training steps, we only trained the parameters related to symptoms covered in the knowledge graph. These are marked as blue nodes in Figure 1. This prevents other parameters from being misadjusted. In addition, we performed training steps on the knowledge graph for every 10 iterations of training steps on the training dataset.

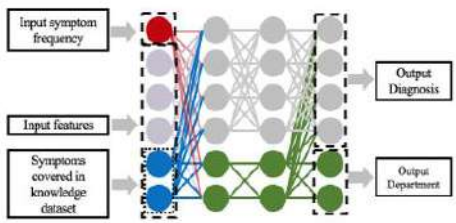

Figure 1 - Neural network Integrating all three types of domain knowledge.

Secondly, we made use of clinical department information. The green nodes represent the network for department prediction. The model for disease prediction shares nodes of the model for department prediction through the last hidden layer of the latter. During model training, the training step for the department prediction model is executed once after every training step for the disease prediction model to maintain the functionality of the hidden nodes for department prediction.

Finally, we added symptom frequency into the input layer. Aside from external informational like the knowledge graph and hierarchy information, there is information inside the data itself that can contribute to the classification model. The conditional probability of a symptom given each disease (referred to as symptom frequency) is such information inside the data that we can extract before training the neural network. We added that information into the input of the neural network, which is represented by the red node in Figure 1.

Results

The CDC dataset was randomly split into training and test datasets with a ratio of 8 to 2. We also retrieved data from Ping An Good Doctor, one of the largest disease diagnostic consulting online platforms providing real time connections between patients and doctors, as an additional test set to check model generalization [4]. We used metrics of micro and macro AUC [5], and accuracy on the test dataset, knowledge graph, and Ping An Good Doctor dataset as criteria to evaluate our five models. Accuracy at X (accu@X) is calculated as the ratio that the top X output diagnoses cover the true label.

Models 1-5 represent, respectively, the baseline model, model integrating the knowledge graph, department information, and symptom frequency, and the final model integrating all three above. As shown in Table 2, Model 4 achieved the best performance. It also can be seen that the five models didn't outperform each other significantly on the test dataset, which means that all five models fit the CDC dataset well. Table 3 shows the model performance of the Ping An Good Doctor dataset and knowledge graph. Model 2 and Model 5 were much more consistent with the knowledge graph compared to the other three models. It indicates that our method of iterative training on data and knowledge can successfully improve model consistency with the knowledge graph without sacrificing accuracy on the CDC test data. As for the accuracy of the Ping An Good Doctor dataset, all the modified models outperformed baseline Model 1. Among the modified models, Model 2 presented better generalization and higher accuracy on the Ping An Good Doctor dataset compared to the other models. Taking all results into consideration, Model 5, the model that integrated all the three types of domain knowledge, provides good knowledge consistency and high accuracy on both the CDC test data and Ping An Good Doctor dataset.

Table 2- Performance on test dataset.

Model	micro AUC	macro AUC	accu@1	accu@3	accu@5
1	97.09%	95.46%	47.93%	72.19%	81.24%
2	96.95%	95.10%	47.27%	71.66%	89.83%
3	97.28%	95.71%	48.38%	72.90%	81.79%
4	**97.34%**	**95.82%**	**48.38%**	**72.98%**	**81.71%**
5	97.22%	95.71%	47.38%	71.97%	81.14%

Table 3- Performance of the Ping An Good Doctor and knowledge graph datasets.

	Accuracy on Ping An Good Doctor data			Accuracy on knowledge graph
Model	**accu@1**	**accu@3**	**accu@5**	**accu@3**
1	21.16%	36.65%	45.31%	34.81%
2	23.30%	41.05%	50.57%	84.65%
3	23.30%	37.78%	47.44%	34.85%
4	22.87%	39.49%	49.29%	38.15%
5	21.31%	38.92%	50.85%	81.20%

Conclusions

In this study, we introduced an approach to integrate domain knowledge into a neural network for general disease diagnosis. The evaluation results showed that compared with the pure data-driven approach, our approach can lead to better performance in terms of knowledge consistency and model generalization on other data without sacrificing accuracy on the test data.

Abstract

Nephrosis is disease characterized by abnormal protein loss from impaired kidney. We constructed early prediction model using machine learning from clinical time series data, that can predict onset of nephrosis for more than one month. Long short-term memory capable of recognizing temporal sequential data patterns, was adopted as early prediction model for nephrosis. We verified our proposed prediction model has higher accuracy compared with those of baseline classifiers by 5-fold cross validation.

Keywords:
Decision support techniques, supervised machine learning, nephrosis

Introduction

Nephrosis is disease characterized by abnormal protein loss from impaired kidney. The disease sometimes results in acute kidney injury, venous thrombosis, or severe infection due to lowered oncotic pressure and immunoglobulin loss. Therefore, early detection is beneficial for patients.

In this research, we aimed to develop early prediction model using machine learning from clinical time series data that can predict rise of nephrosis. There were several issues to tackle when constructing the nephrosis prediction model, including selection of interpolation and classifier methodologies. As for interpolation, clinical time series data were sometimes partially collected, we must compensate missing values with consideration of temporal transitions. Selection of classifier also must consider temporal relationship of clinical time-series data.

To solve these problems, we adopted Recurrent Neural Network Model (RNN), which can recognize sequential data patterns, to deal with time series information. Subject examination data covered in this study was multi-dimensional, and number of examinations varied among patients. RNN is suitable for these kinds of data [1]. Unlike ordinary neural networks such as Multi-Layer Perceptron (MLP), RNN learns with consideration for relationship of continuous data by constructing weighted join that loops to hidden layer. In RNN architecture (simple RNN) composed only of simple weighted connections, vanishing gradient problem occurs at time of updating weights, and learning taking long-term time-series information into account is not guaranteed. To tackle this problem, Long Short-Term Memory (LSTM) had been proposed [2]. LSTM networks are well-suited to classifying, processing, and predicting based on time series data, since there can be lags of unknown duration between important events in a time series. In this study, LSTM was adopted as early prediction model, and results of prediction using simple RNN and LSTM model were compared.

As for interpolation methods, we selected basic mean-value interpolation and linear interpolation methods, and adopted the most accurate method.

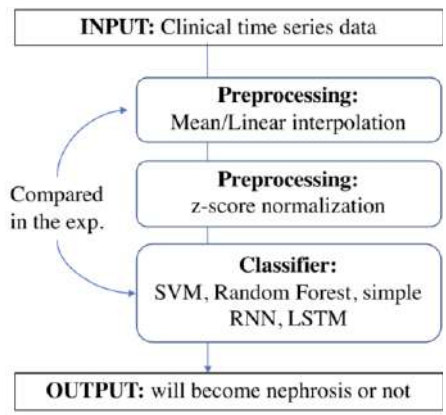

Figure 1 – Process of nephrosis prediction

Methods

Figure 1 illustrates steps of nephrosis prediction. The process of prediction can be divided into preprocessing and classification. In preprocessing, system first interpolates them with either mean-value interpolation or linear interpolation and then normalizes clinical time-series data with z-score normalization. After preprocessing, data is given to the classifier and acquire positive/negative value, meaning that patient may become nephrotic or not.

The prediction model was implemented with Python 3 and conventional classifiers, Support Vector Machine (SVM) [3] and Random Forest [4] were implemented with *scikit-learn* package; while simple RNN and LSTM were implemented with *keras* package (*tensorflow* backend). RNN and LSTM used in this experiment only had one hidden layer and number of units was 10. To prevent over-fitting, we added a dropout layer and set its probability as 0.3. Finally, softmax layer was applied to classify the positive/negative of future rise of nephrosis. The error function was categorical cross entropy, optimization method was Adam. The mini batch size was 16, and learning epoch was 50.

The clinical time-series data was collected from anonymous dataset of patients who visited Kyoto University Hospital over more than four times. Approximately 50,000 samples of 2,700 patients (377 patients were positive and rest negative) for five years were collected for the experiment. In addition, with

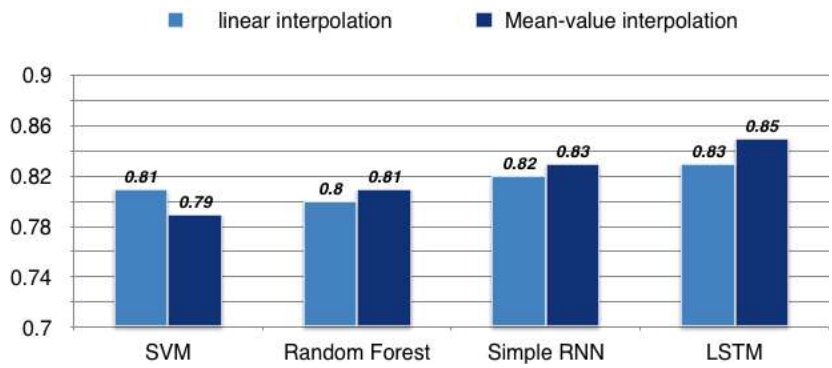

Figure 2– Accuracy comparison

Figure 3– Transition of accuracies in temporal domain

reference to opinion of the internal medicine kidney doctor, 12 examination items; *ALB, BUN, CRE, CRP, Ca, Cl, IP, K, Na, T-CHO, PCR and TP*, were extracted as values to be correlated with nephrosis.

Results

To verify our proposed early prediction model, we conducted two types of experiments, comparison with baseline methods and verification of the proposed model in temporal domain.

As for comparison with baseline methods, we verified the proposed nephrosis prediction model with combinations of two types of interpolation, which were mean-value interpolation and linear interpolation, and four types of classifiers, which were SVM, Random Forest, simple RNN, and LSTM. In total, we verified accuracies of eight kinds of identification methods by 5-fold cross validation (80% for training, 20% for validation). Figure 2 shows comparison of prediction accuracy of each method. LSTM had highest accuracy among prediction models. In comparing interpolation methods between RNN and LSTM, mean-value interpolation was more accurate than linear interpolation.

As for verification of proposed model in temporal domain, we collected another dataset 1, 2, 3, and 4 months respectively before detection of nephrosis and fed each ranged data to the LSTM classifier with mean-value interpolation. Figure 3 illustrates transition of accuracies of the proposed prediction model. From Fig. 3, we can see that the shorter the term, the more accurate the prediction was with the proposed model. Meanwhile, accuracy was not drastically decreased, even with the test-set from the entries of four months before.

Discussion

The comparison of baseline methods (Fig. 2) revealed that combinations of mean-value interpolation and LSTM has a higher performance with the experimental data. The results that mean-value interpolation has higher performance than linear interpolation indicate that transition of clinical data is non-linearly distributed and mean-value interpolation could be relatively better for the clinical time-series data. To apply more appropriate method to compensate for missing values, such as [5], would be future work.

Verification of the proposed prediction method with temporal domain (Fig.3) reveals that even with clinical time-series data that is collected four months before the detection of nephrosis, our proposed method has a good performance. This indicates that our proposed prediction model is suitable for early detection of nephrosis.

Conclusions

In this study, we aimed to develop a prediction model based on LSTM that enables early detection of nephrosis. Experimental results showed that the prediction model using LSTM with mean-value interpolation had the best performance among the comparison of two interpolation methods and four types of classifiers. The experimental results with temporal domain comparison reveals that the proposed prediction model could have a stable prediction rate even with the clinical data that was collected four months or less from the detection of nephrosis. The experimental results indicate that our proposed nephrosis prediction model is effective for the early detection of nephrosis both for accuracy and foresight.

Top-Level Design of a Normalized Chinese Clinical Terminology: An Integrated Application of National and International Data Standards and Terminologies

Haixia Sun[a], Yujing Ji[a], Panpan Deng [a], Junlian Li [a], Huiling Ren[a], Liu Shen[a], Ming Feng[b], Yi Wang[b]

[a] Institute of Medical Information, Chinese Academy of Medical Sciences, Beijing, China

Abstract

This work describes the design and building of a Chinese clinical terminology (called CCTS). The terminology is similar to an ontology, and will promote the use of Chinese clinical data, such as indexing, retrieval and exchange. The terminology is a TOPL concept framework, which integrates hierarchical structures of Chinese and interenational reference terminology standards for health. Our framework includes 14 subtrees, 2286 classes and 65 relationships.

Keywords:
Vocabulary, Electronic Health Records, Reference Standards

Introduction

Wide implementation of electronic health record systems in China has made clinical data available electronically. However, little effort has been devoted to building a national clinical terminolgy, limiting the use of clinical data for indexing, retrieval, and exchange. Motivated by this, we developed a Chinese clinical terminology, named *Chinese Clinical Terminology System (CCTS)*. We divided this work into two phases: the first phase is the top-level design, constructing the top concept framework of CCTS; the second phase is the refinement and expansion, collection and organization of more terms and concepts according the top concept framework. In this paper we introduce the top-level design.

Methods

First, we analyzed main knowledge types in Electronic Medical Records (EMR) according to the Specification for Sharing Document of Electronic Medical Record and Basic Dataset of Electronic Medical Record released by National Health Commission of the People's Republic of China (NHCPRC). This analysis indicated the scope of the terminology. Domain experts then manually selected the 14 top classes.

Then, we extracted the top 5 level concepts from terminologies and code systems (Table 1). These concepts are recommended in Chinese and international health information standards. The 5 level concepts were extracted in the following steps:

1. Manually determine the best reference subtree for different classes by evaluating and ranking them for different classes
2. Merge other related subtrees by string matching and rules
3. Recommend preferred term for classes according to reference books published by the China National Committee for Terms in Sciences and Technologies (CNCTST)
4. Inspect hierarchical relationship manually
5. Define other medical semantic relationships among the first 5 level classes referring to semantic relationships in the Unified Medical Language System (UMLS)

Results

Our top-level design phase produced 2369 high level concept classes, organized into 14 subtrees (Table 2) with 65 kinds of semantic relationships. We recommend 136 core reference sources for lower subtrees. We are in the process of extracting and fusing lower subtrees from those sources.

Discussion

This paper describes the development of CCTS through a top-level concept framework that integrates hierarchical structures of Chinese and international reference standards for health terminology, as well as expert knowledge. Reference sources for each subtree to build lower subtrees were also recommended, which will be used to guide the construction of the terminology system.

Information model design for different concept classes and extracting Out-of-Vocabulary words from EMRs using medical natural language processing (MedNLP) technology will be used in future work. We anticipate that CCTS will cover common medical terms and concepts in various EMR systems in China, and can be used to greatly facilitate EMR searching, retrieval, clustering, and reasoning, by providing rich sets of synonyms and various clinical relationships. Correspondingly, it also can promote the interoperability of EMRs by intergating Chinese and international health reference standards.

Conclusions

Design of the top concept framework is the first step towards building a domain terminology system or ontology. Integrating multiple resources is an efficient way to achieve this goal, and domain experts are indispensable. We envision the top concept framework will be used to guide the next phase of CCTS.

The Acquisition of Structured Clinical Data from a Document-Based Electronic Medical Record System

Toshihiro Takeda[a], Dongyao Zhang[a], Shoya Wada[a], Akito Nakagawa[a], Kento Sugimoto[a], Shirou Manabe[a], Yasushi Matsumura[a]

[a] Department of Medical Informatics, Osaka University Graduate School of Medicine, Suita, Japan

Abstract

Our hospital stores all clinical records as Portable Document Formats (PDFs). These PDFs are delivered by each system with a document profile XML file. Using this interface, the items thought to be important for clinical studies are described in the document profile XML and delivered to the data warehouse (DWH). In case clinical data not stored in the DWH are needed, we extract the data from PDF documents. Even from scanned PDFs, the data can be extracted with high accuracy.

Keywords:

Electronic Health Records, Data Warehousing, Information Storage and Retrieval

Introduction

In parallel with the normal electronic medical record (EMR) system, our hospital operates a document-based EMR system called the Document Archiving and Communication System (DACS) [1]. With the DACS, the printed images of all medical records stored as Portable Document Formats (PDFs) are delivered to the DACS database with its document profile XML file. The DACS has a mechanism for promoting the secondary use of EMR data, especially those from departmental systems. In this paper, we outline the methods of transferring clinical data to the data warehouse (DWH) using the DACS.

Clinical data not stored as structured data are often needed in clinical retrospective studies. Since examination reports tend to be described in the same fixed format at each hospital, the data may be extracted from PDF documents. For the data extraction, Ortigosa et al. [2] tried to extract data from electrocardiograms. However, no other studies have evaluated the ease of extracting data from PDF examination reports, especially from scanned reports stored as PDFs. The secondary purpose of our study was therefore to verify the accuracy of the values extracted from examination reports stored as PDFs.

Methods

The Collection of Clinical Data from Departmental Systems

The DACS is configured with a document generator, deliverer, archiver and viewer. The document deliverer transfers the document profile XML to the document archiver. Using this interface, the items thought to be important for clinical studies (important items) are selected beforehand, described in the document profile XML and delivered to the DWH. To assess the current status of data stored through the document deliverer, we analyzed how many records are stored in our DWH in a one-month period (August 1-31, 2018).

Acquisition of Data from Examination Reports by Analyzing the Contents of PDF Files

In case clinical data not stored in the DWH are needed, the contents of the PDF files must be analyzed in order to acquire the data. Since examination reports often have characteristic layouts for each type of examination, the target result values can be identified by the fixed expression described in the examination report.

System Overview

We used the programming language Python to develop our program. From the Python library, we used pdfminer.six for operations involving the PDF contents. In the PDF file, the contents are defined by character strings and the coordinates of their four corners. Our program performs the following processes: identification of the target page, identification and acquisition of the target data, accuracy management of the acquired data, and writing out the acquired data.

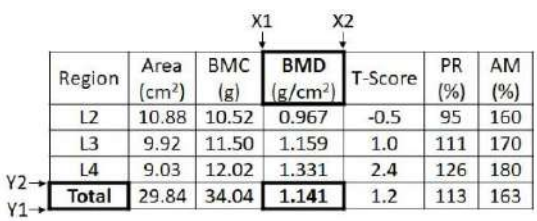
Identification of the Target Page

In order to identify the target page in which the target data is described from multi-page reports, we used the character string existing only on the target page as a marker.

If there was no single marker that existed only on the target page, pages were identified based on multiple markers or markers and their coordinate values.

Identification and Acquisition of the Target Data

If the target data is in the form of a character string in which the descriptions of the same column are invariant is used as a marker. For example, using "patient ID:" as a marker, the program searches for the target character string on the page, and the subsequent numerical value is acquired as the patient ID. If the target data are described in tabular form, a character string in the first column (title column) and in the first row (title row) are set as markers to determine the coordinate at which the target data are described.



Region	Area (cm^2)	BMC (g)	BMD (g/cm^2)	T-Score	PR (%)	AM (%)
L2	10.88	10.52	0.967	-0.5	95	160
L3	9.92	11.50	1.159	1.0	111	170
L4	9.03	12.02	1.331	2.4	126	180
Total	29.84	34.04	**1.141**	1.2	113	163

Figure 1 – Explanation of the method for acquiring tabular data.

Figure 1 shows a sample attempt at acquiring data using this method. The target value was the average bone mineral density (BMD) (target value = 1.141). We set “Total” in the first

column and "BMD" in the first row as markers. "Total" defines the coordinate of the Y-axis (Y1 and Y2), and "BMD" defines the coordinate of the X-axis (X1 and X2). The target data point is defined as the value from (X1, Y1) to (X2, Y2).

Data Acquisition from Scanned PDF Documents

For the scanned PDF documents, we used the optical character recognition (OCR) software program, the ABBYY Fine Reader 14 (developed by ABYY Company). The function ABBYY Hot Folder can convert images of printed text to machine-encoded text. In order to acquire the target data from scanned PDF documents, the device for marker selection, the setting of the acceptable range of coordinate values, and the accuracy management are needed due to the scanning condition and OCR accuracy.

Validation Target

In this study, we focused on a respiratory function test report and an X-ray BMD measurement report.

The respiratory function test report consists of a single page. The target data were the forced vital capacity percent (FVC(%)) and forced expiratory volume one second percent (FEV1.0%). The markers we set were "FVC" and "Ps/Pr" for the FVC(%) and "zissoku (described in Japanese *kanji* characters)" for the FEV1.0%.

The X-ray BMD measurement report is scanned document, so OCR must be used to acquire the target data. We attempted to acquire the BMD values of lumbar spine and femur and their peak reference (PR) values. The target data were the report name, patient ID, examination date, BMD and PR. The X-ray BMD measurement report consists of several pages. To identify the target page, we searched for the character string "f Lumber Spine", "f Left Hip" and "f Right Hip", all of which indicate the examination region, and "Total" with its coordinate. The target data of the report name, patient ID and examination date are described in the form of character strings, so we set the fixed characters "Scan Type", "Patient ID" and "Scan Da" as markers. The target data of the BMD and PR are described in tabular form, so we set "Total", "BMD" and "PR" as markers. To ensure the accurate management, we defined the "BMD" as a 5-digit number over 0.1 and "PR" as an integer over 10.

Results

The Current Status of Data Storage through the DACS

On August 31, 2018, the main system and 21 departmental systems were connected to the DACS, and 1,614 document types totaling 484,479 documents were registered to the DACS from August 1-31, 2018. A total of 9,291 kinds of important items were set in 697 documents from 13 departmental systems. From August 1-31, 2018, a total of 4,636,976 important items from 44,818 documents were stored on the data sharing server and in the DWH.

Acquisition of Data from Examination Reports by Analyzing the Contents of PDF Files

The Analysis of the Respiratory Function Test Report

We analyzed 147 respiratory function reports stored as PDFs. Our system was able to acquire the FVC(%) and FEV1.0% values from every report. We visually confirmed that all values had been accurately acquired.

The Analysis of the BMD Measurement Report

We analyzed the X-ray BMD measurement reports of 598 patients. A total of 2,735 pages were analyzed, with target data written on 1,057 pages. If all target data could not be obtained from the target pages, these pages were treated as errors by our system. The number of such pages that the system treated as error was 165; the reasons for the errors are misidentification of the target page (misrecognition of the marker used to identify the target page, 62 pages), misidentification of the target data (misrecognition of the marker used to identify the target data or of the entire character string of the target data, 73 pages) and the errors by the accuracy management (misreading of the target data by the program, 30 pages). These errors occurred mainly because the OCR software program misread the character string. We confirmed that the values obtained from the remaining 892 reports are all accurate.

Discussion

The EMR system must be designed to accumulate structured data in the DWH for the secondary use of clinical data. It is difficult to store data from every departmental system because of the increased costs. The infrastructure of the DACS to deliver PDF clinical documents from departmental systems to the DACS server with their respective document profile XML files could be used to store such clinical data in the DWH.

Despite our efforts to accumulate a substantial amount of data in the DWH, some clinical data are still not stored in the DWH because of the difficulty of the setting due to manufacturer's technical reasons. The findings of the present study concerning the acquisition of data from PDF reports show that our approach can be used to obtain data for clinical research.

However, markers for each kind of report must still be manually set using our system. Multicenter clinical studies will likely include data in different formats for each facility involved, and marker setting will be required for each format. If markers could be automatically set based on marked target values by machine learning, our program could be applied more widely.

Conclusions

Important items can be stored in our DWH from various departmental EMR systems using a document profile XML file based on the infrastructure of our document-based EMR system. Even data not directly stored in the DWH can be extracted by analyzing the clinical document PDF with high accuracy. The combination of these methods can promote the secondary use of clinical data.

[c] *Center for Biomedical Informatics, Regenstrief Institute, Indianapolis, Indiana, USA*

Abstract

The objective of this study was to determine how well a subset of SNODENT, specifically designed for general dentistry, meets the needs of dental practitioners. Participants were asked to locate their written diagnosis for tooth conditions among the SNODENT terminology uploaded into an electronic dental record. Investigators found that 65% of providers' original written diagnoses were in "agreement" with their selected SNODENT dental diagnostic subset concept(s).

Keywords:

Electronic Health Record; Electronic Dental Records; SNOMED-CT

Introduction

Recently, SNODENT (a subset of SNOMED CT since 2013) and DDS (an interface dental terminology) were harmonized [1-3]. The combination of these two terminologies led to the 2017 accreditation of *SNODENT, a dental diagnostic terminology* as the standard by the American National Standard Institute (ANSI) and the American Dental Association (ADA), and the creation of two subsets, SNO-DDS and SNO-DDS General Dentistry [2,3]. To date, *SNODENT, a dental diagnostic terminology*, or any of its subsets, have yet to be thoroughly evaluated for content coverage and completeness. The ADA Practice Institute developed a subset through expert opinion and consensus for use in the dental clinics of the School of Dentistry, University of Detroit Mercy, MI. The subset was developed to facilitate efficient documentation of common dental conditions seen in a general dentistry setting. Therefore, the objective of this study was to determine how well this subset of SNODENT met the needs of dental practitioners.

Methods

A subset of the SNODENT terminology (410 unique concepts), was uploaded into the training module of axiUm 6.x (Exan corporation, Vancouver, BC, Canada), the Indiana University School of Dentistry's electronic dental record (EDR).

We recruited a convenience sample of 20 participants, consisting of six faculty and fourteen third-year and fourth-year dental students. Participants were either full-time clinical faculty or third-year or fourth-year dental students to ensure they were familiar with documenting patient care in the EDR system.

Investigators selected a record describing a dental case-patient (herein referred to as "case-patient"), originally explained in a previous study [4]. The record included the case patient's health history information and oral findings related to periodontal disease and caries. Specifically, the case-patient had poor oral hygiene, generalized gingival inflammation, mesial and distal primary caries on anterior teeth, cracked teeth, secondary caries, extensive decay with pulp exposure, and a periapical radiolucency.

Upon enrollment into the study, participants were asked to review the record and to "think aloud" as they examined the case patient's medical history, dental findings, clinical photographs, and radiographs. The "think aloud" method includes the participant verbalizing their thoughts and actions as they carry out tasks [5-7] The entire session was audio-and video-recorded to capture participants' interactions and thoughts. Each participant thought aloud while reviewing the case-patient record and while writing dental diagnoses for eight teeth and the overall gingival health of the case-patient on a paper form.

Continuing to "think aloud," participants next worked within the treatment planning module of the EDR to locate and select the "best" SNODENT diagnostic terminology(s) for each of their written diagnoses. Afterward, participants rated their satisfaction on their selected SNODENT concept and its ability to represent their original written diagnosis. Specifically, each participant was asked to determine if they were "completely," "partially," or "not at all" satisfied with each SNODENT concept selected within the EDR.

In addition to participant observation, we recorded participants' interactions with the EDR using screen and voice capturing software Camtasia® (TechSmith Corporation, Okemos, MI, USA). At the end of the study session, each participant completed a questionnaire consisting of four Likert scale questions as well as two open-ended questions. The questionnaire was designed to assess the participants' opinions on the use and clinical value of the subset presented to them in the EDR.

Data Analysis

Two investigators (HT & ZS) independently compared each participants' written diagnoses and the corresponding SNODENT concept selected from the subset of SNODENT concepts uploaded into the EDR. Written diagnoses and selected SNODENT concepts were considered in "agreement" if they represented analogous clinical meanings. Conversely, if the written diagnosis and the selected SNODENT concept were different in meaning or intent, the match was labeled as "non-agreement" by investigators. Differences between the

two investigators' classification of "agreement" and "non-agreement" cases were resolved through discussion with a third investigator (TT). Inter-rater reliability between the two investigators was calculated using Cohen's Kappa coefficient. Further, the percentage of SNODENT concept selections deemed in "agreement" with the participant's written diagnoses was calculated. In addition, the percentage of agreement among subgroups (students versus faculty) was compared using a generalized estimating equation (GEE) model for logistic regression.

We calculated the overall percentage of participant satisfaction with their selected SNODENT concept. Students' satisfaction with their selections was compared to faculty' satisfaction using a GEE model for ordinal logistic regression. Regressions were performed with a 95% confidence interval at a p-value of 0.05. The software IBM SPSS Statistics Version 23 (SPSS, Inc., Chicago, IL, USA) was used to perform statistical analysis. Descriptive statistics were utilized to evaluate the Likert scale questions of the end questionnaire. Qualitative content analysis was used to determine any recurring themes in the open-ended responses of the end questionnaire. The recordings were evaluated to determine what barriers, if any, limited the participant's experience using the subset of SNODENT concepts within the EDR.

Results

Twenty participants selected a total of 251 SNODENT concepts (42 unique codes) to diagnose the specified dental conditions of the case-patient. Study investigators compared participants' written diagnosis and the selected SNODENT subset concept(s) for similarity in conceptual representation. Inter-rater reliability between the two investigators was 89%.

Investigators found that 162 (64.5%) of the written diagnostic concepts were in "agreement," and 89 concepts (35.5%) were in "non-agreement" with the participants' corresponding selected SNODENT concept(s).

The subgroup analysis revealed that students selected a total of 169 diagnostic concepts and had 75% "agreement" between their written diagnoses and their selected SNODENT subset concepts, whereas faculty selected a total of 82 diagnostic concepts and had 44% "agreement." The percentage of concept "agreement" among students was significantly higher than faculty (p=0.0270, odds ratio 3.1).

Participants' were asked to subjectively report their satisfaction with the SNODENT concept(s) and its representation of their original diagnosis. They reported "completely" satisfied with 155 (62%) of their selected SNODENT subset concepts, "partially" satisfied with 82 (32.5 %) and "not at all" satisfied with 14 (5.5%) of their selections. No significant differences were observed in satisfaction levels between students and faculty (p=0.54, odds ratio 1.5). Our end study questionnaire revealed that participants perceived value in this particular subset of the SNODENT terminology.

Analysis of the participants' open-ended responses to the end questionnaire revealed issues with the subset of SNODENT concepts and the EDR interface. Participants who were frustrated with the terminology reported that there were too many concepts to search through, too many options with similar meanings, and concepts missing. Regarding the EDR interface, participants noted their frustration with the categorization of certain concepts, the necessity to search for the "exact" concept with correct spelling (the EDR search toolbox offered no suggestions for misspelled words), and the time required to locate concepts.

Video analyses revealed that 75% (15) of participants experienced difficulty finding all of their written diagnoses within the subset of SNODENT concepts. To compensate, participants found substitute diagnostic concepts for the majority of their original diagnoses. For 11 searches, participants were not able to locate a substitute. Both students and faculty had difficulty in determining which SNODENT concept within the subset was the "best" selection, especially among concepts with similar meaning.

Conclusions

The majority of participants in this study agreed that a subset of SNODENT concepts within the EDR could add value to patient care and treatment planning. Investigators found that 65% of providers' original written diagnoses were in "agreement" with their selected SNODENT dental diagnostic subset concept(s). Our findings illuminate the need for continual improvement of dental diagnostic terminologies through revisions and updates. We recommend training on the use of dental diagnostic terminologies for documentation of dental diagnoses, and findings for all dental providers. In addition, an intuitive user interface has a major role in supporting accurate and complete documentation of diagnosis and findings using controlled terminologies.

Abstract

Assigning ICD-10 code of sepsis in regard of a pathogenic bacterium found in an haemoculture requires knowledge of microbiology because of the difference of granularity. The aim of this paper is to automate this coding thanks to the use of SNOMED-CT. A dichotomous classification of bacteria causing sepsis has been generated in respect of ICD-10. Our algorithm follows this and explores SNOMED-CT to assign the right ICD-10 code of the sepsis. Applied to a list of 164 bacteria, the system has an error rate of 1.22 %.

Keywords:

Medical coding, International Classification of Diseases, Systematized Nomenclature of Medicine

Introduction

Using medical terminologies to code health care data is an essential process, it allows the standardisation of this data, which is a necessary condition of their re-use in computer processings. The coding procedure is complex and it is difficult to achieve proper coding in terms of completeness or accuracy [1].

The cognitive process to code often implies to conciliate natural language data in clinical documentation and terminology concepts. It requires medical knowledge to find synonyms, to infer aggregation or specialization reasonings, and to get acquainted with the terminology usage rules [2,3].

In the field of infectiology, the available data is often a precise and textual description of the infection, with the identification of the pathogenic agent, easily trackable in lab results. In order to match this description into ICD-10 codes, there is a necessary operation to switch from a thin granularity (bacteria name) to a larger granularity (bacteria group).

To infer this transformation, a knowledge mobilization is necessary. This knowledge may be unavailable, or forgotten. In the domain of microbiology, a reasonning mediator may help to achieve this task [4] . For exemple, to assign the ICD-10 code A415 (Gram negative sepsis) from the result of a positive blood-culture containing Escherichia coli, knowledge about gram coloration is needed.

Systematized Nomenclature of Medicine - Clinical Terms (SNOMED-CT) terminology covers every field of medicine and depicts bacteria into multi point-of-view hierarchies (cultural characteristic, taxonomy…). The hypothesis is that SNOMED-CT can create the necessary pivot to infer the correct affiliation to a bacteria to a more generic group as described in ICD-10.

The aim of this study is to developp a method to assign the right ICD-10 code for a sepsis, based on the name of the bacteria that caused it, found in the bacteriological results.

Methods

Constitution of a Gold Standard

A list of bacteria was created using an anonymous and agregated collection of positive blood-cultures extracted from the microbiological lab of Avicenne Hospital between January and July 2018. The positive blood-cultures not associated with any antibiotic resistance testing has been excluded. The list is composed of 164 distinct bacteria.

For each bacteria, two microbiologists gave an ICD-10 code for the potentially associated sepsis. The coding was later checked by a specialist in medical information coding. The discrepancies have been jointly corrected. This final list of ICD-10 codes constitutes the Gold Standard.

Construction of a classification of bacteria causing a sepsis according to ICD-10

The classification of spesis causing bacteria follows the logic behind the ICD-10 classification of sepsis. The two ICD-10 classes of interest are A40 (Streptococcal septicaemia) and A41 (Others septicaemia). They describe most cases of sepsis, except some exclusions.

The ICD-10 classification of these two categories have been studied, along with all the exclusions in order to build a dichotomous decision tree for the speis causing bacteria. Every leaf of the tree correspond to a ICD-10 code. This dichotomization allows to push as the last class the unprecise codes (A 408 : "Other streptococcal sepsis" or A418 : "Other specified sepsis"). Furthermore, the code A419 : "Sepsis, unspecified" is excluded because in our study the bacteria are identified from the blood sample, thus the "unspecified" code doesn't apply here.

ICD-10 sespsis coding algorithm

The principle is to find for each bacteria found in blood cultures sufficient information to map to the bacterial point of view of ICD-10 previously described.

For each bacteria tested, the algorithm (developed in Python) browses the preceding tree by verifying the matching with the leaf. There are three different situations.

Codes mentioning a bacteria defined by its species

The leaf describes a named bacteria. For instance, the code A410 is sepsis due to staphylococcus aureus. When the algorithm comes to the leaf "Staphylococcus aureus", it checks if the bacteria is a staphylococcus aureus, and assigns the code A410 if it is the case. This situation is the simplest, the assignation of the code is direct.

Codes mentioning a disease

The exclusions of the classes A40 and A41 can mention diseases associated with sepsis without the name of pathogenic bacteria (e.g. "Sepsis in tularemia"). SNOMED-CT is here used to find the causative agents of diseases. The PyMedTermino [5] module allows to explore these relationships. When the bacteria tested is part of the causative agents, the ICD-10 code is attributed.

Codes mentioning a bacteria defined by a grouping (genus, resiratory mode, etc.)

The leaf describes a group of bacteria. For instance, the code A415 is sepsis due to gram-negative bacteria. In order to check if the bacteria is a gram-negative bacillus, the algorithm exploration is managed with the PyMedTermino module.

First, the SNOMED-CT concept associated with the bacteria tested is retrieved. Then, the list of the parents of this concept is searched. The algorithm verifies the presence of the name of name of the group (e.g. "gram-negative") is found, the algorithm stops at this leaf. Else, the algorithm goes to the next leaf.

Evaluation

The results of the algorithm for the 164 bacteria have been confronted to the Gold Standard. Any difference of coding is a wrong assignation of the code by the algorithm.

Results

The 164 bacteria of the Gold Standard are split into 14 ICD-10 codes. 7 codes are represented by only one bacteria. The code A418 ("Other specified sepsis") contains 42 bacteria and A415 ("Other Gram-negative sepsis") contains 47.

A code has been found for each the bacteria in the list extracted from the lab. Only 2 bacteria were in the category "wrongly assigned code" : Actinobaculum schaalii and Sutterella wadsworthensis. The algorithm has an error rate of 1.22 %.

Sepsis caused by Actinobaculum schaalii was coded A414 by the algorithm, as a sepsis caused by an anaerobic bacteria. The Gold Standard says A418, which describes sepsis caused by gram-positive and not strictly anaerobic bacteria. No information about the aerobic status of this bacteria was found in SNOMED-CT. Sepsis caused by Sutterella wadsworthensis was coded A415 by the algorithm (gram-negative and aerobic bacteria), instead of A414 in the Gold Standard. No information about the respiratory status either anaerobic ou aerobic was found in SNOMED-CT.

Assignation mistakes are due to the absence of essential characeristics in SNOMED-CT for the classification. Furthermore, the concept of anaerobia is not clear and hard to discriminate from aerobia in some cases. For instance, the bacteria "Suterella wadsworthensis" is identified as a micro-aerophilic [6], and thus a sepsis would have been coded A415, like the algorithm returned but was classed as an anaerobic bacteria by the two microbiologists.

Conclusion

We developed a method allowing the coding of a sepsis from to the bacteria found in the haemoculture. This will dispense the coder to search the category of the bacteria and mobilize microbiology knowledge. A study of the impact on the precision of the coding has to be lead to verify the interest of the method, and its eventual scalability in other domains, presenting other caterogies of structured data (drugs treating a disease, procedures to treat a traumatism, etc.).

Representing Rules for Clinical Data Quality Assessment Based on OpenEHR Guideline Definition Language

Qi Tian[a,b], Zhexi Han[a,b], Jiye An[a,b], Xudong Lu[a,b,c], Huilong Duan[a,b]

Abstract

Data quality assessments (DQA) reveal quality problems in electronic medical records (EHR) data. Generally, DQA methods describe quality rules in programming languages through hard-coding, which limits the implementation of DQA between heterogeneous systems and the interoperability of quality rules. To cover this gap, we conducted a case study applying Guideline Definition Language (GDL) in DQA to assess the quality of patient admission data in an EHR system of a hospital in China.

Keywords:

Data accuracy, electronic health records, programming languages

Introduction

Since electronic health record (EHR) data provide numerous opportunities for clinical research and decision-making, governments and experts advocate for the reuse of EHR data in such practices [1]. Unfortunately, the growing availability of EHR data is accompanied by a growing concern about the quality of EHR data [2]. Data quality assessments (DQA) are able to reveal data quality problems and indicate the level of data quality. Assessing the quality of EHR data is necessary before using such data in research and clinical practices.

Currently, hard-coding data quality rules and accessing data with query languages such as Structured Query Language (SQL) is the general way to evaluate data quality. However, to implement the rules corresponding to DQA requirements the evaluators must know the system's programming. Moreover, since EHR data structures are usually heterogeneous among different scenarios, the interoperability of DQA is difficult to achieve.

OpenEHR is an international health information standard focused on facilitating the universal interoperability of clinical data from EHRs and related systems [3]. The openEHR Guideline Definition Language (GDL) [4] is a language proposed by the openEHR community and used to represent clinical knowledge in clinical decision-making. As GDL is based on the openEHR archetype, a clinical concept model with standard clinical semantics, assessing data quality in GDL is a potentially promising means to facilitate semantic interoperability between different clinical scenarios. The feasibility of applying GDL in DQA, however, has not been investigated. To cover this gap, we conducted a case study applying openEHR GDL to represent the data quality constraints in DQA to assess the quality of patient admission data from an EHR database in China.

Methods

We initially analyzed the data quality requirements from a well-known DQA framework [5] and aligned it with the GDL to identify deficiencies to assessing data quality. Three deficiencies were identified and we extended the original GDL definition to address these deficiencies. First, we introduced new operators since the express operators in GDL were not adequate to describe data quality constraints. Second, new keywords were established in GDL to sufficiently describe data relationship such as *distinct*, *dependency*, and the coding system of an attribute. Third, the relationships of data records and data sets are inadequately expressed in GDL. For this deficiency, we defined new keywords to describe constraints of data sets, such as *count* and *sum*. The details of these extensions are shown in Table 1.

Since SQL is a widely-used query language which operates on data efficiently, we parsed the GDL data quality rules and converted them into SQL to obtain the target data. The workflow of parsing data quality rule is shown in Figure 1:

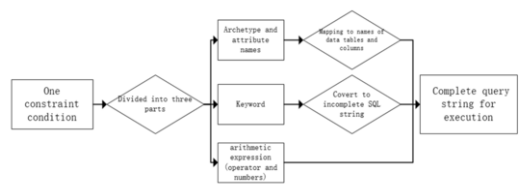

Figure 1. The workflow of parsing data quality rules.

For one data quality rule condition, we first divided it into three parts which are archetype or attribute name, keyword, and arithmetic expression including operator and numbers. Secondly, we mapped the archetype name and attribute name to the corresponding database table name and column name. At the same time, the keyword was converted into a corresponding incomplete SQL string. Finally, we assembled these parsed parts as a complete data query string to retrieve the satisfactory data records and calculate the counts of those records.

Results

The extending of GDL

The operators and keywords related in this case are shown below in Table 1.

Table 1– Instructions of operators and keywords

Type	Operator/ Keywords	Example	Description
Logical	||	RecorderName is not null ll RecorderCode is not null	Or
Logical	Not	Weight is not null	Not
Relational	== / is	WeightUnit is "cm"	Equal
Relational	<	Height < 200	Less than
Relational	<=	Height <= 200	Less than or equal
Relational	>	Heartrate > 0	Greater than
Relational	>=	Height >= 0	Greater than or equal
Keyword	Null	Weight is not null	Incomplete value or data value is null
Keyword	Unique	Entrynumber is unique	Not duplicate
Keyword	Exists in	Weight exists in Patient	Dependency of concepts.
Keyword	Code by	Gender is coded by T120	Assigning coding system of an attribute.
Keyword	Count	Count of patient >2000	Counts of the attributes
Keyword	Sum	Sum of cost <2000	Sum the values of an attribute

Assessing data quality of EHR in a hospital of China

We deployed the extended GDL to evaluate the patient admission data of an EHR database in a Chinese hospital. More than 88,000 person-time visits and 120,445 records of patient diagnosis are included in the extracted data. We evaluated 10 key data fields. The data quality rules and assessment results are showed in Table 2.

Table 2– the details of rules and executed results

Data field or data records	Rule description	Result(%)
Name	Name is not null	99.91
Patient ID	Patientid is not null	100
	Patientid is unique	100
Gender	Gender is not null	99.90
	Gender is coded by	100
Birthdate	Brithdate is not null	99.9
Date of visit	Adimit date/time is not null	100
Visit ID	Encounter identifiers is not null	100
Department of visit	Department is not null	93.94
	Department is coded by	99.9
Type of visit	Admission type is not null	100
	Admission type is coded by	100
Attending doctor	Attending doctor is not null	85.36
Date time of diagnosis	Date of diagnosis is not null	99.99
	Date of diagnosis > Adimit date/time	97.67
Content of diagnosis	Description is not null	97.29
Type of diagnosis	Class of diagnosis is not null	100
	Type of diagnosis is coded by	100
Patient demographics	Patient Demographics is unique	100
Admission	Admission is exists in Patient demographics	99.41
Diagnosis	Diagnosis is exists in Admission	99.56

Discussion

Assessing data quality with hard-coding in a programing language limits the interoperability of data quality rules. The GDL is based on openEHR, an international health information standard, which could promote the semantic interoperability of quality rules. Since the syntax is similar to natural language, GDL is also more readable to clinicians than professional programming languages. This case study shows that GDL is able to assess data quality in clinical practice. However, the quality requirements of this study are limited and this approach should be tested in other clinical scenarios.

Conclusions

In this study, we implemented an extended version of GDL successfully to assess the quality of patient admission data in a Chinese hospital EHR system. Future work should foucs on developing a systematic and professional domain-specific language for describing data quality constraints in clinical DQA.

NimbleMiner: A Novel Multi-Lingual Text Mining Application

Maxim Topaz [a,b]

[a] *School of Nursing & Data Science Institute, Columbia University, New York City, NY, USA*
[b] *Visiting Nurse Service of New York, New York City, NY, USA*

Abstract

This demonstration showcase will present a novel open access text mining application called NimbleMiner. NimbleMiner's architecture is language agnostic and it can be potentially applied in multiple languages. The system was applied in a series of recent studies in several languages, including English and Hebrew. The system showed good results in terms of text classification performance when compared to other natural language processing approaches.

Keywords:

Data mining; Medical informatics; Natural language processing,

Introduction

Natural language processing (NLP), is an important set of techniques aimed at extracting insignias from narrative health data. However, the vast majority of published NLP studies and existing NLP systems focus on processing information in English, while most of the languages around the world are described as low-resource languages in terms of NLP. More tools and approaches are urgently needed to overcome the resource barrier so advances in NLP can deliver more widespread benefits to health providers, researchers and patients.

Through this poster we will present a novel open access text mining application called NimbleMiner. NimbleMiner's architecture is language agnostic and can be potentially applied in multiple languages. So far, the system was applied in a series of studies in several languages. Examples include identifying fall in formation in clinical notes in English [1] and finding diabetes in clinical documents in Hebrew [2]. The system showed good results in terms of text classification performance when compared to other natural language processing rule-based or machine learning approaches. We will present the system and demonstrate the necessary steps in applying our pipeline. Examples in English and Hebrew will be provided throughout the presentation.

NimbleMiner's Architecture Overview

In general, NimbleMiner 's workflow is as follows (see Figure 1 for graphical depiction): **Stage 1- Language model creation** (Word embedding): The user selects a large corpus of clinical notes and defines word embedding model parameters including word window width (ranges between 1-10) and how many similar terms to present for every term entered by the user (ranges between 5-200). **Stage 2- Interactive rapid vocabulary explorer:** The user provides a query of terms of interest, and the system returns a list of similar terms identified as relevant (based on a combination of a cosine and Levenshtein distances) [1,2]. The user selects and saves the relevant terms. **Stage 3 - Labels assignment and review:** The system uses previously discovered similar terms to assign labels to narrative documents (while excluding notes with negations and other irrelevant terms). The user reviews and updates, when needed, lists of negated similar terms and other irrelevant similar terms. The user reviews the narrative documents with assigned labels for accuracy. **Stage 4 - Machine learning:** The user choses a machine learning algorithm that will be applied to create a predictive model. The model is then applied to predict which narrative document might contain the concept of interest. The user reviews the predicted documents and can repeat stages 2-4 to add new labels.

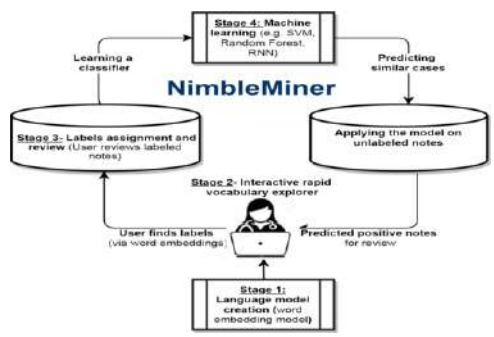

Figure 1– NimbleMiner's Architecture Overview

Follwing are further details on the system's architecture. Throughout the system description, we provide examples of words and phrases indicating patient's fall history, in accordance with a recent case-study [1]. The case-study aimed at identifying whether patients who received treatments from nurses in their homes had a history of falls. The narrative documents were nurses' clinical notes from each patient visit.

Stage 1: Language Model Creation (Word Embedding)

To prepare clinical notes for the word embedding model training, NimbleMiner pre-processes the notes to remove punctuation and lower-case all letters. Additionally, we convert frequently co-occurring words in the clinical notes into phrases with lengths of up to four words (4-grams). Next, NimbleMiner's workflow continues with generating a word embedding vector for all the clinical notes in the corpus. We use a skip-gram model (specifically the word2vec

implementation) to provide NimbleMiner users with an interactive way to rapidly identify words similar to the concepts they want to find in the text.

Stage 2: Interactive Rapid Vocabulary Explorer

The interactive rapid vocabulary explorer process consists of four steps.

Step 1: The user starts with inputting one or more keywords to the system, for example "fell" and "fall". The system suggests the most similar terms that appear in the same context, for example "tripped", "fell down", "had fallen", etc. In our approach, part of the potential similar terms are identified automatically based on the cosine similarity. Cosine similarity ranges between 0-1, with higher similarity being indicative of terms that are more similar. Terms are sorted based on the largest cosine similarity and a list of similar terms for each target word is generated. In our approach, the similar terms are called "simclins" (SIMilar CLINical terms). Simclins are defined as "words or phrases that have high positive predictive value in identifying the concept of interest". If a simclin is present, then the patient should almost always have the condition or a problem we are trying to find. For example, phrases like "pt collapsed" or "she fell down" are considered simclins indicating the presence of fall history. ***Steps 2-3****:* NimbleMiner suggests potentially similar terms and the user selects simclins. We ask the user to choose only definite synonyms (simclins) from the list of similar terms. For each simclin chosen by the user, the system presents the user with random sentences including this specific simclin. For each chosen simclin, NimbleMiner presents users with a list of additional 50 terms and asks to iteratively choose new simclins until the system cannot suggest any more new potentially similar terms. ***Step 4:*** Steps 2-3 are repeated until (1) the user cannot identify any additional simclins based on expertise or literature, and (2) the user finished reviewing all system suggested potential new similar terms. The process of simclin discovery stops at this point.

In summary, NimbleMiner's interactive rapid vocabulary explorer allows users to create large vocabularies of simclins in a very short time. The output of this stage includes a list of simclins curated and selected by the user.

Stage 3: Labels Assignment and Review

Next, NimbleMiner implements the positive-only labels learning framework to prepare the data for the machine learning stage. Previously discovered simclins are treated as positive labels. NimbleMiner uses simclins to identify and label all the clinical notes where the phenomenon of interest is described. Regular expressions are applied to identify vocabulary terms in the notes, labeling cases as "positive" when the term is present, and "unknown" when the term is absent. Negated simclins are labeled as "unknown" using the Negex vocabulary (e.g., notes with expressions like "no falls"). NimbleMiner allows users to add new negations beyond the exiting vocabulary and specify whether the negation should be searched for before or after the term (or both).

Finally, the user can review information and examples of all the clinical notes with simclins and negations. NimbleMiner also offers a summary statistics, including frequencies and percentages of each type of notes. The output of this stage is a list of clinical notes labeled as either positive or unknown. Based on the the positive-only labels learning framework, unknown narrative notes might contain negated simclins.

To create a full training set for machine learning, NimbleMiner extracts all positively-labeled clinical notes and an additional randomly selected corpus of clinical notes without the positive labels (labeled as "unknown"). Both positive-labeled and unknown-labeled corpora are then combined to create a training set that is processed by a machine learning classification algorithm of the user's choice. The output of this stage is a trained machine learning model that can be used to predict weather a narrative document, such as a clinical note, has a phenomenon of interest, for example information about patient's fall history.

Based on the resulting machine learning model, the system generates predictions for the remaining ("unknown") notes and the user can review the notes predicted as "positive" to identify additional simclins and then specify them using the interactive rapid vocabulary explorer (stage 2). New positively-labeled cases (if any) are added to the previous positively-labeled cases and the system goes through another machine learning step with an updated positively-labeled corpus. Users can decide to go through vocabulary explorer and machine learning phases until saturation is achieved (i.e., no additional training is needed, as perceived by the user). When learning is completed, the user can export the positively predicted/labeled cases for further research or clinical purposes.

Method Validation

NimbleMiner was validated and compared against other natural language processing approaches in a series of recent experiments. For example, NimbleMiner outperformed a well performing rule-based system in fall-related information classification tasks. NimbleMiner's overall F- score was 85.8% compared to 81% by the rule based-system [1]. In an additional ongoing project NimbleMiner was applied on a large sample of inpatient clinical notes in Hebrew to identify instances of diabetes mellitus (both insulin dependent type I diabetes and insulin resistant type II diabetes). NimbleMiner achieved high performance measures (average F-score = .94)[2].

Acknowledgements

This work would not be possible without Dr. Ludmila Murga, who created NimbleMiner's user interface. I am also thankful to Dr. Yoav Goldberg (Department of Computer Science, Bar Ilan University, Tel Aviv, Israel) who provided insights into improving NimbleMiner.

A Search Method to Support Temporal Transcriptome Analysis

Guenter Tusch[a], Shahrzad Eslamian[b]

Abstract

Recently, there has been an increasing interest in mining time series databases with a focus on data representation. We propose a hybrid statistical and temporal logic model to yield search pattern that can be used for pattern matching and database search to identify novel and common patterns in temporal expression experiments. The method accounts for various challenges that can be found in publicly available gene expression databases.

Keywords:

Gene Expression Profiling, Time, Database

Introduction

Public gene expression databases make enormous amounts of transcriptomic data available to researchers through the Internet. The most popular databases are GEO (Gene Expression Omnibus) at the NCBI and ArrayExpress at the EBI. NCBI GEO contains more than 105,000 series of gene-expression data collected from over 2.7 million samples and over 19,000 platforms (as of November 2018) and ArrayExpress over 2.3 million assays and some 71,500 experiments. Researchers attempt to translate the wealth of information captured in these rapidly growing biomedical and genomic databases into actionable data for health care or prevention, however the proper treatment of temporal data remains a challenge.

Biologists typically rely on statistical measures to determine trends. Time-course experiments allow them to study the dynamics of transcriptomic changes in cells exposed to different stimuli by investigating pathways or "curated gene sets". Those can be found in the Gene Ontology (http://www.geneontology.org), a framework defining concepts to describe gene function and their relationships, and the Kyoto Encyclopedia of Genes and Genomes (http://www.genome.jp/kegg/), a database integrating information on genomic and systemic function.

Traditional approaches to find gene pattern across studies are clustering and meta-analysis. Clustering approaches typically are based on GLM and splines to model profiles [1], while a meta-analysis attempts to either analyzing pooled data sets or aggregating p-values (see, e.g., [2]. One popular clustering approach for temporal data is statistical model-based clustering as describes for instance in [1] assumes that data is generated from a mixture model of probability distributions or spline approximations of the data. The mixture parameters can be estimated by maximum likelihood estimation.

A different approach used to model complex time pattern in patient records is Knowledge Based Temporal Abstraction (KBTA) to transform the raw data into a qualitative representation of temporal change based on time intervals, not discrete temporal data. KBTA is the task of summarizing large amounts of time-oriented data using domain-specific knowledge. For KBTA genomic clustering see [2].

The goal of our study is to enable the user to compare his/her own data to public datasets, regardless of the platform used.

Methods

Finding patterns of interest in time series databases (Query by Content) can be described as follows: Given query time series and some similarity measure, find the most similar time series in a given database. The two primary difficulties in this kind of similarity search are time complexity and defining a similarity measure.

Time complexity refers to efficiently finding a sub pattern in a larger pattern sequence. The approach in this paper is based on temporal logic. Finding sequential patterns in a database is implemented through Horn-like rules that can be expressed in terms of Web Ontology Language (OWL) concepts and that can reason about OWL individuals. A query is represented in a logical clause structure and a pattern matcher is used to search for complex sequence patterns of interest in a given database. This could include logical interdependencies between the elements of a sequential pattern including potential constraints as combining individual profiles in pathway or integrative genomics, e.g., genome-wide microarray expression signatures.

With our approach there are some similarities between clustering and database search. A database search for similar temporal pattern can be viewed as finding a temporal cluster that includes the query sequence. The key difference is here the variety of data sources. While clustering is typically applied to data from one experiment and one single platform, the queries under consideration here might include data from different, for example, Affymetrix platforms. While genes from different species can be compared using ortholog databases like PANTHER (pantherdb.org), the data (expression profiles) itself most likely won't fit the same statistical model due to different measurement techniques. The problem exacerbates if we compare profiles stemming from different manufacturers like Ilumina, or even microarray and next generation sequence data.

For our method, in order to increase the signal-to-noise ratio, the first step is signal averaging, i.e., averaging a set of replicate measurements of gene expression values. After averaging and piecewise linear approximation, temporal modeling through KBTA allows for conversion of expression values into an interval-based qualitative representation in a similar way as the well-known SAX method [4]. Change in the proposed method is determined by statistical significance of the paired t-test in consecutive time points. If the difference is significant, the interval is labeled as increasing or decreasing depending on the direction of change. Therefore, for the proposed method the p-values and the direction of the change inform the temporal abstraction. Time

points in temporal gene expression data are not standardized but change from experiment to experiment. If a biological signal is present, it is assumed not to depend on the interval length. Our method allows to compare studies independently from time points or scaling in the time axis or amplitude.

Since gene expression studies measure up to 40K genes or gene products on a single array with very few replicates two issues are critical for our implementation, first, to increase the power of the statistical tests (paired t-test) by empirical Bayes methods, and second, p-value adjustment. A moderated t-statistic shrinks the polled variance by borrowing information across all genes of the particular chip. Since a multitude of genes has to be tested for differential expression on the same data set, the p-value has to be adjusted. We use the False Discovery Rate.

The voom transformation RNA-seq data to be handled the same way as microarray data.

Implementation

Most of the data are preprocessed and stored in a MySQL database for performance reasons. Our plan is to migrate to an Apache Hadoop environment using Apache Hive when the numbers of the available time series data increases significantly. As of November 2018, we found in NCBI GEO 4357 microarray data sets (or 21,320 arrays) and 323 RNA-seq datasets (or 15,539 arrays). We use the GDS format with annotation files, which are normalized, and then extract the data matrix for microarray data. For high throughput sequencing RNA-seq studies data are preprocessed and normalized using standard procedures. We use R Bioconductor (BioC - bioconductor.org) with limma throughout and additionally the voom transformation for RNA-seq data. The necessary databases are accessed using standard BioC tools like GEOmetadb. This implementation has been integrated into the SPOT web application via HTML, JavaScript and PHP that feeds into Protégé. For modelling complex time patterns, we use Protégé (http://protege.stanford.edu) with the help of Allen's temporal logic as has been described in an earlier publication. We used as an example a microarray study with differentially expressed genes grouped into three peak clusters.

Discussion and Conclusions

Our model differs from statistical model-based clustering as it only assumes the general linear model, but does not model the time courses explicitly. This approach allows to cluster gene expression profiles that stem from different platforms, even microarray and nextgen sequencing RNA-seq data sets while still taking the temporal information into account. Our approach also borrows from KBTA. One of the weaknesses of the KBTA approach is that arbitrary ("knowledge based") thresholds have to be determined. In our application thresholds would need to be determined for each platform, manufacturer and technology. The key advantage of our approach is that it implicitly estimates the thresholds from the data itself and uses statistical significance to generate biologically meaningful clusters. The temporal relationship is represented by comparing the means in each pair of groups.

Due to the complexity of the transcriptome and the limited knowledge so far, there are two main approaches to evaluate the feasibility of our method. The first is to rely on existing across platform studies especially with known homologous genes and use the results and determine some form of recall and precision. The second is to perform a simulation study and generate artificial gene expression sets with realistic features. There are a variety of cautionary points: Besides limma, there are other common algorithms to determine significance in time-series gene expression data, as for instance SAM, EDGE or BETR. Typically, a p-value is assigned to an entire gene set or time series, often incorporating a sophisticated weighting schema [4-7] Our approach could be adapted.

If a microarray study or RNA-seq study finds significant gene expression changes, those typically are verified through fluorescent, one-step reverse transcription-polymerase chain reaction (RT-PCR) or quantitative polymerase chain reaction (qPCR). Since so far there are several viable alternative approaches (esp. for RNA-seq data), each study potentially uses a different method to identify differentially expressed genes and similarly for clustering the gene sets as for example STEM, GQL [4-7] or TimeClust [2], the significant genes that our algorithm finds, may not be verified. One solution could be implementing different standard pipelines and giving the user the choice. Given, that we describe an exploratory and not modelling approach, we face the same challenges as other search tools in bioinformatics in terms of how to implement biological knowledge in a computer system.

We will compare ours to those published results and continue to evaluate our program on a representative set of sample studies.

Design of Biomedical Informatics Framework for Personalized Medicine in Healthcare Organizations

Mohy Uddin

Executive Office, King Abdullah International Medical Research Center, King Saud bin Abdulaziz University for Health Sciences, Ministry of National Guard - Health Affairs, Riyadh, Kingdom of Saudi Arabia

Abstract

To implement personalized medicine effectively at organizational level, it is vital to identify, organize, integrate and leverage multi-dimensional patient data from heterogeneous and distributed resources within an organization. This paper presents the design of a novel informatics framework, to identify, organize and integrate patient's clinical, genomics and environmental data from existing clinical and biomedical resources, and to explore how this patient's data can be leveraged by informatics tools to achieve the goal of personalized medicine.

Keywords:
Personalized Medicine; Data Warehousing; Risk Assessment

Introduction

The new era of life sciences has brought many promising innovations to improve healthcare and personalized medicine is one of them. It is an advancing field of healthcare that is based on each patient's unique clinical, genomics and environmental profiles; thus providing individualized care and treatment using integrated, coordinated and evidence based approach. Using a case study of a hospital and research center, preliminary requirement analysis was performed. The needs of utilizing latest approaches of translational and personalized medicine were observed for the hospital to improve quality of patient care services; and the needs of improved biomedical data storage, analysis and interpretation methods were observed for the research center to develop a centralized biomedical research data platform. Based on these requirements, this paper presents the design of a novel biomedical informatics framework for Integrating Clinical, Genomics and Environmental Data (ICGED), which provides a roadmap for personalized medicine by integrating and utilizing patient's data from existing clinical and biomedical resources in an organization.

Framework

Objectives

Our framework is aimed to serve the following purposes:

- Identification, organization and integration of patient's data from diverse organizational resources
- Development of a centralized platform for data provision
- Data analytics, mining and interpretation
- Transformation of existing data into meaningful information
- Knowledge extraction from the available information

This framework is targeted for the following stakeholders:

- Healthcare professionals for finding patient's information to be used for individualized and tailored care and treatment.
- Biomedical researchers and investigators for utilizing existing information and using it for further research studies.

Information Resources Used by Framework

Our framework is built on holistic approach of utilizing and integrating following existing clinical and biomedical information resources within the organizational structure (see Figure 1). Some main resources identified using our case study includes, but are not only limited to, the following: electronic health records (EHR) / clinical information systems (CIS), ancillary / auxiliary information systems, disease registries, biobank, and bioinformatics research databases.

Categories of Patient's Data Used in Framework

Using available resources, our framework aims to extract following patient's data: clinical, demographics, lifestyle, phenotype and -omics (Figure 1).

Design of Tools Provided by Framework

Our framework suggests the following tools that can integrate and leverage multi-dimensional patient's data from various resources to provide approach of personalized medicine.

Data Integration and Analysis Tools (DIAT)

To implement the DIAT, Informatics for Integrating Biology and the Bedside (i2b2) [1] data warehouse (star schema) can be built by extracting and integrating the clinical and genomics data from different resources, such as clinical information system, biobank and disease registries (see Figure 1).

Risk Assessment and Prediction Tools (RAPT)

To implement the RAPT, data can be extracted from different resources, e.g. EHR and existing patient's disease and genetic registries, (see Figure 1). Using the machine learning algorithms [2], models for disease prediction can be constructed.

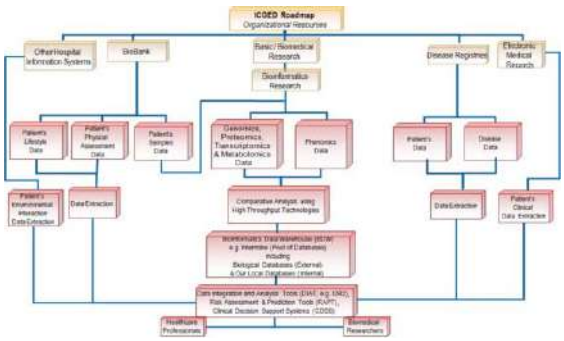

Figure 1 – Design of Informatics Framework for Integrating Clinical, Genomics and Environmental Data (ICGED)

Clinical Decision Support Systems (CDSS)

Using EHR, applications like SMART [3] and customized RAPT (see Figure 1), the decision support features can be implemented and used in the clinical practices.

Bioinformatics Data Warehouse (BDW)

The literature contains several examples of biological data warehouses, e.g. InterMine [4] that can be implemented by integrating various heterogeneous biomedical data formats.

Discussion

Though the future of personalized medicine is promising, but there are several challenges and barriers associated with it. In terms of implementation, there are always challenges of data standardization, quality, accuracy and ownership. Also, the technical issues must be dealt for data implementation aspects, such as extract, transform and load (ETL) process, data interoperability and data governance associated with data warehouses and analysis tools [5]. The revolution of big data is continuously changing the ways of analyzing and interpreting the data in precision medicine [6] that must be considered. In addition, the challenges of data interoperability, data harmonization and fine-grained data access are some other important aspects for future precision medicine [7]. In terms of economics, risk assessment, cost-benefit analysis, insurance policies and reimbursement issues should also be carefully weighed [8]. The consideration of ethical aspects [9], such as security, privacy and confidentiality related to the use of multi-dimensional patient's data is a sine qua non; moreover social and legal questions [9] in using genomic information in patient care practices are still a big challenge for personalized medicine and must be addressed by the future research.

Conclusions

This paper presented a biomedical informatics framework that utilizes and integrates patient's data from existing clinical and biomedical resources in an organizational setting. It provided a novel approach for identification of various patient information resources, extraction of different types of patient's data from these resources, and leveraging the patient's combined profiles through the DIAT, RAPT, CDSS and BDW tools in order to achieve the goal of personalized medicine.

Characterizing VA Users with the OMOP Common Data Model

Benjamin Viernes, Kristine E Lynch, Brett South, Gregorio Coronado, Scott L DuVall

VA Informatics and Computing Infrastructure, Department of Veterans Affairs, Salt Lake City, UT, USA,
Department of Internal Medicine, Division of Epidemiology, University of Utah, Salt Lake City, UT, USA

Abstract

In 2015, the VA Informatics and Computing Infrastructure, a resource center of the Department of Veterans Affairs, began to transform parts of its Corporate Data Warehouse (CDW) into the Observational Medical Outcomes Partnership) Common Data Model for use by its research and operations communities. Using the hierarchical relationships within the clinical vocabularies in OMOP we found differences in visits, disease prevalence, and medications prescribed between male and female veterans seen between VA fiscal years 2000-17..

Keywords:

Electronic health ecords; systematized nomenclature of medicine; veterans

Introduction

The development and implementation of common data models (CDMs) address some of the logistical challenges of performing research on data generated from disparate healthcare systems by using standardized terminology to express clinical information unambiguously.[1] Even within a single healthcare system, a CDM can be advantageous as the standard representation of clinical concepts improves data quality, allows for rapid and reproducible execution of data management and analysis, and reduces barriers to entry for new researchers to complicated data systems such as electronic health records (EHR). The Veterans' Affairs (VA) is the largest integrated healthcare system in the United States and its EHR is especially complex, with data being sourced from what is analogous to >130 distinct medical systems. Theoretically, the same clinical concept (e.g., blood glucose lab test) may be represented more than 130 different ways, to represent each distinct VA medical facility.

In 2015, the VA Informatics and Computing Infrastructure (VINCI) began transforming parts of the VA's Corporate Data Warehouse (CDW) into the Observational Medical Outcomes Partnership (OMOP) CDM (hereinafter referred to as VA OMOP). VA OMOP version 5.2 contains a large portion of the CDW and allows for less complex, high-level views of many parts of the VA healthcare system. While OMOP is available to VA researchers, to date no one has provided a comprehensive clinical characterization of the VA population using OMOP. Thus, we sought to complete a characterization of veterans who utilize the VA for healthcare services using VA OMOP.

Methods

We compared male and female veterans with respect to visits, conditions, and medications. We utilized the Visit_Occurrence, Drug_Exposure, Condition_Occurrence, Death, and Person fact tables of the OMOP CDM for this analysis. Comparatively, these 5 OMOP tables comprised data transformed from >14 patient level fact tables and a large number of meta-data tables from the CDW data model.

Inclusion Criteria

Using the Visit_Occurrence table, we required patients to have an outpatient visit between fiscal years (FY) 2000 to 2017. Although VA enrollment data was not yet available in VA OMOP, we required patients to have been enrolled in the VA after 10-01-1999 (FY 2000) to ensure that we were only analyzing patients whose VA medical history began during our study period. Patients had to have a valid birthdate (i.e., be 18-114 years of age on the first day of the FY of their first visit), have a defined gender (male or female), and a date of death, if applicable, within or after the FY of their first visit.

Person and Visit Characteristics

We assessed basic patient characteristics using the Person table, a one row per patient table that contains information on demographic factors. We described the VA population using data representing characteristics of race, ethnicity, and deaths. Using the Visit_Occurrence table we calculated the number of outpatient visits, counts of new patients, and counts of returning patients, each overall and by year. The Visit_Occurrence table specified inpatient, outpatient, and emergency room visit types, and for this analysis, outpatient and emergency room visits were combined as outpatient visits. To understand the difference between genders, we compared mean visits per year by gender, percent of all new patients by year and gender, and percent of all patients who are returning patients by year and gender. Finally, we adjusted the mean visits per year per patient by creating rules for patient activity. Assuming that patient activity required constant system use, and based on distributions of visits, a FY was counted as active for a patient if a visit occurred during the year and there was no 1 year no gap preceding a year of no visits.

Condition Occurrence

We extracted the most common conditions by Systematized Nomenclature of Medicine—Clinical Terms (SNOMED CT)

classifications, OMOP's standard vocabulary for conditions. Within the SNOMED hierarchy, many levels were available to potentially evaluate the clinical concepts that described records in the OMOP Condition_Occurrence table. After identifying the most common overall SNOMED concepts in the Condition_Occurrence table, it was determined that the SNOMED 'Disease' concept (i.e., SNOMED code 64572001) and its related descendants was an optimal method for evaluating the burden of different diseases in the VA. This approach created disease classifications with minimal deviation from the standard mappings of International Classification of Disease diagnostic codes, the VA's condition vocabulary, to SNOMED. There were 89 immediate descendants, of the SNOMED disease hierarchy, of which only 74 had been observed in VA from FY 2000-2017. These 74 descendants helped to organize the 13,922 descendant concepts that described diagnoses in the VA OMOP.

We created a frequency table of the SNOMED disease child (e.g., mental disorder), the disease descendant (e.g. depressive disorder), and assessed differences between genders. The most prevalent diseases were then organized by overall patient prevalence during the study period, the most prevalent by each gender, and the comparative rankings for the opposite gender for highly prevalent diseases among each.

Drug exposure

RxNorm is the standard vocabulary to represent drug exposures. We used the RxNorm hierarchy that has been pre-processed and built into the OMOP Concept_Ancestor table to describe outpatient prescriptions at the level of ingredient. The ingredient can be derived from any RxNorm clinical drug form through the hierarchy of the RxNorm vocabulary. Of 7,612 unique RxNorm ingredient values present in the OMOP Concept table, 1,688 RxNorm ingredients had been prescribed in the VA with 1.1 million clinical drug descendants.For the most common prescribed ingredients, we assessed the patient frequency of prescription ingredients and gender differences.

Results

After applying our inclusion criteria, our final analytic sample contained 8,401,080 distinct Person_IDs with at least one outpatient visit from FY 2000-17. The majority (93%) were male, white (65%), and not Hispanic/Latino (77%). For the male population, 66.2% identified as white, and 10.9% identified as black. For the female population, 54.4% identified as white and 24.8% identified as black. Females were statistically significantly younger at age of first visit (39.75) compared to men (56.28). During the 18-year study period, 27% of males died compared to 7% of women.

The most common conditions as defined by SNOMED disease descendants were hypertension and hyperlipidemia with over 50% of all veterans having a recorded diagnosis (see Table 1 for comparison of conditions between genders).The order of most prevalent conditions in women (highest to lowest) was depressive disorder (32.9%), anxiety disorder (28.7%), hyperlipidemia and hypertension. Of the top ten prescribed medications, five were for pain management, two for blood pressure, one for cholesterol, one was an antibiotic, and one for gastroesophageal reflux disease (see Table 2). Female veterans had lower prevalence of many of the most commonly prescribed medications for chronic diseases. This makes sense intuitively due to the fact that on average VA women are younger than men and have lower prevalence of hypertension and diabetes. The top three drugs for women were for pain. Aside from aspirin, men had lower rates of prescription for all pain medications in the top ten.

Table 1. Ten Most Common SNOMED Diseases and Corresponding Rank and Percentage by Gender, VA 2000-17

Disease concept	Percent	Male	Female
1. Hypertension	53.3	1 (55.1)	4 (28.3)
2. Hyperlipidemia	47.9	2 (49.3)	3 (28.4)
3. Presbyopia	25.3	3 (25.7)	8 (19.6)
4. Sensorineural hearing loss, ilateral	22.5	4 (23.8)	62 (6.5)
5. Obesity	22.6	5 (22.2)	5 (27.3)
6. Type 2 diabetes	20.9	6 (21.8)	42 (8.8)
7. Gastroesophageal reflux disease	21.4	7 (21.7)	9 (18.5)
8.Tobacco dependence syndrome	20.9	8 (21.1)	11 (17.4)
9. Depressive disorder	21.9	9 (21.1)	1 (32.9)
10. Nuclear senile cataract	17.2	10 (17.9)	43 (8.6)

Table 2. Ten Most Common RxNorm Drug Ingredients and Corresponding Rank and Percentage by Gender, VA 2000-17

Ingredient	Percent	Male	Female
1.Acetaminophen	33.9	1 (33.5)	1 (39.0)
2.Simvastatin	30.3	2 (31.5)	33 (13.9)
3.Lisinopril	29.8	3 (31.0)	35 (13.4)
4.Omeprazole	26.2	4 (26.3)	4 (24.7)
5.Hydrocodone	22.6	6 (22.3)	3 (25.4)
6.Hydrochlorothiazide	22.3	5 (22.8)	25 (14.8)
7.Ibuprofen	18.4	7 (17.5)	2 (28.8)
8.Amoxicillin	17.5	9 (17.1)	7 (22.4)
9.Aspirin	16.8	8 (17.4)	62 (8.8)
10.Naproxen	16.5	11 (16.0)	6 (23.3)

Outpatient visits increased over time from FY 2000-17. This occurred for both genders, but for women, the number of visits had a higher rate of increase than men. In 2000, patients had an average of 4.84 visits per year with little difference between men and women. By FY 2017, that average had increased to 13.31 visits with women averaging almost three more visits per year than men. Although the majority of new patients each year were male, the relative proportion of new women veterans increased from 5% in 2000 to 9.4% in 2017.

Conclusions

A characterization analysis of VA users is important to best align research questions and methodological approaches to the VA EMR data, and aligns with the educational mission of VINCI. Additionally, by leveraging the hierarchical features of the OMOP CDM, we were able to understand gender differences in ways that would have been more difficult with VA CDW.

Data Mining in Nursing: A Bibliometric Analysis (1990-2017)

Qian Xiao[a], Jiani Wang[a], Yanling Wang[a], Ying Wu[a]

[a] *School of Nursing, Capital Medical University, Beijing, China*

Abstract

To explore the current trends and future directions of data mining in nursing, we systematically searched English and Chinese databases (from 1990 to 2017) with data mining and nursing related keywords. We found 407 papers, which increased rapidly in the recent five years. Data mining was the most widely used in clinical nursing (50.6%). Chinese papers focused on exploring new nursing knowledge and rules, while English papers focused on promoting nursing practice by data mining.

Keywords:
Bibliometric analysis, Data mining, Nursing informatics

Introduction

Data mining is the process of unearthing information from large datasets using methods at the intersection of machine learning and statistics [1]. Data mining has become useful in assisting the discovery of nursing knowledge from big nursing data and transforming it into an understandable structure for further use [2]. This study aims to explore the current trends and future directions of data mining in nursing.

Methods

We systematically searched English databases (including Pubmed, Embase, and CINAHL), and Chinese databases (including China Biology Medicine, China National Knowledge Infrastructure and Wan Fang Database) with data mining and nursing related keywords. The database search covered the papers published between 1990 and 2017.

We analyzed the changing trend of literature, the main application areas of data mining in nursing, and the comparison between Chinese and international literature using bibliometrics analysis.

Results

We selected 407 papers, of which 112 (27.5%) were Chinese papers and 295 (72.5%) were English papers. The development of the literature presented an increasing trend annually, especially in the past five years (Figure 1). The number of papers from 2013 to 2017 accounted for 50.6% of the total papers. Data mining was the most widely used in clinical nursing (218, 53.6%), followed by community nursing and health management (61, 15.0%), nursing management (50, 12.2%), nursing education (37, 9.1%), and other aspects (41, 10.1%). The comparisons of the top 10 most cited articles showed that Chinese literature focused on exploring the new nursing knowledge and rules, while the English literature focused on promoting nursing practice by data mining. Table 1 lists the high-frequency keywords of data mining in nursing.

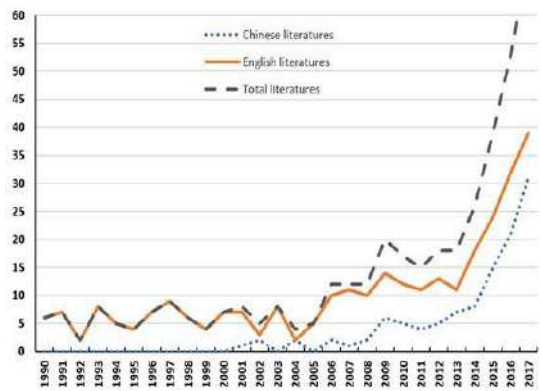

Figure 1– The trends of data mining papers published in English and Chinese databases

Table 1– The top ten high-frequency keywords of data mining in nursing

No.	Chinese literatures		International literatures	
	Keywords	Frequency n (%)	Keywords	Frequency n (%)
1	Data mining	112(100.0)	Data mining	295(100.0)
2	Nursing	98(87.5)	Nursing	233(79.0)
3	Medical informatics	52(46.4)	Nursing records	102(34.6)
4	Decision-making	43(38.4)	Decision-making	77(26.1)
5	Predictive model	36(32.1)	Nursing care	72(24.4)
6	Artificial intelligence	33(29.5)	Nursing informatics	70(23.7)
7	Nursing records	27(24.1)	Risk assessment	53(18.0)
8	Health policy	22(19.6)	Predictive model	51(17.3)
9	Knowledge discovery	17(15.2)	Elderly care	32(10.8)
10	Elderly care	13(11.6)	Nursing practice	11(3.7)

Discussion

The results are discussed in the context of data mining in clinical nursing. The authors offer their perspectives and insights on the results in this section. Potential impacts, plans, and recommendations for future work may also be presented here. It is important for authors to include a discussion of the limitations of their work and potential pitfalls in the interpretation of their results.

Conclusions

The data mining has penetrated different clinical nursing branches and has received attention progressively. The data mining concept is spread and accepted, and more efforts should be initiated to further strengthen the application of data mining in nursing.

The Hotspots Analysis of Education and Management of Childhood Asthma Based on Cluster Analysis Method

Yana Xing[a], Yibo Wang[b], Wei Zhang[a], Hongmei Duan[a]

[a] *The School of Nursing, Beijing University of Chinese Medicine, Beijing, China*
[b] *Peking University Library, Peking University, Beijing, China*

Abstract

By the use of SPSS software and computer programs, this paper gives a co-word clustering analysis of the articles on education and management of childhood asthma worldwide published in the Web of Science before September 2018. Correlation and dissimilarity matrix and hierarchical clustering were constructed. Finally, 66 high-frequency keywords of 6147 papers were included, 9 hotspots in this field emerged by cluster analysis, which could provide some valuable information of hot research on this field.

Keywords:

Asthma; Co-word analysis; Cluster analysis

Introduction

Asthma is the most common chronic respiratory disease in children, affecting 1-18% of the population worldwide [1]. Recurrent attacks of asthma may lead to irreversible lung function damage and poor quality of life, causing substantial social and economic burden to the whole society [2].

Asthma can be controlled well through effective management and education, although it cannot be cured. However, uptake of treatment and management for childhood asthma remains disappointing, only 14.2% of patients were well controlled according to the Global Initiative for Asthma (GINA) criteria in major cities of China [3]. Suboptimal management and education are vital to asthma control for children.

The co-word analysis method is a form of content analysis technique in bibliometrics, with original information like keywords to include all published articles and produce a good sight into the development of scientific fields. It could reveal the co-occurrence relationships between a pair of keywords in the same context. The more similar the keywords are, the closer the distance [4]. This method was used to analyze the research hotspots and inner construction in the field of education and management of childhood asthma.

Methods

The articles about education and management of childhood asthma were retrieved from Web of Science database before September 2018, by using the subject term (Education OR management) AND (children OR pediatric OR adolescent OR infant OR childhood) AND asthma. As a result, a total of 6357 records were retrieved. After the removal of records of no keywords and abnormal data, 6147 papers were finally included.

Excel, computer program and SPSS 18.0 statistical software were mainly used to process and analyze the data below. In the first step, keywords frequency were counted by computer programs, some general keywords with no practical meaning such as asthma, education, etc. were removed to get more precise results; secondly, a series of mapping rules were formulated to merge the synonyms manually; thirdly, the keywords were replaced according to the above rules, and frequency of keywords were counted once more.

Next, high-frequency keywords were identified to yield the co-occurrence matrix. The value of the matrix represents the co-occurrence of a pair of keywords. Ochiia-coefficient was used to transform the co-occurrence matrix into the correlation matrix. Then, the dissimilarity matrix was constructed by subtracting the value of each element in the correlation matrix from 1. Finally, dissimilarity matrix was imported into SPSS18.0 software to perform hierarchical clustering analysis, a tree diagram was plotted.

Results

In total, 66 high-frequency keywords with frequencies ≥35 were identified after screening (Table 1). Based on characteristics of keywords, 66 high-frequency keywords were extracted for clustering and 9 clusters were formed at last (Figure 1).

Table 1– High Frequency Keywords of Literature（Part）

Keywords	Frequency	Keywords	Frequency
prevalence	794	self-management	331
adolescent	641	health	328
quality of life	638	risk	326
randomized controlled trial	527	guidelines	309
care	502	impact	301
united-states	442	diagnosis	297
symptoms	428	risk-factors	292
outcomes	366	severity	291
adherence	361	lung-function	290

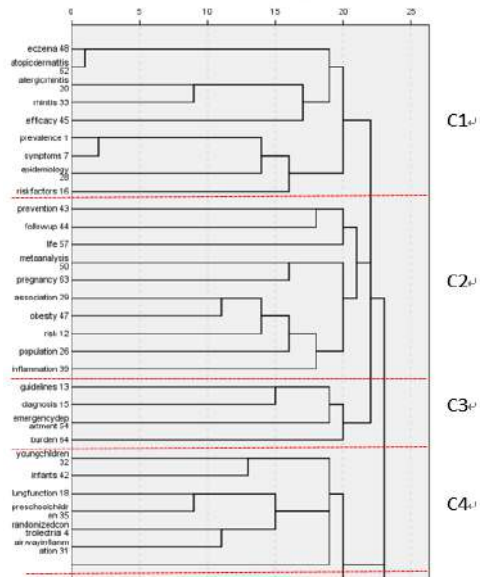

Figure 1–Clustering Results of High Frequency Keywords of Literature (Part)

Discussion

We summed up nine main research subjects in the field of education and management of childhood asthma worldwide, as shown below: epidemiology of allergic diseases in children, maternal obesity in pregnancy and the risk of asthma for offspring, burden of asthma, lung function in infants and preschool children, corticosteroid therapy for childhood asthma, development and validation of asthma related questionnaires, asthma morbidity for inner city children, self-management in adolescent and medication adherence, and food allergy management in children with asthma.

This field covers a wide range of sub-directions of research, involving the epidemiology, prevention, burden, lung function test, medication and food management of childhood asthma. Future research is required to investigate specific directions more deeply and guide the development of nursing practice and disease management.

Conclusions

In conclusion, this paper explored nine research hotspots in the field of education and management of childhood asthma by using co-word clustering analysis method. To some extent, these findings may provide new insight for understanding and predicting the dynamic directions of childhood asthma and could provide some reference and information support for clinical practice and theoretical basis for scientific research.

Evaluation of Similar Term Definitions in Medical Device Adverse Event Terminology

Ayako Yagahara[a], Masahito Uesugi[b], Hideto Yokoi[c]

[a] Faculty of Health Sciences, Hokkaido University of Science, Sapporo, Hokkaido, Japan,
[b] Department of Medical Management and Informatics, Hokkaido Information University, Sapporo, Hokkaido, Japan
[c] Department of Medical Informatics, Kagawa University Hospital, kita-gun, Kagawa, Japan

Abstract

The purpose of this study is to extract similar term definitions used in the terminology of Japanese medical device adverse events. We employed Levenshtein and Jaro–Winkler distances as edit distances and Skip-gram, continuous-bag of words, and fast text to produce distributed representations in Word2Vec. A comparison of the accuracies of the models showed that Levenshtein distance had higher specificity whereas Skip-gram had higher sensitivity as compared to the other models.

Keywords:

Machine Learning; Vocabulary, Controlled; Equipment and Supplies, Hospital

Introduction

In Japan, medical facilities and medical device manufacturing companies are required to submit medical device adverse event reports (MDAER) to the Ministry of Health, Labor, and Welfare when medical device adverse events (e.g., catheter breakage) occur during a medical procedure. Since detailed descriptions of adverse events and problems caused to patients by medical devices are documented through free-text in MDAER, they are hard to categorize and conduct statistical analysis.

Therefore, to standardize the terms in MDEAR, medical device adverse event terminology (terminology of Japan Federation of Medical Devices Associations: JFMDA terminology) was published in March 2015 [1]. This terminology consists of 89 medical device terminologies developed by 13 industry groups that are members of JFMDA. Each terminology has three categories: medical device problem, patient problem, and component. In addition, each term in "medical device problem" and "patient problem" categories have definition sentences, synonyms, and FDA code from the Center for Devices and Radiological Health (CDRH) Terminology [2] as shown in Fig. 1. Internationally, between 2009 and 2011, ISO TC 210 worked in conjunction with Global Harmonization Task Force (GHTF) and FDA to produce ISO/TS 19218 - 1 Medical devices-Hierarchical coding structure for medical device adverse events, including both event codes (part 1) and evaluation codes (part 2). In 2011, International Medical Device Regulators Forum (IMDRF) was conceived to accelerate international medical device regulatory harmonization and convergence [3].

The 13 industry groups independently constructed each terminology using a bottom-up approach by gathering the terms used regularly in medical facilities to facilitate communication between medical staff and medical device manufacturers. We are now trying to map these terminologies to ensure consistency. One problem associated with mapping these terminologies includes cases where the notation of terms is considered to be the same concept but differed depending on the terminologies. Because there are about 3,500 terms related to medical device problems, manual verification requires great effort.

Thus, the purpose of this study was to detect synonyms automatically using definition sentences of the terms used in the JFMDA terminology.

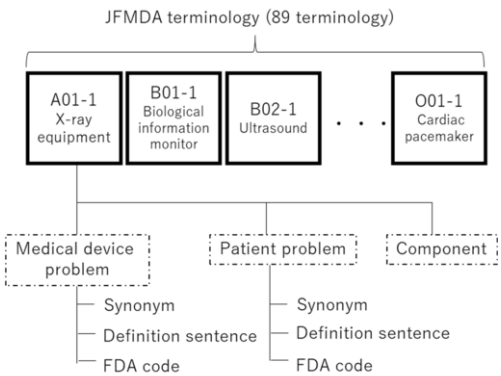

Figure 1–Overview of JFMDA terminology

Methods

Data

Terms used for describing medical device problems were the focus of this study. At first, we extracted the terms and their definition sentences. We made approximately 600,000 definition sentence pairs, of which 125 pairs were extracted arbitrarily.

Similarity Detection

We employed edit distance and Word2Vec as similarity detection methods. Edit distance is an algorithm for quantifying how two dissimilar strings are related to each other by counting the minimum number of operations required to transform one string into the other. Word2Vec is used to group vectors of similar words together into vector space to detect their similarities mathematically.

In this study, we employed Levenshtein [4] and Jaro–Winkler distances [5] as the edit distance and Skip-gram, continuous-bag of words [6], and fast text [7] to produce distributed representations in Word2Vec.

Japanese Wikipedia was used to create a distributed representation model of Word2Vec. In each model, the number of dimensions of the vector was set to 300.

Evaluation

As a gold standard, 50 similar definition pairs and 75 other definitions from the 125 pairs were identified by three experts in medical device safety. Receiver operating characteristic (ROC) analysis was carried out to evaluate the extraction accuracy of similar definition sentences, and area under curve (AUC) was calculated. The cutoff value was identified from the ROC curve using the Youden Index. Sensitivity and specificity were also calculated. ROC analysis was conducted using JMP 13.2.1.

Results

The AUC obtained from the ROC curve analysis and the sensitivity and specificity obtained from the cutoff value are shown in Table 1.

In comparing the models, we observed that both editing distance algorithms tend to have higher AUC and specificity compared to the three Word2Vec models. In particular, the AUC and specificity of the Levenshtein distance algorithm were highest. In Word2Vec, the sensitivity of Skip-gram had the highest score.

For the Levenshtein distance algorithm, the difference in the number of characters of definition sentence pairs was small, and the more common characters they had, the higher was the similarity between them. However, even though the concepts are the same, if the difference in the number of characters of a definition sentence pair is large, the similarity becomes low. Conversely, the accuracy of Skip-gram in Word2Vec did not depend on the number of characters. Therefore, to further improve accuracy, we believe that devising a method that is a combination of both Skip-gram and Levenshtein distance methods is necessary.

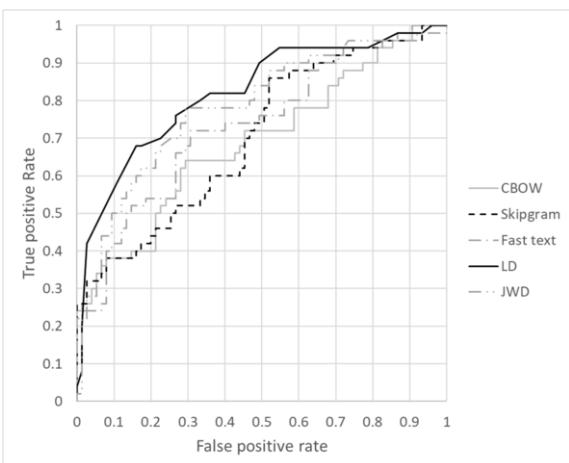

Figure 2–ROC curve

Conclusions

As a result of the experiments performed in this study to extract similar words using definition sentences, we drew the following conclusions: Skip-gram was the most sensitive and Levenshtein distance had the highest specificity and high AUC. To further improve accuracy, we suggest that devising a method that is a combination of both Skip-gram and Levenshtein distance methods is necessary.

Table 1–Comparison of the accuracy of each algorithm

Algorithm		Sensitivity	Specificity	AUC
Edit distance	Levenshtein distance	0.680	0.840	0.821
	Jaro–Winkler distance	0.780	0.707	0.782
Word2Vec	CBOW	0.640	0.707	0.690
	skip-gram	0.860	0.480	0.703
	fast text	0.720	0.693	0.734

A Graphical Representation Model for Electronic Health Records: A Preliminary Study

Lin Yang[a], Xiaoshuo Huang[a], Li Hou[a], Qing Qian[a], Jiao Li[a]

[a] Institute of Medical Information and Library,
Chinese Academy of Medical Sciences/Peking Union Medical College, Beijing, China

Abstract

To facilitate experts to find relevant clinical information models, we took a case study of openEHR. We proposed to use a graphical model to represent EHR archetype sets, aiming to optimize clincal information retrieval performance. In this study, we applied our graphic model to 523 OpenEHR archetypes and represented them as a graph with 5,008 nodes and 6,908 edges, which consists of 3,982 term nodes, 504 concept nodes, and 523 archetype nodes. On basis of the graphical model, it improved the performance for retrieving the clinical queries.

Keywords:
Electronic health record; Computer models; Information storage and retrieval

Introduction

A key requirement to achieve semantic interoperability is the standardization of clinical concept representation within electronic health record (EHR) data. The openEHR is a two-level modeling approach, which separates knowledge from information models. It consists of a Reference Model (RM), archetypes and templates. Archetypes define real world clinical concepts, such as "blood pressure", and concept-related data elements at knowledge level. Reuse of these clinical information models (archetype) could help interoperable information be created and shared in health records in a standard manner.

Archetype modeling methodology (AMM), proposed by Moner D[1], shows that searching for reusable archetypes from archetype repositories is an essential part throughout the development process. The openEHR community provides the Clinical Knowledge Manager (CKM)[2] to be a library of openEHR archetypes and templates. It supports the retrieval based on clinical concepts in different section of archetypes. It could help find reusable archetypes[3]. However, experts involved in modeling are mainly concerned about whether the concept name and core data items are covered[3-4]. For better results, end users usually need to do a large amount of preparatory work[3-4].

Since archetypes usually have their own hierarchical structures, and there are semantic relations between them, we considered that graphical representation of these potential knowledge may support clinical information models retrieval. Previous studies show that graphs could efficiently represent clinical knowledge[5]. Moreover, retrieval based on a graphical model, such as Bayesian networks, have been proved to be efficient and reliable[6]. In this paper, we aims to graphical represent of openEHR archetype sets to help identify archetypes that are relevant to a particular information need.

Methods

Archetype feature identification and extraction

As end users are mainly concerned about whether an archetype covers the concept name and core data items, we attempt to use clinical concepts and data elements to represent each archetype. An archetype is expressed in Archetype Definition Language (ADL), and mainly consists of three sections. Header contains a unique identifier for the archetype, and includes some descriptive information, such as concept name. Definition contains the main formal definition of the archetype, including all possible data elements that could be relevant for the clinical concept. Ontology contains the code that represents the meaning of nodes. Moreover, there is a relationship called specialization between archetypes. An archetype is a specialization of another archetype if it mentions that archetype as its parent. Thus, we extracted archetype ID, concept, data elements and parent archetype ID based on ADL files parsing as features (Table 1).

Table 1–Examples of Archetype Features

Archetype ID	**openEHR-DEMOGRAPHIC-ADDRESS.address-provider.v1**	**openEHR-EHR-CLUSTER.exam_urethra.v0**
Concept	Healthcare provider address	Examination of the urethra
Data elements	Address lines Building/complex sub-unit number Address site name Floor/level number ……	No abnormality detected Clinical description ……
Parent archetype ID	openEHR-DEMOGRAPHIC-ADDRESS.address.v1	Null

Graphical representation of archetypes

We used a directed acyclic graph (DAG), which called clinical resource graph, to represent the dependences among archetypes, clinical concepts, and data elements (Figure 1).

The clinical resource graph contains three layers. The first is the term layer. It contains the set of indexing data elements $T = \{T_i, i = 1...M\}$, M being the number of data elements from a given archetype collection. Each term node is linked to its corresponding concept node in the clinical concept layer. The second is the clinical concept layer. It contains the set of indexing concepts $C = \{C_j, j = 1...N\}$, N being the number of concepts. The third layer contains the set of archetypes $A = \{A_k,$

k = 1. . . K}, K being the total number of archetypes in the collection. If A_k is a specialization of another archetype A_p which defines Cj, there is a link joining the concept node Cj and the archetype node A_k.

Thus, this DAG has the set of variables V = TUCUA. The topology avoids connections between nodes in the same layer, and facilitates the inference process.

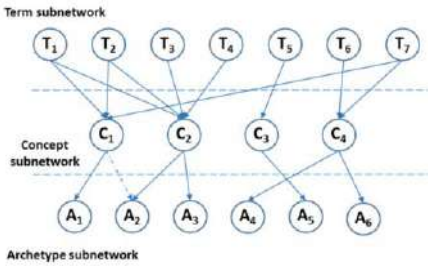

Figure 1–Topology of clinical resources graph

Data source

We downloaded 526 archetypes from CKM on August 30th, 2018. All files were in ADL format. We used the ADL parser (https://github.com/openEHR/java-libs/tree/master/adl-parser) to extract related features described above. In this collection, 3 archetypes did not use English as the description language, so the total number changed to be 523.

Results

Overview of clinical resources graph

We extracted 6504 object nodes from the collection, including 5981 data elements and 523 concept nodes. After removing the the duplicated ones, we got 3,560 and 504 respectively. Besides, there were 31 specialized archetypes, involving 20 parent archetypes while 8 of them were no longer in CKM. Therefore, the clinical resources graph had 5,008 nodes and 6,908 edges, which consisted of 3,982 term nodes, 504 concept nodes, and 523 archetype nodes. And 12 concept nodes had specialized relations with archetype nodes.

Evaluation of the performance

We formulated two test queries : Q-1 was “admit date/time, attending doctor, clinical description, discharge date/time”; and Q-2 was “report, test name, test results”. Then, we manually annotated all 523 archetypes, according to their relevance to each query, as the ground truth. To validate our clinical resources graph in supporting retrieval, we used retrieval model based on Bayesian Network proposed by Acid S[6]. Meanwhile, CKM and BM25F were selected as baseline methods. BM25F is an extension of the BM25 ranking function, which is applicable to structured documents consisting of multiple fields. We supposed that an archetype was decomposed into two fields: concept and data elements, and used the function proposed by Zaragoza H [7].

We evaluated the result in terms of Precision at cut-off points 1 (P@1) and 3 (P@3), as well as Recall (R). The result (Table 2) showed that our method was better than the two other methods. For instance, for Q-2, our method, BM25F and CKM achieved a P@3 of 1, 0.67 and 0.33, respectively. Besides, our mehtod could identified the specialized archetype “openEHR-EHR-COMPOSITION.report-result.v1”, which BM25F could not find. All these indicated that it was effective to use a graphical representation of relationships among data elements, concepts and archetypes to support search.

However, there were some important limitations. First, our approach could not solve the basic problem of semantic interoperability in EHRs, which must be solved from the perspective of the business domains the concepts originally belong to. Second, it was not clear that whether our method could be applied to other clinical information models. Third, our method could not find semantic associations when archetypes had few data elements, and terms used were totally different.

Table 2– Results of the experiment

	Q-1			Q-2		
Method	**P@1**	**P@3**	**R**	**P@1**	**P@3**	**R**
CKM	0	0	0	1	0.33	0.89
BM25F	1	0.67	1	1	0.67	0.16
Our method	1	0.67	1	1	1	1

Conclusions

To facilitate clinicians to find relevant clinical information models, we took a case study of openEHR. We tried to graphical representation of archetype sets to optimize existing retrieval results of CKM. The result showed that our method could support efficient search. This is a preliminary study. In future work, We will optimize the existing method according to its shortcomings, and validate its feasibility on other clinical information models.

Using Inpatient Portals to Engage Family Caregivers in Acute Care Setting : A Literature Review

Bader Alshoumr, Ping Yu, Tingru Cui, Ting Song

Centre for IT Enabled Transformation, School of Computing and Information Technology, Faculty of Engineering and Information Sciences, University of Wollongong, Wollongong, NSW 2522, Australia

Abstract

This study aims to review the literature evaluating the design, acceptance, use and usability of inpatient portals for family caregivers. Fourteen articles were included. Information about patient medication, lab results and healthcare team was most important. Most caregivers were satisified and perceived the ease of use and usefulnesss of portals. Further research is needed to collect sufficient evidence with regard to the impact of inpatient portals on patient engagement and quality of care.

Keywords:
Patient portals, caregivers, Quality of Health Care

Introduction

An inpatient portal is a secure website application through which patients can access the health service information, perform online health- and administration-related transactions, communicate directly with providers, and access clinical information during hosptalization [1]. Family caregivers might need to act on behalf of patients during hospitalization due to the patient's disability or very young age. Therefore, they should also be offered access to an inpatient portal. In this review, we aim to assess the use and usability of the portal for family caregivers within an acute care setting. We also explore the information and design recommendations needed for effective engagement.

Methods

PubMed, Scopus, and CINAHL databases were searched for articles published between 2008 and 2018. We used three main terms to identify eligible articles: 1) engagement, 2) patient portal, and 3) acute care or hospital. We followed PRISMA guidelines to screen potential articles in the literature. We excluded articles which were either not written in English, were commentaries, or were disccussion papers.

Results

Of the 731 articles identified through database search and reference review, 14 articles were found to meet the final inclusion criteria (see Fig.1). The study design was a mixture of quantitative and qualitative methods. The main outcomes reported were family caregivers' information needs, portal design recommendations, acceptance, use and usability. Most studies were performed at multiple tertiary teaching hospitals while only four studies were performed at children's hospitals [2–5]. 78% of studies were conducted in the United States, two studies in Canada [2,6], and one study in South Korea [7].

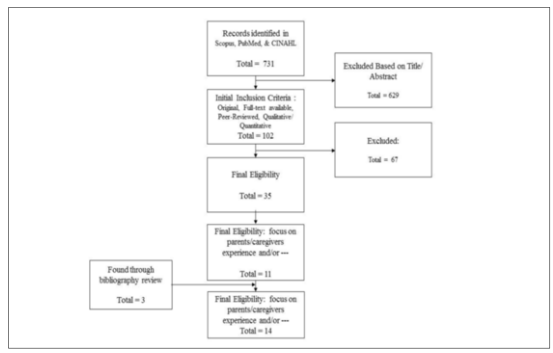

Figure 1– Article selection flow chart adapted from Kelly MM, Coller RJ, Hoonakker PLT. Inpatient Portals for Hospitalized Patients and Caregivers: A Systematic Review. J Hosp Med [8]

Caregivers' Information Needs

Three studies reported the desire of family caregivers to be offered real-time access to the patient's clinical information [8–10]. One study stated the importance of adding the patient's care plan on the portal during hospitalization [9]. Another study reported the preference of caregivers to view the health care team profiles online [10]. Two studies recommended offering detailed information about upcoming trials, uploading signed consent forms, and adding general information about the patient's transition to home care [10,11].

Portal Design Recommendations

Three studies provided design suggestions and recommendations. Caregivers suggested allowing them to customize the display of information based on patient's condition, presenting lab results as graphs instead of numbers [10] and adding functionality to notify them about upcoming clinical events and new lab results [8]. Others recommended to use the same themes, designs and functionalities in both, the inpatient and outpatient portals [12], to apply the bring your own device (BYOD) strategy inside the hospital, and also allow out-of-hospital access to the portal [12].

Caregivers' Portal Acceptance

Generally, family caregivers had positive perceptions toward the use of inpatient portal during their family members' hospitalization. They perceived a moderate satisfaction and

utility with the use of secure messaging in a rehabilitation care setting [6]. Parents of children who were admitted to either a medical or surgical unit at a pediatric hospital found the real-time visualization of the child's clinical information useful in tracking the child's progress and making critical decisions during hospitalization [5,13]. Some parents thought that the use of the portal during hospitalization might also enhance patient safety [5].

Caregivers' Portal Use

Three studies provided quantitative data about the use of an inpatient portal by caregivers. The first study reported that 90% of 300 caregivers at a tertiary children's hospital accessed the portal and used all of its functionalities [5]. Another study reported that 84% of 120 caregivers at a tertiary hospital used a web-based inpatient portal for less than 4 days, and 16% continued to use it for 5 to 10 days [9]. The last study found that the average caregivers' use of the portal was 2.5 times/month during 14 months of the study at a children's rehabilitation hospital [6].

Portal Usability

Two studies performed a usability evaluation test for caregivers in two different contexts; oncology [2] and neonatal care [9]. The tools examined were a web-based toolkit for oncology and intensive care [2] and a parent decision support tool for neonatal care [9]. Findings from both studies indicated that these tools were useful, efficient, and effective for engaging caregivers in the patient care process.

Conclusions

The overall findings of this review indicate that an inpatient portal has a great potential to enhance patient engagement in health care during hospitalization. However, study in this area is still in its early phases. Previous studies were mainly focused on exploring the design requirements or assessing the feasibility of the portal. Future work should evaluate the impact of using the portal with particular focus on caregiver's engagement, patient safety, and the quality of care.

Quick Cognitive Impairment Test for Cancer Patients Using Emotional Stroop Effect

Eiji Aramaki[a], Chihiro Honda[a], Shoko Wakamiya[a], Akira Sato[b], Isao Myashiro[b]

[a] *Nara Institute of Science and Technology (NAIST), Nara, Japan,*
[b] *Osaka International Cancer Institute, Osaka, Japan*

Abstract

Recent studies have attributed impaired cognitive function in cancer patients, or Cancer Related Cognitive Impairment (CRCI), to various causes. CRCI screening is vital for guiding important decisions about treatment options. This study investigates the emotional Stroop-test-based CRCI screening, examining response time when naming the colors of negative emotional words. Cancer patients (n=17) participated in two tests: (1) the Stroop task; (2) State-Trait Anxiety Inventory. Results suggest that Stroop-based CRCI screening is feasible.

Keywords:

Cancer, Cognitive Assessment Screening Instrument, Stroop Test

Introduction

With advancing technology in the medical field and increasing treatment options available, it is important for patients to engage in decision making with intact cognitive processes. However, recent reports have described Cancer Related Cognitive Impairment (CRCI), a phenomenon in which the cognitive function of cancer patients might be impaired. The risk factors for CRCI remain unclear, but research suggests causes such as chemotherapy, surgery, radiotherapy, hormone therapy, cancer-related inflammation, physical and mental stress, and attentional fatigue [1]. Although various pathways have been proposed, little is known about CRCI mechanisms. Studies also indicate that the CRCI is a common phenomenon: 75% of cancer patients potentially have CRCI [1].

To elucidate CRCI mechanisms, this study proposes a quick measurement based on a Stroop task [2]. A Stroop task is a widely known psychological method named after John Ridley Stroop. The Stroop phenomenon illustrates the difficulty of naming the color of a word when a mismatch exists between the color and the word, such as the word GREEN printed in red color. Many variations on the Stroop task use stimuli other than colored words. One variation applied to clinical areas uses the word set related with the anxiety of participants. This Stroop task is called an Emotional Stroop task. Such a test works by assessment of the response time of the participant when naming colors of negative emotional words. For example, depressed participants are slower at naming the color of depressing words than doing so for non-depressing words. Non-clinical subjects have also been shown to name the color of an emotional word (e.g., "war," "cancer," "kill") more slowly than when naming the color of a neutral word. This effect is called an emotional Stroop effect [3-6]. Particularly, the cancer-related emotional Stroop effect is called the cancer Stroop effect [7-9].

The proposed quick cognitive impairment screening is based on the cancer Stroop effect, specifically, the degree to which a small word set can capture the cancer Stroop effect.

Materials and Methods

We designed a three-minute screening method using 20 words (10 for cancer-related words and 10 for natural words).

Participants: Cancer patients were recruited at the venue of a classical live music concert held at the Osaka International Cancer Institute on May 12, 2018. Seventeen completed all the trials and questionnaires before and after the concert. All participants were Japanese and fluent Japanese language speakers.

Evaluation Metrics: This study investigated patients to ascertain their (1) anxiety and (2) attention.

- **Anxiety: State-Trait Anxiety Inventory:** The State-Trait Anxiety Inventory (STAI) developed by Spielberger et al [10] is a broadly used measure to assess the states of anxiety (A-State) and trait anxiety (A-Trait). Toccafondi et al [11] found that cancer patients' A-State scores in this scale improved after attending an hour-long live music concert, although A-Trait did not change significantly. For this study, A-State, translated into Japanese [12], was used to assess participants' states of anxiety. The 20-item questionnaire used 4-point scales (1-4).
- **Attention: Cancer Stroop Task:** The Cancer Stroop Task consisted of 10 cancer-related words and 10 neutral words chosen for earlier research [7] investigating attentional biases of women who had a family history of breast cancer. This study examines patients without specific cancer type. Therefore, breast-cancer-specific words used in the earlier study were replaced with general cancer-related words. Our preliminary experiments found no significant difference between word types in terms of word length, frequency, or character strokes. A Stroop task application was developed (Apple iPad; Apple Corp.). The words were presented at the center of a black screen in one of four colors: red, blue, green, or yellow. While the word was presented, four gray boxes at the bottom of the screen displayed the name of each color written in black in each box (*Figure 1*).
- Participants were instructed to ignore the meaning of the displayed words and tap one box that corresponded to the color of the word as quickly as possible. In addition, to begin each trial at a fixed distance to the color options, participants were asked to tap a gray circle with the word 'Next' appearing at the center of the screen after answering each trial. The word order of the presentation was randomized. The reaction time for each word and incorrect answers were recorded and saved in the device as a screenshot at the end of each session.

Table 1. Cancer Words and Normal Words

	CANCER WORDS	NEUTRAL WORDS
1	生検 (Biopsy)	足首 (Ankles)
2	がん (Cancer)	小冊子 (Booklet)
3	化学療法 (Chemo)	噴水 (Fountain)
4	白血病 (Leukemia)	家具 (Furniture)
5	腫れ (Lump)	公平 (Impartial)
6	悪性 (Malignant)	雑誌 (Magazine)
7	緩和ケア (Palliative Care)	ピッチャー (Pitcher)
8	医療用麻薬 (Medical drug)	粉 (Powder)
9	放射線治療 (Radiation)	着実 (Steady)
10	腫瘍 (Tumor)	衣装部屋 (Wardrobe)

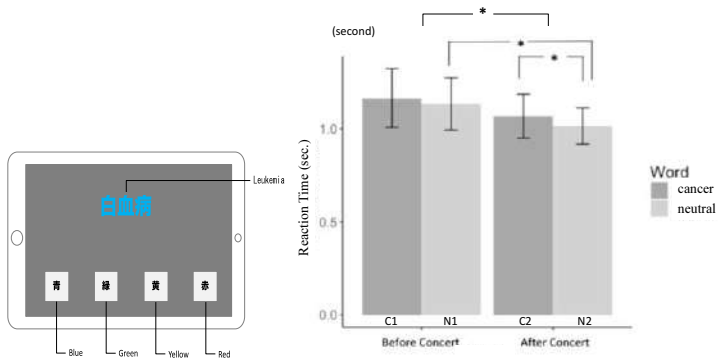

Figure 1. Stroop application made for use on an Apple iPad (left) and Interaction between word type and time condition (right).

Procedure: The Stroop task and STAI A-State questionnaire were completed before and after the monthly live music concert held at the Osaka International Cancer Institute on May 16, 2018. Before the concert, participants completed STAI A-State questionnaire after providing written informed consent to participate. Then, participants received instruction and practiced the Stroop task, doing 20 trials consisting of 10 practice words. After the practice session, participants completed the main trials (80 trials; 20 wrods * 4 times). They attended an hour-long classical music concert, after which they completed the questionnaire and main Stroop trials again.

Paired student's *t*-tests were used to compare mean STAI A-State scores before and after the concert. Latency exceeding 3 SDs from the mean were excluded from analysis. Study protocol was approved by the Medical Ethics Committee of Osaka International Cancer Institute (#18009) April 27, 2018.

Results and Discussion

The participants were all cancer patients (they provided their hospital identification numbers). Pparticipants included 2 men and 15 women, with ages of 45–65 (mean=69.1, SD =9.23). Anxiety before and after (A1 vs. A2): Anxiety after the concert (mean=25.5, SD=5.8) was significantly lower than that before the concert (mean=33.4, SD=9.1) in *t*-test. Music concerts significantly reduced the patients' anxiety. We investigated the music concert effects and the Stroop effect. Various comparisons exist for the Stroop effects (*Figure 1*).

Total comparison between results obtained before and after (C1+N1 vs. C2+N2): Average latency (or Reaction Time; RT) for cancer words was significantly longer (mean=1.14, SD= 0.28) than that for neutral words (mean=1.04, SD=0.20). The Neutral word comparison between results obtained before and after (N1 vs. N2): The neutral words RT after the concert (mean=1.01, SD=0.18) was significantly shorter than that before the concert (mean=1.13, SD=0.26). Comparison between after cancer and after neutral (C2 vs. N2): After the concert, the cancer word RT (avg.=1.06, SD=0.22) was significantly longer than the neutral word RT (mean=1.01, SD=0.18) (*Figure 1*). No other relations were statistically significant.

How to Measure Circadian Rhythms of Activity and Their Disruptions in Humans Using Passive and Unobtrusive Capture of Phone Call Activity

Timothée Aubourg[a,b], Jacques Demongeot[a,c], Félix Renard[a], Hervé Provost[b], Nicolas Vuillerme[a,c]

Abstract

Monitoring circadian rhythms of social activity is crucial for preserving the health and wellness of ill elderly people. In this paper, we assess the ability of phones to be used as a temporal and social daily activity sensor from a passive and unobstructive measure of phone call activity. To this end, we introduce a methodology specifically designed to automatically measure both persistence and disruptions in circadian rhythms of phone call activity with 26 adults older than 65 years.

Keywords:
Circadian Rhythm; Cell Phone; Elderly

Introduction

Biologically, circadian rhythms are cyclical processes characterized by a near-to-24-hour period according to the individual [1]. The analysis of their expression is crucial for preserving the daily health and wellness of the older person at home by capturing its routines of activity and their probable disruptions in order to anticipate potential health issues [2]. Unfortunately, it must be acknowledged that, although innovative approaches as actigraphy have shown promising results for capturing the physical activity of the individual, the sensors needed often show limitation for collecting other types of data about the individual's activity as social interactions [2,3]. This point is problematic insofar as social disruptions in the older person's habits may directly reflect severe issues occurring with the aging process, like social isolation or depression for instance.

Thus, whether and how circadian rhythms of social activity and their disruptions could be measured in older adults on a passive and unobtrusive way remain to be investigated. The present paper is specifically designed to address this issue.

Methods

We introduced the phone device as a temporal and social sensor of the individual's daily activity, and we used a passive and unobstructive measure of phone call activity. We analysed the outgoing phone call detail records (CDRs) of 26 volunteers older than 65 years on a period of twelve consecutive months, and we focus on two specific phone call parameters, namely (1) the date and (2) the hour of call. We further describe a methodology specifically designed to automatically assess (1) the existence of circadian rhythms in outgoing phone call activity by leading persistence analysis that was developed in recent system complex literature [4], and (2) the existence of significative disruptions in these rhythms by calculating their monotony signatures [5].

Calculating Circadian Rhythms

We followed the descriptive approach recently proposed in [4] for circadian rhythm estimation in phone call activity. This approach consists in (1) coarse-graining the time dimension into a unique day divided into 24-one-hour time slots, and (2) calculating the average phone call frequency for each time slot.

Assessing the Consistence of Circadian Rhythms

We followed an analytical approach of persistence [4]. For each individual, at each 4-month period of time, T1, T2 and T3 :

We note D_{self} a measure such as:

$D_{self}(i,T,T+1) = \sqrt{JSD(P_i^T, P_i^{T+1})}$, where P_i^T is the discrete probability distribution of ego's i calls ratio at time period T.

We noted $< D_{self} >$, the average of D_{self} such as:

$< D_{self} > = \left(\frac{1}{N_T}\right) . \sum_{T=1}^{N_T-1} D_{self}(i,T,T+1)$, where N_T is the number of time periods, here 3.

Then, we noted D_{ref} the reference scale such as:

$D_{ref}(i,j,T) = \sqrt{JSD\left(P_i^T, P_j^T\right)}$, where P_i^T is the discrete empirical probability distribution of ego's i calls ratio at time period T and P_j^T is the discrete probability distribution of ego's j calls ratio at the same time period T with $i \neq j$.

We noted $< D_{ref} >$, the average of D_{ref} such as:

$< D_{ref} > = \left(\frac{1}{n-1}\right) . \sum_{i=1}^{n-1} D_{ref}(i,j,T)$, where n is the number of individuals, here 21.

Finally, persistence of circadian rhythms of a given ego is validated if and only if $< D_{self} > / < D_{ref} > < 1$.

Assessing the Existence of Disruption in Circadian Rhythms

To assess the existence of disruption(s) in circadian rhythms, we used the stochastic monotony signature of a function that indicates if the function is increasing-or-constant or decreasing through a sequence of, respectively, sign + and sign -. In practice, we assessed the existence of a significant disruption between two successive, and independent, circadian rhythms X and Y after testing the similarity of these signatures due to a common causality between X and Y (hypothesis H1) against a

random choice of the values of the successive sgnXi's (hypothesis H0) [5].

Results

Existence of persistent circadian rhythms

The consistence of circadian rhythms was confirmed by a persistence analysis (see Methods section). Results stand out all the egos have their self-distance lower than their reference distance, which means their pattern tends to retain their shape through time. Numerically, averaging results for the whole egos, $<D_{self}>$ = 0.24 (± 0.06), whereas $<D_{ref}>$ = 0.38 (± 0.07).

Disruption in circadian rhythms

The stochastic monotony signature comparison tests highlighted the existence of variations between two successive time periods of the year in the way the individual allocates his time of communication throughout the day. Figure 1 illustrates these results by mapping the monotony signatures variations of circadian rhythms in outgoing phone call activity for each individual into a heat-map.

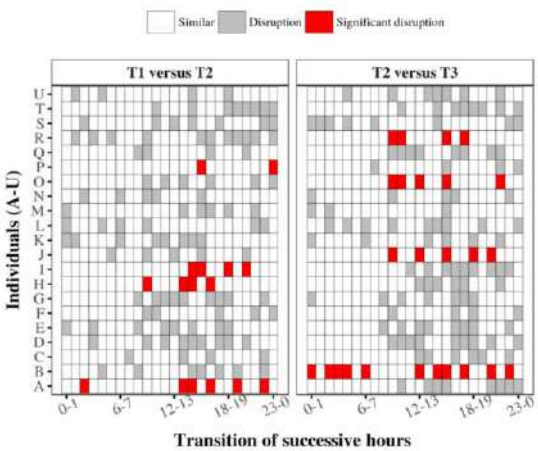

Figure 1– Existence of disruption(s) between two successive circadian rhythm calculated from two successive periods of time.

Discussion

Our results suggest the persistence of daily social interactions in phone communication in the older population, and disruption(s). These features could be advantageously used for completing traditional health monitoring approaches using circadian rhythms analysis by giving daily data of social interactivity. However, a number of caveats and limitations have to be taken into account.

First, any rapid generalization of our results might be avoided because of rather small sample size (n = 21). Then, we insist on the fact that analysed circadian patterns concerns only the outgoing phone call activity. It could be relevant to enhance robustness of such circadian estimation by combining outgoing call pattern with corresponding social interaction data as incoming phone calls, text messages, location data and, more generally, in leading multi-dimensional analysis based on temporal active and passive data from phones [6].

Conclusions

In this papier, we assessed the use of phone device as a temporal and social sensor of the daily social activity of the elderly individual for a health monitoring purpose. To this end, we analyzed the outgoing phone call detail records of 26 volunteers older than 65 years on a period of twelve consecutive months. We give a methodology to automatically assess (1) the existence of circadian rhythms in outgoing phone call activity by leading persistence analysis, and (2) the existence of significant disruptions in these rhythms by calculating their monotony signatures. Within our population, we showed that older adults have consistent circadian rhythms in phone call activity, which is reflected by their ability for persisting in time. Then, we demonstrated that, despite this persistence, disruptions could occur through time in circadian rhythms of outgoing phone call activity by comparing their monotony signatures.

Clinical Decision Support System for Evaluation of Patients with Musculoskeletal Disorders

Lecian C. Lopes, Sayonara de Fátima F. Barbosa

Graduate Program of Health Informatics, Universidade Federal de Santa Catarina, Florianopolis, Brazil

Abstract

Clinical evaluation of the patient and the follow-up of the rehabilitation process are pillars of physical therapy care. The SIAVA-FIS decision support system is presented, which accesses graphical evaluation and evolution data, allowing physical therapists to follow the results of the therapeutic procedures in a mobile and web platform. Results indicate that SIAVA-FIS meets physical therapists´ needs and that usability presents effectiveness, efficiency and satisfaction in the use of tasks evaluated by users.

Keywords:
Clinical Decision Support Systems; Rehabilitation; Diagnosis

Introduction

The field of health informatics has emerged as an interdisciplinary science that evaluates how health information and knowledge can be effectively used for clinical decision making[1]. Multidisciplinary care is an integrated team approach to healthcare and involves different healthcare professionals, like physical therapists, that are movement experts who provide services that help restore function, improve mobility, relieve pain, and prevent or limit permanent physical disabilities in patients with injury or disease[2]. Physical evaluation, tests and measurements are means for collecting information and the physical therapist uses them to identify signs or symptoms of changes in health conditions, diagnosis, prognosis and treatment decision making[3]. A clinical decision support system favors the reduction of costs by searching for alternatives for displacement, technological resources, information in the diagnosis and evolution of conduits[4].

Methods

The method used in this study was based on the development and evaluation of a web-based system and mobile application (app) for physical therapy assessment of outpatients with musculoskeletical disorders. It was composed by two phases. The first phase was the development. The system was developed using free software, in the PHP language, MySql database, with the IONIC framework for the hybrid application, and the Angular Material for the web framework. Unified Modeling Language (UML) was selected. For the hosting services in the cloud, Hostgator Brazil was used. To capture users requirement, we conducted two workshops with 06 physical therapists from the service. In the first workshop, we asked users about specific requirements for the application to fit into their practice, including clinical parameters and subjective data to be considered for assessment. Participants presented their suggestions and discussed in the group. One week after the first workshop, the group met again and presented a synthesis of previous suggestions along with suggestions obtained from review from textbooks, that discussed and revised.

The second phase was usability evaluation. The system was evaluated by physical therapy students and professors at a private university in Brazil. They answered a questionnaire that was developed according to NBR-9244-11, with 17 questions, distributed in three criteria: system use (four questions), system content (eight questions) and system interface (five questions). These criteria were assessed based on a five point Likert scale (1-5), with the following response categories: 1 = strongly disagree, 2 = disagree; 3 = neutral; 4 = agree, and 5 = strongly agree. The top three points (3,4,5) were considered to have indicated criteria approval. This study was approved by the Research Ethics Committee.

Results

The system was named SIAVA-FIS (Assessment and Reassessment System in Physical Therapy) and is intended to assessment and follow-up of patients through the measurement of data collected. SIAVA-FIS decision support system comprises 2 modules: the first is a web module, where the data is registered and the items collected are configured, as well as the possibilities of printing and alerts of the system; the second module is a mobile application, that will collect the selected information and send it to the web system to generate the various types of graphics. As a result, the system presents clinical parameters such as vital signs (blood pressure, temperature, heart rate and respiratory rate), body mass index as well as other assessment measures according to the segment assessed, such as goniometry, muscle strength, perimetry, muscle tone, and pain, among others. The respective alerts were also included when were not in agreement with the current and updated reference values.

The SIAVA-FIS web module has a login screen for each registered user and is hosted on a server in the cloud at the URL www.siavafis.com.br. As every physical therapist make their own planning in consultation with their patients, after the identification login, the initial screen presents the patients that were already registered in the clinical system by the physical therapist, and their respective appointments, or no information when no patient has been registered until that moment.

In addition, through the web system it is possible to visualize the data collected by the mobile application and verify in the web module its graphical presentation, presenting the data as specified by the physical therapist, such as values and instructions on clinical parameters.

The SIAVA-FIS mobile application is an interface to the web module. It does not allow double entry by physical therapists, as they do not exchange patients with each other, unless they change their working schedule with each other.

Usability Evaluation

The system was evaluated in different criteria. In the system use criterion, consisting of four items, averages were between 4.27 (± 0.59) and 4.53 (± 0.74), with an overall mean of 4.4666 and the standard deviation 0.677, demonstrating that the evaluators agree partially with the use of the system according to the application of the concepts defined in the methodology. In relation to the system content criterion, composed of 8 items, the general average of this criterion was 4.36 and the concept was partial agreement in the evaluation. In the system interface criterion, the five items were evaluated with averages between 4.13 (± 0.640) and 4.73 (± 0.210) with an overall mean of 4.51 and the standard deviation 0.55, demonstrating that the users agree fully with the system interface. The average of the majority of questions was positive, with a score higher than 4.

Discussion

Physical therapists need to manage a vast amount of information to make clinical decisions, and the use of information technology for systematically processing data and supporting information and knowledge[1] can improve their practice. Clinical decision systems (CDS) help front-line staff to select interventions for patients with musculoskeletal disorders, and may be classified into computer-based tools/ questionnaires, treatment algorithms/models, and clinical prediction rules/classification systems. CDS tools, especially those employing rapidly advancing computer technologies, are under development and of potential interest to health care providers, case management organizations and funders of care[5]. The use of a decision support system may also help to standardize outcome measures collection, build standardized measurement into clinical workflows, and show the process and outcome of patient care, and the use of standardized functional measurements that can be used across disciplines [6]. Physical therapists are fundamental to define specific requirements on the practical use of software which cover the administration, documentation and evaluation of the entire therapy process, adapted individually by the therapists [7,8]. The system was developed considering the data that are part of the physical therapist assessment, and it was planned so that information can also be inserted remotely, at the point of care, allowing the graphic visualization of all the consultations. In this way, although the use of SIAVA-FIS can make it possible to identify patterns and trends of abnormalities, allowing a quick and accurate identification so that the physical therapist assessment can occur in a more precise way [7], it must be subjected to further validation before can be recommended for large-scale implementation [8].

Conclusions

The SIAVA-FIS presents good usability, as well as efficiency and satisfaction in the use of the tasks and can contribute to the evaluation of quality indicators and improvement of the physiotherapeutic care.

Abstract

Access to specialized care remains unsolved in Brazil. The National Telediagnosis Project was created to expand successful telediagnosis experiences nationwide. The Telehealth Network of Minas Gerais (TNMG) was selected as a reference for tele-electrocardiogram (ECG). We aim to describe the experience of TNMG of developing and implementing the Brazilian National Service of Telediagnosis in Electrocardiography. Implementation planning includes discussion of workflows, standard procedures, responsibility definition for stakeholders, and adaptation of TNMG telediagnosis system. Tele-ECG has been implemented in 79 municipalities in 5 states. In a survey with 152 health professionals, 57% noted that ECG was not available in the local public health system before, 63% indicated tele-ECG service utilization ≥3 days per week, 96% considered the service very useful and 89% were very satisfied with it. In conclusion, the service fills a gap in specialized care in the public system and can improve access to a basic exam in remote and underserved regions.

Keywords:

Electrocardiography, Telemedicine, Access to Health Care

Introduction

Brazil is a country with continental dimensions, divided into 5 regions, including 27 states and 5,507 municipalities. There are important economic, social and cultural differences among the regions. Although the universal public health system, created in 1988, operates nationwide, with a broad coverage of Primary Care, access to specialized care is still an unsolved problem. These inequalities made the country a promising field for the implementation of telehealth. Therefore, in 2007 the Brazilian Ministry of Health (BrMoH) created the Brazilian National Telehealth Program, to support family health teams through teleconsultation, telediagnosis and teleducation performed by Telehealth Centers (TC) established in different states of the country. Currently, there are 25 TC in operation at different development levels.

The Telehealth Network of Minas Gerais (TNMG) is a collaborative network of seven public universities in the state of Minas Gerais, Southeast Brazil, coordinated by the University Hospital of *Universidade Federal de Minas Gerais* [1]. It was implemented in 2005 and currently provides telehealth care for 813 municipalities in Minas Gerais, mainly in primary health care (PHC) centers, but also in emergency departments, ambulances and hospitals. Being one of the first TC to participate in the Brazilian National Telehealth Program, it has a long and wide experience in telediagnosis in cardiology. Over 3.8 million tele-electrocardiogram (ECG) reports and over 124,000 teleconsultations have already been performed, as well as tele-retinography, Holter and tele-education activities, with quality assured by regular audits.

In 2017, the BrMoH established a National Telediagnosis Project as part of the Brazilian National Telehealth Program, in order to expand successful telediagnosis regional experiences to a nationwide scale.

The preliminary telediagnosis experiences chosen comprehended ECG, retinography, dermatology and spirometry. The TNMG was chosen to be one of the first National Telediagnosis Project participants, helping BrMoH in its conception and offering tele-ECG reports.

The present work describes the experience of developing and implementing the Brazilian National Service of Telediagnosis in Electrocardiography (BrNSTE) during its first year of operation, under the framework of the BrMoH National Telediagnosis Project.

Methods

The BrMoH National Telediagnosis Project was conceived as an innovative process to perform exams using telemedicine tools in an organized way, with quality and low cost, to significantly improve the availability of certain exams, especially to remote regions with low human development index (HDI) and restricted access to specialized care.

The Project consists of a partnership of BrMoH, State Health Department, Municipal Health Department, specialized TC and regional TC (RTC). The criteria used by the BrMoH to choose a specialized TC to offer certain exam are based on the TC previous proven experience and capacity to significantly expand its offer at low cost. BrMoH only selects states to implement the project which have a RTC in operation with ongoing funding by BrMoH.

A National Telediagnosis Platform, developed by BrMoH demand to *Universidade Federal do Rio Grande do Norte* (UFRN), was integrated to TNMG telediagnosis system in order to manage the project. The TNMG telecardiology service, besides performing the ECG reports, also provides synchronous teleconsultation to local medical doctors to discuss the severe clinical cases. Educational material for tele-education in cardiology is available on TNMG website to support local health professionals.

Implementation planning includes flows and standard procedures, role and responsibility definition for stakeholders, adaptation and customization of TNMG telediagnosis system. The implementation process starts with a presencial two-day training of the RTC team at TNMG. The two first local

implementations are made by RTC team together with the TNMG team to guarantee the success of the implementation.

The impact of implementation of BrNSTE on local healthcare was assessed in a survey with health professionals, health unit coordinators and health managers from 35 towns in Acre, Bahia and Mato Grosso in June and July 2018. A Likert-scale questionnaire with 8 questions was developed. Professionals were contacted at last 3 times by telephone or email. There were attempts to contact 409 professionals, but email addresses and telephone numbers were wrong for some of them. We tried to get at least one professional of each category (doctors, nursing staff, coordinators) in each health unit.

Results

In September 2017, the BrNSTE was launched in the remote town of Xapuri (state of Acre), in the Amazonian region. Since then, the service is being expanded to other Brazilian states, as Bahia (November 2017), Mato Grosso (February 2018), Ceará and Roraima (October 2018). Other states have been chosen by the BrMoH to receive the Project for the next months.

From September 2017 to October 2018, the BrNSTE delivered through the TNMG 33,178 tele-ECGs for 79 municipalities.

TNMG telecardiology service works 7 days / 24 hours. It has a response time below 10 minutes for emergency ECGs and between 2 and 4 hours for elective ones. On average, each town performs 90 ECGs/month. Utilization ratio (defined as number of towns using the system divided by number of towns with the system implemented) is monitored monthly, and is always above 90%.

With regards to the questionnaire, from the 152 respondents 57% informed that, before the implementation, the ECG was not available in the local public health system; and even when it was available, no standardized report was provided. After implementation of BrNSTE, 63% indicated tele-ECG service utilization ≥3 days per week; 94% considered as adequate the time to receive the report. In addition, 96% of respondents reported the tele-ECG service very useful, 98% indicated much benefit for patients and 89% were very satisfied with it. There were not significant differences in responses according to professional category.

Discussion

The present study describes the deployment of a large and complex telehealth service, developed under the guidelines of a national policy with the collaboration of different stakeholders, including a TC with expertise in tele-ECG, regional TCs, responsible for local implementation, an University (UFRN) that provides support for the BrMoH activities and the BrMoH itself. The results reported above demonstrated that the project was successful, reaching 79 towns in 5 different Brazilian states, including some very remote locations, in the Amazon region and in the Northeast of the country. A large number of ECG from these places have been performed and analyzed, with a utilization ratio of more than 90%. For most of these places, an ECG service was not available before the implementation of the BrNSTE. Health professionals, coordinators and managers have shown to be satisfied with the service.

Cardiovascular diseases are the most important causes of death in Brazil and in most developing countries. ECG is a basic method of recognition of cardiovascular diseases, useful also for risk stratification and evaluation of prognosis. For some cardiac diseases, as myocardial infarction and arrhythmia, ECG is the basic diagnostic tools and treatment is not possible without rapid and immediate availability of the exam. Since BrNSTE provides timely and accurate diagnosis 24/7, it has an enormous potential of improving the access of patients from these remote and resource-constrained localities to adequate health care, reducing acute and long-term morbidity and mortality.

There are other experiences of large tele-ECG services, in Brazil [2] and other developing countries [3], but many projects are devoted to acute coronary syndrome or have a more restricted area of coverage. The present report describes a nationwide initiative that seems to be unique, with high utilization ratio and excellent satisfaction of the users.

The study also opens the possibility of universalization of the access to medical diagnostic methods through the use of simple, low-cost telehealth systems. Indeed, the possibility of scaling-up the service provided, as well as other diagnostic methods, to the whole Brazilian population points out for a solution for some of the access barriers that currently hasten the effectiveness of the Brazilian Universalized Health System. Additional challenges include the full integration of this service to the electronic health records provided by the BrMoH and the sustainability of the BrNSTE as a permanent policy of the country.

Conclusions

In conclusion, a Brazilian National Service of Telediagnosis in Electrocardiography was implemented in 2017, based in the experience of the state of Minas Gerais, and it is now established in 5 other Brazilian states, with several other states already waiting for implementation. The service fills a gap in specialized care in the Brazilian public health system and can improve access to a basic exam in remote and underserved regions, with a potential to decrease morbidity and mortality related to cardiovascular diseases, the most common cause of death in Brazil.

Acknowledgements

The Brazilian National Service of Telediagnosis in Electrocardiography is funded by the Brazilian Ministry of Health. ALPR was supported, in part, by CNPq (research fellowship number 310679/2016-8) and FAPEMIG (PPM-00428-17), and is a member of the National Institute of Science and Technology for Health Technology Assessment (IATS) (CNPq/465518/2014-1).

Accuracy of Self-Reported Weight Collected Through a Web-Based Platform in a Weight Loss Trial: Validation Study of the POEmaS Clinical Trial

Alline M Beleigoli[a,b,c,d], Andre Q Andrade[e], Maria de Fátima H Diniz[a], Roberta S Alvares [a], Marina H Ferreira[a], Leticia A Silva [a], Marcia C Rodrigues [a], Luma Jacomassi[a], Amanda G Cerqueira [a], Antonio L Ribeiro [a, d]

Abstract

Self-reported anthropometric data in web-based weight loss interventions may be inaccurate. We studied the agreement between online self-reported and measured weight in the course of the POEmaS randomized controlled trial. Measured weight was not different from reported one (- 0.4 kg; 95%CI -0.93 to 0.12). 95.6% of the cases were within the limits of agreement (Bland-Altman method). Self-reported weight collected online was accurate, which suggests that interventions and outcomes assessment can rely on these data.

Keywords:
Body weight, ehealth, data accuracy

Introduction

Delivering weight loss interventions via the web have been increasingly more common. Accessibility 24hours/7days, anonymity and cost-effectiveness are some of the advantages when web-based is compared to face-to-face interventions.

Weight self-monitoring is one of the key components of weight loss interventions. Regular self-monitoring has been associated with better outcomes for weight loss and maintenance. Accurate and reliable anthropometric data are essential to intervention planning and progress monitoring. Discrepancies between measured and self-reported anthropometric data can lead to misclassification of weight status and in the context of weight loss trials can bias the outcomes. Therefore, it is fundamental to have validation studies of self-reported web-based data.

The aim of this study was to validate self-reported weight collected via a web-platform for weight loss adult participants of the POEmaS randomized controlled trial.

Methods

POEmaS trial

Students (current and past) and staff of the Federal University of Minas Gerais (UFMG), Belo Horizonte, Brazil, were recruited from September to October, 2017. Inclusion criteria were age between 18 and 60 years, self-reported BMI >=25 Kg/m^2, intention to lose weight by changes in lifestyle habits, internet access [1]. Subjects who reported comorbidities that demanded specific dietary or physical activity recommendations participants of other weight loss programs were excluded.

1,298 participants were randomized by a stratified randomized block to one of three groups: (1) Minimal intervention for 24 weeks with subsequent access to the platform; (2) Platform group -received the weight loss program delivered by the web-based platform for 24 weeks; (3) Platform weight loss program for 24 weeks plus online dietitian coaching for 12 weeks.

Sample and procedures for the validation study

We randomly selected 12.5% of the POEmaS' population balanced across study groups to guarantee that the validation study sample is representative of the study population.

Participants were contacted by email for the validation study and instructed to report weight on the specific questionnaire on the web platform. Weight (kg) was measured using calibrated Welmy® scales (to the nearest 100 g. Participants were wearing light clothes and without shoes during the measurements. A minimum 4-hour fasting and voiding 5-10 minutes before the measurements were recommended to all participants.

Ethics

All participants signed a specific consent form for the validation study. The Federal University of Minas Gerais (UFMG) Ethics Research Committee approved the POEmaS trial and the validation study (CAAE: 73545717.5.0000.5149).

Statistical analysis

Frequencies and mean (standard deviation) were used to describe qualitative and continuous variables, respectively. A paired t-test was used to determine the differences between reported and measured weight. To evaluate agreement between paired anthropometry we applied the Bland–Altman method.

Results

A total of 159 individuals predominantly females (129; 80.1%) participated in the validation study. Mean age was 36.5 years (11.1). Other characteristics are displayed in Table 1.

Table 1 Characteristics of the validation study´s participants

Characteristic	Validation study (n=159)
Gender	
Female	128 (80.5)
Male	31 (19.5)
Age, years	36.5 (11.0)
BMI, kg/m^2	29.4 (4.1)
Education	
Undergraduate	39 (24.5)
Graduated/post graduated	120 (75.2)
Group	
Minimal intervention	59 (37.0)
Platform	42 (26.4)
Platform plus online dietitian	58 (36.6)

Differences between reported and measured weight were not significant (Table 2).

Table 2 Measured and self-reported weight and difference

	Reported	Measured	Difference (measured – reported)	P value
Weight, kg	80.0 (77.8 to 82.2)	79.8 (77.6 to 82.0)	- 0.40 (-0.93 to 0.12)	0.13

The difference between measured and reported weight plotted against their mean stayed within the limits of agreement for 152 of the 159 cases (95.6%), which shows high agreement between measured and reported data (Figure 1).

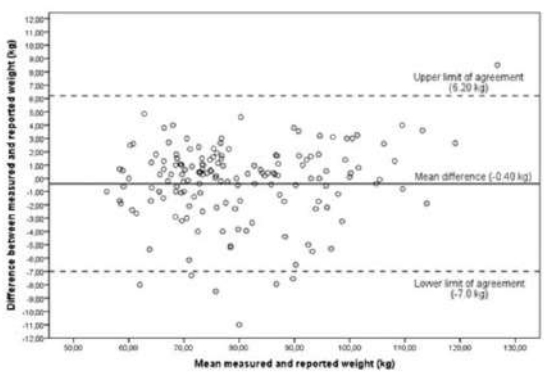

Figure 1 - Bland Altman plot for self-reported and measured weight (in kg)

Discussion

In this validation study with participants of a randomized controlled trial for weight loss, we found good agreement between measured and self-reported weight through the web-based platform.

Validation studies of self-reported anthropometric outcomes in web-based weight loss interventions are scarce. Contrarily to our findings, Harvey-Berino et al. [2] found a significant mean difference of -0.86kg, whereas Jerome et al. [3] found a progressive underreporting from -0.5kg at 6 months to -1.1kg at 24 months. A particular feature of our population that might explain this difference is the extremely high education level - 75.2% were graduated or post-graduated.

One limitation of our validation study is that, due to organizational issues, it was not possible to guarantee weight measurement and online reporting at the same time. Weight variation during the day under certain conditions, such as fasting, might have influenced our results.

Conclusions

Weight self-report through web-based questionnaires in weight loss interventions can be accurate. This suggests that individual interventions planning and outcomes' assessment can rely on these data.

Cloud-Driven Application for Measurement of Wound Size

Suryaprakash Kompalliy[a,b], Vivek Bakarajuy[a], SB Gogia[c]

[a] *International School of Engineering (INSOFE), Hyderabad, India*
[b] *ECE Department, Carnegie Mellon University, Rwanda*
[c] *Society for Administration of Telemedicine and Healthcare Informatics, New Delhi, India*

Abstract

A web-based tool is described to store images of ulcers and measure ulcer size automatically. The web tool enables doctors and caregivers to upload images from any device. The ulcer size is automatically extracted using image processing algorithms.

Keywords:

Wound size, internet

Introduction

Measurements are key to management, especially for long term problems like ulcers. Size variation helps, but accuracy of measurement has issues related to depth, body, and curvature. We hereby describe an open source web application for measurement of ulcer size for consistent and comparative documentation with device and lighting independence. Application features and usage methodologies are suitable for standalone, team-sharing and tele-monitoring scenarios.

Prior Methods

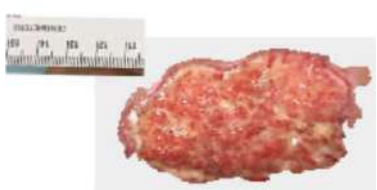
Existing methods of measuring wounds include scale/ruler measurements (linear measurements), acetate paper measurements [1,2], depth gauges, and ultrasound imaging. (Figure 1). Tracing the wound perimeter with a marker on clear acetate can be more accurate but is complicated by condensation related fogging and obscuration of wound margins. Contact with the wound area can lead to patient discomfort and even infection. Automated techniques have been developed [1] to overcome these drawbacks.
Stereophotogrammetry reconstructs a 3D image through twin cameras [3]. A variant is to use a single camera with Image J™, [4] a target sheet for calibration [5], laser based triangulation [6], and structured light [7,8], to map the 3D surface of a wound and then segment out the wound region which can be more accurate but expensive.

Methodology

Our technique matches [4,5] and involves the following broad steps:

1. User takes image of the wound region, with a known scale placed in background,
2. The scale and wound are extracted from the image.
3. Measurements on the scale are used to determine how many pixels correspond to one mm^2,
4. The image is loaded after login on to the free access website – http://med.insofe.edu.in:8282/(Username: test, Password: testp@ss1234),
5. At the site, the image becomes visible along with an online drawing tool which allows the user to broadly mark out the area of interest by drawing two quadrilaterals – one outside the wound area, and the other inside the wound,
6. Image processing is used to convert the image to an identifiable number of pixels corresponding to this marked region which are used to determine the wound area in mm^2.

(a) Image of wound with scale



(b) Wound and scale extracted

(c) Extent and size measured using algorithms

Figure 1 - Workflow

Discussion

You cannot manage what you cannot measure. Wounds and ulcers need daily assessment which includes the size and depth of

wounds. We offer an easy method which can be used by clinicians. It is currently free for use by anybody.

Abstract

Recent statistics have demonstrated that Emergency Departments (EDs) in Greece lack in organization and service. In most cases, patient prioritization is not automatically implemented. The main objective of this paper is to present IntelTriage, a smart triage system, that dynamically assigns priorities to patients in an ED and monitors their vital signs and location during their stay in the clinic through wearable biosensors. Initital scenarios and functional requirements are presented as preliminary results.

Keywords:

Triage, Clinical Decision Making, Wearable Electronic Devices

Introduction

Screening and monitoring of patients in Greek hospitals' EDs and clinics is poorly organized and seriously understaffed. An exception is the AHEPA General Hospital, which uses a 5-level triage system, using the ESI (Emergency Severity Index) algorithm [1]. This system provides patient priority data through monitors which then appear to the corresponding doctor, however it does not provide an evaluation based on the patient's vital signs. This paper proposes the design of a system that i) implements dynamic prioritization of patients within EDs and ii) improves the 24-h monitoring efficacy of patients in a clinic. The novelty of this approach lies in the fact that real-time screening and continuous monitoring of ESI level 3 incidents, is automated via intelligent bio-monitoring sensors and customized machine learning algorithms. In addition, through an appropriate network infrastructure, it is possible to trace the patients routes. In this way, administrative coordination between individual hospital departments is strengthened as it will be possible to extract statistical data on patient flows within the hospital. Similar attempts have been recently documented in literature [2-3].

Methods

The proposed system, the overall concept of which is shown in Figure 1, combines collecting measurements from body sensor networks, transferring them to a central point and processing these measurements to draw conclusions about the severity of the medical incident and the appropriate notifications for the medical staff. More specifically, IntelTriage consists of the following subsystems: i) Portable Subsystem of Biosensors and Tracking Devices, ii) Medical Decision Support, iii) Interoperability, iv) Networking and v) Security.

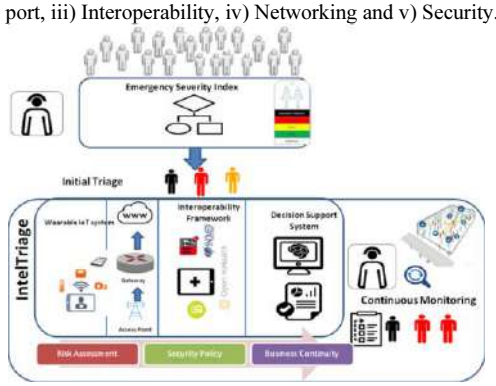

Figure 1–Conceptual diagram of IntelTriage solution

Portable Subsystem of Biosensors and Tracking Devices

The portable system consists of a Recording Platform with Body Sensors. This subsystem will gather information such as heart rate, breath rate, oxygen saturation, and transmit them to the central system database. In addition, the portable system will send beacons, which will be received from fixed 802.11 Access Points (APs).

Medical Decision Support Subsystem

Bio-parameters and Wi-Fi signals will be analyzed to assist the physician managing critical patients. The integration of machine learning algorithms and statistical models will provide dynamic monitoring of the progress of patients' health, using time series analysis and real-time changes detection, aiming at optimal triage of cases and reprioritization on the fly.

Interoperability Subsystem

While developing the monitoring, processing, and medical support subsystems, appropriate user interfaces (APIs) and RESTful Web Services will be developed to support the exchange of medical data. Based on international e-health standards, such as Health Level 7 (HL7), ICD-10 and SNOMED,

the conceptual interoperability of the end-to-end system will be ensured.

Networking Subsystem

The use of optic network in the wired section will be studied, with Bandwidth Dynamic Assignment and effective handling of the different motion priorities. The same priority system will be used for the wireless section as well. Parameters such as information priority, performance and energy consumption will be considered.

Security

Regarding data security, the key issues to address are: (a) Protection of confidentiality in the transmission, storage and processing of medical data; (b) Protecting the integrity of data (c) Availability of the data to authorized system users and (d) Detailed access control based on the need-to-know principle.

Results

Scenario

As an example of the operation of the system, the following scenario of use is provided. The patient GV enters the specially designed area of ED, where he is assigned to two nurses and one doctor. The patient has a symptom of acute appendicitis and, based on the ESI, he is categorized as Level 3 with a surgical need. The supervising physician decides to use the IntelTriage system to monitor the patient. The information received from the wearable system is available in the patient's medical records. As the patient goes through laboratory examinations, a significant increase in heart rate (> 120 / min) and respiratory rate (20% increase beyond normal) is observed. The Decision Support System then classifies the patient at Level 2, automatically alerting the medical staff about the issue and the location of the patient, in order to take appropriate actions.

Initial list of functional requirements

Based on the scenario provided by clinicians and a literature review, the initial list of functional requirements that IntelTriage shall meet are listed in Table 1.

Table 1– IntelTriage functional requirements initial list

No	Requirement	Ref.
1	Recording data from a biosensor device, incl. heart rate and oxygen saturation	[4]
2	Algorithmic breathing rate calculation	[5]
3	Local storage of data in the biosensor device	[6]
4	Wearable functionality in case it is out of WiFi range	[6]
5	Encoding data to be send	[7]
6	Data transmission taking into account energy consumption and data loss	[8]
7	Patient indoor location tracking	[6]
8	Automatic recognition of abnormalities in vital signs	[8]
9	Set a threshold for acceptable values of vital signs	[9]
10	Send notifications to the physician about the patient under monitoring	[9]
11	Visualization of indoor location patterns	[8][9]

Discussion & Conclusions

This paper presents an initial attempt towards the definition of functional requirements of the main subcomponents of the IntelTriage system, a smart triage and hospital monitoring system. However, during the lifetime of the project several new versions of functional requirements and implementation refinements will take place based on the active involvement of both clinicians and patients in small scale pilots either in the lab or the actual field of application, the ED and the clinics of the hospital. The system will be installed at the AHEPA ED and 1st Surgical Clinic premises, for a 6-10-month evaluation period. The following outcome measures are expected to be collected:

- Reaction times of nursing and medical staff when an event occurs
- Burn-out levels of nurses and doctors after a shift
- Changes in morbidity and mortality
- Level of patient satisfaction with the services provided

Acknowledgements

The IntelTriage project has received funding from the Ministry of Economy & Development, Special Secretary for ERDF & CF, Managing Authority of EPAnEK Competitiveness Entrepreneurship Innovation operational program, under grant agreement No. T1EΔK-02489.

StudyAlert: From eCharts to Modern Messengers

Florian Brenck[a], Achim Michel-Backofen[b], Christian Katzer[a], Nathan Smykalla[a], Constantin Bott[b], Christian Koch[a], Michael Sander[a]

[a] *Department of Anesthesiology, Operative Intensive Care and Pain Therapy, Justus-Liebig-University Giessen, Germany*
[b] *Department of Clinical Data Management, Justus-Liebig-University Giessen, Germany*

Abstract

We developed a tool to detect patients possibly elegible for clinical studies by analysing the HL7-message-stream of the patient management system and notifying study investigators by email or a common messenger service via secured communication channels.

Keywords:

Electronic Health Records, Clinical Trial, Health Level Seven

Introduction

Electronic patient charts are a widespread method of clinical documentation across hopsitals in Europe and Northern America. As documentation is easy configurable in these systems it is a great resource for screening hospitalised patients for the ability of being included into clinical studies [1-2]. We developed a tool for scanning all messages sent by the clinical documentation software ICUData to the server. These messages are sent as HL7-2. Our tool is adjustable to every other patient data management system (PDMS) using this international communication standard [3-4].

Methods

Using Java we developed a graphical user interface (GUI) to allow setting up screening protocols. Investigators could be registered together with their contact information. In this GUI elements of interest within the patient chart could be defined. It is possible to scan HL7-messages for any item that is available in the patient chart and is chosen/filled out or even provisional. Furthermore items can be defined to exceed or fall below defined cut-offs before raising an alert. Messages from the PDMS are read by the StudyAlert-application server and the bitestream is analysed to meet any of the defined criteria. If an item is found the preferred method of notification is selected and the registered investigator is informed about this hit.

This will be done by either email or the threema(R) messenger service. Complying with the strict security measures of a university hospital we employed a bridge communication between the hospital-IT-infrastructure and the Internet. All necessary information about a hit are sent from the StudyAlert-Server to the StudyAlert-Notifier Server via email from the hopsital-network to the university-IT-network where the latter server is installed. Using SMTP email communication the investigator is informed when chosing email. If the messenger service is used we employed the threema-API to send out messenger notifications stating patient-id and name of study for which this patient might be eligible according to the scanning criteria. A third server process receives delivery and read notifications using http-POST-requests so that the whole process of scanning, hit, sending notification and read status can be traced.

Results

We developed a fully scalable screening tool for possible study patients employing only standard technologies and allowing to record a complete tracing protocol.

Discussion

Scanning clinical information entered in PDMS or HIS in real-time to raise alert upon certain conditions is a developing use case in these systems [5]. Screening for study patients in large university hospitals is often hard to manage because of the number of paitents and the various criteria to be met. Analysing the complete HL7-Data traffic is a sufficient and time safing way, using a common messenger service for notification of the study personall allows a complete trace documentation about notification process.

Assessment of Kuwait Health System Towards Telemedicine Readiness & Adoption: Organizational and Technical Issues

Ali Buabbas [a], Hamza Alshawaf [b]

[a] *Community Medicine & Behavioural Sciences, Faculty of Medicine, Kuwait University*
[b] *Health Informatics & Information Management Department, Faculty of Allied Health Sciences, Kuwait University, Kuwait*

Abstract

This study aims to assess the organisational readiness to predict the success of telemedicine system implementation in Kuwait. Semi-structured interviews were conducted with: (1) IT managers to assess the readiness of the technical infrastructure of Kuwait health system; and (2) policy makers to assess the organisation's ability to receive telemedicine. A set of policies and strategies were developed to demonstrate how the Kuwaiti health system could be ready for telemedicine services.

Keywords:
Adoption, health planning, telemedicine

Introduction

New and significant changes are expected in healthcare organisations upon the adoption of telemedicine technology. Implementation of information system (IS) in health care sector is not easy; it is a multi-dimensional process, wherein the failure rate of US projects can reach at least 40% [1, 2]. This failure deters managers and policy makers from easily accepting change. A literature review showed how the adoption of telemedicine depends on acceptance by different stakeholders [3]. Therefore, the success of an IS project relies on meeting the requirements of the users. The importance of readiness appears often in the literature due to the impact that the current abilities of an organisation can exert to inhibit or support telemedicine adoption. In the Telemedicine Maturity Adoption Model by HIMSS, the first level requires providers to have a telemedicine strategy in place, with assurances of regulatory compliance and security [4].

The aim of the research study was to assess the organisational readiness to predict the successful implementation of telemedicine adoption in Kuwait health care system. The research objectives were: (1) To explore and identify the factors that support or hinder the adoption of telemedicine systems from the perspective of the organisation and the technical issues; (2) To develop a policy for overseas referral patients to complement the existing policy; (3) To develop a strategy for optimum implementation of a telemedicine system in Kuwait.

Methods

A qualitative study was used through conducting semi-structured interviews with: (1) Six information technology (IT) managers who were responsible for Information and Communication Technology (ICT) implementation in the six health regions at the Ministry of Health; (2) and seven policy makers who were responsible for overseeing telemedicine adoption.

Our main thematic groups for the interview questions were based on the literature and considered the research setting. Each thematic group was sub-divided into sub-topics: (1) Current referral abroad system, which included size of budget and patients' issues; (2) ICT and telemedicine context, which included ICT use and potential of telemedicine; (3) Telemedicine adoption, which included factors of inhibiting and supportive, and the impact of culture; and (4) Decision makers and organizational readiness, which included existing and new polices, and the role of the Ministry of Health.

Regarding the interviews of IT managers, two main thematic groups were identified with associated sub-topics: (1) Readiness of ICT infrastructure, which included the currant capability of ICT, telemedicine technical requirements, and policy of ICT use; and (2) telemedicine adoption, which included institutional plans and managerial and cultural factors

Interviews were 30 minutes in duration. The interviews were transcribed manually, and thematic analysis was performed, wherein sub-topics were developed and confirmed by the two researchers.

Results

The demographics of the participants (IT managers and policy makers) consisted of all being male and Kuwaitis. All the policy makers were physicians with a minimum of ten years of administrative experience. IT managers were computer engineers and had a minimum experience of five years.

The policy makers confirmed that the Kuwait Ministry of Health had concerns over the size of the budget that had been allocated annually to refer Kuwaiti patients abroad for treatment. They also stated that there were psychological pressures on patients who travelled abroad for treatment, such as emotional effects from leaving their home. Limited awareness and abscence of a leader specialist in using ICT in medicine was attributed to the lack of consideration for telemedicine. All of the participants agreed that telemedicine would be useful and cost effective if implemented properly. Staff's resistance to change, work overload, and legality issues were identified as inhibitors specific to the Kuwait health system. The participants agreed that the cultural and social concerns of the patients should be carefully considered, including supporting privacy and confidentiality through a secure telemedicine system. Policy makers agreed that to avoid misuse new policies should be developed to organise the teleconsultation process.

IT managers stated that available equipment (i.e. computers, networks, servers, printers) in the six health regions in Kuwait were compatible and reliable. However, electronic health

record system implementation has not been completed, and although there are future government plans to enhance internet connection, it currently is not always available. Participants were not aware about the concept of telemedicine. They reported the obvious bureaucracy of the main administration, where its centralization was attributed to a slow decision-making process. Most of the participants indicated that no policy existed for purchasing and use of ICT.

Discussion

Strategies for the implementation of a telemedicine system in the Kuwaiti healthcare system include complete implementation of health information systems and electronic patient records in the hospitals, and awareness campaigns for telemedicine use among the medical departments. [5]

A policy has been developed to demonstrate how telemedicine can be integrated with the Kuwaiti healthcare system. A limitation of this study is the few numbers of participants.

Conclusion

The qualitative approach succeeded in assessing the current technical infrastructure of ICT use in the Kuwaiti healthcare system, as well as the organisational readiness.

Impact of the Performance Gap Between Interactive Alerts and Quality Metrics

Kari Bunkers[a,b], Daniel Cronk[b], Marcia Core[c], David Blair[a], Mark Parkulo[b,d], Pedro J. Caraballo[b,d]

[a]*Department of Family Medicine*
[b]*Center for the Science of Health Care Delivery,*
[c]*Department of Information Technology,*
[d]*Department of Medicine. Mayo Clinic, Rochester, Minnesota, USA.*

Abstract

Interactive alerts are used to enhance compliance with primary prevention and have been shown to improve quality metrics. However, the degree of impact of these alerts is controversial and there is concern with excessive alerting. Our objective is to develop reliable processes to assess the direct impact of interactive alerts on clinical performance. Here we present preliminary finding related to the evaluation of the performance gaps between alerts and clinical practice.

Keywords:

decision support systems, quality indicators, prevention and control.

Introduction

A plethora of clinical research and national guidelines supports the implementation of multiple primary prevention interventions. Modern electronic health records use clinical decision support (CDS) as integrated on-screen interactive alerts to facilitate ordering these interventions and improve compliance with related quality metrics [1]. However, alerts are not usually implemented in isolation and their direct impact has been difficult to measure. We need reliable tools to critically assess the direct and indirect impact of interactive alerts. Here we present our preliminary work assessing clinical practice interaction with alerts, and the clinical outcome gap as a tool to easily detect opportunities for improvement.

Methods

Interactive alerts allow ordering suggested tests directly from the alert and are available during the entire primary care encounter. Providers can also order the tests outside the alert using regular orders. We retrospectively (1/2018 to 9/2018) collected data: 1. Use of the alerts to order recommended tests, 2. Orders placed outside the alerts. 3. Performance of related quality metrics. We represent these data as proportions of all eligible adult primary care encounters (Figure 1) and defined as performance gaps: Gap 1, the difference between ordering the test inside the alert (dark grey) and outside the alert (light gray) and Gap 2, the difference between ordering the test (dark + light gray) and the quality metric (red line).

Results

Evaluation of 4 interactive alerts (depression screening, breast cancer screening, colon cancer screening and lipid panel follow up) showed variable gaps that are easily visualized in a graphical representation (Figure 1). These gaps vary among interventions and can guide better understanding of the true impact of the alerts and related workflows. For adult depression, the quality metric can be explained by all the orders (Gap 2 is zero). However, only approximately 50% of the orders were done using the alert (Gap 1). Conversely, the other 3 interactive alerts showed a poor performance. The orders done with the alert among all the orders (Gap 1) for breast cancer, colon cancer and lipids were 28%, 50% and 27%, respectively. But more important, Gap 2 is also large, 56%, 70%, and 75%, respectively. These large gaps are likely related to direct outreach to patients via portal and mail using health maintenance registries to identify patients with gaps and bypassing orders done during the clinical encounter and data captured in the CDS transactional system. Although, these proportions are approximations, these preliminary results require additional evaluation of the workflow and consideration to change the alerts

Conclusions

Systematic assessment of the performance gaps of individual interactive alerts could be an important step to enhance clinical impact and manage potential alert fatigue. Additional evaluation is underway to better characterize the different types of gaps and define follow up interventions to correct the gaps including decommissioning of ineffective alerts.

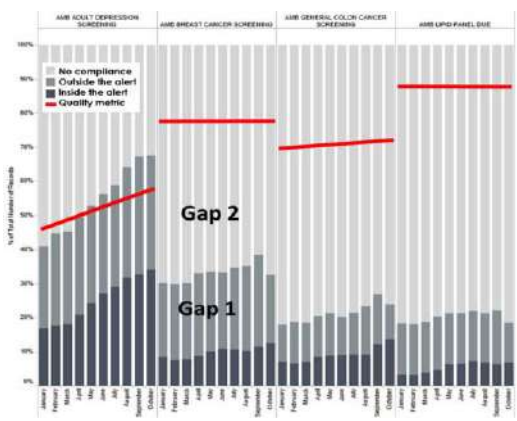

Figure 1– Performance of four interactive alerts comparing the actions taken using the alert, outside the alert and the overall performance of the clinical practice (quality metric).

First Feasibility Analysis of Ballistocardiography on a Passenger Flight

Marie Cathrine Wolf[a], Nico Jähne-Raden[a], Henrike Gütschleg[a], Ulf Kulau[b], Mario Kallenbach[c], Klaus-Hendrik Wolf[a]

[a] *Peter L. Reichertz Institute for Medical Informatics, Hannover Medical School, Hanover, Germany*
[b] *Institute of Computer Engineering, Technische Universität Braunschweig, Germany*
[c] *Institute of Flight Guidance, Technische Universität Braunschweig, Germany*

Abstract

The project SCARAB² (Scalable, Robust and Adaptive on Board Ballistocardiography) aims to use Ballistocardiography (BCG) to monitor flight passengers. In order to show that recorded BCG data from flights give evaluable information even in the noisy environment of an airplane, we monitored a heart-healthy passenger using BCG. Furthermore, we show that there can be a conclusion to heart activities from the recorded ballistocardiogram by comparing the data to a concurrently recorded electrocardiogram (ECG).

Keywords:

Ballistocardiography, Micro-Electrical-Mechanical Systems, Accelerometry

Introduction

A significant number of the world's population suffer from cardiovascular diseases, out of which about 17.7 million people die as a result [1]. If a heart-related issue occurs, fast and professional help is needed to prevent worse consequences. However, on an airplane flight, it is indeed hard to handle such an emergency.

Within the SCARAB² project, we try to develop a small, lightweight system to monitor heart-related signals from the passengers to detect potential problems early and provide information for a professional diagnosis, as well as first possible treatment options by the crew.

The chosen method for this is the Ballistocardiography (BCG). With the BCG the cardiac contraction forces transferred via the body's surface on other structures like seats can be used to gain information about the heart's functionality. This method derives from early space measurements, without external disturbances [2; 3]. Unlike space, there are external disturbances such as noisy environment on earth, while talking, walking, and in cars or buses. BCG sensors measure all the acceleration and not only the ones made by the heart. It is, therefore, necessary to know the characteristics of the surrounded noise by measuring them as well as the heart's vibrations on the surface. Nevertheless, this technology has found its place in clinical diagnostics with the help of researching groups, while having nearly noise-free surroundings [4; 5].

To proof the general feasibility of usable BCG measurements from passengers while on an aircraft, we planned a first non-laboratory trial.

The motivation for such an environment is the ever growing air traffic and passenger volume, therefore, the number of medical emergencies during a flight is growing accordingly [6].

Since the aircraft can be perceived as a system that has only the frictional resistance of the air during a flight as an external factor and otherwise represents a self-contained system, we have opted for this measurement environment.

For example, when the passenger is already suffering from cardiac diseases, the stress and the changed pressure or the anxiety can lead to a deterioration of the health state.

Monitoring the passenger's health status during the flight, or in the best case before departure (e.g. during boarding), supports flight attendants to initiate counter procedures. Unlike traveling by car, bus or train, the airplane is not able to stop at need and such incidents cause flight abortion and huge financial loss for the airline and a lot of stress for the passenger [7].

With these motivations in mind, we worked on a method to validate the hypothesis, if it is possible to measure vital parameter of a subject during a flight.

Methods

For the real environment trial, one male, healthy subject with an attached sensor system [shimmer3 ExG] including a 4-lead ECG unit and a triaxial accelerometer was measured during a regular three hours passenger flight with an average passenger airplane (Airbus A330).

The Shimmer is equipped with a Freescale MMA7361 accelerometer sensor with a range between 1.5 and 6g, for the measurement, the 1.5g setup with a sample rate of 204.8Hz was used [8].

The Shimmer was placed on the sternum due to the fact that it has been shown as one of the best points to measure the heart's contraction on the chest surface, using the built-in accelerometer of the Shimmer sensor [9].

Figure 1 - Picture of the Shimmer3 ExG.

Furthermore, the ECG electrodes for the ECG were attached at the predetermined locations on the upper body of the subject, as shown in *Figure 2*. The electrodes are attached to the body using the Einthoven's triangle electrocardiography derivations. Furthermore, one-fourth derivation was measured using the right leg position.

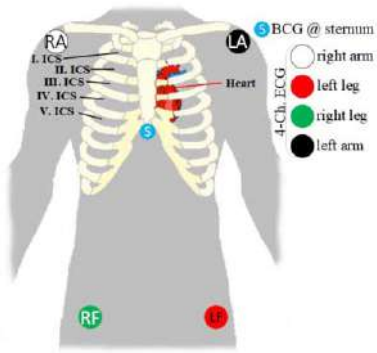

Figure 2 - Sketch of the attached Shimmer 3 ECG Unit (BCG) and the positions of the electrodes on the upper body.

To gain a comparable data stack, the digital output of the accelerometer was calibrated, using the 3D-ellipsoid equation [10]. The further preprocessing was realized using the statistical computing language R (v3.5.1).

The first step of analysing was the detection of the QRS-complex within the ECG reference data by peak detection (package pracma, v1.9.9), which exposed the ECG-R-peaks.

In order to be able to analyze the accelerometer data in relation to the encountered R-peaks, the accelerometer signal had to be filtered, so inadvertent frequencies, e.g. the movement caused by respiration and vibration noise caused by the aircraft itself, could be filtered out. After spectrum analysis via Fourier transformation, we used second order Chebychev band-pass filter with the selected lower and upper frequency of 25 Hz and 60 Hz.

The graph was evaluated by searching for a periodic pattern in the ballistocardiogram in a range of time after the QRS complexes. The delay between the ECG (QRS complex) and the BCG measured contraction derives from the time of muscle stimulus to actual movement.

Results

The heart of an adult human beats with a frequency of approximately one beat per second (Pulse at rest of an adult is between 50 to 90 beats per minute). Following, the localisation of the BCG sensor on the subjects thorax, the frequency of the measurements must be half of the pulse rate, in order to be able to measure the contraction of the left and the right ventricle; so called seismocardiography effect.

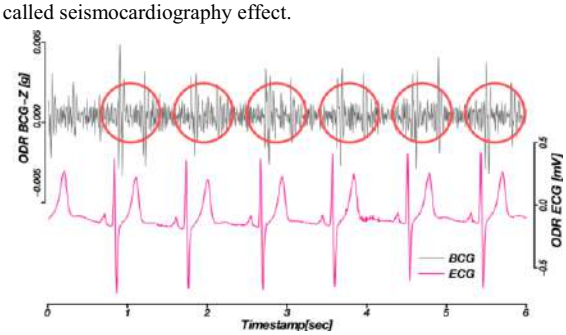

Figure 3 - Electrocardiogram (ECG) and Ballistocardiogram (BCG) with periodic pattern marked with circles.

In Figure 3 the BCG data (only z axis) related to the ECG data can be seen for a signal snippet of 7 seconds. It becomes apparent that periodic pattern in the ballistocardiogram is well identifiable in a range of time after the QRS complexes, which is known to be in average 120ms after R peak [3].

Conclusions

With this work, we present first analyzed inflight measured BCG data from a digital accelerometer attached at the sternum position including an ECG reference signal. It becomes apparent that peaks in the ballistocardiogram are well identifiable and an assessment of acceleration data recorded on a passenger flight is possible without a high amount of data processing.

Furthermore, the graphical representation of the recorded data reveals that a statement over heart activities from the acceleration data is possible. We presented that in the ballistocardiogram, peaks are identifiable in a range of time after the QRS complex in the electrocardiogram.

With this knowledge, we currently prepare further steps, first to increase the accuracy of the data output and to later develop a BCG health monitoring system for passenger flights [7].

Responses of Staff Nurses to an EMR-Based Clinical Decision Support Service for Predicting Inpatient Fall Risk

Insook Cho[a], Insun Jin[b]

[a] *Department of Nursing, Inca University, Incheon, Republic of Korea,*
[b] *Department of Nursing, National Health Insurance Service Islam Hospital, Gyeonggi-do, Republic of Korea*

Abstract

Wide spread of electronic medical records provide an opportunity to use time-variant longuitudinal data near real time. Hospital nurses would benefit greatly from the ability to use such data to predict adverse event risks of individual patient. We have developed an clinical decision support service to predict inpatient falling using machine learning and clinical big data approach. This study reports the initial responses of nurses to the service in an acute care setting.

Keywords:

Clinical Decision Support Systems, Accidental Falls, User–Computer Interface

Introduction

One-third of inpatient falls are preventable, but actually preventing them remains difficult and complex due to several common problems,[1] among which the authors noticed on inadequate assessments with limits of current fall-risk assessmnet tools. We have developed an evidence-based prediction model for the individual-level risk of falling based on more than 70 longitudinal data elements that are routinely captured by nurses in electronic medical records (EMR).[2] The model uses a Bayesian network inference and machine learning techniques, and it produced high values of the c-statistic of 0.96 and 0.99 in a cross-site validation study conducted at two large hospitals.[2] The performance was compared with those for the Hedrich II fall risk assessment tool (c-statistic=0.69) and the STRATIFY tool (c-statistic=0.65), respectively. The EMR data included in the model were medication, patient classification (KPCS), the fall risk assessment tool, and the nursing-process (assessment, diagnoses, and intervention), demographics, and administrative data. In implementing the prediction model in a clinical decision support service (called IN@SiGHT, Intelligent Nursing @ Safety in Guidance of Health Technology) at a hospital of 800-bed size, the model was customized along with the request of department of nursing of the hospital, asking they want to no longer use of STRATIFY tool. Without the data of STRATIFY tool, we readjusted the model and have gotten the performance of 0.87 for c-statistics. In 2017, the service was integrated with the EMR system of the hospital, and have provided nurses with information about which individual patients are at risk of falling, along with recommendations for planned nursing interventions. The IN@SiGHT service was initially introduced to six medical-surgical nursing units. We have monitored the performance of the service including the changes of response and behavior of its users prospectively. Here we report the short-term responses of nurses in practice over the 6 months since the IN@SiGHT service was started.

Methods

We used a repeated survey approach for data collection and analysis to understand the responses and experiences of nurses. There were 209 nurses working at the 6 included units. We randomly selected 3 nurses from each unit—a senior nurse (experience >5 years), a junior nurse (1 year < experience ≤5 years), and a newer nurse (experience ≤1 year)—and analyzed the total of 18 nurses twice. Repeated sampling of nurses was conducted.

The first survey was performed in May 2017 after launching the service. A training session that introduced the service with guidance on how to use it was provided by the unit for 1 week. The second survey was completed in a self-reported manner 9 months later.

The survey questionnaire consisted of five sections: (i) user experience with the service, (ii) perceived effect on fall prevention tasks, (iii) overall satisfaction, (iv) perceived advantages and disadvantages of the service, and (v) knowledge about fall prevention, including how this is affected by demographics. User perception was measured by the Korean version of the System Usability Scale (SUS),[3] with overall satisfaction scored on a global scale ranging from 0 to 100. Knowledge was measured by the AHRQ Fall Knowledge Test tool.[4] The perceived effect and perceived advantages and disadvantages were queried using open-ended questions. Quantitative data were analyzed as frequency and ratio values, while thematic data analysis was applied to qualitative data. This study was approved by the hospital IRB review board (IRB # 2016-08-005-005).

Results

The average ages of the participants were 28.7 and 27.9 years at the two surveys, and the average lengths of their clinical experience were 5.0 and 5.4 years, respectively. Their level of knowledge about fall prevention, SUS score, and overall satisfaction score all increased during the study. (Figure 1)

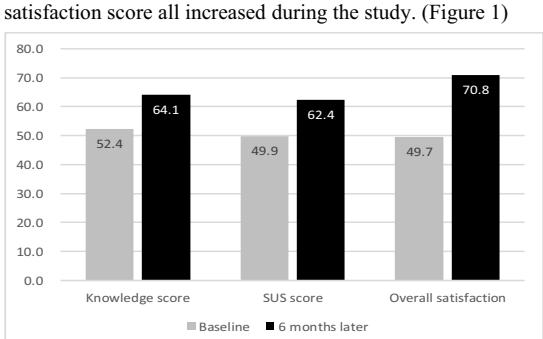

Figure 1. Comparisons of knowledge score, Sysyem Usability Scale (SUS) score, and overall satisfaction

Regarding the perceived effects on fall prevention tasks, most of nurses said that they became very careful about documentation due to the thoughts that the data they entered will be used to infer risks of falling. In addition, the care plan suggested along with fall risks makes their work be efficient. But, on the other hand, they felt burdensome to enter assessment data. These results were consistent at the answers on the questions about the advantages and disadvantages of the CDS service. (Table 1) As the advantages of the service, overall helpfulness and trustfulness were the frequent themes and the number of mentioning also increased. Regarding the disadvantages, several nurses said that the CDS information of risk was different from their own judgment, which decreased at six months later. The number of nurses stating that the burden of documentation was 31% (= 9/ 29) and decreased to 28% (= 7/25). Several nurses expressed concerns on the increase of just entering nursing interventions which were suggested by the system, but not conducted by them.

Table 1. Responses of the nurses about the advantages and disadvantages of the clinical decision support service (IN@SiGHT)

		Frequency(%)	
Responses		**Start point**	**6 months later**
Adva-ntages	The CDS service was helpful overall	14 (52)	18 (42)
	The CDS information helped them pay attention to risk patients and their factors	9 (33)	17 (39)
	The information of CDS was trustful	4 (15)	8 (19)
	Subtotal	27 (100)	43 (100)
Disadv-antages	Sometimes the CDS information was different from their own judgment	13 (45)	9 (36)
	They became more careful for documentation with increased burden on it	9 (31)	7 (28)
	Concerns for increased documentation of not conducted interventions	5 (17)	6 (24)
	Hard to understand the system algorithm	2 (7)	3 (12)
	Subtotal	29 (100)	25 (100)

Discussion

The nurses had attitudes that were neutral or even slightly negative when the IN@SiGHT risk prediction service was first introduced. Some of the experienced nurses reported that the predictions were different from their judgment. Nurses clinical judgment depends on individual experience and expertise, and bedside nurses have different levels of nursing expertise, which tends to lead to variation in clinical judgment and decision-making. However, the clinical judgment combined with objective observations and measurements is the most accurate way to predict safety risks. Some of junior and newer nurses were more cooperative and had more-positive attitudes associated with their curiosity about the service. Most of the nurses showed better knowledge, satisfaction, and attitudes after the 6-month intervention. On the other hand, we found that some nurses were not familiar with predictive analytics and might not be able understand or interpret the analysis results.

Conclusions

The widespread adoption of EMR is making clinical big data a frequently discussed topic that presents new opportunities in practice. To achieve it more efficiently, we need to assess users understanding, knowledge, and attitude on such approaches and consider their sociotechnical aspect's concerns including workflow and workaround patterns.

Adverse Drug Event Reporting Rates After the Implementation of an EHR Integrated Reporting System

Eunice Correa, Oscar Ignacio Jauregui, Julia Frangella, Verónica Peuchot, Carlos Otero, Daniel Luna

Department of Health Informatics, Hospital Italiano of Buenos Aires, Buenos Aires, Argentina

Abstract

Under-reporting of adverse drug events (ADEs) is a common issue across healthcare systems, and lack of integration with clinical workflow and systems are among the leading causes of this problem. We sought to describe the development of an ADEs reporting system within an EHR that represents user needs and captures relevant data. We compared periods before and after the implementation, and describe the corresponding reporting rates.

Keywords:

Drug-Related Side Effects and Adverse Reactions; Pharmacovigilance; Electronic Health Records

Introduction

Adverse drug events (ADEs) are a leading cause of emergency department visits and hospitalization. They tend to occur in healthcare facilities even if there are means to prevent them, because ADEs information transfer is inadequate causing unintentional re exposures to the substance [1]. To ensure pharmacovigilance activities, robust ADE reporting mechanisms should be in place to deliver timely and comprehensive data to assess safety of used drugs [2,3].

Underreporting of ADEs to internal or external pharmacovigilance entities is a major limitation to drug safety surveillance systems, estimated in 80% to 95% [4,5]. Among the reasons are time constraints and duplication of the documentation, since most reporting systems are not integrated with EHRs. In that matter, ADEs reporting systems that are embedded in the clinical workflow, that make use of existing data to avoid duplication of documentation and capture the complex nature of adverse drug events may address this problem and increase ADEs reporting rates [6].

The aim of this study is to compare the ADEs reporting rates before and after the implementation of an EHR integrated electronic reporting system, and to describe the design and development of such functionality.

Methods

Setting

HIBA is a non-profit healthcare academic center that has a network of two hospitals with 750 beds (200 for intensive care), 41 operating rooms, 800 home care beds, and 25 outpatient clinics located in Buenos Aires city and its suburban area. Since 1998, the HIBA has run an in-house-developed health information system, supporting both clinical and administrative operations [7]. It has been recently certified by the HIMSS as level 7 in the Electronic Medical Record Adoption Model, being the first hospital in Argentina and the second in Latin America reaching this stage.

The HIBA has an informatic tool for the reporting of ADEs to the pharmacovigilance section that can be accessed within the incident reporting form, located in the hospital's intranet. The report can be done in a free text form, and has no integration with patient or professional master indexes, nor with the Hospital's EHR.

Reporting System Design and Development

An interdisciplinary team was formed, which carried out interviews with physicians, nurses and pharmacists that were users of the ADEs reporting systems, and with members of the pharmacovigilance section to better understand the causes of the under reporting of events. Then an interface mockup was design taking into account the elements that should be present. A series of user testing sessions were performed, and usability flaws were detected and solved prior to the design of the high-fidelity mockup, which was again tested by end users in an iterative process. Finally, the software was developed, and prior to the implementation a series of education material was released to users by email and in the institution´s intranet.

Substance Controlled Subset Development

The HIBA has a terminology server that is offered as a service for applications inside and outside of the institution achieving semantic interoperability [8]. In that context, a substance valueset was created within the terminology server by automatic mapping all of the substances present in SNOMED- CT database.

Data Collection and Analysis

The study design was a before and after study. The inclusion criteria were adult hospitalized patient with an ADEs report during hospital stay.

Observation period was divided into two:

- Pre-implementation group was defined as patients hospitalized between August and October 2017. During this period the main tool for ADEs reporting was not integrated into EHR.
- Post-implementation group was defined as patients hospitalized between August and October 2018. During this period the developed tool to report from EHR for ADEs reporting was available.

Statistical analysis was performed using Chi-squared tests in the STATA software.

Results

ADEs Report Interface

The reporting interface consisted in a pop-up menu that could be triggered from different modules inside the EHR. A "substance" and a "clinical manifestation" fields were created, in which the user could select a term from a specially created subset of terms.

Then the user had to select the severity of the reaction, the date if known, and a checkbox to report the reaction to the hospital's pharmacovigilance section. The generated adverse reactions would be loaded as a problem into the patients' problem list. Also, an email would be sent to the pharmacovigilance section if the corresponding checkbox was selected by the user.

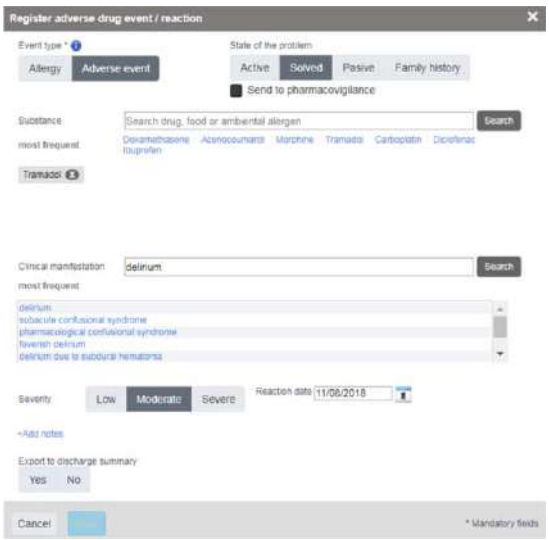

Figure 1 – ADEs Reporting System Interface

ADEs Reports

The number of reported ADEs in both periods are presented in Table 1. The number of reports per hospital day was 0,9/10000 in the first period and 1.9/10000 in the second period. Table 2 depicts the characteristics of the reported cases in both periods.

Table 1– ADEs Reports Before and After the Intervention

	Before	After	p-value
Admitted patients	12,810	12,848	
Total inpatient days	75,853	71,712	
ADEs reports *			
Total	7(0.5‰)	14(1.1‰)	0.128
By incident report	7	5	0.561
By EHR tool		9	
Inpatient day &	4 (2-6)	3 (2-6)	0.116

*Absolute frequency (Relative rate per 1000 patient)
&Median (Interquartile Range)

Table 2– ADEs Report Cases Characteristics by Period

	Before (n=7)	After (n=14)	P value
Inpatient day &	5 (2-6)	6.5 (4-20)	0.226
Patients age	73 (66-79)	58 (30-71)	0.03
Inpatient day &	4 (2-6)	3 (2-6)	0.116

&Median (Interquartile Range)

Conclusions

After our analysis we arrive to the conclusion that having the possibility of reporting adverse reactions integrated into the EHR, seems to facilitate the reporting and to improve communication with the pharmacovigilance sector. However, it is necessary to explore larger periods of implementation of the tool and to carry out the educational stage to users.

Patient Health Information Technology Designed for Shared Decision Making: If We Implement It, Will It Become Normal Clinical Practice?

Selena Davis

University of Victoria, School of Health Information Science, Victoria, Canada

Abstract

Personal health records designed for shared decision making have the potential to engage patients in self-management decision making. This pre-implementation evaluation was underpinned by Normalization Process Theory and utilized mixed methods to describe the cognitive and behavioral work of implementation, and its potential to integrate into practice. Participants invest in sense-making, commitment and appraisal processes with strong agreement for positive impact on engagement. Future implementation success will depend on a systemic investment of collective action.

Keywords:

Personal Health Records, Decision Making

Introduction

Today there is increased interest in health information technologies (HIT) that engage patients in decision making as part of health self-management. Health decisions are important, and an optimal and collaborative approach is shared decision making (SDM) between the patient and care provider. SDM that results in a treatment decision and care plan at a specific point in time combines the best available evidence and patient values and preferences [1]. The process of SDM is modelled [2][3] to include four core elements:

1. Acknowledge – awareness that a decision is needed, and choice exists;
2. Consider – receive and interpret options, including benefits and risks;
3. Decide – explore preferences, values, and goals and incorporate them into the making of the decision; and
4. Act – record the decision and track outcomes.

SDM is fundamental to person-centered care, increases patient and provider satisfaction, improves quality of life and clinical outcomes, and fosters a better patient–provider relationship [4]. However, implementation into practice has been difficult [5].

Personal health records (PHR), a patient-facing HIT, is a promising technology to overcome barriers for integrating SDM [6]. PHRs offer patients access to their health information, the ability to contribute information to their health record, health management and decision support tools, and the means to communicate with their providers. Patients' experiences with accessing their PHR are positive and offer feelings of empowerment and engagement [7] and the use of a PHR improves communications with care providers, as well as a sense of self-management [8]. Yet PHRs have not seen widespread adoption, often a result of system architecture or functionalities [9].

*e*nhanced-*PHR* System (*e-PHR*)

A conceptual framework for PHR technology designed to enable SDM (*e-PHR*) indicated 22 PHR functions to enable the four core elements of SDM [10]. For example, the SDM core element Decide is enabled by the PHR core functions of *Access health information* and *Communicate with others,* and comprises 11 sub-functions, such as access to provider clinical notes and care plan and message care team. The scoping literature study [10] also indicated the environment for *e-PHR* is architected as an interconnected PHR – i.e. it gathers and auto-populates patient data from multiple health information systems and applications.

Designed for function and the broader digital health ecosystem, PHRs present an opportunity for improvement in SDM and patient engagement. To implement *e-PHR*, a process evaluation is useful since the literature informs us that the number of implemented interventions that become 'normalized' is limited (i.e. fits in with the work of individuals and the context of practice and no longer requires additional effort). Normalization Process Theory (NPT) seeks to understand the cognitive and behavioral process work people do, individually and collectively, to integrate an intervention in its social context [11].

Guiding Theoretical Framework

NPT provides a framework to analyze four mechanisms and their constructs known to influence implementation success. Coherence is the sense-making work required by individuals in teams. Cognitive Participation is the work done as they anticipate roles and tasks to accomplish the new ways of doing things. Collective Action is the work of operationalizing the intervention. Reflexive Monitoring is comprehending the effects. NPT has been used to aid implementation planning, and evaluating and understanding implementation processes [11].

This research aimed to understand: (i) the integration work of *e-PHR* that participants do, individually and collectively; and (ii) the potential for *e-PHR* to integrate into practice to engage patients in self-management decisions.

Methods

This mixed methods investigation utilized a triangulation convergence study design. This design concurrently collects and equally-weights quantitative measurement instruments and surveys, and qualitative semi-structured individual interview data. The approach offered a deeper level of understanding and gave a voice to the multiple participant types (patients, care providers, and organizational HIT and clinical leaders).

The first quantitative measurement instrument of NPT, the NoMAD [12], describes the level of agreement of participants with

statements of the four NPT mechanisms and related constructs. Utilizing the same five-point Likert scale as the NoMAD instrument, a fixed survey of practice-related outcomes scored the level of agreement with potential outcomes, such as engagement in self-management decision making. A semi-structured interview, guided by NPT, was used to describe the work of integrating *e-PHR*. The concurrently-gathered qualitative and quantitative data were collected to thematic saturation. Survey data was analyzed using R statistical software for descriptive statistics. Interview data were transcribed and imported into Atlas.ti and coded for evidence of the constructs of NPT via a deductive approach. Finally, emergent descriptive themes were identified, along with quotations that best illustrated the themes. The analyzed quantitative and qualitative data were amalgamated to present findings.

Results

Twenty-seven participants in British Columbia, Canada participate: patients (*n=8*), care providers (*n=11*) and organizational leaders (*n=8*). The qualitative results produced a rich explanation of the implementation work. The quantitative results offered mean scores and indicated a direction of agreement with measures of normalization and potential outcomes.

Congruency was observed between the quantitative and qualitative data. Qualitative results indicated that *e-PHR* made sense as explained by two themes for Coherence: a *game changing technology* and *sensibility of change*. To participants, *e-PHR* is a supportive approach to healthcare for patients and would formalize collaborative relationships, provide access to a comprehensive set of data, and offer timely and convenient communications. Meaning was also linked to concerns of workload and workflow, and a limited shared understanding of purpose. Participants strongly agreed (4.6/5) with Cognitive Participation processes. This was explained qualitatively by two themes: *sharing ownership of the work* and *enabling involvement*. To participants, *e-PHR* is the right direction for healthcare. Participants expressed an openness to new ways of working individually and together, as well as some fear of change and lack of systemic ownership of the change. Weak agreement (3.6/5) was observed with Collective Action processes. This implementation mechanism was best explained qualitatively by one theme: *uncovering the challenge of building collective action*, and three sub-themes: *assessing fit*, *adapting to change together*, and *investing in the change*. The effort to enact *e-PHR* would require an upskilling of care providers, a shared accountability among patient and care providers, and sufficient leadership and financial investment. Participants expressed a potential disruption of current relations and a concern for a systemic willingness to adapt to change together; as well as, challenges with team work and some lack of trust and confidence in others ability to carry out tasks. Participants appraised *e-PHR* as explained by two themes for Reflexive Monitoring: *reflecting on value*, and *monitoring and adapting*. To participants, *e-PHR* would remove barriers to care and increase care efficiency, but outcomes must be measured, and benefits demonstrated. Finally, participants strongly agreed (4.5/5) that *e-PHR* would positively affect engagement in self-management decision making and agreed (3.9/5) it would become routine work, offering two descriptive themes for the practice-related outcomes: *care is efficient,* and *care is person-centered*.

Conclusions

The state of SDM in clinical practice is not a question of whether we should do it, rather it is a question of successfully integrating it within today's evolving EHR–PHR ecosystem and person-centered care approach, and with tomorrow's mobile, interconnected, and ubiquitous technology environment to engage patients in self-management decisions. Using the NPT framework, findings from this pre-implementation process evaluation indicated participants invest in sense-making, commitment and appraisal work of e-PHR; but, integration into practice will only be attained when systemic effort is invested to enact it. Further research is needed to explore this gap to inform priorities and approaches for a future implementation.

Abstract

Health programs are reliant on complex decision-making to efficiently utilize limited resources, but local-level data use is still challenging. This study aimed to assess barriers to fostering local-level data use culture at each level of a health system. Results show that awareness gaps, lack of motivation, inconsistent supervision, poor community engagement, and lack of accountability are major bottlenecks. Establishing an accountability system and capacity building on health data use could improve its implementation.

Keywords:
Health information systems, Ethiopia

Introduction

Health programs are reliant on a complex decision-making process to efficiently utilize limited resources at the local level. Health systems require quality data from health information systems to plan and ensure that the workforce is fully funded and equipped with the necessary commodities, infrastructure, resources, and policies to deliver services [1]. Health data enables health planners and managers to make decisions regarding the effective functioning of health facilities. At higher levels, health information is needed for strategic policy-making and resource allocation [2]. The relationship between data quality, demand for data, and data use creates a cycle that leads to improved health programs and policies [3]. Evidence shows that organizational and technical factors can affect data use culture [4].

A study in Uganda showed that health care data use was 24% [5]. A study in Ethiopia indicated that data use for decision-making was not adequate at lower levels and feedback mechanisms were weak [6; 7]. A data quality and information use assessment in Ethiopia showed a limited culture of data use for decision-making. Only 37% of the facilities based discussions and decisions on findings from routinely collected health information [8]. The use of health data for decisions and actions to improve the quality of health services and achieve performance goals is also vital to improve shared accountability within organisations [9].

Existing evidence indicates that data quality and the culture of data use in Ethiopia is poor, however little is known about the major barriers that affect data use at local levels of the health system. This study aimed to identify barriers to establishing local-level data use practices that could help to inform the creation of interventions to address bottlenecks.

Methods

This study was conducted in North Gondar Zone, Amhara region, Northern Ethiopia. The zone has 22 Districts and 557 Kebeles (lowest unit of administration). A qualitative study was conducted from January to September, 2017. Data was gathered through key-informant interviews using a semi-structured question guide. Data producers, data users, community members, and decision makers were engaged for key informant interviews. Community leaders, Health Develoment Armies (HDAs), and health extension workers (HEWs) from the community were involved. Facility managers, health information technicians (HIT) and case team leader were selected from health facilities. Managers, plan and program experts, and one selected expert were purposively selected from District Health Offices, Zonal Health Departments, and Regional Health Bureaus. Questionnaires were adapted from the Performance of Routine Information System Management (PRISM) conceptual farmework [4]. Document review of monthly, quarterly, and annual reports and supervision feedback were also assesed using checklists. A thematic content analysis was undertaken.

Results

Characteristics of study participants

This study engaged 21 key informants: 7 from the community, 6 from Health Centers, 6 from Woredas (districts), 1 from a Zonal Health Department, and 1 from a Regional Health Bureau. The majority of the participants were males 13 (62%). Eleven (52%) of them were aged below 34 years.

Data use culture

Community level

All community-level decision makers believed that information use has a positive role in supporting data quality, though the practice was not routine. A 27-year-old HEW mentioned that:

> *"The culture of information use is very poor at all levels. The more we use data, the better we know its function. Then we take care of quality. The more we ignore data use, we can't understand its benefit then we don't care about its quality."*

Community leaders reported that community engagement in local decision-making was limited only to planning and performance reviewing.

Health facility level

This study found that Performance Monitoring Teams (PMT) were in place at all health facilities, but only 25% of them were functional. Among all of the respondents at different levels, 11 (52.4%) strongly agreed and 7 (33.3%) somewhat agreed that decisions were made based on evidence. In health facilities where PMTs were functional, participants reported unfocused meetings. One Health Management Information System (HMIS) focal person mentioned that:

> *"….Yes, we want to have the meetings regularly, but we don't have clear guideline and expected results. People talk many unrelated and non-useful things in the meetings …"*

District and higher levels

At the decision-maker's level, all respondents reported that data use can ensure shared accountability. A 29 female respondent noted that:

> *"…Yes, data use improves accountability, it's only the presence of data that somebody to be accounted for both failure/success."*

Overall, respondents agreed that increased data use can lead to better data quality and better health service delivery at the lower levels and better health coverage at the decision-maker level. One District manager said:

> *"If we are just pipeline for the data to pass through us without use, we will not improve data quality and our decisions will not be based on evidence."*

Barriers to effective data use culture

Table 1 shows identified barriers to local-level data use culture.

Table 1 - Major Barriers to local-level healthcare data use

No.	Barriers	Health system level
1	Awarness gaps	All levels
2	High staff turn-over	Health facilities
3	Lack of motivation	Health facilities
3	Poor community engagement	Community
5	Inconsistent supervisions	All levels
6	Poor accountability system	All levels

Discussion

The value of health data is determined by its utilization in decision-making. Quality data provide accurate and timely information to manage services and aid in prioritizing and ensuring the best use of resources. This study shows that using data for decision-making can improve data quality. Evidence indicates that increased use of data will help to improve its quality, which will in turn lead to more data use [1; 4].

The national strategy established PMTs to conduct monthly meetings for performance review, problem analysis, and solution planning [3; 6; 10]. While PMTs were established at all health facilities in this study, only 25% of them ran PMT functions. Similar studies also report weak data use [3; 6; 10].

Fabricated reports and reporting data to the next level with minimal or no usage were the most common challenges [8, 10, 11]. All respondents agreed that the awareness gap experienced by health professionals was a significant obstacle to using data for decision-making. One female nurse respondent said:

> *"We have awareness gaps and there is no motivations… Health workers are overloaded and negligent to data use."*

High turnover of staff is the largest challenge that regional health bureaus face in terms of data management and information use for decision-making. One mentoring and evaluation team leader mentioned that:

> *"...For example, last year we trained all focal persons [HMIS focal] and when we did quick assessment at the end of the year, around 62% have left from their work. When untrained health workers were hired, they face difficulties to manage the data properly."*

Shared accountability leads to better use of health data for decision-maiking and actions to improve the coverage and quality of health services [9]. All respondents reported that there is no accountability system or written documents for data quality and data use.

Conclusions

In this study, the culture of local data use for decision-making at the local level was low. Awareness gaps, lack of motivation, inconsistent supervision, poor community engagement, and the lack of accountability were major bottlenecks. Establishing accountability systems and capacity building on health data use could improve its implementation.

Variation in National Clinical Audit Data Capture: Is Using Routine Data the Answer?

Dawn W. Dowding[a], Natasha Alvarado[b], Lynn McVey[b], Mamas Mamas[c], Rebecca Randell[b]

Abstract

National Clinical Audit (NCA) data are collected from all National Health Service providers in the UK, to measure the quality of care and stimulate quality improvement initatives. As part of a larger study we explored how NHS providers currently collect NCA data and the resources involved. Study results highlight a dependence on manual data entry and use of professional resources, which could be improved by exploring how routine clinical data could be captured more effectively.

Keywords:
Clinical Audit; Quality Improvement; Information Systems

Introduction

In the UK, there are over 100 National Clinical Audits (NCAs) that are either centrally developed and managed through the National Clinical Audit and Patient Outcomes Programme (NCAPOP) or by independent professional organisations. The aim of the NCAs is to provide data for measuring the quality of care provided by National Health Service (NHS) providers, as well as stimulating quality improvement (QI) initiatives [1]. There is evidence that NCAs have led to improvements in the quality of patient care [2]. However there have also been reports of variation in how NHS Trusts engage with the NCA data, with reports of a lack of resources and variations in data quality impacting on their value as feedback on performance [3].

We are currently undertaking a study to develop and evaluate QualDash, an interactive web-based quality dashboard that supports clinical teams, quality subcommittees, and NHS Trust Boards to understand and make use of NCA data. This poster reports a subset of the findings from Phase 1 of the study, focusing on how NCA data are currently collected across NHS Trusts, and the resources involved. It then reflects on the implications of these findings, in terms of the utility of using electronic health record data for capturing NCA and other audit data.

Methods

The study focuses on two NCAs; the Myocardial Infarction National Audit Project (MINAP) and the Paediatric Intensive Care Audit Network (PICANet), with evaluation of cardiology departments and Paediatric Intensive Care Units (PICUs). MINAP provides data on the management of ST-elevation myocardial infarction (STEMI) and non-ST segement elevation myocardial infarction (NSTEMI), compared to national and international standards to participating hospitals and ambulance services. PICANet records admission details and treatment provided to all critically ill children in PICUs.

A total of 5 NHS Trusts (providers) participated in the first phase of the study; all 5 take part in MINAP and 3 of the 5 have PICUs and also take part in PICANet. The number of staff at each site varied from 20,000 (site 4) to 8,000 (sites 2 and 3), and patients seen per year from 700,000 (site 3) to 1.5 million (sites 1 and 4). Semi-structured interviews were conducted with 54 individuals across the NHS Trusts and the wider NHS organisational regional structure, including NCA leads, members of NHS Trust quality and safety committees, Trust Boards, and clinical commissioning groups (CCGs). CCGs are the statutory NHS bodies responsible for planning and commissioning health care services in localities in England.

Interviews focused on participants' role and their experience of, and involvement with, NCAs. We also explored what data were collected for each NCA, how data are captured and how they are used in the NHS Trust and by whom. All interviews were audio-recorded, transcribed and entered into a qualitative software program (*NVivo 10*) for indexing. Interview data were analysed using framework analysis. After familiarisation with the data, a thematic framework was developed to index the data before interpretation of key themes.

Results

Interview data were collected between November 2017 and June 2018. Participants, 30 of whom were female and 24 male, worked in both clinical and non-clinical roles. Twenty-eight of the participants were clinicians (14 doctors/surgeons and 14 nurses), 22 had non-clinical managerial or support roles (including senior managers who were members of Trust Boards and quality and safety committees; some of these participants had clinical backgrounds and some did not), and 4 participants worked within CCGs. An overview of the key results are summarised in Table 1.

Resources used to support NCA data collection, entry, submission, validation

There was considerable variation in the resources used by each site to support the various NCAs, both within NHS Trusts and across Trusts. For **MINAP**, 3 of the sites had designated

clinicians who were responsible for data collection, entry, submission, and validation. This varied from having a full-time nurse with overall responsibility for collection and evaluation of data (Site 1) to having nurses collecting data alongside their clinical responsibilities (Sites 2 and 3). Site 4 had mixed usage of non-clinical and clinical resources, with a non-clinical primary PCI project assistant collecting data for STEMI patients and 2 acute chest pain specialists collecting and entering data for NSTEMI patients. Site 5 used non-clinical personnel to collect and enter MINAP data, employing a non-clinical cardiology information analyst, assisted by another team member.

The picture for **PICANet** across the 3 NHS Trusts that participated in this NCA was different. In all three of the sites clinicians initially fill out the PICANet forms, with non-clinical staff (database managers, audit-coordinators and audit clerk) then collating and checking the information, identifying missing and inaccurate data.

Table 1 – How NCA data are captured

	MINAP	**PICANet**
Resources		
Clinical	Full-time nurse (site 1) Nurse + clinical resp (sites 2, 3) Specialist nurse (site 4)	Clinicians fill out the form (sites 1, 4, 5)
Non-Clinical	Project assistant (site 4) Information analyst (site 5)	Database manager, audit coordinator/clerk – (sites 1, 4, 5)
Systems		
Database	Sites 1, 2, 4, 5	Sites 1, 4
Excel	Site 1	Sites 1, 4
Directly into portal	Site 3	Site 5

Systems for data collection, and entry

Similarly, there was considerable variation in the systems' NHS Trusts used to collect and enter the data into the NCA web portals. For MINAP, all of the sites apart from Site 3, had some form of in-house database that was also used to record data (Site 1 also used Microsoft Excel spreadsheets) before uploading to the web portal. Site 3 was the only site to enter data directly into the web portal. All sites relied on manual data entry by an individual into the database/web portal.

For PICANet two sites used in-house databases/spreadsheets for data collection that were then uploaded to the web portal. At site 5, data were copied and pasted from the Trust's patient data management system directly into the PICANet online portal retrospectively after a patient's discharge.

Use of NCA data

The way in which NCA data were captured by NHS Trusts affected how they were used. Issues raised included the accuracy of the data (with some Trusts highlighting concerns about data reliability) and timeliness. The way NCA data were both collected by Trusts (sometimes retrospectively) and then reported by suppliers (often yearly) meant that data were considered by some Trusts to be out-of-date and not useful to inform practice.

Conclusions

There is variation in how NHS Trusts capture NCA data, with organisations dedicating expensive resources (such as highly trained professionals, like nurses) to ensure data are collected, uploaded, and checked for reliability. All of the NHS Trusts in our study collected data manually, with some automating the uploading process to web portals. With the growing implementation of electronic health records in the NHS, emphasis should be given to how to more effectively use routine data for data capture. Considering the burden of NCA data collection and processing in the NHS (over 100 NCAs currently), this could free valuable professional resource for care elsewhere in the healthcare system.

[d]Kennell and Associates, Falls Church, VA, USA

Abstract

The Department of Defense (DoD) and Department of Veterans Affairs (VA) Infrastructure for Clinical Intelligence (DaVINCI) creates an electronic network between the two United States federal agencies that provides a consolidated view of electronic medical record data for both service members and Veterans. This inter-agency collaboration has created new opportunities for supporting transitions in clinical care, reporting to Congress, and longitudinal research.

Keywords:

Electronic Health Records, Health Information Exchange, Government Agencies

Introduction

The DoD and VA Infrastructure for Clinical Intelligence (DaVINCI) was sponsored as a Joint Incentive Funded (JIF) inter-agency project. It built on existing data and governance processes to reduce cost and most immediately provide return on investment. On the VA side, the Veterans Health Administration Health Services Research and Development VA Informatics and Computing Infrastructure (VINCI) formed the core infrastructure. On the DoD side, the Defense Health Agency Information Delivery Division Health Services Data Warehouse (HSDW) and the Military Health System Data Repository (MDR) formed the core infrastructure. DaVINCI provided the first DoD-VA full population data integration and brought together medical records, claims, and benefit information from both agencies. Combining records from multiple data sources presented several challenges, but the potential benefits for properly credenetialed teams to access and seamlessly utilize relevant information from multiple source systems in both agencies provided motivation for DaVINCI.

Methods

The goal of DaVINCI is to increase DoD-VA data integration for interagency collaboration and resource sharing in support of the Joint Strategic Plan and each agency's healthcare and benefits missions [1]. DaVINCI creates a cornerstone of informatics and data sharing that support health analysis, operations, and other secondary uses of health care data. The special relationship between DoD and VA (that is, all those eligble for care in VA were first armed forces service women or men in the DoD) means that the data sharing and overlapping populations are distinct from most other overlapping healthcare systems [2, 3]. Three distinct populations are included in DaVINCI. The DoD Only population contains persons who have electronic medical records from DoD, but not from VA. This includes active duty, guard, reserve personnel, and those who have completed service but who have not yet received care in a VA facility. The VA Only population consists of those who have electronic medical records from VA, but served before DoD used computerized record systems. The DoD and VA population contains electronic medical records from both agencies.

Instead of building interfaces with each source system, DaVINCI built on the many years of work aggregating and cleaning source systems into data warehouses (VINCI, HSDW, and MDR). Crosswalk lists are generated from the respective data warehouses and then combined and compared. This process removes employees, service member dependents, and others that are outside the DaVINCI populations. Following best practices, the data from both systems were transformed into a common data model [4] called Observational Medical Outcomes Partnership (OMOP) [5]. This allows VA and DoD data to be joined seamlessly in a longitudinal record regardless of which source agency or source system the data originates.

Once the crosswalk is complete, data files from each agency are prepared and transmitted securely. The governance process transfers stewardship of the data as well, meaning that VA medical record data becomes part of the service member's DOD medical record and vice-versa. In this way, the service member or Veteran electronic medical record follows them in subsequent care episodes.

Results

To date, DaVINCI contains more than 33 billion rows of electronic medial record data including VA data for 22,763,277 Veterans and DoD data for 6,947,102 service members. Of these, 4,039,155 (17.8% of Veterans and 58.1% of service members) have medical records in both VA and DoD.

The magnitude of current DoD and VA databases is considerable. These data are diverse and include not only healthcare untilization including inpatient, outpatient, pharmacy, immunizations, vitals, but also data on eligiblity, service theater, and demographic information. The push for precision medicine and the future influx of genomics data could be included in future data transfers to make meaningful conclusions to improve outcomes.

DaVINCI has been used to plan and evaluate mental health care utilization after military service has ended, report to Congress, reply to inquiries from top VA and DoD leadership, and measure health outcomes and utilization during transition from military service.

DaVINCI deploys and evaluates solutions for governance, data integration, data security, analysis, and supercomputing to provide a solid foundation for integrated clinical and business intelligence platforms. By allowing a more complete read-only view into a service member or Veteran record, DaVINCI can facilitate improved coordination of polytrauma patients and accelerated disability evaluations. By allowing more rapid analysis of many service member and Veteran longitudinal records, this program can facilitate more accurate and efficient screening for syndromes such as traumatic brain injury and planning for joint activities such as inter-agency resource balancing of specialty-care.

Over the next decade, all VA and DoD facilities will transition to a joint-hosted instance of a commercial electronic medical record system. This move will drastically increase the interoperability of care and data sharing between VA and DoD. It is also likely that in the future, a shared data warehouse containing all data from VA and DoD would be created. In this scenario, not only is the current DaVINCI project an effective bridge providing the only combined-population analytics solution while the new infrastructure is fully implemented, but has the potential to speed the transition process. The work of standardizing and combining VA and DoD data together can mean that initial loads of a combined data warehouse can take advantage of the linking and mapping that is already done. This may reduce the need to extract from all source systems and even allow both institutions data sets to be loaded together.

The dynamic computing environment created through this collaboration not only supports the magnitude of data needed to be stored but also utilizes parallel computing to support quick responses for queries. The end result is a solution which can handle the current data requirements, can easily expand with increasing data, and supports quicker query requirements.

Conclusion

The DaVINCI project has already proven useful in determining which resources are needed on the VA side for separating service members and coordinating test results already performed on the DoD side to reduce duplication. It has been used to determine immunization status and overlap in utilization in areas where DoD and VA share medical facilities. Finally, it has supported several research projects studying conditions ranging from hearing loss to traumatic brain injury and heart disease to prostate cancer.

The opportunities that DaVINCI creates for caring for and studying the overlapping patient populations of VA and DoD will continue to benefit the health of active duty personnel and Veterans.

Abstract

The amount of text of electronic medical records and its changes over time are not clear. In designing an electronic medical records system, prediction of the amount of text is important. We analyzed the number of characters described in the electronic medical records. As a result, it became clear that the annual text quantity of electronic medical records follows the lognormal distribution, and also the amount has been increasing year by year.

Keywords:
Electronic Medical Records, Prediction Model, Medical Records.

Introduction

In addition to digitization of clinical records centered on electronic medical records (EMR), expansion from information system for each medical institution to electronic health records (EHR) is proceeding. As a result, very large amounts of data are accumulated in EMR and EHR. In considering system design and UX, the amount of data stored in the system is a very important factor. If it is possible to predict the amount of text of EMR, it can contribute to system design and UX.

There is a prior study that the page number of the paper chart approximates the lognormal distribution [1]. There is also a report that the amount of information for each outpatient visit increases due to electronic medical record [2]. However, it has not been clarified about the amount of text of the entire EMR including outpatient and hospitalization and the change over time of EMR.

In this research, for the purpose of constructing a prediction model of the amount of text of the electronic medical record, we analyze the amount of text of the electronic medical record.

Methods

We need to consider the method of measuring the amount of text stated in EMR. If EMR over multiple years are simply aggregated on a patient basis, changes over time can not be analyzed. In addition, it is inappropriate to compare them each other because the start point of the medical treatment is different between patients.If simply counting on a unit of time (year, month, etc.), although temporal changes can be considered, it becomes impossible to identify patients included therein. It is necessary to examine the correlation between patient attributes and the amount of EMR described in order to construct a prediction model, which is the purpose of this study. Therefore, it is not appropriate to simply aggregate only in units of time. From the above discussion, we take both the patient and the time unit as parameters, and we counted characters of EMR for each patient per year. In this study, Each separated EMR is named as “patient annual EMR”, and also numbers of characters written in a patient annual EMR is named as "patient annual EMR text amount".

In this study, we will use EMR data of Kyoto University Hospital written from 2006 to 2016 as a data set. It contains no image data but text data by medical staff. Character counting was performed using SQL on IBM DB2 10.5. Statistical analysis was conducted using R 3.4.2.

Results

Characteristics of All Periods

The data set has 883,312 patient annual EMRs. Table 1 summarizes the patient annual EMR text amounts over the target period. Figure 2 shows the histogram of the patient annual EMR text amounts. The difference between the mean and median and the histgram show the patient annual EMR text amounts not following normal distribution.

Table 1– The Patient Annual EMR Text Amounts

	Total	Outpatient	Inpatient
Mean	25,647	10,401	88,940
Median	4,285	3,833	28,342
Maximum	8,209,843	839,453	8,203,040

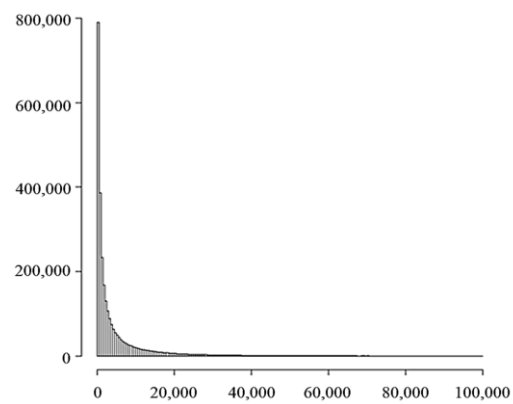

Figure 1 – Histgram of the Patient Annual EMR Text Amounts.

Table 2 summarizes the results of the logarithms of the patient annual EMR text amounts over the target period. Figure 3 shows the histogram of the logarithms of the patient annual EMR text amounts. Results of Kolmogorov–Smirnov test and Shapiro-Wilk test and the histogram show that the patient annual EMR text amounts follows the lognormal distribution.

Table2- Logarithm of the Patient Annual EMR Text Amounts

	Total	Outpatient	Inpatient
Mean	8.412	8.167	10.227
Median	8.363	8.251	10.252
p-value of Kolmogorov–Smirnov test	0.772	0.2209	0.8638
p-value of Shapiro-Wilk test	0.4889	0.6805	0.477

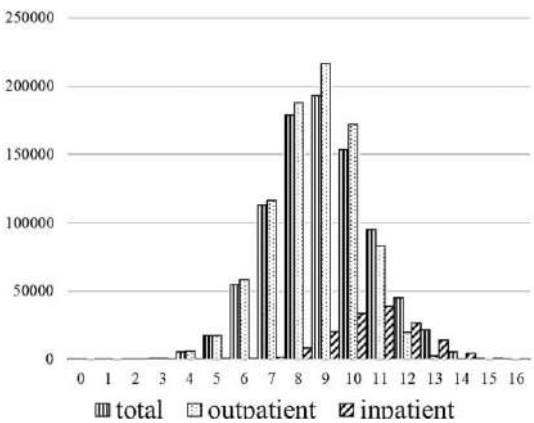

Figure 2 –Histgram of Logarithm of the Patient Annual EMR Text Amounts.

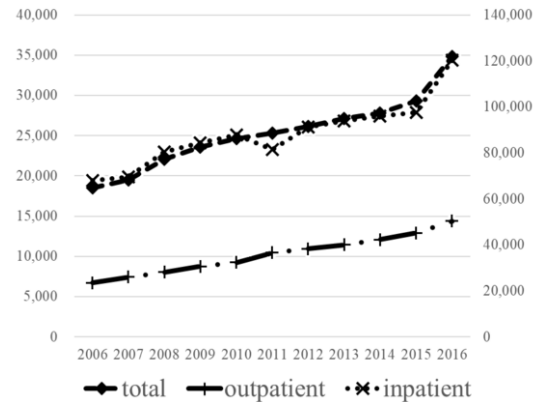

Figure 3 –Mean Trend of the Patient Annual EMR Text Amounts.

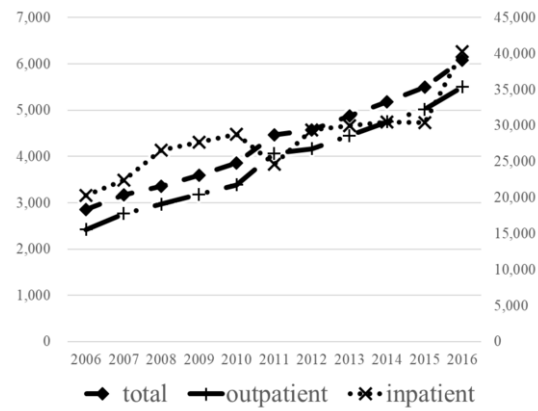

Figure 4 – Median Trend of the Patient Annual EMR Text Amounts.

Chronological Change

Figures 3 and 4 show the trends in the mean and median of the patient annual EMR text amounts for each year in the target period. For total, outpatients, and inpatients, the patient annual EMR text amounts continued to increase in both the mean and the median.

Conclusions

In this research, we analyzed the characteristics of the patient annual EMR text amounts in the target period and its change over time. As a result of the analysis, it became clear that the patient annual EMR text amounts follows the lognormal distribution, and the amount has been increasing year by year. The data set of this study is EMR of one hospital, and it is necessary to investigate EMR of multiple hospitals for validating the above conclusion.

In future research, we will investigate factors that increase the amount of EMR text and search for explanatory variables of the prediction model.

Abstract

Augmented Reality technology can provide useful tools and devices to support healthcare services. The aim of this study is to investigate the intention of IT and health care scientists' to use Augmented Reality technology in Healthcare. A survey was conducted using a questionnaire based on a theoretical research model. According to the results, the participants seem to have positive perception about using the Augmented Reality technology in health domain, and they intend to use it.

Keywords:
Technology Assessment, Delivery of Health Care, Augmented Reality

Introduction

Augmented reality (AR) can be defined as an interactive visualization system (e.g. a head-mounted display, a computer, a game console, a smartphone, a tablet) allowing the merging of digital content with the real environment sourrounding the user, and blending both "real-world" elements with "virtual" ones [1]. The evolution in the area of mobile and wearable devices, has led to a rapid growth of AR technologies. AR can provide useful tools combining innovative devices and software, which can contribute positively to the domain of healthcare [1-3].

In this context, much scientific work is taking place on the assessment of the AR technology [4,5]. The acceptance of this technology is crucial and promising [6-8], especially in the health domain [9].

The aim of this ongoing study is to investigate the intention of information technology (IT) and healthcare scientists' to use AR technology in healthcare.

Methods

For the aim of our study, a questionnaire was developed based on a theoretical research model. The proposed model was a combination of Davis' Technology Acceptance Model (TAM) [10] and other related research work [11,12]. Our model included six dimensions with at least two questions (items) per dimension. All items used a 7-item Likert scale from "strongly disagree" to "strongly agree". The questionnaire was anonymous and distributed through Google forms to Greek IT and healthcare scientists during 2018. Specific relationships between the dimensions were tested, based on the following hypotheses (Figure 1):

- H1: Does "Perceived Usefulness" positively affect "Attitude Toward Use".
- H2: Does "Perceived Ease of Use" positively affect "Attitude Toward Use".
- H3: Does "Attitude Toward Use" positively affect "Behavioral Intention to Use".
- H4: Does "Compatibility" positively affect "Behavioral Intention to Use".
- H5: Does "Relative Advantage" positively affect "Behavioral Intention to Use".

The sample consisted of 81 IT and healthcare professionals. Descriptive statistics and structural equation modeling data analysis was performed using SmartPLS 2.0 M3 to conduct partial least squares path modeling [13].

Results

The participants of this study were 34.2% males and 65.8% females. The average age of the participants was 27.6 years old. According to the descriptive statistics, the mean and median value for all items values were above 4, which reveals the positive attitude of the participants (Table 1).

Table 1– Survey Results

Items	Mean	St. Dev	Median	Individual Item Loadings
ATT1	6.07	1.00	6	0.88
ATT2	5.68	1.20	6	0.82
BI1	5.95	0.93	6	0.76
BI2	5.67	1.10	6	0.86
BI3	5.40	1.29	6	0.75
COMP1	5.98	0.98	6	0.84
COMP2	5.79	0.98	6	0.70
PEU1	5.53	1.24	6	0.93
PEU2	4.48	1.53	4	0.70
PU1	6.06	1.00	6	0.86
PU2	5.85	1.07	6	0.89
RA1	5.57	1.09	6	0.73
RA2	5.94	1.03	6	0.79
RA3	5.83	1.01	6	0.81

Based on the partial least squares analysis, the measurement and the structural models were examined. To test the validity and the reliability of the models, individual item loadings (for indicator reliability), internal consistency, convergent and discriminant validity, were tested and produced reliable results [14].

The coefficient of determination (R2) was 0.612 for the "Behavioral Intention to Use" and 0.456 for "Attitude toward Using". All relationships between the dimensions (as described

in the hypotheses, Figure 1) were found to be statistically significant. The structural model was validated by applying a bootstrapping technique (with 5000 resamples) based on a two-tailed t-test (with α=0.05 or 0.01). All the hypotheses were confirmed (Figure 1), with at least 95% significance (p-values<α).

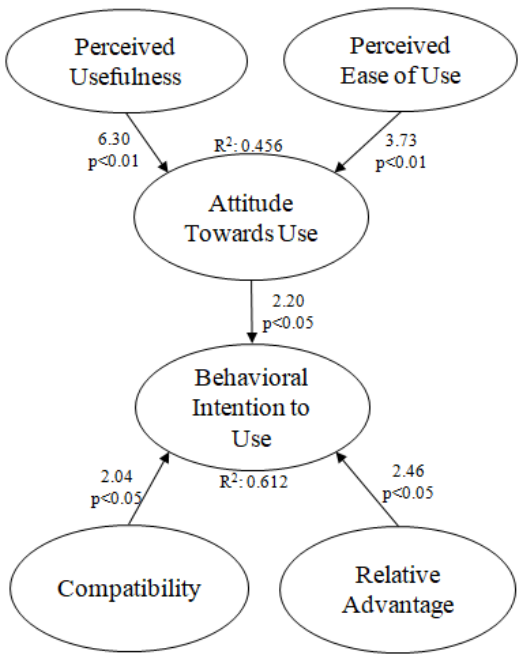

Figure 1– Theoretical research model

Discussion

According to the study results, the participants seem to have positive perception about the implementation of the AR Technology in health domain, and they intend to use it. Perceived Usefulness and Perceived Ease of Use positively affect the participants' Attitude towards Using AR technology in Healthcare. Additionally, Relative Advantage and Compatibility, as well as Attitude towards Using positively affect the Behavioral Intention to Use AR technology. These findings present the positive attitude of the paerticipants towards AR technology, their positive view as they consider it as useful and usable technology, and their intention to use it in their professional healthcare enviroment.

Conclusions

The survey results indicate that the participants have a positive attitude towards the Augmented Reality Technology in health domain and they express their intention to use it. Limitations of this survey may be the young age of the participants, as younger professionals might be more familiar with new technologies compared with older professionals. Future work may include further investigation of behaviors and attitudes of IT and health care professionals towards virtual and augmented reality technologies being used in healthcare.

Acknowledgements

Authors would like to thank the participants, who formed the population of the survey.

Abstract

Integrating evidence from systematic research in daily clinical practice is one of the pillars of evidence-based medicine. Electronic data capture tools simplify data collection from different centers and supports the management of multicenter clinical trials. The Ligurian HIV Network (LHN) is one such tool, originating from a regional effort to integrate clinical trial capabilities for HIV and other chronic infectious diseases. In order to manually collect a complete report of all clinical tests on patients enrolled in a trial, a strenuous human effort and the allocation of great resources would be necessary. Moreover, the risk of error in a manual system is very high. The proposed system automatically extracts clinical data from the EHR of three hospitals of the LHN in a standardized way, and enhance their re-use in clinical trials. Through dedicated questionnaires, physicians reported a strongly positive feedback about the efficacy of the platform in supporting clinical research.

Keywords:

Electronic Health Records, Health Level Seven, Clinical Trial

Introduction

Clinical Trials are indispensable tools for Evidence-Based Medicine [1]. To collect the large amounts of data needed for clinical research, the implementation of a system, which coordinates the conduction of scattered clinical trials, is required. The interchange of data coming from different and heterogenic medical structures has to be managed. The ARCA (Antiretroviral Resistance Cohort Analysis), ICONA (Italian COhort Naïve Antiretroviral) and CISAI (Italian Coordination Study for Allergies and Infections from HIV) databases constitute the most important Italian clinical cohorts for HIV studies.

In 2013, a regional research network called the Ligurian HIV Network (LHN) was implemented by some of the authors [2]. The LHN was originally conceived as a mere web platform to enable the collection of data from HIV patients using a web interface, in order to perform multi-centric clinical trials at a regional level [3]. For the first year, the platform was consistently used for its initial scope, supporting about half a dozen local studies. Routine use of the platform, together with the intention to address the well-known problem of errors due to manual data input into web interfaces, led to a consecutive gradual evolution of the system. The leading idea was that clinical data, already available in digital format in the LIS (Laboratory Information System) and other components of the Hospital Information System (HIS), could be extracted and automatically exported to the LHN database. In this way, patients' laboratory data could be updated daily without human intervention. Clinical data was chosen since laboratory data is the largest data set used in clinical research concerning infectious diseases. Once this first process was completed, having reached a fully updated database, the authors decided to automatically connect the repository to the national HIV clinical studied mentioned above.

Methods

The LHN technical implementation choices are guided by the Electronic Source Data Interchange (eSDI) group recommendations. The scenario adopted and the architectural approach of the developed solution are thoroughly described in [4], while the technical approach is similar to those described in [5][6]. In order to protect patients' privacy, only indispensable personal information is managed such as year of birth, sex and nationality. The patient hospital code, that cannot be directly connected to the identity of the patient, makes it possible to track each patient through various hospital departments. If a patient moves to another hospital, explicit medical coordination is required.

A tool for the direct extraction of laboratory information was implemented, so that the data can be conveyed from the Laboratory Information System (LIS) towards the LHN. Depending on the hospital's level of IT support, two different scenarios arise: 1) the hospital does not have a LIS in which digital data are stored or it has LIS but does not allow external agents to access data; 2) the hospital has a LIS and allows external agents to access data. Hospitals belonging to the first scenario could participate in the LHN by inserting data manually from the web interface, while those belonging to the second scenario could exploit the paradigm of data reuse. Automatic clinical data flow from a hospital LIS towards the LHN is allowed by a Windows Console Application that encapsulates clinical data in standard Health Level 7 Clinical Document Architecture (HL7 v3 CDA r2) documents and sends them through a web service that is responsible for document validation and data recording. During this process, the web service also involves a terminology service, in conformity with the standard CTS2 (Common Terminology Service Release2), which allows the translation of local hospital terms to LOINC (Logical Observation Identifiers Names and Codes)[7]. This ensures a

correct understanding of the data exchanged between different laboratories that use their own terminology. A trigger launches the console application program once upon a night, searching for registered patients who have done laboratory exams during the day. When the program encounters for the first time a patient just registered on the platform, all historical data are retrieved.

Results

The LHN currently involves the Infectious Diseases Departments of eight hospitals in Liguria and Piedmont. Three hospitals (IRCCS AOU San Martino IST, Galliera and Sanremo) use the second scenario while the others use the first.

The three hospitals in the second scenario have two different informative systems, so two different methods for sharing clinical data were developed. The Galliera Hospital offers several services to access patients' clinical data, including a data management service to access laboratory test results. After authentication, data are available on demand in XML or JSON proprietary format. On the other hand, IRCCS AOU San Martino IST and Sanremo hospitals do not share data through services, thus the only way to access data is to extract them directly from the LIS, installing the console application inside the hospital firewall. Currently 4338 patients from eight different hospitals are involved in the LHN. Among them, data from 1851 patients from San Martino hospital, 1241 from Galliera hospital and 267 from Sanremo hospital are automatically updated using the described tool. The EHRs of the Galliera and San Martino hospitals started working at operating speed in 2008. There is a consistent difference among hospitals belonging to the first and the second scenarios in terms of quantities registered. In the data for Sanremo hospital, this trend is not yet appreciable, since the automatic connection with the LIS was only set up recently. Automatized centers insert 10 times lab test per year more than non-automatized ones (10679 vs 1910) and also a greater number of parameters per test is considered (41 vs 31). Using this tool, anonymized data were automatically transferred from the Electronic Health Records (EHR) towards the Clinical Data Management System (CDMS). This enhanced clinical trials conduction on chronic viral infections, the project has recently been expanded to include HBV and HCV diseases. Presently nine regional studies are supported by the platform as they are listed in the left menu of the web site (https://reteligurehiv.it/Default.aspx), pressing each button a short description is available.

This fully updated database is a reliable source of information that could be reused to fill national databases, like ARCA, CISAI and ICONA. At present, 1243 LHN patients are registered in the ARCA database, 590 in CISAI and 458 in ICONA. A program has been developed to continuously update the ARCA database with CD4+, HIVRNA and genetic sequence data for all patients included in the LHN. The CISAI study also involves HCV infected subjects and collects a greater amount of data. A collaboration with the ICONA data manager has not yet been arranged. Temporarily, a tool for data extraction in Excel format, which is available on the platform, helps in collecting data to be sent to the ICONA database.

Statistical reports and charts are prepared from the data collected using tools available on the web interface, in order to show continuously updated information. An extraction tool has been set up on the web interface to enable physicians to export selected information from the database to spreadsheet files. The extraction engine is flexible and optimized in timing. Patients, time range and the parameters of interest are customizable by the user.

Discussion and Conclusion

The LHN was initially set up to provide physicians with a web-tool to administrate data from HIV-positive patients in primary-care and to re-use the collected clinical information to perform CTs in Northern Italy. In this paper, an extension of the former architecture is presented, which provides the development of a system that automatically transfers clinical information from the hospitals' EHR towards the LHN database. A further extension enables direct communication between the developed system and the main HIV national databases.

The proposed system works properly for the two illustrated scenarios. In particular, for the second scenario, data can be automatically extracted in a standardized way, and conveyed towards the central repository for their re-use in clinical trials.

In order to manually collect a complete report of the laboratory activity for all the patients involved, a strenuous human effort and the allocation of great resources would be necessary. Moreover, the risk of error in a manual system is very high. Instead, a tool able to automatically transfer all data, such as the one described in this paper, is essential to rapidly collect all laboratory information in a reliable manner. The use of medical standards ensures possible future integrations with additional health care structures, enhancing the expansion of the project. Currently this system manages and elaborates data coming from regional hospitals, but in the near future, it would be possible to expand it, involving extra-regional facilities, thanks to interoperability efforts.

Statement on ethics vote

The research was approved by the Liguria Ethics Committee (directed by prof. Manlio Ferradini) on August 28th 2013,

Linking Care Coordination Measures to Care Outcomes to Improve Care Quality

Rima Artonian Gibbings[a], Nilmini Wickramasinghe[b]

[a] University of Illinois in Chicago, Chicago, USA,
[b] Swinburne University and Epworth HealthCare, Melborne, Victoria, Australia

Abstract

Currently, poor patient experience coupled with too many instances of missed care, repeated treatments/tests and poor quality all detract significantly from high value care delivery and are plaguing the healthcare systems globally and especially in the US. A care co-ordination solution enabled by technology is proffered as an appropriate remedy in this research in progress.

Keywords:
Patient care, Treatment outcomes

Introduction

Isolated healthcare information systems based in hospitals, provider practices, pharmacies, and laboratories are resulting in fragmented care delivery systems [1] and inefficiencies in care outcomes. Joining these disintegrated information systems efficiently to one another becomes imperative when caring for patients suffering with one or more chronic conditions. In the U.S., the number of patients with chronic diseases, functional limitations or disabilities exceeds 120 million [1] and these Medicare beneficiaries with seven or more conditions on average see eleven physicians including three primary care physicians and eight specialists [2]. Each of these providers could potentially own and operate stand-alone information systems which could potentially result in lack of coordinated care and become a major contributor to complications which occurs during various stages of the patient journey [3] and thus, to address this growing problem we proffer a technology enabled care co-ordination solution.

Methods

To demonstrate the role of the proffered technology solution and establish fidelity and usability, we adopt a multi-phase mixed method study. Phase 1 consists of a systematic literature review to identify all key factors which then leads to the developed conceptual model. Phase 2 includes a two-arm trial at healthcare facilities in the US and Australia where identified critical care measures are tracked by clinicians as compared to standard care approaches. By choosing to look at the same technology solution in different healthcare systems, i.e., US and Australia, we anticipate uncovering initial insights regarding macro level issues. The technology solution used to enable this process is the OneView Point-of-Care system. Phase 3 includes analyzing the data gathered using a mixed methodology. In Phase 4, the technology solution care protocols are revised as required.

Results

Enhancing care coordination has been associated with improved care quality and the patient experience [4]. To do this effectively, it is essential to accurately/precisely detect care coordination measures that are associated with certain healthcare outcomes. Categorizing patient care activities under coordination measures and associating these measures with care cycles (outcomes) will facilitate the formation of strategic care plans that emphasize accountability and efficiency. Our research in progress addresses this key need by using technology as an enabler. We present the theoretical framework of our systematic literature review in Figure 1.

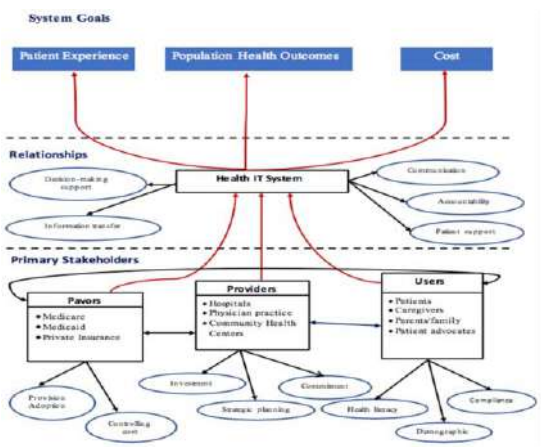

Figure 1. The theoretical framework of the literature review.

Conclusions

A sustainable solution that ensures superior patient experience, high quality care outcomes and at the same time minimizes healthcare costs by limiting duplicated care and/or unplanned readmissions requires high level of care coordination. In today's healthcare context, this necessitates a technology solution. Assessing coordinated measures within current health information systems must include all determinants that could impact healthcare tasks. These measures will transfer care facility processes from a reactive practice into an integrated and collaborative one. We believe our proffered solution will provide a superior patient experience coupled with adherence to a value-based care paradigm.

Abstract

The concern for aging, chronic illness, and dependence is relevant in today's society. The Nursing discipline is responsible for its approach to care. Furthermore, this profession must develop technologies to assist. The main objective is the development of a robotic system for assessment of fall risk and adherence to pharmacological treatment. The magnitude of this prototype design and its validation by experts warrant the attention to support care for the vulnerable and fragile with technology.

Keywords:
Frailty; Nursing Care; Robotics

Introduction

The present study starts with the following research aim: *Design of a robotic agent that assesses fragility by the following two measures: risk of falls and pharmacological adhesion.*

The current paradigm places us before the reality of aging, its chronic illnesses, vulnerability, and fragility, which are far-reaching in our society [1]. It is therefore necessary to identify potential risks and prevent them. [2] In this research we will focus on the approach of two care problems that can usually be seen in the frail elderly: the risk of falls and the difficulty of pharmacologic adherence. Both care problems are related to each other.

Assessment of the Risk of Falls in the Frail Person

In Spanish territory, the modified Downton Scale has been used to evaluate the risk of falls in people based on five criteria [1].

Adherence to Pharmacological Treatment in the Fragile Person

There are studies that show that older and fragile people are more susceptible to the adverse medication effects [3]. Not to mention, they usually take a greater amount of medication (polypharmacy) that increases risks, including the risk of falls [3].

In Primary Health Care, in the Community of Madrid, the test used for the assessment of pharmacological adhesion is the "Morisky-Green Test" [4]. Some articles show the advantages of using this questionnaire [4-6].

Robotics in Health Care for People

The repercussion of the new advances is evident in society: the incorporation of Knowledge-Based Systems [7] in devices managed by people. Health professionals need to undertake new strategies in the development of technology to care for patients [8-11]. Recent research in the European framework stress the importance of paying attention to the daily life of people, especially in the context of fragility in relation to robotics [6,12-19].

Methods

The present study employs a deductive methodology using a knowledge extraction technique and the learning of that knowledge. The research study was carried out from March to May 2018 in the Computer Science Department of the Polytechnic School of the University of Alcalá. The study consisted of the following phases:

- Phase I: Extraction of knowledge about the research problem
- Phase II: Development of the prototype
- Phase III: Implementation of the algorithm
- Phase IV: Verification and validation by experts

Results

The study shows the following results for each planned phase:

- Results for Phase I: **The knowledge extracted led to the creation of** the Downton Scale Modified Downsizing and Morinsky-Green Test prevention algorithm.
- Results for Phase II: Hardware elements were used for the following functions: execution of algorithm, data storage, bluetooth communication, transmission of information to the user. The robotic system interacted with mobile devices allowing a human-robot interaction experience.
- Results for Phase III (Included General and Specific Description):
  - Product Perspective - The system has been designed for the assessment of the frail elderly people, identifying potential risks for the subsequent prevention of them through health care. The product was designed to work on mobile devices via Bluetooth connection.
  - Characteristics of Users - Users of the tool were nursing professionals and caregivers.
  - External Interfaces - The user interface implemented was an Android App, and the

hardware and software interface was the robot and the software Arduino.

- Results for Phase IV: The results obtained were presented in different congress and international publications. The experts' validation carried on with the testing of the tool. The objective was to verify its validity for the international expert community and to link its relationship to the multidisciplinary and interdisciplinary communities with computer and health knowledge through a group of experts (Doctors in Nursing and Computer Science). It is expected that the tool will be validated at the community level through piloting in health and non-healthcare centers.

Discussion

At present, there are multiple studies that contemplate the importance of using robotic agents and computer tools in the care of the frail elderly. As a result of this research, the use of this technology for vulnerable groups, such as children and the elderly, are now being explored. Except, in addition, one should focus on creating a new care model based on the indispensable mechanisms for the maintenance of life that represents human needs and responses of the population.

Conclusions

The robotics of care proposes to include assessment systems for the care of vulnerable people (15,16). Its use in the field of Nursing favors a new vision applicable in healthcare and home settings and promotes the approach of a new sustainable model of care robotics that adapts to different communities.

Using Contemporary e-Learning Tools to Teach Staff How to Use New Online Documentation Systems

Jeffry S. Gordon, Ryan E. McNew, Elizabeth E. Weiner, and Patricia Trangenstein

Vanderbilt University School of Nursing, Frist Nursing Informatics Center, Nashville, TN, USA

Abstract

Medical centers, hospitals, and health care practices are implementing electronic documentation systems and regularly adding new features to these systems. Training users to effectively use these systems in a scalable way has been a challenge. Learners learn at different rates and have different needs. While traditional face to face instruction has been the gold standard, eLearning technologies can provide acceptable alternatives. This poster will demonstrate three eLearning methodologies for training.

Keywords:
Education, Nursing, Documentation, Staff Development

Introduction

Clinician education and training on new EHR systems is one of the biggest hurdles encountered when implementing a new documentation system. Omaya, Cipriano, et al., claim that the frustration experienced by clinicians with their inability to use the EHR efficiently leads to significant burnout, particularly since up to 50% of a clinician's time can be spent in clinical documentation [1]. Roney reports that, "Training sessions for complex EHR systems can be overwhelming and time consuming." According to Andres Jimenez, MD, CEO of ImplementHIT, "Many hospitals may not receive optimal outcomes from EHRs because hospital staff and physicians are not trained effectively" [2].

Kim, Rodriguez, et al. state that competencies in using an EHR are a critical skill for health care professionals [3]. Even our own informatics users have identified training existing hires on new EHR features and new hires on the system are among their biggest problems, but unfortunately, according to Karimzadeh and Hoffman, "Academic bioinformatics curricula rarely train users in documentation." They further claim that this failure results in "documentation debt" where more time is spent answering questions one on one than it would have taken to develop the right documentation in the first place [4].

Face to Face Instruction vs. Distance Learning

The traditional standard for training has been face-to-face education where users are often seated at computers and taught how to navigate the system. Learning theory is clear. Thalheimer claims that without appropriately spaced practice and repetition, learning is not as effective as it can be. He recommends widely spaced repetition as more effective than narrowly spaced repetition or no repetition at all [5]. Single session face-to-face training cannot accomplish that.

Providing the bulk of the content asynchronously via a distance platform provides several key benefits. First, employees can learn at their own rate. Secondly, employees do not have to be taken, en masse out of production. Third, there is no travel or meal expense for either the users or the instructor. Fourth, because of no travel or removal from production, widely distributed repetition is an attainable learning practice. Fifth, there is commonality of experience. Sixth, learners model an expert.

Methods

We taught our students in our Informatics program each of these techniques over a two semester course. They insisted on this type of content to help them meet their training and documentation needs.

Rapid turn-around just in time documentation

Rapid turn-around just in time documentation is that type of text-based materials with screen captures that can be produced quickly in response to a specific instructional need or question/problem from a user. Text-based materials are generally the easiest to produce with few resource requirements and they can be very effective in getting new content out to large numbers quickly. The advantages here are speed of development and speed of distribution, thus the name, "rapid turn-around documentation". Gerchev recommends a flexible approach to documentation that includes a variety of the approaches described here. He emphasizes capturing images and making sure the documentation is up to date with the latest product, which is easily accomplished with rapid turn-around documentation [6].

One of the more popular contemporary platforms for these text-based files is Wordpress. Wordpress provides an organizational structure that can be used to later search for stored text documentation. Typically, these searches are based on keywords embedded within document itself. By providing links to documents in a Wordpress environment, changing the document there only once means everyone with the link to the document always sees the latest version. We currently have over 230 documents in our Wordpress site.

Narrated screen recordings

Screen recordings are an excellent way of presenting dynamic content to demonstrate a specific procedure on the computer. Yearwood states in an interview by Robert Kelly, "It is almost like having your personal tutor whose message never changes regardless of how many times you rewind or review the content" [7].

Three major advantages to screen recordings are that the user can rewind the video and review sections that were originally confusing. Secondly, the instructor can use mouse highlighting to put the focus on an exact the area of the screen he wants to emphasize. Thirdly, depending on how these videos are stored, they can be accessed at any time from any place with an internet connection. Camtasia is our product of choice.

Creating an online simulation/tutorial

Krueger and Barnes demonstrated that regular continual practice helps retain skills [8]. One approach is to develop a simulated application using an eLearning development tool such as Lectora, from Trivantis, to duplicate many of the features inside an EHR. These applications can provide online guided instruction when the system detects the user needs help. Zhang, et al, refers to this as the Virtual Mentor (VM). The VM contains multimedia integration, just in time knowledge acquisition, interactivity, self-directivity, flexibility, and intelligence [9].

The instructional development team uses the product to create simulated cases from a set of contrived cases that cover the concepts and skills on the EHR the user needs to learn. A script is developed based on learning outcomes. This script allows the developer to capture screens from the actual simulated EHR and sets the sequence with which those screens will be displayed.

Comparison of features and requirements

Rapid turnaround documentation with screen capture	Narrated screen recordings of the Application	Tutorial-simulation with Real Screen Captures
Quick to develop and inexpensive	Quick to develop; daunting for stage fright instructors	Takes time to develop and is relatively more expensive
Good for quickly needed response	Good for visual learners	Allows users to develop "muscle memory"
Can be emailed or stored on any server	Requires a media server to deliver	Requires a web server with database storage capabilities

Movement through the simulation is governed by the developer of the application using the button and logic capabilities available in the eLearning tool and match very closely to the actual EHR. Areas in the EHR the developer does not want the user to wander in will be disabled. Total control of where the user goes is up to the developer using the software tool. This

way the lesson is focused only on those areas that are part of the specific set learning outcomes. The user cannot go down rabbit holes that will not get them to their final goal. Responses and response rates can be stored for future discussion with a live instructor trainer.

Results

Student course evaluation feedback from the Technology Components for Informatics class was that all seven students responding reported they strongly agreed with the statement that this content was relevant to their course of study. The six students responding in the Web Development for Healthcare Applications class reported they agreed or strongly agreed that the online simulation/tutorial content was relevant to their course of study. Typical comments were, "A valuable learning approach by having us create our own learning module using the tools required." Another said, "It significantly increased my confidence and skills in using this type of platform for creating interactive eLearning modules. Learning, "How to use Lectora to create interactive EPIC training".

Conclusion

The techniques described here can solve many of the problems that face to face instruction cannot solve. Our students advocate the need for individualized pace instruction, rapid response to questions, common experience, repetitive learning, modeling an expert, reducing travel costs, and reducing the need to take people out of production for training.

Introduction of a Program to Improve the Information Sharing System of Food Allergy Patients

Ji Su Ha, Su Hyun Kim, Sang Hee Lim, Tae Hoon Ko, Sae Won Choi, Hae Young Lee, Kyung Hwan Kim

Department of Medical Informatics, Seoul National University of Hospital, Seoul, Republic of Korea

Abstract

Although the symptoms of food allergy are diverse and sometimes dangerous to life, we have not been able to effectively share information on patients' food allergies. In this study, we developed a program to prescribe the allergic formula for each patient and to establish a series of processes for safe allergenic meal delivery based on the standards and guidelines of food allergy management. We then assessed the utility of the "introduction of food allergy program" by comparing the number of allergic prescriptions before and after the program application for inpatients. Through the development and introduction of the program, all hospital staffs, including medical staff and dieticians, can share information on food allergy patients. Systematic management of food allergy patients from doctor's prescriptions has provided the basis for safe meal preparation.

Keywords:

Food allergy, Hospital Information Systems, Prescriptions

Introduction

Food allergy is an adverse reaction caused by immunity after ingestion of food [1]. Food allergy is a common disease experienced by 6 ~ 8% of children and 2 ~ 3% of adults [2]. According to an epidemiological survey conducted in 2000, 43,045 children aged 6-15 years at the Pediatric Allergy Respiratory Society, the prevalence of diagnosed as food allergy more than once was 4.7% [3]. In a study of 25,000 children whose ages were 6-12, "self-reported" food intake was 10.9% [4]. The food allergy usually grows naturally as it grows [5]. This is an increasing trend [6].

Although food allergies vary in their severity, severe reactions such as anaphylaxis, angioedema, hypotension, and asthma attacks may pose a life threat if they fail to receive early first aid treatment [7]. At the Seoul National University Hospital, there was a case in which complaints occurred due to proximity errors and side effects due to missing food allergy information by patient when issuing meal orders, but there is no systematic program for sharing food allergy information.

Methods

Since June 2017, the Allergy Internal Medicine, Feeding and Nutrition Department, Nursing Headquarters, QA Team, and Information Development Team have gathered and organized a process to share food allergy information. Based on this, we developed and introduced food allergy information sharing program in the Hospital Information System (HIS).

To evaluate the effectiveness of the food allergy program, we surveyed the status of food allergy information sharing among patients admitted to Seoul National University Hospital from March 1, 2018 to August 31, 2018.

In addition, the number of prescriptions for allergic meals in July 2017 before the introduction of the program and the number of prescriptions for allergic meals in July 2018 after the introduction of the program were compared.

Results

The information sharing and coping process for food allergy patients were prepared as follows.

1) Establish criteria to be managed and guidelines for food allergy management.

2) Categorize allergy information and systematically classify and input information when hospitalized.

3) Physicians will prescribe the allergic formula for each patient, and provide the allergic formula in the nutrition course, explain the treatment formula and adjust the meal plan.

4) Rapid first aid and patient monitoring based on [Alert] information from doctors, nurses, and food and nutrition department in case of food allergy symptoms.

According to the above work process, the food allergy program in HIS was developed as follows.

1) In order to systematically share allergy information, the food allergy item of the hospital nursing information survey system was changed from the free text to the categorized check item. One thing to consider is ‘Mackerel / pupa / lacquer / hemp / taro’ are not likely to be classified by item, but collecting items that are not provided in patient formula improves the convenience of registration (Fig. 1).

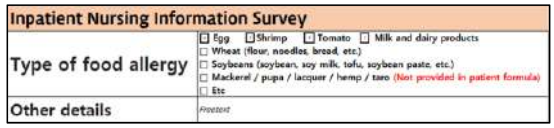

Figure 1

2) When you check the food allergy item on the inpatient nursing information search page, it linked to 'Food Allergy' item of [Alert] (Fig. 2).

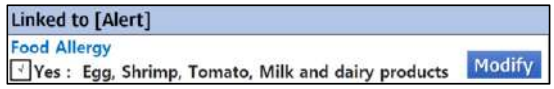

Figure 2

3) In case of adding or modifying the items of food allergy since the creation of the inpatient nursing information survey system, add or modify through the 'Food Allergy' item of [Alert] (Fig. 3).

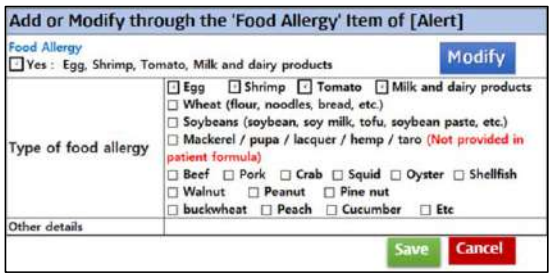

Figure 3

4) The primary care physician issued an allergic meal order (the name of 'other treatment formula').

5) The nurse issues an allergic meal order as prescribed by the doctor.

6) Dietitians provide allergic meals by patient through food management program of food allergy patients.

7) At the time of hospitalization after the patient is discharged from hospital [Alert], the food allergy information is linked to the inpatient nursing information survey.

8) Dietitians are able to manage food allergy categories, manage food allergy categories.

From March 1, 2018 to August 31, 2018, 2,033 patients (5%) were enrolled in a total of 37,429 hospitalized patients with food allergies. As a result of analyzing the number of registered food allergies, the most frequent item among all 2,666 food allergy items was mackerel / pupa / lacquer / hemp / taro item, and total 321 (12%).

Table 1- Number of food allergies registered by Seoul National University Hospital (March to August 2018)

Type of food allergy	Number of registrations (times)
Mackerel / pupa / lacquer / hemp / taro	321(12.0%)
Peach	296(11.1%)
Shrimp	202(7.5%)
Milk and dairy products	122(4.6%)
Egg	106(4.0%)
Pork	97(3.6%)
Chicken	60(2.3%)
Crab	58(2.2%)
Wheat (flour, noodles, bread, etc.)	58(2.2%)
Other (crustaceans)	44(1.7%)

Of the total 76,623 meals prescribed by physicians in July 2017 before the introduction of the program, 34 (0.04%) were allergic. It was analyzed that 2,303 (3%) out of 76,623 of the total meal prescriptions were provided to the patients, and 98.5% of the allergic diets provided through the intervention of nurses and food and nutrition. After the introduction of the program, the physician's diet was revised to be linked to the actual meals provided. In July 2018, the total number of allergic prescriptions and recipes out of 80,766 prescribed by physicians was 2,784, or 3.4%.

Discussion

The purpose of this study is to evaluate the utility of food allergy program based on the process to improve the information sharing system of food allergy patients.

Through the reflection of the computerized system and the data analysis, we obatained the following positive evaluation.

1) The proportion of patients enrolled in a specific period of time with food allergy is 5%, which is similar to that reported in adults with a prevalence of approximately 3-4% [5].

2) By categorizing the items subject to food allergies, it is possible to provide more systematic food allergy meals.

3) Prior to this program, there was no program to share the fact that all hospital staffs such as medical staff and nutritionist were food allergy patients. It is possible to share food allergy patient information through [Alert] 'Food Allergy' as an effective opportunity to treat patients.

4) The number of allergies provided after the introduction of this program was about 3% and 3.4%, respectively, compared to the one month before and after the introduction. However, the rate of providing food allergy was 0.04% and 3.4%. This means that doctors, nurses, and nutritionists are able to manage food allergy patients in an integrated manner through the introduction of computerized programs.

Conclusions

In conclusion, the development and introduction of the program allowed all hospital staffs, including medical staff and dieticians, to share information on food allergy patients, and managed the food allergy patients in an integrated manner to lay the groundwork for a safe meal recipe.

Acknowledgements

The author thanks for the development of the program based on this study, the allergy medicine, the food and nutrition department, the nursing headquarters, and the QA team are united and the improvement plan is derived. In addition, I would like to thank the team members / developers who helped me to develop the Food Allergy Program.

Alicanto Online Latin American Maternal Informatics Community of Practice

Juan Henao[a], Yuri Quintana[a,b], Charles Safran[a,b]

[a] *Division of Clinical Informatics, Beth Israel Deaconess Medical Center, Boston, MA, USA*
[b] *Harvard Medical School, Boston, MA, USA*

Abstract

Most cases of maternal deaths could be avoided with timely access to quality healthcare, but a key challenge in addressing quality of care in maternal health is the lack of accurate data and analytics. Implementing online communities of practice is a way to resolve this, but in low--and middle-income countries this is particularly challenging. We discuss the design of the Alicanto Online Latin-American Community of Practice that focuses on both outcomes and process indicators.

Keywords:

Information Technology, Pregnancy, Quality Improvement

Introduction

The health of pregnant women is critical for global development. The Sustainable Development Goals (SDG) agenda and the Global Strategy for Women's, Children's, and Adolescent's Health 2016–2030 aim to reduce maternal and newborn deaths [1]. Most cases of maternal deaths could be avoided with timely access to quality healthcare, but a key challenge in addressing quality of care in maternal health is the lack of accurate data. Accurate data improves our knowledge of whether the effective interventions are being received by pregnant and post-partum women and enables the targeting of resources to those most in need. However, diverse outcomes of interest, variable standards of care, quantity and quality of data can be drastically different, as well as cultural and other differences; can substantially modify measurements depending on the outcomes of interest studied.

To improve maternal outcomes in Latin America (LA), we are implementing an online community of practice that can deliver evidence-based guidelines and collect priority indicators, while providing spaced learning medical education and guidance for the measurement and monitoring of maternal and health. This paper describes the challenges in maternal data collection in low- and middle-income countries, and the design of the Alicanto Online Latin-American Maternal Informatics Community of Practice.

Challenges in Global Maternal Outcome Networks

In many low-income countries, maternal deaths go uncounted and frequently the cause of death is unknown or not recorded correctly and the maternal care process is equally poorly registered or not registered at all [2]. Many patient registration systems and electronic health records in low resource settings have problems with non-standardized record-keeping techniques which result in missing records, inconsistencies, poor data quality, and inaccuracies and hence undermine evidence-based decision making in healthcare service delivery [3]. This makes it difficult for national health programs to allocate resources where they are needed the most. To achieve this goal is necessary the integration and harmonization of high amounts of heterogeneous medical data that is stored in different health information systems. Such a task is challenging in both developed and developing countries [4]. Comprehensive database applications for a domain can reduce such variation within this domain. The Netherlands established national domain information models to support electronic information exchange, using cases from perinatology as a national pilot [5]. They found that in some instances, additional agreements are necessary about the preferred vocabulary because the professional organizations need to harmonize their materials and the limitations are reached for what should be part of the standard, and what professional organizations should develop and maintain within their realm. Another challenge is data aggregation and overlap. For maternal care, clinical data is often generated from various sources (prenatal screenings, primary care providers, midwives) and the health information may exist in both paper-based and computer-based systems at institutions located in different geographical locations. The overlap across systems introduces the potential for data variation through duplication of data entry and differing concept definition or context of use. Studies show that redundant and inconsistent records lead to errors, extra effort, misdirected data, over-reliance on the spoken word, inaccuracies, information loss, limited standardization, miscommunications and limited outcomes evaluations being a major cause of medical incidents [6]. Research has also shown how coordination and communication among clinicians and across settings resulted in greater efficiency and better clinical outcomes [7]. In general, the burden on individual providers of collecting data has been well documented, as has the lack of use of data collected at such great cost [8], which breaks the feedback mechanism whereby monitoring and review can result in improved delivery of interventions.

Alicanto Network Objectives and Approach

The network objectives are to strengthen and enhance the existing national data systems and evaluation programs through information and communications technology (ICT). The project builds on existing regional communities of practice in maternal health, in which we will leverage technical expertise across LA to foster the exchange of lessons learned, building a sustainable and reproducible capacity of Human Resources for Health (HRH). These HRH can provide high-quality maternal care interventions for developing countries, particularly for hard-to-reach populations and vulnerable groups, maximizing the use of resources and guiding policymaking, in an attainable, informed and sustainable manner. At this point, the stakeholders of the network include hospitals and regional governments, member clinics at Argentina, Chile and Colombia

and the Division of Clinical Informatics (DCI) at Harvard Medical School (HMS), which has previously signed a framework agreement with PAHO to collaborate in supporting the advancement of eHealth in Latin America and the Caribbean. The network members are involved in co-creating the system and educational content for management of high-risk pregnancies relevant to their needs and agreeing on data encoding standards. The initial courses focus on pre- eclampsia and hemorrhage, which are the causes of most maternal deaths. This co-creation uses S.M.A.R.T goals and Bloom's Taxonomy [9] and is being done via weekly web conference meetings, sharing data dictionaries and database designs to achieve consensus on common data formats for outcomes comparison and establishing methods to capture process metrics.

Strategies aimed at reducing maternal deaths need to address inequities in access to good quality maternal health interventions, which are based on learning and applying best medical practices protocols, step-by-step labor, delivery and immediate postpartum period management guidelines. We will deliver those using web-based and mobile app tools (eLearning, mhealth) inside Alicanto Integrated Mobile Health Network, but also the platform provides an online consultation system (telehealth) for obstetric emergencies between rural HRH and experts at reference hospitals, allowing for appropriate, coordinated and timely patient referral to a higher level of care if needed. Participating centers will also have access to an asynchronous discussion forum to discuss with colleagues the guidelines and lessons learned from the cases; using validated, structured, and process-focused frameworks to reflect and learn from experiences, given the fact that it has been showed that medical knowledge, job satisfaction, and self-efficacy do not increase by only using an SMS-based continuing medical education (CME) intervention that fails to stimulate lateral learning i.e. learning from your peers [30]. Since processes variables are included in our design, these can be used in a feedback mechanism to identify areas for improvement and allocating resources in areas likely to have the greatest impact.

The first pilot is being conducted between Fundación Valle del Lili, a major teaching hospital in Cali, Southwest Colombia and a small rural clinic in the West Coast Pacific region. Despite recent efforts in Colombia to improve the number of health professionals in rural locations and implement a red code for postpartum hemorrhage in accordance with international standard obstetric protocols, Maternal mortality ratio (MMR) remains high and lags behind Latin American countries at a similar level of economic development (e.g., Mexico and Argentina). The isolated and discontinuous Colombian Pacific coastal lowlands have a majority of population with a uniquely African genetic heritage (90%) but there are also populations of mixed race (6%) and Native Americans (4%). This region has an MMR similar to 2010 African countries, like Ethiopia, Ghana, and Ruanda, or similar to Haiti, the country with the highest MMR in Latin America and the Caribbean [10]. The Alicanto platform will provide a scalable mobile solution to support rural clinics across Colombia with expansion to other Latin American centers. The second pilot is scheduled for Southern Chile and third pilot in northern Argentina, both in locations where experts are far away from major teaching hospitals.

Conclusion

By having co-creation of the network, we are achieving a standardized set of common goals and data metrics that can be useful at the local level while being also useful at a regional level for data comparing. By having harmonized sets of data and tools, according to site characteristics ranging from minimal to optimal infrastructure and clinical conditions, it will be possible to compare outcomes across similar centers. This will help to create a policy development platform that introduces a systematic approach to policymaking informed by evidence and collaboration between institutions and nations. The indicators and methodology can be reused by projects that map to the same core dataset and will be available in an online public repository and a community of practice will support the use and adaptation of the tools in the repository.

Open and Linkable Knowledge About Management of Health Information Systems

Konrad Höffner[a], Franziska Jahn[a], Anna Lörke[a], Thomas Pause[a], Birgit Schneider[a], Elske Ammenwerth[b], Alfred Winter[a]

Abstract

Given a care delivery organization, its health information system can be defined as the part of the organization that processes and stores data, information, and knowledge. There is an enormous number of frameworks, textbooks and articles that describe the scope of health information system management from the perspective of medical informatics. Transforming this knowledge to Linked Open Data results in a structured data representation that is accessible for both humans and machines, the Semantic Network of Information Management in Hospitals (SNIK). We present interfaces that are useful for researchers, practitioners and students, depending on their objectives and their Semantic Web skills.

Keywords:

Semantic Web, Information Management, Health Information Systems

Introduction

Given a care delivery organization, its health information system (HIS) can be defined as the part of the organization that processes and stores data, information, and knowledge. It usually consists of a large number of different application systems, computers, and network components (Winter et al. 2011). Managing an HIS comprises planning, monitoring and directing activities. Due to the complexity and the unique conditions in health care, HIS management is an exceptionally challenging task. There is an enormous number of frameworks, textbooks and articles describing the scope of HIS management from the perspective of medical informatics. However, the disciplines of business informatics and information systems (IS) provide an even broader view on information systems and their management. A holistic view on HIS management comprises knowledge from different scientific disciplines and requires well-defined links between these different worlds. These links help researchers and students connect their existing knowledge with further knowledge from other sources during research and learning.

In order to integrate different knowledge sources and to provide the knowledge in a structured, machine-readable data format, we extracted knowledge about HIS management from three textbooks and other sources (see Table 1) and converted it to RDF [4]. The combination of this knowledge results in SNIK, the Semantic Network of Information Management in Hospitals ("Krankenhaus" in German), which is freely and openly accessible by open tools. In order to encourage and enable other researchers, students and health informatics professionals to use available knowledge of HIS management, we interlink classes from different sources, and present and compare the interfaces of SNIK for different target audiences.

Methods and Materials

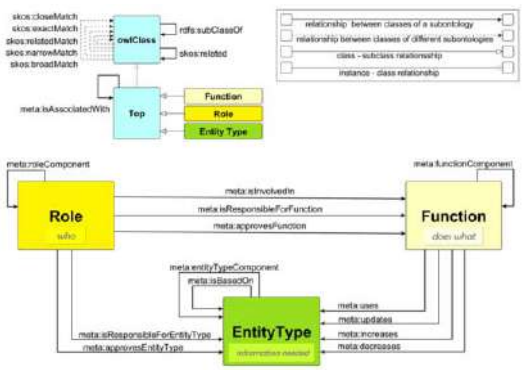

Figure 1—The SNIK Meta Model

SNIK is modelled as a modular (see Table 1) OWL 2 DL ontology. The Meta Model is the central module and provides a common vocabulary for the domain of HIS management (see Figure 1). It contains classes (rectangles in Figure 1), which represent concepts of HIS management and relations (the labelled edges in Figure 1), which represent possible interactions between them. For example, a role and a function can be connected by "is involved in", "is responsible for" or "approves". The Meta Model is extended by five subontologies (see Table 1). At the head of the class hierarchy is the "Top" class, which has exactly three disjunctive subclasses. Following the Meta Model, each class has to be a subclass of exactly one of them. The superclass of a new concept can be found by answering the question: "Who ("Role") does what ("Function") and which information ("EntityType") is needed to perform this function?"

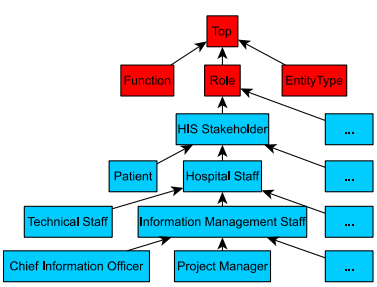

Figure 2—Excerpt from subclass hierarchy of the Meta Model and the subontology

Results

SNIK v0.8 contains 4729 classes, 329 properties, 713 interlinks and 112747 triples and is available under the CC BY-NC-SA 4.0, using open standards over interfaces with different compromises between expressivity and accessibility.

RDF Dump

In line with the *Linked Data* principles [2], we assign a unique URI to each class and follow the specifications of the Resource Description Framework (RDF), which states how facts about concepts can be modeled as *triples*. Each triple contains a subject, property and an object. There are multiple RDF serializations, such as Turtle [3], which allow abbreviating URIs using prefixes, see Table 1. SNIK is available as Turtle files at http://www.snik.eu/download/snik-0.8.zip.

RDF Browser

Users can look up a resource using the HTTP protocol to receive a description of the class, using the standards RDF and SPARQL. The LodLive RDF browser at http://www.snik.eu/ontology offers a human-readable description. Triples between URIs can be followed so that new information can be discovered.

SPARQL

The SPARQL Protocol and RDF Query Language (SPARQL) [3] allows us to manipulate and query SNIK as RDF. We offer free read access to the SPARQL endpoint (query service) at http://www.snik.eu/sparql both for manual queries and as an API. The SNIK project uses the endpoint as an API in several applications, both custom made, such as SNIK Graph (see Figure 3), and adapted software, such as the RDF browser and the OntoWiki ontology editor, see [4]. The endpoint presents the most expressive interface but requires knowledge of both the SPARQL syntax and the SNIK Meta Model.

Table 1—Modules of SNIK

Ontology	Prefix	Source
http://www.snik.eu/ontology/meta	meta	All Sources
http://www.snik.eu/ontology/bb	Bb	Textbook
http://www.snik.eu/ontology/ciox	ciox	CIO Interview
http://www.snik.eu/ontology/ob	Ob	Textbook
http://www.snik.eu/ontology/he	He	Textbook
http://www.snik.eu/ontology/it4it	It4it	Standard

SNIK Graph

SNIK Graph, available at http://www.snik.eu/graph, visualizes the structure of SNIK by modelling each class as a node and each RDF triple and OWL restriction as an edge.

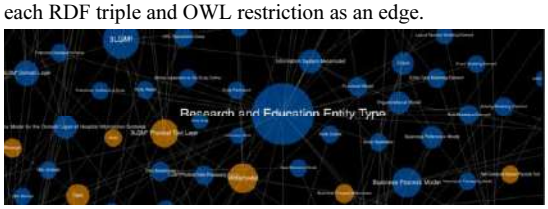

Figure 3—The SNIK Graph Visualization

Interlinks

As an open, linkable ontology, SNIK can be connected to other ontologies, especially in the field of Medical Informatics. Some concept pairs are homonyms: they have the same label but differ in meaning. For example, bb:InformationManagement has the same label as dbr:Information_management, but the definition of information management differs. There should thus be no interlink between homonyms. On the other hand, dbr:Picture_archiving_and_communication_system and bb:PictureArchivingAndCommunicationSystem have a very similar meaning, so that an interlink is generated. Label-based interlinks are generated using LIMES in previous work [4].

Discussion

SNIK is based on the Meta Model from Figure 3. It can be considered an archetype for ontologies describing a given domain (here "HIS management"), which functions in a certain role to be carried out, with information a person with this role needs and provides while carrying out those functions. This is valuable knowledge, for instance as a basis for systems analysis projects [1]. Different user groups can use the interfaces of SNIK that are most suitable to them: Semantic Web experts can use the RDF dump and the SPARQL endpoint to integrate applications with the SNIK ontology. They can also use SNIK as a vocabulary to integrate data from different formats that result from applications from different vendors. Those experts can also use the SPARQL query editor directly to answer specific questions. Students and teachers use the RDF browser and SNIK Graph, which intuitively presents knowledge without requiring knowledge of the query language and the Meta Model.

Conclusions

We publicize knowledge on the management of information systems in medicine and health care using open standards over interfaces with different compromises between expressivity and accessibility. It can be combined with other knowledge in biomedical and health informatics and in other disciplines.

Healthcare Professionals' Expectations of a Diabetes Care Performance Management System

Iiris Hörhammer[a], Juulia Jäppinen[a], Miika Linna[a]

[a] *The Institute of Healthcare Engineering, Management and Architecture, Department of Industrial Engineering and Management Aalto University, Espoo, Finland*

Abstract

The objective of this survey study was to identify health professionals' attitudes towards performance evaluation and their expectations of a diabetes care performance monitoring system. On average, the professionals supported the implementation of the system, and were interested in using cost-effectiveness information. Usability and willingness to compare performance results between units were most strongly associated with support. Clinicians' involvement in developing and using performance monitoring systems is encouraged.

Keywords:

Diabetes care, Healthcare professionals attitudes, Monitoring systems

Introduction

Performance monitoring systems can provide important information on the quality, effectiveness and cost-effectiveness of care. Observed deficiencies in practices require changes at managerial and clinician levels of the organization. In implementing new organization and management innovations, the role of the personnel at the clinical and operational level has, indeed, been found even more important than that of managers [1]. Despite healthcare professionals' crucial role in operational change and therefore as users of performance information, there is limited knowledge on how performance monitoring systems are accepted and used by this group. This study uses the extant literature on technology acceptance to shed light on what affects the healthcare professionals' acceptance of, and therefore intention to use a performance monitoring system in a pre-implementation phase.

In line with Davis' Technology Acceptance Model [2], Gagnon et al. [3] literature review found that the perceived benefits of the technology (*usefulness*) are the most common facilitating factor of ICT adoption among health care professionals, followed by *ease of use*. Professionals' perception of system usefulness is related to whether they find the information contained by the system interesting and whether they find their role in using this information as a developer as important. Therefore, professionals' *interest towards cost-effectiveness* information and perception of the importance of their *role in developing* care practices may affect their support for a performance monitoring system.

Healthcare professionals' typically work under tight schedules and therefore *time constraints and work load* related to the use of the new technology is a notable barrier to technology acceptance [3,4]. In the implementation phase, *sufficient resources* offered by the management and *support in the use of the new system*, especially in terms of a *super-user* in the clinical unit, contribute to the success [3].

In this survey study, we tested whether diabetes care professionals' interest towards and perceived role in performance management, their expectations of the performance management system, and perceptions of resource availability are associated with their support for the new reporting system.

Methods

Data

The study was conducted in a Finnish social and health care district serving a population of 170 000people. We conducted a web-survey to all potential future users of the system, that is, the health professionals treating patients with diabetes in the district, and their supervisors, altogether 170 professionals.

The questionnaire included questions on the present diabetes care practices in the region, care quality and cost-effectiveness improvement, and the implementation of the new monitoring system. Most of these questions were statements with a five-point Likert scale.

The invitation letter included a description of the new performance management system. The monitoring system allows evaluation of the quality of diabetes care, and the follow-up of the health outcomes, diabetes-related treatments and contacts of the entire diabetic patient population in the region. The system will be developed to also provide information on the association of cost and effectiveness of diabetes care (cost-effectiveness).

Analysis

Statistical analysis was performed with descriptive and linear regression analyses to assess different factors association with professionals' support for the monitoring system to be implemented.

In the linear regression analyses, professionals' support for the system was used as the dependent variable (DV). Professionals' perception of their role in quality improvement, interest in cost-effectiveness information, willingness to benchmark results with other units, expected usefulness, usability and willingness to develop the new system, time available for quality improvement at present, expected support from an expert user and having used and having tested the system were used as independent variables (IV). We first tested the associations of the IVs with the DV separately using univariate regression. Secondly, to test the relative contribution of each of the IVs to the total variance of DV explained, we used multiple regression analysis. Predictors that were significant in univariate regression were included

in the multiple regression analysis. All statistical analyses were performed using Stata version 15.0 (StataCorp LP, College Station, TX, USA).

Results

Responses from 86 professionals (response rate =51%) were received. Majority of the respondents were doctors (44%) and nurses (29%) who treat patients with diabetes, and a minority were doctors' (10%) and nurses' (10%) supervisors. Majority of the respondents work in primary care (70%). Little over half (53%) of the respondents had heard about the new system to be implemented and only 7% had tried the demo version. Respondents' support for the system was rather high and 92% reported that they are interested in the cost of care and the association between cost and health outcomes. Only 29% expected that it would be easy for them to use the system (Usability). At present, the respondents did not agree to have enough time for quality monitoring and 41% expect that there will not be enough resources for the implementation of the new system (see Table 1).

Table 1. Descriptive Information (n=86)

Characteristic or Factor		
Profession, N(%)		
	Doctor	38 (44%)
	Nurse	25 (29%)
	Doctors' supervisor	9 (10%)
	Nurses' supervisor	10 (12%)
	NA	4 (5%)
Support, Mean (SD)		4.4 (0.73)
Perceived role, Mean (SD)		4.0 (1.13)
Interest in cost-effectiveness, Mean (SD)		4.6 (0.70)
Willingness to benchmark, Mean (SD)		4.1 (0.95)
Expected usefulness, Mean (SD)		4.1 (0.74)
Expected usability, Mean (SD)		3.3 (0.98)
Willingness to develop, Mean (SD)		3.7 (0.96)
Available time, Mean (SD)		2.3 (1.09)
Expected resources, Mean (SD)		2.8 (1.03)
Expected support from expert user, Mean (SD)		3.7 (0.98)

To assess which factors would best predict support, we fitted a multiple regression model with support as the DV (see Table 2). In model A, all variables with significant association in the univariate regression were included as IVs. Available time and expected resources had not been associated with support in univariate analysis and were thus left out from this model. The results showed that only willingness to benchmark, expected usefulness and expected usability have significant association in the multiple regression. Model B shows that these variables alone explain 65% of the variation in the DV. The magnitude of the positive effect on support is moderate for expected usefulness and willingness to benchmark. In the multiple regression analysis, the association of expected usability with support changed signs.

Table 2. Multiple Linear Regression Analysis for System Support

	Model A	Model B
Independent variables		
Perceived role	-0.02 (0.10)	
Interest in cost-effectiveness	-0.02 (0.11)	
Willingness to benchmark	0.26 (0.08)**	0.29 (0.07)***
Expected usefulness	0.52 (0.09)***	0.50 (0.06)***
Expected usability	-0.14 (0.06)*	-0.13 (0.06)*
Willingness to develop	-0.01 (0.09)	
Expected support from expert user	0.05 (0.08)	
Has heard of the system	0.03 (0.13)	
R^2	0.68	0.65

Conclusions

In this survey study, we identified health professionals' attitudes towards performance evaluation and their expectations of a diabetes care performance monitoring system. The findings are representative of the diabetes care professionals in a Finnish integrated health and social care district. We found that clinicians who treat patients are interested in using performance management systems with information on cost-effectiveness at population level. Usefulness of the system is the most important aspect in professionals' support for a performance monitoring system. To encourage professionals' support towards performance monitoring, information provided by the systems should be used for constructive benchmarking.

Acknowledgements

This study is a part of the Service Solutions to Support Social Welfare and Health Care Reform (IMPRO) project funded by the Academy of Finland. The authors also thank Siun site personnel for their efforts in performing the survey in the district.

Can Solo Practitioners Survive in Value-Based Healthcare? Validating a Predicative Model for ED Utilization

Pamella Howell[a], Peter L. Elkin[a]

[a] *Department of Biomedical Informatics, State University of New York at Buffalo, Buffalo, New York, United States,*

Abstract

The health industry will see increased implementations of value-based models. This study validates a predictive model for determining emergency room utilization. Data from 2991 records are used for the analysis. To validate the model we used Poisson and random forest models. The results indicate that patients with one of six chronic conditions, who missed scheduled appointments or had higher body mass indexes were more likely to utilize the emergency department.

Keywords:

Value-based Healthcare; Machine Learning; Resource Allocation

Introduction

The value-based healthcare model is poised to change the practice of medicine in the United States. Value-based care addresses two concerns: are the available resources distributed to those who need it and how clinicians use the resources optimally [1]. Participating insurers and providers have aligned valued based programs with broader strategic objectives on quality. Value-based care serves three primary functions to reduce cost, improve outcomes and improve quality. As participation expands, patients, payers, and providers will experience a wide range of changes due to its effect. The most significant impact for patients is the improvement in the quality of care and outcomes. Both public and private sector insurers will benefit from any reductions in the cost of care. Insurers are yet to propose methods for decreasing premiums, which is a salient topic; however, it is beyond the scope of this study.

Clinicians serve dual roles in the value-based model. Firstly, they are primarily responsible for improving the quality of care and outcomes of patients. Secondly, they must assist payors by lowering the cost to care for patients. This study aims to provide a predictive model for identifying patients associated with high cost. Using the Health Cost Guidelines (HCG) as a reference, we have identified five categories of cost that a physician may need to reduce, including inpatient, outpatient, prescription drugs, physician, and other. Historical estimates show that inpatient, outpatient and pharmacy cost are highest representing 62 % of the national expenditure for 2016 [2]. The emphasis here will be outpatient cost specifically those incurred in the emergency department. Approximately 3.3% of all emergency department (ED) visits are avoidable [3]; however, statistics also show increased utilization for the treatment of chronic diseases [4].

How does the clinician identify patients who are likely to incur high ED cost? Can the factors that cause high ED usage be eliminated? In answering these question, we attempt to address two of many challenges. One, individuals might argue that the insurers will provide the information needed to monitor cost. The information provided by insurers is generally delayed due to claims processing; this significant time lag reduces a provider's ability to act. Delayed responses when attempting to improve patient adherence can have a negative impact. In this research, we utilize secondary data from the electronic health record (EHR) to reduce data lags and the resource intensity associated with value-based analytics.

The second challenge is that providers need technology and analytics infrastructure to explore cost. Though organizations like hospitals and large health systems have met some of these requirements, the outlay of capital has been significant. For solo and medium-size practices, the ability to participate effectively in the value-based ecosystem will be limited by finite human and financial resources. Clinicians need resources to implement value-based programs such as advanced analytic platforms. Given the current interoperability issues between EHRs and the limited efforts by some vendors to provide analytics support providers must find a way to supplement the need for these services. By implementing our proposed model physicians can reallocate current health information technology resources including team members without significant expenditure.

Methods

Using predictive analytics and machine learning models, we validate a model for predicting patient utilization of the outpatient services. To evaluate the research objective, we utilize a two-stage combination model. The first stage uses the outcomes of a model developed with regression-based machine learning techniques and standardized statistical techniques [5]. The second stage also used standardized regression techniques in the form a Poisson regression and a classification machine learning technique in the form of a random forest model. The feedback loop uses data from the EHR to create a predictive model, then in this study we validate the model using a new patient cohort covering a different period and with more observations. The dataset contains a total of 2991 records with six de-identified variables collected between 2017 and 2018.

Variable Selection and Description

The model variables include age, a polynomial age variable, body mass index (BMI), depression screen indicator, number of no-show appointments, gender and a chronic disease indicator – diabetes, heart failure, COPD, Hypertension, Hyperlipidemia and asthma. The variables can be subdivided into process variables including no-show visits and depression screens indicator and clinical outcomes such as chronic conditions and BMI. All the variables were established as significant in a prior study. The dependent variable is emergency department visits.

Statistical Methodology

We use two approaches to analyzing the dependent variable. For one method the dependent variable is a count of the discrete non-negative integer ED visits. The Poisson or negative binomial regression models are typically the first recommended

models. For the second method we dichotomize the count variable and use the random forest for the following benefits: it gives estimates of what variables are important, offers a technique for detecting variable interactions and has methods for balancing error in unbalanced datasets. Classification and Regression Trees (CART) like random forest are powerful predictive tools, they allow for the combining of predictors [6] [7]. The random forest model generates many CART models in which it chooses that model classification with the most votes.

Results

Using SAS 9.4 and R, we validate the model using Poisson and random forest models. We analyzed the response variable first as a count, then as a dichotomous indicator for the random forest model. We examine the association of ED count with age, gender, no show visits, depression screening, six chronic diseases, and body mass index. The model results suggest that four variables have a significant impact on the frequency of emergency room visits at $p < 0.05$.

The relationship between the response variable and age is convex when compared to the previous study; this likely due to the increased distribution of age. For a given level of all x variables, the expected number of emergency visits will decrease by a factor of exp(-0.055)=0.946 to its lowest, at this point the expected number of emergency department (ED) visits would increase by a factor of exp(0.004)=1.004. The number of ED visits for patients one of 6 chronic diseases is exp(1.362) = 3.90 times more than patients without one of the chronic diseases. No-show visits positively impact the expected number of ER visits for patients by a factor of exp(0.351)=1.420. Body mass index positively impacts the expected number of ER visits for patients by a factor of exp(0.099)=1.104. In this cohort, depression screen indicator and gender did not impact the utilization of the ED.

The preliminary model validation results using random forest, show that the area under the curve (AUC) 0.825 indication good discrimination. The accuracy of the test model is 0.983, sensitivity - 0.884 and specificity - 0.996. The variable importance results showed that the chronic disease indicator held the highest rank followed by no-show visits, BMI, gender, depression, and age.

Discussion

The movement of medical practice away from fee for service toward a value-based system will take time. Insurers have not changed their current products instead — for example, the Center for Medicare and Medicaid Services (CMS) as piloted some value-based programs for diseases such as end-stage renal disease. Private insurers have taken a different approach by contracting with health care providers to implement value-based services for population subsets. Solo and medium-sized practices will face many challenges when making decisions on how best to utilize limited human and financial resources to meet value-based objectives. Physicians who intend to benefit from participating in value-based quality initiatives must leverage their limited resources by using predictive modeling to define parameters that enable the reduction of patient cost like emergency rooms utilization.

The regression model indicates that chronic diseases indicator, no-show visits, BMI, and age can be used to predict the count of ED visits. By combining these finding with the CART prioritization estimates, we can provide suggestions for physicians on how to allocate resources. We suggest creating electronic patient registries that capture parameters outlined in the model. Providers should limit registries to patients with the six diseases indicated in the model due to the higher likelihood of predicting ED use. With a focus on a subset of the population, the practice can assign specific team members to work with the registry. The random forest importance also indicated that physicians should monitor patients with high no-show rates and body mass index this can also be achieved with a registry in the electronic health record. An automated alert and calling feature is available on most EHR; this feature permits the increases monitoring of patients who no-show with little human intervention. Clinical decision support systems parameters can be developed to encompass all the predicated variables for assisting physicians on which patients to counsel for increased risk of ED use. Otherwise, patients who do not meet these criteria should be monitored lightly freeing up human and technological resources.

Conclusions

Utilizing minimal data from the electronic medical record physicians can use existing resources to meet cost related value-based metrics. This method ensures that providers can implement the model by merely using registries in the EHR. Partnering with the insurer and utilizing our predictive model will delay a significant outlay of capital for specialized analytic technology and team members. To better understand the research question, future research will use additional machine learning techniques to improve the prediction capability of the model.

Electronic Progress Note Reading Patterns: An Eye Tracking Analysis

Gretchen M. Hultman[a], Jenna L. Marquard[b], Swaminathan Kandaswamy[b], Elizabeth A. Lindemann[c], Serguei Pakhomov[a,d], Genevieve B. Melton[a,c]

Abstract

This study used eye-tracking to understand how the order of note sections influences the way physicians read electronic progress notes. Participants (n=7) wore an eye-tracking device while reviewing progress notes for four patient cases and then provided a verbal summary. We reviewed and analyzed verbal summaries and eye tracking recordings. Wide variation in reading behaviors existed. There was no relationship between time spent reading a section and section origin of verbal summaries.

Keywords:
Electronic health records, health communication

Introduction

The process of reviewing electronic progress notes is important for patient care but can be complex due to several factors. Practices by clinicians such as copy-paste and auto-population of structured data (e.g., medications, allergies, problem list), often result in clinical notes that are difficult to read with large amounts of redundant information. Moreover, users often use customized note templates resulting in inconsistent note formatting [1-3]. This points to a need to improve the experience of clinicians in reviewing progress notes.

Previous studies have shown that clinicians find the Assessment and Plan sections of progress notes to be the most important. However, this section traditionally appears later in the notes and clinicians need to scroll or click through lengthy supporting (often irrelevant) data to get to this section [1]. As a result, some have suggested that the top sections of progress notes should include Assessment and Plan sections [3,4], which would simplify the process of information retrieval in electronic progress notes [1,5]. Some clinicians are currently writing notes in this order.

Objective

The purpose of this study was to use eye-tracking to understand how progress note section order influences the way clinicians read electronic progress notes.

Methods

We conducted this IRB-approved study at the University of Minnesota. An Electronic Health Record (EHR) system prototype designed to mimic CPRS/VistA was populated with four de-identified patient cases [6]. Each case contained nine notes documenting visits to primary care physicians and various specialists. To test the impact of section order on note reading patterns, each patient case used a different section order within the notes. The four section orders were: SOAP (Subjective, Objective, Assessment and Plan), APSO (Assessment and Plan, Subjective, Objective), SAPO (Subjective, Assessment and Plan, Objective) and Mixed (the section orders were inconsistent across the nine notes in the case, with three notes of each order). Participants wore an eye-tracking device (Applied Science Laboratory; Bedford, MA) during the experiment and a screen capture software was used. Participants sat at a desktop computer with the EHR opened to the notes section of the first patient case. They were asked to review the notes for that patient as they normally would, and then give a brief verbal summary of the case. Participants repeated this process for the remaining three patient cases.

Visual Attention Analysis

We calculated three metrics for each patient case related to how they read the electronic progress notes: 1. the amount of time into the patient case when participants first glanced at each section (time to first fixation); 2. the total amount of time participants spent looking at each section over the course of the patient case (duration of glances); and 3. the total number of times participants looked at each section over the course of the patient case (number of glances). To determine whether there were significant differences in these measures across section orders, we used a mixed effects model to account for the repeated measures design of this experiment.

Verbal Summary Analysis

Verbal summaries were transcribed and parsed into discrete statements; an approach used in a previous study [7]. Each statement was mapped to note section(s) with that information. If a statement was found in more than one section, it mapped to all sections. A clinician with experience in qualitative analysis provided guidance and feedback on the coding process.

Results

Visual Attention

Glance Duration and Frequency

There was high variability across participants, sections, and patient cases. Within a single patient case, the number of glances at a specific section ranged from 1-86 separate glances, and the total duration of the glances at a specific section ranged from 1-356 seconds. The variability in total durations of glances

appeared to be lowest for SOAP ordered notes, and highest for the Mixed section ordering. The mixed order trials had especially high variation in numbers and durations of glances with respect to the subjective and objective sections.

Time to First Fixation

Time to first fixation (TFF) measures the first time an individual looked at a specific section in a note. We calculated two measures with regard to TFF: the actual time the participants first looked at that section, and the first time they looked at that section for longer than one second. While there was wide variability in TFF, participants seem to have glanced at the Subjective and Objective sections earlier, regardless of the note section order. It also appears that, for APSO section orders, participants were more likely to start reading the sections immediately or shortly after first looking at them.

Verbal summary Analysis

Figure 1 compares the average total duration of the glances at a specific section to the average number of verbal statements that correspond to that section. The section character count is represented by the size of the mark. Circles are drawn around data points corresponding to each information type. The subjective section does not have a circle around the data points due to the large variability in these data points. Although the Objective section had relatively higher character counts, relatively fewer verbal statements referred to information from this section. Regardless of the time spent looking at the Assessment section, relatively more verbal statements referred to information from this section. The highest variability was observed for the Subjective section, where there were inconsistent patterns related to the duration of glances and number of statements referring to information in that section.

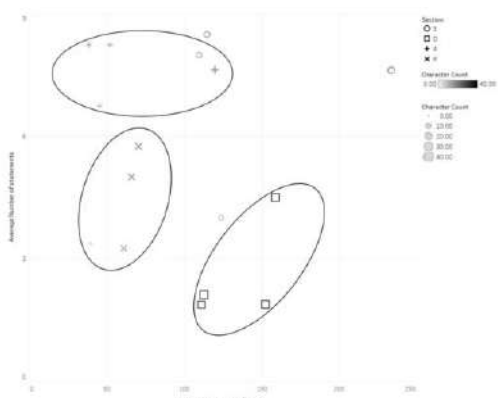

Figure 1-Verbal summary analysis

Conclusions

This study used eye tracking methodology to examine the influence of section order on clinician note reading patterns. Our study revealed several key insights about note reading patterns including high variability in reading patterns. Limitations of this study include having a small sample size and only including resident physicians. Future work should expand on the current study and examine the role of training, experience, and speciality in reading patterns. Work should also focus on identifying strategies to standardize note structure and present clinicians with the most relevant information in a way that is easy to locate.

Realizing the Benefits of Managing Health Appointments via Mobile Application: Start of the Journey

Veronica Hung[a], Vicky Fung[a], Erica Lau[a], Stephen Lau[b], Dick Lam[b], Mavis Pow[a]

[a] *Health Informatics Section, Hospital Authority, Hong Kong Special Administrative Region*
[b] *Information Technology Department, Hospital Authority, Hong Kong Special Administrative Region*

Abstract

The Hospital Authority of Hong Kong ("HA") launched an interactive mobile application "BookHA" intending to use innovative technology to support healthcare delivery. "BookHA" provides an 'easy and convenient' alternative for patients to book specialist clinics along with the current methods – in-person or via fascmile. Patients, clinical staff, and the corporates benefit from this initiative as evidenced by the utilization figures, and the findings from patients surveys and staff surveys.

Keywords:

Ambulatory Care, Appointments, Mobile Applications.

Introduction

Hospital Authority (HA) is responsible for managing Hong Kong's public hospitals' services including 43 hospitals and institutions, 48 specialist out-patient clinics (SOPCs), and 74 general out-patient clinics. The hospitals, institutions, and clinics are organized into seven hospital clusters based on locations.

SOPC clinics serve more than 7 million attendances per year, of which around 10% of them were new cases. In 2015, a comprehensive review of the HA operation was conducted. The review recommended providing an alternative and more convenient means to empower patients to book SOPC new case appointments.

"BookHA" is the first interactive mobile application launched by HA for patients to request new SOPC appointments with smartphones. Users and patients can download the application from the Apple App Store or Google Play for free and is available in traditional Chinese and English languages, which are the official languages in Hong Kong.

"BookHA" empowered patients to manage their care process and enjoy the privileges of (i) submitting appointment requests anytime and anywhere, (ii) completing the booking request easily with three simple steps in a few minutes instead of going to the clinic in person or doing via fascimile, (iii) being notified of the appointment date via Short Message Service (SMS).

After the pilot launch of "BookHA" at Gynecology clinics in March 2016, HA rolled out the application to 10 specialties within two years (see Table 1). In parallel to the rollout, the agile development cycle of "BookHA" continued. HA upgraded "BookHA" with advanced features to enhance user experience including (i) appointments cancelation which is no longer be required, e.g., patients sought care from private doctors, (ii) "appointment reminders" that patients receive before their appointment dates, and (iii) notification if patients or providers reschedule the appointments.

Table 1 – Implementation Schedule of "BookHA" at Speicalist Out-patient Clinics

Specialtist Out-patient clinic	Rollout date
Gyneacology	March 2016
Ear, nose & throat	September 2016
Eye	September 2016
Neurosurgery	September 2016
Orthopaedics & traumatology	September 2016
Cardiothoracic surgery	March 2017
Medicine	March 2017
Surgery	March 2017
Obstetics	January 2018
Paediatric	January 2018

Mobile apps for booking health appointments are not rare. However, a large scale implementation with a usability survey in public settings with long term result would be valuable.

Methods

To identify the usability of "BookHA", we reviewed utilization figures. We conducted patients survey and staff survey to determine if the application requires any improvement.

Review on Utilization Figures

Leveraging on the utilization of "BookHA", the following figures were retrieved for analysis from the launch of "BookHA" till the end of 2017.

1. The number "BookHA" downloads
2. The number of requests for SOPC new appointment submitted via "BookHA"
3. The usage in office hour and non-office hours
4. The usage in weekdays and at weekends

Patient Survey

Complementary to the utilization figures, we designed a patient survey on the user experience with "BookHA". The application directed the persons who submitted appointment requests via "BookHA" to the survey within the app. We retrieved data from December 2016- December 2017 in this study. The survey included six questions:

1. "BookHA" makes submission of booking request easy and convenient
2. I am satisfied with my experience in using "BookHA"
3. I can complete booking request in a single attempt
4. I submitted booking request for myself/other people
5. I know about 'BookHA' from poster, pamphlet/hospital, or clinic staff/HA electronic

platform/HA referral letter/media, newspaper or magazine/others

6. Other comments

Staff survey

To prove that SOPCs staff benefit from "BookHA" in streamlining the workflow, we conducted a staff survey at two time points, i.e., June and December 2016. The survey included three questions:

1. The handling on "BookHA" request is simple
2. The instruction on handling BookHA request is clear
3. Comparing with fax booking, BookHA request is easy to handle

Results

Since the launch of BookHA in March 2016 till the end of 2017, the application had more than 178,000 downloads. Appointments were arranged for over 50,000 patients out of some 70,000 appointment requests. Patients and staff submitted around 60% of requests during non-working hours and around 20% of the requests during weekend and holidays.

Patient Survey

We collected a total of 25,500 surveys out of a total of 66,340 appointment requests via "BookHA", with a response rate of 38%, over 13 months (December 2016 – December 2017). Respondents found "BookHA" was easy and convenient, with an average score of 4.54 out of 5. In the surveys, 88% of patients were satisfied with the experience of using "BookHA". For the online appointment questions, 92% of respondents said they could complete the booking request in one go and 35% of respondents requested the SOPC new appointment for another person. Finally, comments collected via the open-ended question were overwhelmingly superb, for examples, "Good and user friendly", "Very convenient. Save lots of my time!".

Staff Survey

We distributed the survey in June and December 2016 respectively to ensure those SOPCs with BookHA rolled out were running effectively even with workflow changes. A total of 133 respondents filled out surveys and 90% of staff agreed that handling "BookHA" request was simple, the instruction on handling BookHA request was clear, BookHA request was easy to handle compared to fax booking.

Discussion

Patient empowerment in managing healthcare appointments is one of the most wanted features in mobile hospital applications [1]. The launch of "BookHA" is a win-win-win approach from patients, staff and corporate perspectives.

Patients' access to public health services is greatly enhanced as proven by the high download rate and utilization rate. The result from the patient survey supported "Simple and Easy" and "Anytime and Anywhere" features since the majority of the respondents (92%) could complete the booking requests in one go, over half of the appointments (60%) were being requested during non-office hours, and around one-third of the appointments (35%) were requested by care providers.

SOPC staff find the application appealing as proven by the staff survey findings. With "BookHA", the clinic operation was streamlined. Clinic staff could manage the booking requests by batch more efficiently. The online booking shortened the patient queue for in-person new booking in the clinics which would also reduce staff stress.

From the corporate perspective, "BookHA" is in line with the corporate strategies in optimizing clinic operations, e.g., providing an alert on duplicated appointment requests, reusing the quotas released from canceled appointments via the application. Finally, "BookHA" demonstrated the value of using new technology to engage patients and has lived out as modernized corporate version.

Our study can explore further directions for possible improvement in future studies on health appointment management via mobile applications. A possible direction is analyzing the age of users and the number of canceled appointments as well as no-show cases.

Conclusions

The adoption of mobile health apps in health care settings is encouraged with a view to improving patient experience [2]. The experience of planning, development, and the implementation of "BookHA" set a good reference for upcoming corporate patient mobile application projects. HA is now developing an integrated, personalized mobile application for patients to manage their own health records. One of the modules will provide an integrated appointment management service for patients to book, cancel, request re-scheduling. Moreover, the module will allow patients to mark 'arrival to clinic', make payment etc.

"BookHA" is the first step of HA to realize the benefits of managing health appointments via mobile application. We envisage envisaged that the benefits will further be attained in the integrated personalize mobile application platform in the future.

Technology to Assist Aging in Place: The Perspective of Health Organizations

Inga Hunter[a], Phoebe Elers[a], Caroline Lockhart[a], Dick Whiddett[a], Hans Guesgen[b], Amardeep Singh[b]

[a] *School of Management, Manawatu campus, Massey University, Palmerston North, New Zealand*
[b] *School of Engineering and Advanced Technology, Manawatu campus, Massey University, Palmerston North, New Zealand*

Abstract

This paper presents findings from a series of focus groups which is exploring the implications of, and stakeholder requirements for, integrating social media technologies and 'smart home' technologies to connect older adults with their formal support networks (i.e. to healthcare and social service providers) thus enabling them to live independently at home.

Keywords:
Technology, Delivery of Health Care, Social Networking

Introduction

Like other developed nations, life expectancy in New Zealand is increasing, which is resulting in an aging population. As older adults have higher rates of chronic conditions and disabilities that require regular support [1], this can place increased demand on health services. An option favoured by policy-makers and older adults [2] is to support individuals to remain in their own homes for longer and avoid residential care, known as 'aging in place'. Research has shown how aging in place can be assisted by smart home technologies, such as purpose built smart homes and home monitoring devices.

However, smart home technologies are underutilized [3], and there are challenges which these technologies frequently fail to address. In addition to barriers identified by technology acceptance models, such as the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT) [3], cost, psychosocial factors related to aging [3,4] and the needs of their informal carers who provide 40-90% of the care for older adults need to be addressed [5].

The present study is part of an exploratory project which takes a socio-technical system approach [5], which considers the adoption of new technologies to involve interaction between society's complex infrastructures and human behaviour.

This paper presents the findings from the health provider focus group phase of this project, to understand their perspective on the use of technology to help them provide services to older adults.

The findings, together with those from the older adults and their informal carer networks [6], identified barriers and facilitators for technology to support aging in place, which informed the development of a prototype system connecting older adults to both their formal (health provider) support and informal support networks tested in older adults' homes and currently under evaluation.

Methods

Seven face-to-face focus groups, comprising 44 participants, were undertaken between May and August 2017. Participants were recruited through convenience sampling through health organizations providing support for older adults in the Manawatū region of New Zealand. Four focus groups were held at the local hospital with nurses, social workers, physiotherapist and occupational therapists who worked with older adults in the community. Three focus groups were held at three general health practices, each involved a range of participants including doctors and nurses. Interested participants chose to attend and participate. They did not receive financial incentives for participation. Each focus group lasted approximately one hour and began with an introduction about the project and the use of home monitoring and digital technologies. Questions (at a macro level) covered their information needs, what information should be collected and transferred for what purpose, who should receive information, and ethical concerns. Participants were predominantly female, and their average age was 46.6 years. Study procedures were approved by the Massey University Human Ethics Committee (SAO 16/65).

The focus groups were transcribed and thematically analyzed inductively in NVivo Version 11.0. Due to the nature of focus groups, individual participants were not identified. Coding was an iterative process that involved rereading datasets to establish initial codes covering key ideas. Similar codes were combined into themes, which were reviewed alongside the original dataset. Codes and themes were discussed within the research team until saturation, stability, and logical organisation were attained and all data was accounted for.

Results

Two main themes emerged, relating to information collection and barriers.

Information Collection

Participants wanted more information about their patients, and were enthusiastic about technologies retrieving information, providing that informed consent is obtained. This theme encompasses three subthemes: information systems' disconnect, participants' information needs, and what information should be collected through technologies. A reoccurring issue identified was a disconnect between current information systems within and across organizations and the need for any new systems to be properly integrated with existing systems.

Participants' information needs varied. Compared to participants from general practices, community practitioners wanted more information about patients' living conditions and their social and physical wellbeing, such as whether they are socializing and leaving the house, their diet, home temperature and physical activity. However, the need to obtain informed consent was emphasized.

Barriers

Participants were optimistic about technology retrieving information but were clear about potential uptake barriers. This theme encompasses three subthemes: usability, cost, and privacy and data security.

Participants were concerned about software complexity and usability issues associated with aging, such as dexterity and cognitive decline. Many participants indicated that the training required for older adults would be substantial and that their desire to learn to use technology would be mixed.

Participants considered cost to be another barrier and discussed how it is already a barrier for their uptake of health products.

Ensuring privacy and data security was also considered a requirement to protect patients. Some participants felt that older adults would have concerns about privacy and data security, although this barrier did not present as strongly compared to usability and cost.

Discussion

The key findings identify several user-requirements as outlined in Table 1, below.

Table 1– User Requiremnts

Theme	Requirement
Information Collection	The technology should save users' time. Informed consent is required for collecting, accessing and sharing information.
Barriers	The interface should be stable and easy to navigate, with large text. The technology should be adaptable to meet older adults' changing needs. The technology needs to be low cost, and, when possible, utilize objects that already present within the home. The information needs to be stored securely and this needs to be clearly communicated to users. The technology should save users' time. Information should integrate with existing systems used by health providers

Some issues addressed by these requirements correspond to barriers already identified in health informatics scholarship. For example, cost is an issue for many older adults [3], and one way to address this is to utilize technologies that already exist within the home. Usability is another barrier [3,4], and so the technology should be designed for ease-of-use. In fact, a direct user-interface may not be suitable for some older adults, instead the technology could monitor the environment so that an older adult does not actively engage with the system.

This study has some limitations. Participant recruitment was not drawn from a random sample of subjects but was from organizations that volunteered to be involved in the study. This resulted in participants only being employed at general health practices and hospital departments, although they represented a range of professionals, including general practitioners, physiotherapists, social workers, and nurses.

Conclusions

The 44 health provider participants working in aged care want more information about their patients' wellbeing within their homes, demonstrating a potential for home monitoring and ICTs to connect older adults to their formal support networks. This would not only assist health practitioners, but it would also support aging in place, which is socially and economically beneficial. While the findings should not be generalized beyond the organizations involved in this study, the user requirements identified, regarding consent, cost, information access, data security and usability, have informed the development of a system that is currently being prototyped in older adults' homes.

FAIR Principles for Clinical Practice Guidelines in a Learning Health System

Tiffany I. Leung[a], Michel Dumontier[b]

[a] *Faculty of Health, Medicine and Life Sciences, Maastricht University, Maastricht, The Netherlands*
[b] *Institute of Data Science, Maastricht University, Maastricht, The Netherlands*

Abstract

The learning health system depends on a cycle of evidence generation, translation to practice, and continuous practice-based data collection. Clinical practice guidelines (CPGs) represent medical evidence, translated into recommendations on appropriate clinical care. The FAIR guiding principles offer a framework for publishing the extensive knowledge work of CPGs and their resources. In this narrative literature review, we propose that FAIR CPGs would lead to more efficient production and dissemination of CPG knowledge to practice.

Keywords:

Guidelines as Topic; Delivery of Health Care; Medical Informatics Applications.

Introduction

The *learning health system* (LHS) is a concept for an integrated social and technological system that seamlessly embeds continuous improvement and innovation for the effective delivery of healthcare [1,2]. Key parts of the LHS are collecting, integrating, and analyzing data from different sources. Evidence generated should be rapidly translated to practice, with additional data collected from practice to enable further evidence generation or modification. Ideally, a clinician could draw quickly and precisely from such knowledge to match patients to relevant evidence and data generated. Since the 1990s, encoding CPG knowledge into computer-interpretable guidelines (CIGs) has been one approach to implementing CPGs in practice [3], although this has remained a slow, difficult-to-scale process. Reusable software components will enable faster, cheaper protocol development.

The 2011 Institute of Medicine report on Digital Infrastructure for the Learning Health System envisions infrastructure that enables a variety of health data sources to improve population health. The 2010 President's Council of Advisors on Science and Technology report tasked U.S. government agencies to "establish initial minimum standards for the metadata associated with tagged data elements" towards realizing the potential of health information technology. More recently, a 2018 commentary highlighted the need for sharable digital knowledge objects, representing syntheses, systematic reviews, and scientific data from original studies [4] in an LHS, yet did not describe the principles needed to achieve this goal.

The *FAIR guiding principles* [5] offer an opportunity to address such thorny issues. Initially conceived to address the fundamental challenges associated with finding and reusing research data, the FAIR guiding principles outline 15 points to enhance the *F*indability, *A*ccessibility, *I*nteroperability, and *R*eusability of digital resources [5,6], from data to analytical pipelines. These recommendations include: unique and persistent identifiers for all entities (from documents to individuals, from concepts to medications); machine understandable data and metadata to facilitate structured search and query; the development and use of pragmatic community standards that reduce effort in reuse; use of shared vocabularies to enable aggregation and enhance data mining; improved provenance to support reproducibility; social and technological commitments to realize long term preservation of digital resources; and simpler terms of use to elucidate expectations and intensify innovation. These principles offer a sensible basis for the design of LHS digital infrastructure, towards meeting the data and information needs of a variety of healthcare stakeholders. This paper describes the FAIR guiding principles and their role in LHS digital infrastructure, using CPGs as a use case.

Methods

Citing key literature, we discuss the role of FAIR in reinventing CPGs, and how this would further enable the LHS digital infrastructure. Included literature was identified based on the authors' shared expertise, supplemented with focused literature searches using MEDLINE and Web of Science.

Discussion

Table 1 provides a detailed checklist for making CPGs FAIR. Fulfillment of this checklist can be verified using tools for performing FAIRness assessment [7].

FAIR principles can facilitate the management and stewardship of CPG knowledge.

The FAIRness of digital objects can be assessed, enabling accountability and transparency of data quality on which CPGs are based. Digital resources for clinical knowledge and healthcare systems include CPGs, as well as other forms of evidence and data generatio, such as EHRs, predictive algorithms, etc. In the 6S Hierarchy of Evidence Based Resources model of medical knowledge and information, CPGs are positioned second from the top [8]. At the model's base are original single studies, such as randomized clinical trials (RCTs), which often have highly selective inclusion criteria; this potentially marginalizes subpopulations who are excluded from such trials (e.g. patients with multimorbidity or cognitive disorders, women and minorities, etc.). As a result, a CPG recommendation may be inappropriately applied to a specific patient, for whom the original RCT results did not apply.

The FAIR principles also aim to address issues in data discovery and reuse. For example, consider a simple case where a clinician wishes to recommend evidence-based therapies for a Chinese American woman with diabetes. With findable and accessible data on patient characteristics, pharmacologic treatments, and clinical outcomes in single studies, systematic reviews, and original studies (from the 6S model), these data

can be readily reused in personalizing care for *this* patient – a desirable goal in building an LHS. Moreover, FAIR principles would empower further research involving social determinants of health and vulnerable populations.

The FAIR principles strengthen the connection between CPGs and the best evidence that support them. Multiple relevant CPGs may apply for single conditions, and vary in the quality and strength of their supporting evidence [9]. Inconsistencies between CPGs for the same condition and conflicting recommendations between different conditions can occur. A single guideline can also contain an overwhelming amount of evidence; one guideline update on ischemic stroke management included 217 recommendations and 421 references [10].

Table 1 – Checklist for developing FAIR CPGs

- CPGs are identified with a unique, persistent identifier, such as a Digital Object Identifier (DOI), which can be resolved to the latest version of a CPG.
- CPGs are versioned with an identifier generated through systematic assignment or from CPG content or its metadata, using identifier systems (e.g. TrustyURIs, DataGUIDs).
- CPGs are described with rich, standardized metadata. The NGC had 54 guideline attributes, but the list must be further discussed and adopted by the community.
- CPGs must be represented in a machine processable language that enables automatic document validation.
- CPGs and their metadata must each be released with clear, standard licenses so users understand and agree to the rights and responsibilities expected of them.
- CPGs and their metadata must include detailed provenance regarding how and when they came to be including details of authors, contributors, methods and resources (e.g. 6S components) used to generate them, and the publishers that make them available.
- CPGs should include standard identifiers for key components (e.g. drugs or diseases should use specific terminologies, such as RxNorm or ICD).
- CPG metadata should always be available, even if CPGs are behind a paywall.
- CPGs and their metadata should be searchable and accessible through a variety of human and machine interfaces.

New research that adhere to FAIR principles can more rapidly be identified and incorporated into the CPG literature review process. Each citation, including original and processed study data, would be FAIR and serve as evidence in CPG development and be accessible for the wider community. This can also ensure the inclusion and findability of important but potentially neglected information, such as conflict of interest information for the experts on CPG development committees.

FAIR principles can enable redesign of guideline repositories to facility CPG implementation.

The FAIR principles can guide the construction of a next-generation guideline repository. The National Guideline Clearinghouse (NGC), formerly a publicly accessible online resource for CPGs, performed quality assessments of published guidelines, summarized high-quality guidelines, and curated and annotated key information into guideline summaries [11,12]; each summary was structured using 54 guideline attributes, including tags with UMLS Metathesaurus concepts [13]. The NGC had performed an important public service in curating and annotating CPGs, although the process was resource-intensive. The sunset of NGC in July 2018 signals an opportunity to redesign guideline repository infrastructure in a manner that adheres to the FAIR principles, thereby enabling easier access to CPG knowledge and their digital objects needed for implementation in an LHS.

FAIR CPGs can also pave a way towards their implementation at a systems level. While almost all CPGs publish recommendations in narrative text, some also produce flow diagrams, schemata, and care pathways, which serve as visual summarizations of CPG recommendations. These can be outlines for translating CPG evidence into CIG formats and clinical decision support. Producing these supplementary CPG materials as FAIR digital objects would facilitate their rapid integration and updates into an LHS and clinical care.

Conclusions

In the aftermath of the NGC repository, CPGs are now further away from FAIR than before. We described key features of FAIR and detailed opportunities for next-generation CPG development, which are the next steps for further investigation.

Evaluation of the Fast Healthcare Interoperability Resources (FHIR) Standard for Representation of Knowledge Bases Encoded in the Arden Syntax

Robert A Jenders

Charles Drew University & University of California, Los Angeles, California, USA

Abstract

Context: Arden Syntax is a standard that encodes knowledge as Medical Logic Modules (MLMs) but lacks a standard query data model and terminology. Objective: Assess to what extent FHIR can represent MLMs. Method: A convenience sample of 340 MLMs were examined and tabulated for representation using the PlanDefinition resource. Result: While alignment between structured subsections is uneven, the PlanDefinition resource adequately represents procedural medical knowledge encoded as MLMs Conclusion: FHIR adequately represents Arden Syntax MLMs.

Keywords:
Clinical decision support systems, knowledge representation.

Introduction

Arden Syntax is a formalism supervised by Health Level Seven International (HL7) for representation of procedural medical knowledge to facilitate sharing units of knowledge known as MLMs that are executed in clinical decision support systems (CDSS) [1]. Each MLM consists of four categories - Maintenance, Library, Knowledge and Resources - each of which consists of one or more structured attribute value pairs that contain descriptions of the knowledge and executable statements. Key to interoperability of knowledge representation for CDS is the use of standard formalisms for knowledge representation itself as well as for the query syntax and data elements retrieved from local data stores in order to execute units of CDS knowledge. One increasingly popular formalism for facilitating such interoperability is the HL7 Fast Healthcare Interoperability Resouces (FHIR). FHIR consists of a library of resources, each of which is a standardized structured representation of a collection of closely related data elements [2]. Prior work has established the utility of standards, such as FHIR, to serve as the standard data model for queries within the Arden Syntax, thereby reducing barriers to sharing MLMs and enhancing their interoperability by decreasing the need for local customization when MLMs are moved from one health care organization to another [1].

Beyond standardizing just references to clinical data, a key FHIR resource that offers specific utility in the CDS space is PlanDefinition. A plan definition is a pre-defined group of actions to be taken in particular circumstances, often including conditional elements, options, and other decision points. The resource is flexible enough to be used to represent a variety of workflows, as well as clinical decision support and quality improvement assets, including order sets, protocols, and decision support rules [3]. The present work was undertaken to expand the prior work of standardizing just the queries of MLMs to assess the utility of using FHIR to represent and thereby store, transmit and reuse clinical knowledge encoded in the Arden Syntax in order to better integrate this latter standard within the increasingly popular FHIR framework.

Methods

A previously assembled convenience sample of MLMs was examined. MLMs were examined and tabulated to assess their alignment with and the extent to which they could be represented by FHIR Release 3, version 3.0.1 [3]. This extraction and tabulation process aligned with a similar effort to identify the utility of FHIR to represent the data variables inside non-query data mappings in MLMs [4]. In the present work, however, this was applied toward representation of the standard parts of the MLM outside of the curly braces that encode the details of queries and other mappings and are meant to be institution-specific. In particular, the text of the MLM corpus was concatenated in a single file. Using a text editor guided by Backus-Naur form of Arden Syntax v2.10 [5] and the format of the various kinds of statements, regular expressions were created in order to extract the instances of each kind of statement. Each of these batches of statements then were compared to the corresponding representation in the FHIR PlanDefinition resource by manual inspection. In particular, alignment between the subparts and attributes of the PlanDefinnition resource and the MLM structure were examined and issues related to the encoding of knowledge in the two standards were reviewed.

Results

A total of 340 MLMs were pooled from 5 source CDS systems, including 24 from 2 vendor knowledge bases and 316 from 3 academic medical centers. MLMs concerned with lab tests were the most common (138/340 = 41%), followed by clinical assessment (75 = 22%) and medication (45 = 13%). The remainder addressed administrative and miscellaneous topics. FHIR contains a rich collection of meta-knowledge attributes, so representation of Maintenance and Library category attributes such as author, title, purpose and so on in FHIR is adequate. While FHIR could represent all MLMs in the corpus, the challenge was the level of specificity. PlanDefinition has attributes for condition (or trigger), expression (for Boolean logic) and action (for defnining the result of knowledge execution) but does not support representation of some specific operators (e.g., substring extraction) or some other elements of Arden Syntax knowledge expressions such as fuzzy logic. On the other hand, all MLMs in the corpus contain at least one instance of temporal reasoning, and temporal attributes of the

PlanDefinition resource, including "timingAge" and "timingPeriod" could represent these Arden Syntax constructs.

Consequently, while all the MLMs could be represented in shells defined by PlanDefinition, the actual knowledge expressions and their components in at least some instances were not directly representable by specific FHIR constructs.

While the analysis highlighted constructs in the Arden Syntax that lacked explicit counterparts in the PlanDefinition resource, it also identified constructs in the latter that could be used to represent elements in MLMs that are represented only in narrative format currently. These include the attributes "code" and "reason" of an "action," which are codeable concepts representing the meaning of an action and its justification, providing additional structure that is lacking in the latest version of the Arden Syntax.

Discussion

Despite agreement that a common formalism for representation of computable clinical knowledge would be beneficial in fostering the deployment of CDS systems and reducing the cost of knowledge engineering therein, no widespread agreement has been reached on a specific formalism for doing so [6]. Workers have demonstrated the utility of the Arden Syntax in this space, and this solution for knowledge representation has been adopted by several software vendors, with resulting implementations in a number of countries. Nevertheless, lack of a standard data model and the resulting need to translate references to local data stores at each implementation site has hindered uptake, as this has with other formalisms [7]. Further, with an emphasis on the use of CDS for health care quality improvement and the consequent need to measure quality in reproducible ways, some workers have concluded that Arden Syntax is inadequate for this purpose. This is turn has led to the development of other standards such as the HL7 Clinical Quality Language, and additional attempts to synthesize an acceptable data model [6]. Paralleling these efforts, other work has led to formalisms, such as CDS Hooks, for accessing CDS systems and their underlying knowledge in ways that are agnostic regarding the specifics of the exact knowledge representation formalism [6]. Additional work has demonstrated the need for improved explicit representation of business processes within CDS knowledge bases, and meeting this need will introduce further complexity and utility in CDS standards. With the increasing popularity of FHIR as a data and information exchange formalism, the present work and related prior studies demonstrate that Arden Syntax complements this new milieu of standards through mechanisms for knowledge access and data representation, improving its utility for its original goals of standardizing knowledge representation and reducing its cost.

Conclusions

FHIR is adequate for encoding Arden Syntax MLMs. This would facilitate interoperability of MLMs as well as their integration in the FHIR framework. The FHIR PlanDefinition lacks specific constructs to support the details of knowledge expressions, so while it is a useful framework for storage, transmission and manipulation of knowledge artifacts, a specific expression lanaguage or standard beyond FHIR is required to use the knowledge artifacts within a CDS system. However, some features of the FHIR PlanDefinition provide additional structure for knowledge in Arden Syntax MLMs that currently may be represented only in narrative format.

[e] Department of Computer Science and Engineering, Chungnam National University, Daejeon, Republic of Korea,
[f] Department of Preventive Medicine, School of Medicine, Chungnam National University, Daejeon, Republic of Korea

Abstract

We developed a comprehensive health and social-need assessment system to evaluate the diverse needs of elders with chronic illnesses in the community and to enhance the connection of their needs to health and social services. A comprehensive needs-assessment tool and profiles were integrated into the ICT system. We found that care managers could assess elders' needs comprehensively and connect those needs to suitable health and social services systematically.

Keywords:
community health services, needs assessment, information technology

Introduction

Community health problems are increasing due to the aging of communities and chronic diseases. However, the current healthcare and social services system provides a disease-centered healthcare service and does not consider the comprehensive characteristics and social factors of individuals [1]. This format can risk providing redundant or deficient services that are not well suited to the individual [2]. Another problem is that services are provider-oriented rather than user-oriented, so services cannot meet individual need sensitively [3]. Therefore, in this study, we developed a comprehensive health and social-service need-assessment system based on ICT. The comprehensive health and social-needs assessment system not only enables evaluators to assess the comprehensive needs of elders with chronic illness and share the summarized profile with infographics but also enables them to logically connect individual needs to health and social services.

Methods

The assessment tool for comprehensive health and social-needs assessment system was developed based on the International Classification of Functioning, Disability and Health (ICF) [4], community case management, an elderly situation survey, a community-needs survey, a community health survey, and the WHO Disability Assessment Schedule. The tool was validated by the expert Delphi method. We visualized the assessment tools and evaluation result profiles with ICT, represented by various icons and pictures. We tried to reflect target users' opinions after pilot test using the system.

Results

The comprehensive health and social-needs assessment system tool and profiles with user-friendly design were integrated in the ICT system. The structured assessment tools of the comprehensive health and social-needs assessment system consisted of three areas: initial assessment; daily and social-life activity checklist; comprehensive assessment including physical health assessment, cognition, mobility, self-care, getting along with people, life activities, participation in society assessment, and environmental assessment. This tool is implemented using ICT, so targeted users can mark the answers directly on the Web, and the results appear with familiar images and graphs to easily recognize and store Web data for users. We applied a pilot test to the system to see users' experiences and user interfaces. As a result of the pilot test, first, time was much shorter than when using paper-based assessment forms. Second, need-assessment results were presented as an infographic rather than simply in a narrative format, so they could be easily understood. Third, the system is very useful for storing data so it is possible to compare present data with past data. Fourth, users could share decision making during the evaluation process and connect to appropriate health and social services.

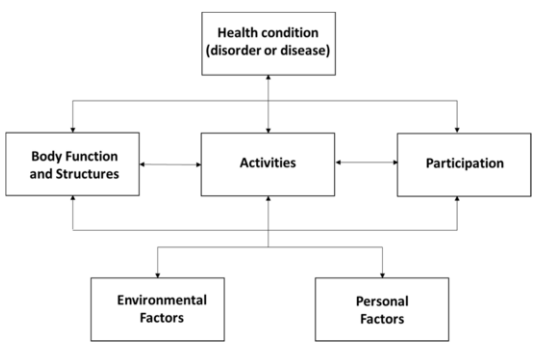

Figure 1– The Model of the International Classification of Functioning, Disability and Health (ICF) [4]

Conclusions

In this study, we developed a comprehensive health and social-need assessment system based on ICT for various needs-assessments of elders with chronic illnesses. An infographic assessment tool and result profiles, based on ICT, helped users to understand and provide information easily and logically. In future studies, we will continue to upgrade the system by applying more cases to the system. Based on the accumulated data, we will conduct further research to evaluate elders with chronic illnesses through a decision support system and present the results sensitively.

Introduction of a Pathophysiology-Based Diagnostic Decision Support System and Its Potential Impact on the Use of AI in Healthcare

Sandra Kühnel, Milan Jovanović, Henry Hoffmann, Lennert Schneider, Sabrina Golde, Martin C. Hirsch

Ada Health GmbH, Adalbertstraße 20, 10997, Berlin, Germany

Abstract

Many currently available Diagnostic Decision Support Systems (DDSS) are based on causal condition-symptom relations that exhibit certain shortcomings. Ada's new approach explores the capabilities of DDSS based on pathophysiology, describing a disease as a dynamically evolving process. We generated a pathophysiology model for 8 conditions and 68 findings suitable to assess this approach. Preliminary results meet our expectations while leaving space for further improvement.

Keywords:

Decision Support Systems, Clinical; Artificial Intelligence; Population Health

Introduction

Artificial Intelligence (AI) in Medicine, first suggested by Ledley and Lusted in 1959 [1], aimed to improve diagnostic performance, treatment and clinical decision making. Today, these AI supported systems are typically referred to as *Clinical Decision Support Systems* (CDSS). [2] Many current CDSS that are assisting clinical diagnosis, more commonly referred to as *Diagnostic Decision Support Systems* (DDSS), are based on a causal condition-symptom relations. [3] This approach assumes the independence between symptoms and conditions. [4] Consequentially, symptoms that are part of the same pathophysiological pathway add redundant information. These so-called *additive effects* can reduce diagnostic precision of DDSS. Furthermore, DDSS based on causal condition-symptom relations do not address a disease as a dynamically evolving process.

Ada's Deep Reasoning (ADR), a new approach on DDSS development, extends current DDSS capabilities by utilizing pathophysiology to describe the dynamic components of disease pathogenesis.

Methods

The core of ADR is a graphical model based on concepts and relations. Concepts used to describe pathophysiological pathways of the model are either a pathological state (*patho-state*) or a pathological process (*patho-process*) (Fig. 1). Patho-states are defined by an *anatomical location* within the human body and an *attribute* describing the underlying pathology. The descriptions of anatomical locations are based on the Foundational Model of Anatomy (FMA). [5] The attributes represent different ordinally scaled dimensions such as structural integrity, functional integrity, or physical and biochemical measures. For example, myocardial ischemia as a patho-state can be described in the following way: the attribute "partial pressure of oxygen" in the state "reduced" within the location "myocardial tissue" (FMA ID: 14068). Furthermore, patho-processes describe the potential transition from one patho-state to another (Fig. 1). They are characterized by the *probability* of a process taking place and its *average duration*. In addition to patho-states and patho-processes, the model contains nodes that represent *conditions* and *findings* (Fig. 1), concepts commonly used in medicine. These are mapped to the underlying pathophysiology by *definition relations* (Fig. 1).

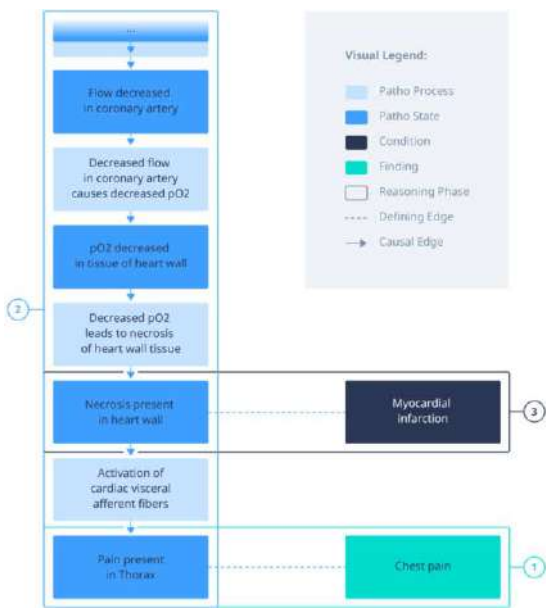

Figure 1 – Excerpt from Ada's Deep Reasoning graphical model for the finding chest pain in myocardial infarction

The pathophysiology model (*patho-model*) contains carefully chosen overall level of detail. It is able to describe the interaction between the components of the human body relevant for disease, while avoiding a granular level used for cell simulation. To create this model within a distributed team of doctors, we created a dedicated editor tool. Finally, we developed a model in order to test whether our approach

actively addresses the previously observed shortcomings of DDSS based on causal condition-symptom relations.

The main purpose of the described patho-model is to enable the inference of the underlying pathophysiological causes from observed findings. The current reasoning approach falls into three phases (Fig. 1). In the first phase, the evidence on different findings is projected through definition relations to the corresponding patho-state constellations. In the second phase, the evidence from these patho-states is propagated through the patho-processes using a probabilistic-deductive approach combining concept form logic and Bayesian inference. In the last phase, the posterior probabilities of all patho-states are finally projected through the definition relations to the condition concept layer.

An assessment of accuracy is performed for the total number of conditions modelled (*global score*). The model is tested against 71 condition-specific reference cases. These reference cases were previously used for the validation of other Ada engines. [6]

Results

The medical knowledge space for testing ADR consists of 8 conditions and 68 findings. The above mentioned assessment on accuracy, matching quality (MQ), was performed for all modelled conditions. The MQ results for ADR were calculated for the top suggestion (M1), the top 3 (M3) and the top 10 (M10) suggestions. The global MQ score for ADR was 0.70 for M1. The global MQ score for M3 and M10 were 0.95 and 0.96, respectively. Results are prior corrected.

Discussion

ADR explores the possibilities of a pathophysiology-driven DDSS. After successfully creating a proof-of-concept engine during the first phase of the ADR development, the current focus lies on reasoning refinement.

ADR introduces a level of detail that is missing in currently available DDSS. We observed that additive effects could be successfully addressed by explicit modelling of pathophysiological pathways that lead to observable symptoms. Additionally, the created editing tool supports the scaling of our existing medical knowledge space. It allows the inclusion of many medical experts to work together on a pathophysiological model for humans.

At this stage, the preliminary results are promising and meet our expectations. ADR is currently not addressing risk factors, e.g. sex, age, or BMI. Additionally, the patho-model neglects information that closely describe findings, e.g., quality, intensity, or position of abdominal pain. Based on our experience with other DDSS built in Ada, we expect these features to increase the M1 score by an additional 8-15%. Finally, our medical knowledge space needs to be extended to allow the testing of new features and support diagnoses of a wider range of conditions.

Conclusions

With ADR, Ada Health successfully demonstrates the feasibility of a pathophysiology-based DDSS. Through this innovative approach, ADR overcomes additive effects problem and considers more information on the underlying biology. This way, a broad spectrum of health-related data can be depicted and an individualized, high resolution model for personal healthcare can be created. Facilitating the integration of this kind of health-related data will significantly advance personalised medicine.

Designed Strategies and Adaptation of a Master Patient Index for Transgender Patients in a Tertiary Care Hospital

Julia Frangella, Melanie Cassarino, Fernando Plazzotta, Fernando Gassino, Carlos Otero, Daniel Luna

Department of Health Informatics, Hospital Italiano de Buenos Aires, city of Buenos Aires, Argentina

Abstract

Transgender people experience their gender identity as different from the sex assigned to them at birth and/or those listed on their legal identification. A Master Patient Index (MPI) is a centralized index of all patients in a health care system. The objective of this work was to describe the designed strategies and adapting of a MPI that contemplates transgender patient registration needs as regards as health and legal context.

Keywords:

Transgender Persons; Gender Identity, Health Information Systems.

Introduction

Transgender people experience their gender identity (GI) as different from the sex which was assigned to them at birth and/or those listed on their current legal identification [1]. "Gender identity data" can be defined as GI, birth-assigned sex, legal sex, chosen name and legal name [2; 3]. Current best practices for the collection of gender identity data recommend collection of both GI and birth-assigned sex [2]. Transgender patients have particular needs in what concerns to demographic information and electronic health records (EHR). Specifically, they may have chosen a name and GI that differs from their current legal name and gender. Transgender people face intense health disparities and lack of access to health care; failure to accurately document transgender identities increase these disparities through negative implications [4]. On the other hand accurate reporting of legal identity is necessary for appropriate insurance billing.

To date, at Hospital Italiano de Buenos Aires, we have a population of 30 transgender patients registered, including adult and pediatric. The lack of a registration method at the moment may underestimate the real number of patients.

The main objective of this work was to describe designed strategies to respond to transgender patient registration needs in a MPI, contemplating patients' GI, chosen name and the possible changes it might have in a health and legal context.

Methods

Settings

Hospital Italiano de Buenos Aires (HIBA) is a non-profit healthcare academic center founded in 1853. HIBA has a network of two hospitals with 750 beds (200 for intensive care), 41 operating rooms, 800 home care beds, 25 outpatient clinics and 150 associated private practices located in Buenos Aires city and its suburban area. Since 1998, the HIBA has run an in-house-developed health information system, which includes clinical and administrative data. It has been recently certified by the HIMSS as level 7 in the Electronic Medical Record Adoption Model [5].

Institutional MPI

Interoperability and Standards

The MPI was developed according to profiles described by the Integrating the Healthcare Enterprise model (IHE) [6]. Fast Healthcare Interoperability Resources (FHIR) was chosen as the health information technology interoperability standard. The administrative gender was taken into account, and the data was modeled from that profile [7].

Matching algorithms

In order to improve the safety and quality of data, patients registration process starts with a candidate search. The search of candidates based on the following data entered: First name; Other Names (Optional); Surname; Other surnames (Optional); Birthdate; Type and number of document; Sex. Different kind of matching algorithms, such as phonetic encoding systems utilized to counter misspelled names, had been used to determine potential matching candidate. At the end of the search process, the user visualized a match weight score, resulting from field match weights assigned to patient-identifying attributes such as last name, first name, date of birth and ID.

Strategies design process

A multidisciplinary group assembled to discuss the topic was formed. The first step was to analyze all possible use-cases, according to the law, literature and hospital previous experience. Then we planned the most adequate solution for each one. For this, tests were carried out with all possible modifications and potential errors that GI and/or name changed could cause in a subsequent search for candidates. According to results, adjustments were performed for the strategy design.

Results

During the registration process the system always takes the data of the National Identity Document (DNI) which has the official data at the time of birth. So that GI and chosen name could be registered in the MPI, two new data fields were added, one for each. If a patient requested to be called with a name or GI different than the one registered on his/her DNI, those fields will be used. In this way, this information is stored as demographic data. Legal name and sex would not be changed at all. After analyzing the data, five use cases (UC) were defined (Table 1).

Discussion

A proposal as an answer to satisfy transgender patients MPI registration needs was developed along the paper. For cases of transgender patients with legal documentation that do not reflect GI or chosen name, we add two new fields in the MPI for registration of GI and chosen named. The system allows to load this data in separate fields from legal name and birth assigned sex. During a candidate search or billing process, system will take the data according to legal data fields. EHR and administrative application will show patient's chosen name and gender, except for the billings system. After MPI new fields deployment, audit for searching duplicating patient will allow to evaluate the effectiveness of our strategy.

Implementation of the new MPI will require special training for employes performing registration process. Patients also need to understand why the issue is important and what they are being asked to do.

Conclusions

The adaptation of MPI to the registration needs of transgender patients is a necessity. Throughout this work the possible use cases were described and proposals were developed to solve each one of them. The design and development of strategies to respond to transgender patient registration needs, its implementation and subsequent audit are the beginning of the fundamental change in information systems.

Table 1 – Use Cases

Patient	ID	Patient's Request	Solution Proposed
New Patient	Original DNI	To be called by a name and GI different from DNI	Patients' register according to legal documentation data. GI and chosen name will be saved in separate fields from those previously mentioned. In a candidate search, the system will take the data from legal identificatory fields. EHR and administrative applications will show patient's chosen name and gender, except for the billings system.
New Patient	New DNI	To be register for the first time	Registration process will be performed according to DNI. If patient expresses gender and/ or name changes, this information will be registered exclusively in the EHR, conforming to the law.
Patient registered	Original DNI	To change Name and GI	Patient's previous data will not be modified. The system allows to load GI data and the chosen new name, in separate fields. During a candidate search, system will take the data from legal identificatory fields. EHR and administrative application will show patient's chosen name and gender, except for the billings system.
Patient registered	New DNI	To change Name and GI	Data modification for name and gender fields will be made, according to new DNI. The log of all changes made will be saved.
Patient registered	New DNI	To be register for the first time without clarifying that it's been already registered before	Registration will begin with a search for candidates. The patient will have a new name and gender, their surname and original identification number. A search for candidates of these characteristics will result in the patient already registered with an estimated weight of 87%. This is enough for the user to notice that the patient already exists in the registry.

Development and Evaluation of a Prototype CDSS for Fall Prevention

Hyesil Jung[a], Hyeoun-Ae Park[a]

[a] College of Nursing, Seoul National University, Seoul, South Korea,

Abstract

We developed a prototype CDSS that 1) provides tailored recommendations by combining a fall-risk prediction model, patients data, and evidence from CPGs, and 2) helps nurses to plan nursing care and document their activities for fall prevention. The accuracy of rules in knowledge base and inference engine was verified using ten scenarios and heuristics of user interface evaluated by four experts. We are currently evaluating the effects of the system on nurses' workflow and patient outcomes.

Keywords:

Accidental falls; Decision support systems, Clinical; Evidence-based nursing

Introduction

According to the AHRQ, the learning health system is a system that integrates internal data and experience with external evidence, and puts that knowledge into practice. As a result, patients receive higher quality, safer, and more efficient care.

We have been working to develop a small scale of learning health system to prevent falls, which is the most common adverse event threatening patient safety in the acute care settings. In our learning health system, EHR data as 'internal data' is integrated with nurses' clinical experience and clinical practice guidelines (CPGs) for fall prevention as 'experience' and 'external evidence', respectively. A fall prevention clinical decision support system (CDSS) is a tool that enables knowledge to be put into practice. The fall prevention CDSS might allow nurses to provide a high quality of care for fall prevention and improve patient safety and efficiency of workflow.

Existing fall prevention CDSSs could not provide tailored actionable recommendations based on evidence at the point of care. Furthermore, CDSSs could not automatically extract patient data which was already inputted into EHR system, so users had to input data manually. To be able to 'learn' in the learning health system, the results of practice must be recorded.

Our final goal is to develop a near real-time fall prevention CDSS that provides tailored nursing recommendations by combining fall-risk model, EHR data, and evidence from CPGs, and supports nursing care plan and documentation. On that journey, we have developed a prototype CDSS.

Methods

Figure 1 represents three components of the fall prevention CDSS which we are developing as a final goal. A fall-risk prediction model (component A.) was developed and validated. In this article, we focused on how we developed a knowledge base, an inference engine (component B), and an user interface (component C).

The scope of development of a prototype CDSS is identical with the fall prevention CDSS except for automatic extraction of EHR data. Finally, we evaluated an accuracy of rules in knowledge base and inference engine, and heuristics of user interface.

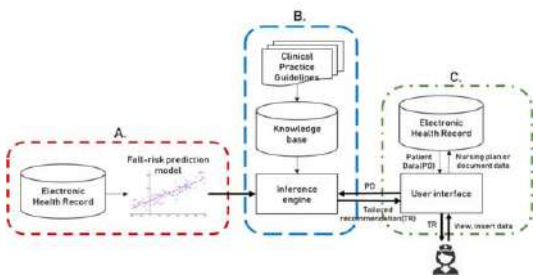

Figure 1-Components of the fall prevention CDSS

We developed the prototype CDSS in accordance with the following four stages of the system development life cycle.

Plan - functional requirements analysis

We examined a variety of tools CDSS encompassed from the literature [1] and specified functions of this system in detail through interviews with three nurses.

Design

Knowledge base

Published CPGs on fall prevention were retrieved from the National Guideline Clearinghouse and Google scholar. Knowledge was extracted from the selected 7 CPGs using MS Excel.

The knowledge was represented by decision rules using the IF-THEN rules.

User interface

Reflecting the results of the functional requirements, we designed a user interface. With our user interface, a nurse can modify information of a patient's fall-related variables and can plan nursing care and document their activities for fall prevention. The user interface was developed using Visual Studio 2017/2017 C#, NetFramework 4.0, and DevExpress 17.2 tools.

We have aligned recommendations with nursing statements the study hospital uses in order to document nursing activities performed according to the CDSS's recommendations. For recommendations not mapped to existing nursing statements, we have added new nursing statements.

Implementation

The fall-risk model, patient data, and knowledge extracted from CPGs were combined in order to provide tailored nursing recommendations by risk group and risk factors a patient has. For example, the process of inferring a patient with 'a high risk of falling' and providing recommendations for them is as

follow: First, patient data is entered into the fall-risk prediction model and the risk of falling is calculated. If the risk of falling is greater than or equal to the cutoff, the patient is identified as 'a high risk of falling'. Then, knowledge on nursing intervention for patient with 'a high risk of falling' is extracted from knowledge base and printed on the screen.

Evaluation

Rules in knowledge base and inference engine

We tested an accuracy of rules that calculate the risk of falling and provide the tailored nursing recommendations using ten scenarios. Of 15,450 patients' data, we randomly selected ten patients and compared their risk of falling calculated by the system to the risk of falling that we manually calculated. In addition, we manually modified values of the fall-related variables of ten patients and verified whether CDSS printed out nursing recommendations accurately based on modified risk factors.

Heuristics of user interface

In accordance with Nielsen's heurisitcs principles [2], four evaluators who majored in nursing informatics were asked to try the prototype and to rate the severity of each usability problem with a scale from 1 to 4. For principles with an average score higher than 3, the system has been revised to fix that issue.

Results

Plan- functional requirements analysis

We defined 'computerized alerts and reminders to care provider' and 'clinical guidelines' as key functionalities of a fall prevention CDSS. Specified functional requirements of the CDSS were 1) the CDSS is able to calculate the risk of falling using patient data, 2) the CDSS is able to alert nurses to identify patients with a high risk of falling, 3) the CDSS is able to provide tailored nursing recommendations according to risk factors that a patient has, 4) the CDSS allows nurses to manually modify a state of patient if necessary, and 5) the CDSS enables nurses to plan and document nursing care for fall prevention according to the recommendations.

Design

Knowledge base

We extracted 75 specific knowledge related to risk factors and 69 general knowledge related to environment. An algorithm was developed by linking 42 rules defining the value of each variable and 19 tailored recommendations.

User interface

When a patient's condition changes, a nurse can modify values of fall-related variables manually (Figure 2). Then, the system recalculates the risk of falling and displays tailored recommendations. Based on the recommendations, the system enables a nurse to plan nursing care and to document nursing activities for fall prevention.

Implementation

Figure 3 shows a screenshot of the prototype CDSS providing tailored recommendations according to a risk of falling (a high risk) and risk factors a patient has. Nurses can track the trends in a risk of falling and get tailored recommendations by risk factor when they click on the risk factors.

Evaluation

Rules in knowledge base and inference engine

There was no inconsistency between the risk of falling the CDSS calculated and the risk of falling we manually calculated. The CDSS printed out nursing recommendations without errors according to the modified risk factors.

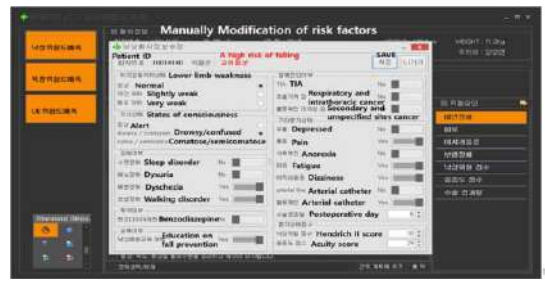

Figure 2-A modification of values of fall-related variables

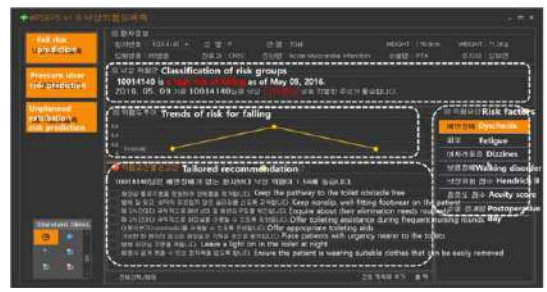

Figure 3-A risk of falling, risk factors, and tailored recommendations,

Heuristics of user interface

Only the 'consistency and standards' principle, which indicates compliance with platform conventions, were lower than 3.

Conclusions

The prototype CDSS has several limitations. First, it cannot extract EHR data automatically. Second, knowledge extracted from CPGs was not tested for its applicability to clinical settings. Thus, a validation of the nursing recommendations by the experts is needed. Nevertheless, this system can help nurses to provide evidence-based tailored nursing for fall prevention without any extra workload.

Designing Archetype Models for Each Step of Workflow in Medication

Shinji Kobayashi[a,b], Naoto Kume[a,b], Hiroyuki Yoshihara[a,b]

[a] *Department of Electroenic Health Record, Kyoto University, Kyoto, Japan*
[b] *NPO openEHR Japan*

Abstract

Medication processes are consisted with multiple steps by professionals and consumers. Physicians prescribe drugs to patient with conformance, but sometimes they were changed to other drugs.

We designed concept models to capture medication workflow process records by openEHR archetype models, and four templates were determined with each step of the medication process.

We will show the detail of clinical modeling about medication workflow in this article.

Keywords:
Medication, openEHR, concept models

Introduction

Medication has four steps (shown below) of process with complex workflow.

1. **Prescribe**: Physicians prescribe drugs to patients with instruction to take.
2. **Dispense**: Pharmacists dispense drugs to patients or professionals by the instruction on prescription with packaging. Drugs might be altered to generics of original or others for some reason, such as allergy or shortage of drugs.
3. **Deliver**: If drugs should be delivered by professional in case of injection or other, dispensed drug are delivered by nurses, or other professionals with instruction by the physicians or pharmacists
4. **Consume**: Patients consume drugs by the instruction on the prescription in general, but sometimes abandoned or changed.

We have developed nation-wide Electronic Health Record (EHR) system based on ISO 13606/openEHR archetype technology to capture health related data from care providers [1; 2]. More than 30 hospitals were connected, and two groups of pharmacies will be connected in 2019. At first, we designed a single openEHR template to capture prescription information, but we found dispense information in pharmacies should be designed separately to involve tasks of pharmacies.

And the next, delivery and consumption were identified as other concepts.

In this article, we describe the concept models for the medication process.

Methods

We figured each concept model, prescribe, dispense, deliver, and consume by Mindmap with existing form of items by XMind8 [3] (Figure 1). 16 concept models were identified and compared with openEHR Clinical Knowledge Manager (CKM) [4].

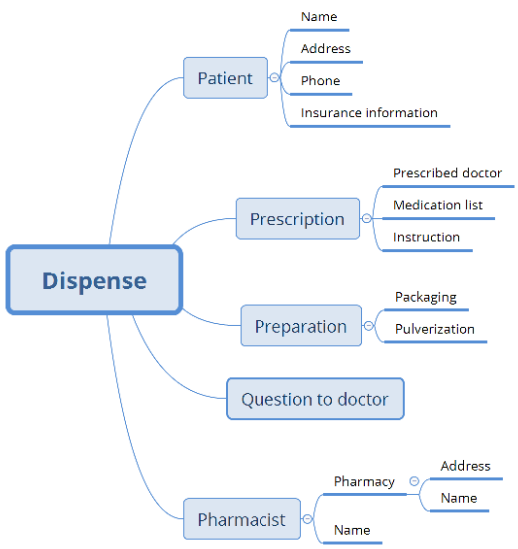

Figure1– Mindmap of drug dispense

Concept models were composed in composite archetypes to conform four openEHR templates by Ocean Template Designer [5].

Results

Table 1 shows the templates and major archetypes that conform medication steps.

Each step of process contains specific information, but existing archetypes on CKM were not well-designed for dispense, deliver, and consume. Therefore, we designed new archetypes, and specialized action-medication archetypes. Because there is specific manners for medication in Japan, specialization for prescription was also requied

Table 1– Major archetypes to construct medication workflow

Template	Archetype
Prescribe	composition-prescription
	instruction-prescription
	cluster-medication-details
Dispense	composition-dispense
	action-dispense
	cluster-packaging
Deliver	composition-delivery
	action-deliver
	cluster-deliver-details
Consume	composition-consumption
	action-consume

Discussion

We idetified clinical concepts in medication process, and designed four templates with archetype models. Prescription data were well-disigned already, but it needed specialization. Because each country or aria has each own manner of medication, universal design of archetypes could not be applicable.

Dispense, deliver, and consumption archetypes were still not well-designed, because the data were not able to capture from pharmacy and patients. However, IoT devices will be able to collect drug consumption data form patients, EHR should have concept model accoring to them.

Even though there are diversity in medication process, standardized process for medication should be desigined for the reference for each derived works.

Conclusions

We designed four steps of medication workflow. Each step required new archetypes and specialization, because existing archetypes were not well designed for dispense, deliver, and consume.

le if printed in black & white. Figures and graphs may span both columns.

Abstract

Our work exhibits how previous projects on the Active and Healthy Ageing field have advanced to the conception of CAPTAIN, a radically new approach towards increased end-user acceptance. The goal is to create intuitive technology that does not require specific skills for interaction and blends in with real life. CAPTAIN will be co-designed by all types of stakeholders, including older adults, involved in all stages, from the initial design to delivery of the final system.

Keywords:

Healthy Aging, Home Care Services, Needs Assessment

Introduction

Ageing is directly related to several issues that may greatly affect the level of independence of an older adult, often requiring institutionalization [1]. However, as a matter of fact, adults typically prefer living at their homes as long as possible retaining their independence. Furthermore, institutionalization has been linked with negative outcomes such as mortality and low quality of life [2].

A wide range of technologies for homecare scenarios have been developed over the last few years including the use of smartphones, tablets, sensors, etc. However, most of them intervene and renovate the user's home or require them to use wearable devices, unable to seamlessly "blend" within the person's daily life and living environment. Moreover, most technologies focus on the patronization of user activity without empowering personalized interventions.

CAPTAIN, which is the acronym of "Personalised coaching for well-being and care of people as they age", proposes an innovative technology that blends in the real-home environments, turning it into an intelligent and ubiquitous coach. The project, which has been funded by the Horizon 2020 work programme proposes to leverage a range of different innovative technologies such as projected augmented reality, 3D sensing technologies, tangible user interaction, and physiological and emotional data analysis to create a virtual coach capable of supporting daily tasks and activities, suggesting a healthy and active lifestyle, and encouraging social participation under the context of a long term coaching strategy.

CAPTAIN System Description

To deliver an intuitive, transparent, and yet effective interaction paradigm, CAPTAIN transforms the older adults' home into a tangible interface where instructions from the virtual coach are projected onto the real context, whenever and wherever needed. Interaction with the environment occurs by touching real life objects, according to the so-called tangible interfaces, and by voice commands using everyday language.

Non-invasive user and environment sensing

User and environmental sensing is done by 3D sensors, RGB cameras, and microphones which are used for:

- User identification and authentication automatically made using face recognition and human body pose recognition (skeleton/silhouette features).
- Creating a profile for each user, not only including data concerning their biological and demographic information, but also their interests and behavioral habits.
- Gait analysis that has been widely used as an indicator of different cognitive impairents [3]. With regards to analysis of movements, CAPTAIN will build upon previous work on indoor analytics [8] where density based clustering was applied to indoor (location) transitions recorded in real older adults' homes for a duration of approximately a year.
- User interaction with so-called "exergames" and cognitive games, engaging the user in physical and

cognitive training tasks, respectively. CAPTAIN will employ a serious games platform, called web-FitForAll [4], incorporating standard physical exercises protocols. The in-game metrics analysis have exhibited a classification accuracy greater than 73% when discriminating between cognitively normal from mild cognitive impaired seniors as well as promising results on creating user profiles using scores created from in-game metrics [5,6].

Coach behaviour design and Artificial Inteligence (AI) algorithms

The data coming from the cameras, projectors, sensors, etc. analyzed using Artificial Intelligence algorithms will permit information to be obtained about the person's behavior and preferences, as well as the environment. Then, the CAPTAIN coach will use algorithms from the fields of Artificial Intelligence and data mining to integrate the higher-level information about user and environment sensing, combined with behavior change models and domain specific knowledge, to produce personalized motivational guidance embodied through a virtual coach persona specifically designed to support physical and cognitive training, improve nutrition, lifestyle habits and social participation, and reduce risk.

Human Computer Interaction (HCI) system

The CAPTAIN's HCI will be based on a new prototype device that will create a living environment capable of turning any surface into a projected (augmented) information source. To do so, a spatial augmented reality pipeline will be developed based on two rendering passes, where the first renders the 3D content from the perspective of the senior while, during the second, the generated image is warped into an image to be projected that looks correct from the perspective of the user's eyes and for the environment's geometry.

Design Approach

While the CAPTAIN's consortium consists of a multidisciplinary team, the main actors of CAPTAIN will be a large group of stakeholders who will be involved throughout the project, providing ideas and insights to which the entire team will be constantly responding and adapting. One of the greatest challenges of introducing new forms of human computer interaction to older adults is to achieve high usability, usefulness, and effectiveness levels, making older adults adopt the solution and not adapt to it.

Agile methodology

CAPTAIN has been entirely conceived around the idea of co-creation, participatory, and user-centered design which have been proposed to mitigate user acceptance failure frequently observed in older populations. To do so, a hybrid approach leveraging on concepts from Design Thinking, Lean, Startup [7], and SCRUM agile framework [8] approaches are followed by the project. Design Thinking allows the consortium to identify unmet needs and create value from these insights while the Lean approach enables delivering a partially functional prototype frequently enough to the stakeholders in order to collect feedback, validate assumptions, and inform readjustment. The use of SCRUM helps organize work across technical development to collaborate towards delivering high value. This hybrid approach facilitates CAPTAIN to solve effectively, and with high flexibility, the complex project's developments required to achieve its goals.

CAPTAIN Stakeholders community

The CAPTAIN Stakeholder community becomes the basic source of requirements throughout the project's lifecycle. The CAPTAIN consortium aims for the creation and maintance of a community with strong support bonds based on two clusters of stakeholders: the first one will include those who will actively use CAPTAIN (older adults and their caregivers), and the second one will include those who can give suggestions or influence (service providers, nursing home management, and patient associations).

Discussion

CAPTAIN's continuous and unobtrusive sensing of physical, cognitive, and social functioning has the significant potential to support lifelong health management. CAPTAIN uses an innovative projective environment to provide a useful and effective contextualized (i.e. direct projection onto the real world) virtual coach to older adults living at home.

The advantages brought by CAPTAIN will be evaluated during an impact assessment phase which will be tailored to measure the effectiveness in terms of quality of life, societal, economic, and psychological terms The information and indicators that will be extracted during the assessment phase will be essential to fine-tune the final value proposition in light of later commercial exploitation of the project's results.

Abstract

Diagnosis Related Groups (DRGs) and the Tenth Revision of the International Statistical Classification of Disease and Related Health Problems (ICD-10) were implemented to Taiwan in 2010 and 2016 respectively. New rules related to the medical costs reimbursement were great challenges facing medical institutions. One of the medical centers in north Taiwan introduced an ICD e-dictionary, DRGs cloud computing system, and integrated them into the hospital information system. Further, developing a medical coder specialization work model optimized the workflow, coding quality, and efficiency, which defeated the adverse effects of DRGs and ICD-10 implementation successfully.

Keywords:

Diagnosis-Related Groups, Hospital Information Systems

Introduction

In 2010, the National Health Insurance Administration (NHIA) of Taiwan applied Diagnosis Related Groups (DRGs) gradually to replace the fee-for-service payment policy, expected it could be comprehensive before 2019 and suppresses medical costs. Moreover, in order to describe disease exactly and conform to the statistical data format worldwide, NHIA announced International Statistical Classification of Disease and Related Health Problems, Tenth Revision (ICD-10) should be used as the basis for medical expenses application since 2016.

DRGs and ICD-10 implementations were great challenges facing the medical institutions. The most direct impact is the complexity of disease coding, which increases after the introduction of ICD-10. According to pioneering research from NHIA, the manpower of medical coders needs to be increased by 2.3 times when ICD-10 implementation [1]. Other impacts may be triggered by financial factors, such as medical ethical problems. Healthcare providers worried about DRGs increased financial burden to medical institutions, so that critically ill patients whose expected costs are higher than the associated reimbursement will be dumped, an experience seen with DRGs in other countries [2-3], even though some supporting measures have been executed by NHIA [4].

To reduce the adverse effects of DRGs and ICD-10 implementations, a medical center in north Taiwan introduced ICD-10 e-dictionary in 2015 and DRGs cloud computing system in 2017, which were integrated into a self-developed DRGs monitoring system. Moreover, they developed s specialized medical coder work model (*Figure 1*) with the systems in 2018. In the model, medical cost management shifts to the period of patients' hospitalization, when doctors could classify patients to appropriate DRGs, controlling the supplemental cost of specialized medical coder. Our hypothesis is that the doctors and medical coders can reach a consensus and propose the disease code that is closest to the disease, which can accurately control the consumption of medical resources and obtain reasonable payment. Also, the work model forms a positive feedback cycle.

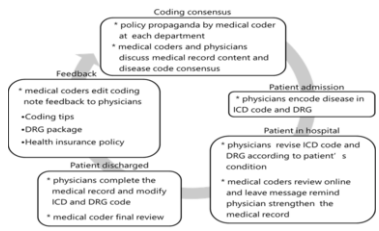

Figure 1–specialized medical coder work model

Methods

To evaluate the effects of the information system and work model, we made some tests and reviewed related indexes:

1. Difference in time distribution of disease coding between using the paper dictionary and e-dictionary

   300 DRGs cases were randomly selected from January 2017 to April 2018. 10 medical coders appointed by a medical center in the north of Taiwan used an ICD-10-CM/PCS paper dictionary (2014 version) and e-dictionary (HISMAX 2014 version) to find the code separately, and recorded the time based on the HIS system. We compared the coding time in different tools, classified by DRGs payments types (full reimbursement, quota, exceed quota). Matched paired *t*-tests were used to test for changes in time.

2. DRGs consistency rate of doctors and medical coders

   We collected all DRGs cases (918 cases in average each month) from January 2017 to August 2018 and compared doctors' last edited DRGs record with the final results of the medical coders, calculating consistency rate as a percentage. Mann–Whitney U test was used to test for change of the consistency rate before and after the specialized medical coder work model was put into practice.

3. Satisfaction with DRGs cloud computing and monitoring system and the specialized medical coder work model

We compiled a structured questionnaire based on the business content of the medical coder and the information system success model proposed by DeLone & Mclean [5]. A 5-point Likert scale was applied, where 1 was very dissatisfied, and 5 was very satisfied. The questionnaire consisted of 19 questions and was distributed to the departments of Infectious Diseases, Neurology, Neurosurgery, and Nephrology in a medical center in north Taiwan between March 2018 to April 2018. A convenience sample of 55 doctors was included. The recovery rate of the questionnaire was 98.2% and Cronbach α=0.967, indicating that the measurement results were highly reliable. Questionnaire scores were analyzed by descriptive statistical methods (mean and standard deviation).

4. Related indexes were also reviewed from the 2016-2018 annual reports of the hospital, including internal and external medical coding experts' review consistency rate (Review sample size: 25 cases; Internal/ External review frequency: monthly/ yearly), manpower of medical coder, and DRGs surplus monthly average ratio.

Statistical analysis was performed with SPSS 20.0 program.

Results

Encoding full reimbursement, quota, and exceed quota case in a paper dictionary took medical coders 11.63 minutes, 7.36 minutes, and 13.06 minutes in average; in the e- dictionary, it took them 9.16 minutes, 5.03 minutes, and 9.28 minutes, respectively. Encoding in e-dictionary required less time (p < 0.001) than paper-based work (*Table 1*).

Table 1 —Comparison of coding time between paper and electronic dictionary

Form of dictionary	DRG reimbursement type								
	full reimbursement			quota			exceed quota		
	n	mean (SD)	p	n	mean (SD)	p	n	mean (SD)	p
paper	40	11.63 (10.61)	<0.001	189	7.36 (7.56)	<0.001	71	13.06 (11.40)	<0.001
electronic		9.16 (8.94)			5.03 (4.65)			9.28 (7.83)	

In 2017, the average DRGs consistency rate of doctors and medical coders was 58.68% and it was a slightly downward trend. In 2018, the average rate was 63.20%. It showed an uptrend after the specialized medical coder work model put into practice. Compared with the average rate in 2017, 2018 was higher significantly (p = 0.003) (*Table 2* and *Figure 2*).

Table 2 —2017 and 2018 DRGs consistency rate of doctors and medical coders（%）

	Mena	Min	Max	SD	p
2017	58.68	54.89	64.58	3.11	0.003
2018	63.20	57.09	65.21	2.74	

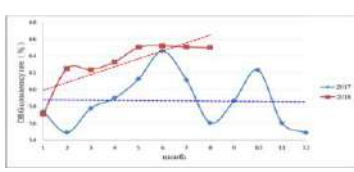

Figure 2 —the trend of DRGs consistency rate (%) of doctors and medical coders (2017-2018)

The satisfaction survey results showed that the average scores of system quality, information quality and benefits with the DRGs cloud computing and monitoring system was 4.28, 4.29, and 4.27 respectively. In the specialized medical coder services, the average scores of policy advocacy and coding services were 4.22 and 4.21 respectively. Overall, the average score of satisfaction was a high rating of 4.25, (*Table 3*).

Table 3 —Questionnaire and scores of satisfaction

Facet	Item	Question	Mean	SD
DRG computing and monitoring system	system quality	Computing speed	4.26	0.42
		Stability of the system	4.26	0.4
		Easy to use	4.31	0.38
	information quality	System could compute the correct DRG and fit the condition	4.28	0.4
		System could be revised instantly whenrule (such as ICD or DRG) are changed	4.3	0.42
		Advanced review could help you choose reasonable DRG	4.31	0.44
		Light can remind you to manage the abnormal medical expenses	4.25	0.35
	benefits	Using the system improves the quality of medical records	4.24	0.45
		Functions of the system can meet clinical needs	4.26	0.4
		Using the system helps increase efficiency	4.31	0.36
Specialized medical coder service	policy advocacy	Whether the content of the promotion is satisfactory	4.26	0.44
		Is the time properly arranged	4.23	0.42
		Policy advocacy and coding discussions are helpful for medical record writing	4.18	0.39
		Policy advocacy and coding discussions are helpful for coding	4.2	0.4
	coding services	Does the medical coder specialization improveyour coding accuracy	4.18	0.4
		The reminder service for the abnormal DRG case	4.2	0.4
		Medical coders review medical record and correct the wrong DRG	4.2	0.36
		Coding note is helpful for coding	4.27	0.45
		Specialized medical coder in charge for discussion on coding	4.22	0.42

By reviewing 2016-2018 annual reports of the medical center, we found out that in the face of ICD revision and DRGs implementation, the manpower of the medical coder was maintained at 10. The external and internal medical coding experts review consistency rate was above 90% each month. In summary, that means the medical coding quality could be maintained without increasing personnel. Moreover, the DRGs surplus rate maintained at 17% to 19% which means the medical expenses were effective controlled.

Conclusions

The information systems do help medical coders work more efficiently, and optimize the workflow and coding quality. The results also confirm our hypothesis. As the DRGs consistency rate of doctors and medical coders was 63.2%, which is higher than before, and the doctors' satisfaction level was rated high, that means doctors are willing to do it and give more suitable disease codes by the system with specialized medical coders' supports so that every DRGs case could be monitored more precisely and reimburse reasonable payment. In this way, it successfully reduced medical resource wasting and potential financial risk which may lead to medical ethics issues.

Implementation of a REDCap-Based Research Data Collection System in Cameroon

Lionel Ngamani[a], Rogers Ajeh[a], Akindeh Mbuh[a], Anastase Dzudie[a], Stephany N. Duda[b]

[a] *Clinical Research Education, Networking and Consultancy (CRENC), Yaoundé, Cameroon*
[b] *Department of Biomedical Informatics, Vanderbilt University School of Medicine, Nashville, Tennessee, USA*

Abstract

Implementing electronic data collection for health research can be challenging in resource-limited settings, where electricity, Internet access, and study staff with computer training may be limited. Our team has established a successful research data infrastructure using the REDCap software at three HIV clinics and one coordinating center in Cameroon. We describe our recommended network architecture and guidance for study data teams working in similar settings.

Keywords:

Data Collection, HIV infections, Cameroon

Introduction

Cameroon is a member country of the Central Africa International epidemiology Databases to Evaluate AIDS (CA-IeDEA), one of seven regional consortia of HIV cohorts encompassing 45 countries globally [1]. Clinics participating in IeDEA contribute longitudinal patient care data for observational HIV research and the development of care guidelines for groups like the World Health Organization. The participating Cameroon HIV clinics used paper charts, so the Cameroon IeDEA research team needed to build a low-cost electronic cohort database for three clinics plus an in-country data center in order to send data to the US-based Regional Data Center. The solution selected should not interfere with the government's long-term planned rollout of electronic health records. Furthermore, the Cameroon National Ethics Committee advised that all data should be housed in-country before sharing with outside collaborators.

Methods

We implemented our research data collection system using REDCap [2], a free, secure and flexible web-based clinical research data capture platform. Unlike the single webserver solution typically seen in high-resource settings, we implemented three tiers of REDCap servers (Figure 1). To accommodate electricity and Internet outages, we set up a Windows desktop at each clinic as a "REDCap server" on a local area network (LAN) with battery backup. Patient enrollment and routine visit data were transcribed from paper forms into REDCap by data entry personnel working on laptops. This enabled data entry work to continue despite recurrent Internet and power interruptions. We configured a REDCap server (with fixed IP address) at the Data Center in Yaounde to receive data from all sites over Internet. Data officers at each clinic pushed data to the central server weekly ensuring timely data availability at the in-country Data Center. We implemented REDCap forms with integrated quality checks (e.g. range and valid values, date formats, skip logic) and conducted a monthly data quality control at the central level. At the end of every data quality review, a report was sent to the sites for verification and correction. The data quality control procedure was repeated to ensure all corrections were implemented. Cleaned data were uploaded quarterly to a regional data center. Variable names and codes were the same across REDCap projects on all server tiers, allowing easy transfer and harmonization of data.

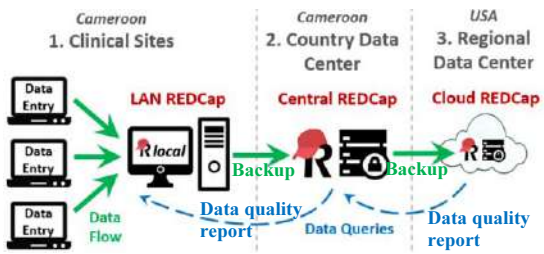

Figure 1 – Diagram of the 3-step data flow from HIV clinics in Cameroon to the regional data coordinating center

Results

This multi-tier REDCap architecture has enabled us to capture high quality, longitudinal data on over 6,000 unique patients despite weeks of Internet interuptions at both the Cameroon data center and participating clinics. Challenges with data collection and entry and REDCap data uploads have been resolved collaboratively with increased site engagement and training [3]. The Cameroon-based server meets requirements for in-country data storage and secure data sharing.

Conclusions

A multi-tier REDCap infrastructure can be a workable data capture solution for research in resource-limited settings.

Analyzing the Demographics of Virtual Care Users

Songzi Liu[a], Tanzila Zaman[a], Barbara Edson[b], Robert Gianforcaro[b], Saif Khairat[a]

[a] *Carolina Health Informatics Program, University of North Carolina, Chapel Hill, NC, USA*
[b] *UNC Health Care, University of North Carolina, Chapel Hill, NC, USA*

Abstract

Using telemedicine to provide care is an attractive alternative for patients. However, few studies have examined the demographics of the patients using virtual care. In this paper, we investigate the demographic features of the Virtual Care (VC) users; Age, gender, roles, and preferred methods of communication are studied.

Keywords:

Demographic features, Patients, Telemedicine

Introduction

Telemedicine is the use of technology to provide care to patients that are at a distance from health care providers [1]. Studies show virtual care is an attractive alternative for in-person urgent care for patients mostly living in the rural communities [2]. Some of the reasons for using virtual consultation are to save cost of travel and time, ease of accessibility, and to reduce pollution [3]. Although there has not been many studies done to understand the demographics of the population using telemedicine, one study shows women over 55 years of age are less willing to use telemedicine for ear and hearing appointments [4].

Methods

The subject of this study is a virtual care, web-portal created to host telemedicine consultation sessions between patients and board-certified providers from multiple disciplines. The virtual care service functions 24 hours a day, seven days a week. Through the portal, patients have the independence to choose to be seen the same day or schedule a visit at a later day. Based on the patient's complaint, a list of expert physicians and their availabilities are presented. Patients have the ability to talk to the preferred physician by phone or video call. This feature is particularly important to accommodate personal preferences with regards to access to technology, privacy, security, and convenience.

Data was collected through the web-portal and stored in a secure, HIPAA compliant server. Institutional Review Board (IRB) approval was obtained to conduct this research. The datasets were cleaned and preprocessed using OpenRefine and Microsoft Excel. All data points were kept because they have complete information. The descriptive statistical analysis was carried out using R. In further examining of the relationship between different variables, Tableau 10 was used in generating data visualizations.

Results

Since Go-Live, a total 2,467 patients registered to the portal; 996 patients completed a visit in Virtual Care over a period of 9 months.

Age

The self-reported age of users ranged from 1 to 118 years old, with a median of 39 and a mode of 34, as seen in Figure 1. The age data is further categorized into four age groups representing different population characteristics: with age 0-18 as *Minors*, age 19-34 as *Young Adults*, age 35-64 as *Older Adults*, and over 65 as the *Elders*. Users aging from 35 to 64 years old composed 57.68% of the entire user population.

Gender

A total of 1,763 female users constituted 71.46% of the user body, significantly outnumbering the 704 male counterparts (28.54%). A closer examination of the relationship between *Gender* and *Age* reveals that the male user population has a more spread-out distribution of users from different age groups. The female users, on the other hand, come heavily from the *35-64* group (63.36%), Figure 1.

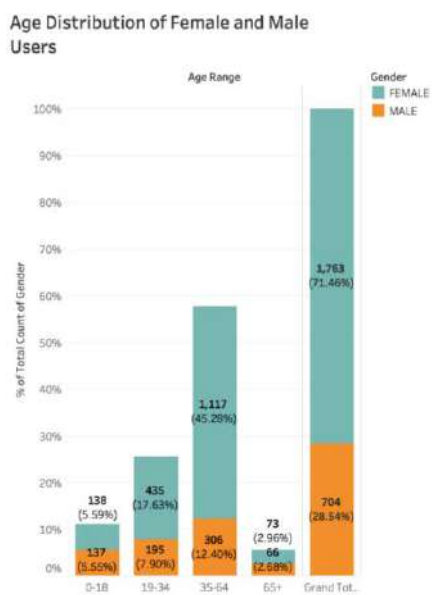

Figure 1. Age Distribution of Female and Male Users

Encounters

Among the 996 instances of patient encounters, 915 (93.56%) were completed and successfully paid. The remaining 6.44% of cases were either *Non-billable due to Missed Session* (46 instances) or either *Non-billable due to Cancellation* (17 instances), where encounters were initiated but never took place. The duration of patient encounters ranges from under 1 minute to 15 minutes, with an arithmetic mean value of 4.55 minutes and a median of 4.51 minutes, as seen in Figure 2.

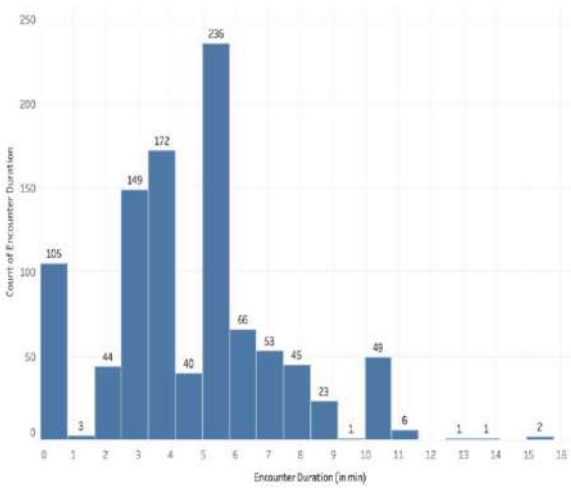

Figure 2. Distribution of the Duration of Patient Encounters

Primary and Dependent Users

2,016 users (81.72%) fell under the *Primary* roles; the remaining 451(12.28%) are classified as *Dependent*. A further look into user roles with respect to the age parameter indicates that 85.82% of Minors are *Dependent*. The other three age groups are predominantly *Primary*, each with over 80% of users being Primary as seen in Figure 3 below.

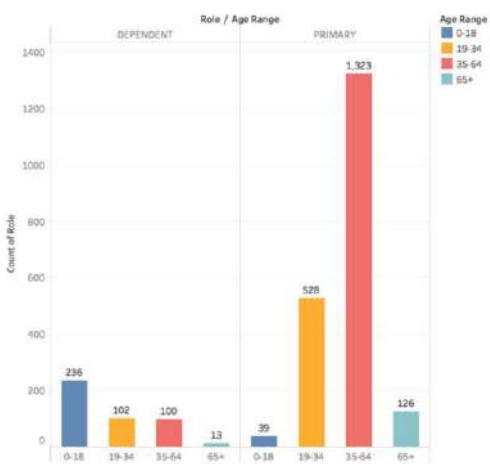

Figure 3. Age Composition of Primary and Dependent Users

Preferred Methods of Encounter

827(83.03%) of instances took place via *Phone* call; the other 167 (16.97%) encounters were facilitated by *Video* call, as seen in Figure 4. A closer look at the preferred methods by gender indicates that a greater percentage of male users prefer *Video* than the female users.

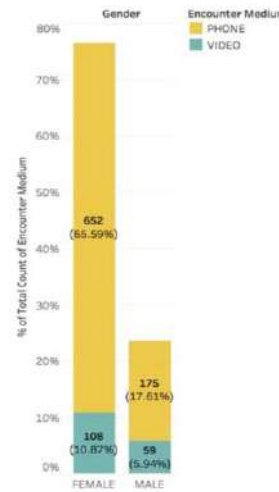

Figure 4. Preferred Methods of Encounters (Video vs. Phone) by Gender

Discussion

The major finding of this study showed 70% of the users were females. A likely explanation of this trend is women tend to seek care in general or are more open to integrating technology into their care seeking efforts. Another rational is that females may use VC to seek consultation or care for their children.

Furthermore, the choice of video or phone call varied by gender. Most female participants preferred a phone call over video, while males had a higher rate of video calls.

More research is needed to understand the reasons behind the choice of encounter. Future work will include the collection and analysis of broader data, such as chief complaint and diagnosis, to assess the efficacy of VC from clinical, technical, and operational perspectives.

Smartphone-Based Self-Empowerment App on Secondary Prevention of Patients with Cardiovascular Disease

Yisi Liu[a], Jingyi Chen[b], Karen V Lamb[c], Peirong Wu[d], Polun Chang[d], Yanyan Cui[d], Ying Wu[a]

[a]*School of Nursing, Capital Medical University, Beijing, China*
[b]*Cardiovascular Unit, Peking First Hospital, Beijing, China*

Abstract

We developed a HeartGuardian app and explored its effects supporting people with CVD on lipid control and medication adherence. Fifty-seven patients were enrolled, 29 in the intervention group and 28 in the control group. The 12-week intervention resulted in a moderate improvement in lipid level and greater improvement in medication adherence (82.14% vs 37.93%, P=0.001). These outcomes translate into significant differences in occurrence of major adverse cardiac events (28.75% vs 72.43%, P =0.001).

Keywords:
Cardiovascular Diseases, Secondary Prevention, Medication Adherence.

Introduction

Cardiovascular disease (CVD) is a leading cause of death. High lipid level and poor adherence to CVD secondary prevention medications have been reported as the main risk factors of mortality in CVD [1]. Yet, lipid control rate and medication adherence are below ideal [1]. Mobile technology, such as smartphone application, might be part of a solution, as increasing evidence indicates that these apps support behavior change [2]. The aim of this study was to explore the short-term effectiveness of a HeartGuardian app in supporting people with CVD on lipid control and medication adherence.

Methods

In this twelve-week, two-armed, parallel, randomised control trial, fifty-seven patients with CVD were randomly assigned to either the intervention group (use of HeartGuardian app on smartphones and receive weekly text messages on health education) or the control group (receive weekly text messages on health education). The inclusion criteria were (1) hospitalized for CVD; (2) prescribed at least one CVD secondary prevention medication; (3) age 18 to 70; (4) owning a mobile phone with Android operating system; (5) competent to receive and read text messages. Patients who were critically ill, at an unstable or acute stage of illness, with mental illness, or unable to communicate were excluded. Approval of the study was obtained from the Capital Medical University Review Board.

The HeartGuardian app is designed based on behavior change theory [3]. Interventions integrated in the app include: (1) health education (tailored health plan and daily updates on lifestyle, diet, and treatment); (2) behavior interventions (medication reminders); (3) follow-up (medication recording and daily feedback. The app will remind the participants when it is time to take their medications and mark the medication as a "taken" or "missed" dose.); and (4) self-empowerment via automatic intelligent, real-time video feedback based on the subjects' adherence to taking medication. The videos show either improved or worsening vessel pathology based on the subjects' specific actions. The app is compatible with the Android operating system.

The primary outcome was the lipid level, including low-density lipoprotein cholesterol (LDL), total cholesterol (TC), triglyceride (TG), and high-density lipoprotein cholesterol (HDL). Secondary outcomes included medication adherence, and the occurrence of major adverse cardiac events (MACE) which are defined as the occurrence of unstable angina, ST-segment evaluation myocardial infarction, non-ST-segment evaluation myocardial infarction, and coronary revascularization. Primary and secondary outcomes were measured at the baseline and twelfth week by a research staff member who was blind to participants' random assignment. The baseline data regarding participants' demographics, medical and medication details were collected from participants' charts before discharge. Participants were required to visit the clinic at the twelfth week after discharge for routine health review and collection of follow-up data. The fasting blood samples of the participants were collected at their clinic visit for measurement of lipid levels. Medication adherence was measured by the Morisky Scale [4]. The occurrence of MACE was collected from participants medical charts.

Statistical analyses were conducted using SPSS 19.0 for Windows (SPSS Inc, Chicago, Illinois). The Chi-square test or Students t-test was used to test the difference between the two groups. A matched paired t-test and McNemar test were applied to test the differences within groups between the baseline and at the twelfth month follow up. Statistical significance was set at $P < 0.05$.

Results

Fifty-seven patients were enrolled with 29 in the intervention group and 28 in the control group. There was no significant difference between the two groups on the baseline data (data not shown here due to word limits). The mean (SD) age was 59.05 (7.23) years. 82.46% were male. 63.16% were retired.

71.70% of the participants were diagnosed with unstable angina and 88.30% had comorbidities.

As shown in Figure 1, no significant difference was observed in the baseline lipid levels between two groups. After the 12 weeks of intervention, both triglyceride and total cholesterol were significantly lower in the intervention group, compared with the control group (P=0.020, 0.014, respectively). Pre-post tests showed triglyceride level at the twelfth week was significantly lower than the baseline in the intervention group with a mean difference in change of -0.263 mmol/l ([95%CI, -0.040 to 0.487], P=0. 024), while it was significantly higher than the baseline in the control group with a mean difference in change of 0.378 mmol/l ([95%CI, 0.044 to 0.712], P=0. 029). No significant changes were observed with respect to low-density lipoprotein (LDL) and high-density lipoprotein cholesterol (HDL).

The baseline medication adherence was similar between the intervention group and the control group (43.33% vs 30.00%, P =0.284). After 12-week follow up, adherence increased significantly in intervention group (43.33% vs 82.14%, P =0.002), while the increase was minor in the control group (30.00% vs 37.93%, P =0.520). The difference was statistically significant, with the intervention group exhibiting higher medication adherence at the twelfth week than the control group (82.14% vs 37.93%, P=0.001).

Regarding the terminal clinical outcomes, the HeartGuardian app achieved a positive effect in lowering the occurrence of MACE in the intervention group, compared to the control group (28.75% vs 72.43%, P =0.001).

Discussion

Recent studies support the effectiveness of applications in improving lipid management and medication adherence [5,6]. But few studies assessed the effects on terminal clinical outcomes, such as MACE [5]. In the current study, a 12-week smartphone-based application intervention resulted in a moderate improvement in lipid level and greater improvement in medication adherence. These outcomes translate into significant differences in the occurrence of MACE. The possible reason that smartphone-based application improves the management of CVD risk factors might be that it enhances patients' self-efficacy and provides a form of social support [7]. This app features multiple integrated interventions and customized health education, which are reported to be a more effective approach to achieve behavior change than single interventions and generic health education [2]. This study has several limitations. One of the main limitations is the Hawthorne bias. Patients in the intervention group were aware that they were enrolled in a study and the improvements in lipid management and medication adherence could just be the result of better motivation in terms of a healthy lifestyle. We sent weekly text messages on health education to patients in both groups to minimize this bias.

Conclusions

A smartphone-based self-empowerment app could help patients with CVD better manage their dyslipidemia and improve medication adherence, and reduce the rate of MACE. This SmartPhone application appears valuable in CVD secondary prevention. Effects longer than twelve weeks are worth further investigations.

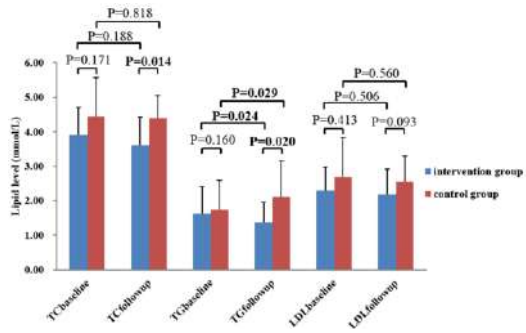

Figure 1. Effects of HeartGuardian Application on Lipid Levels. TC: total cholesterol; TG: triglyceride; LDL: low density lipoprotein; followup: at twelfth week after discharge.

Abstract

openEHR's Guideline Definition Language is designed for standardizing clinical decision support systems. In this study, we use Guideline Definition Language to represent patient safety rules in pre-operation of Percutaneous Coronary Intervention for the dynamic checklist system. After using Guideline Definition Language in this case, we had some results about its expression adaptability to requirements of patient safety rules.

Keywords:

Electronic Health Records, Patient Safety, Checklist

Introduction

The dynamic checklist system is a new type of guideline-based decision support system [1]. It can make judgments on actual data of patients with an execution engine and dynamically generates a personalized checklist accordingly. The core function of such system is based on implementation of rules. However, rules are closely associated with clinical data which makes the systems difficult to implement.

openEHR is an open standard maintained by openEHR Foundation. Its core design is to separate medical domain knowledge from specific clinical information by dividing models into two levels: archetype model and reference model. Its organizers nowadays pay attention to integration problem between clinical decision support systems (CDSS) and electronic health records (EHR). They also found that expressing and sharing computerized clinical decision support content across languages and technical platforms are a long term goal. Lack of commonly shared clinical information models and flexible support for various terminology resources have been identified as two main challenges of sharing decision logic across sites. Therefore, they proposed a new guideline definition language (GDL) and added it to the openEHR Foundation.

We carried out a case study for constructing clinical rules of the dynamic checklist system in preoperative stage of Percutaneous Coronary Intervention (PCI). We used GDL to express decision logic and build knowledge base for the dynamic checklist system. Also, we used openEHR's information models as data model to represent clinical data concepts used in this case. The data source used in this case is a clinical data platform, which is also based on openEHR foundation. Then, we combined them with an execution engine. Based on these steps, we also summarized some general methods about rule editing with GDL. Finally, we discussed advantages, limitations, and directions of its future development.

Methods

Data Models for Medical Concepts

First, we chose several archetypes based on openEHR corresponding to data requirements in the preoperative check procedure of PCI. Archetypes can be searched in the official platform named Clinical Knowledge Manager (CKM) by using keywords corresponding to domain medical concepts [2].

Edit GDL Rules

A complete GDL rule mainly consists of four parts, as shown in Figure 1:

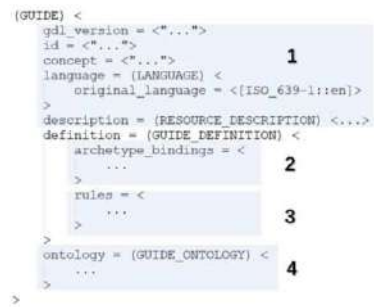

Figure 1– Basic structure of GDL

After editing a large-scale number of GDL rules, we concluded a general method for rule editing based on GDL syntax, which is mainly divided into four steps:

1. **Defining Metadata**: The metadata part is based on metadata description in the ADL, which includes mostly version information, language information, author information, keywords, rule usage and using scopes.
2. **Binding Archetypes and Elements**: We used local variables to associate with unique path of archetypes or elements.
3. **Authoring Rules**: The definition part of the rule is part of the GUIDE_definition module. Keywords WHEN and THEN are used to guide the condition and action of each rule. Priority is used for setting execution order of the rules.
4. **Defining Ontology**: The concept represented by **gt** code used in rule definition is indexed with clinical concept and can also support bindings of external term sets like SNOMED CT and ICD10.

Data Source and Engine for Rule Execution

In this study, our data source was a clinical data center platform called CDR based on openEHR. The CDR uses archetypes as the primary form for storage and access of clinical data. Data stored in CDR can be queried by the interface and returned in JSON format with mapping of path and value. The path corresponds to what we defined in the rules and the value is what we need related to the element in archetypes. By using the CDS Workbench developed by Cambio Healthcare [3], we translated the rule format from GDL to Drools. Then, we used Drools as the execution engine.

Results

The core requirement for constructing rule base is expression of a single rule. Rules were classified into six types and we made an analysis about the percentage of expressing result. The result is shown in Table 1.

Table 1– Results of rule construction

Type	Quantity	Examples	Results
Hospital procedures	5	Name, sex, age, deposit for surgery, medical insurance type.	100%
Surgical preparation	4	Medical orders and drug-related verification.	100%
General risk control	6	Blood potassium, left ventricular ejection fraction, allergies.	100%
Visual signs	8	Blood pressure, body temperature, pulse.	75%
Physical exams	6	Ultrasound, radiation.	67%
Laboratory tests	8	Blood, urine, stool, and blood coagulation routines.	50%

By executing these rules with Drools engine and running with data source from CDR platform [4], a personalized checklist was produced. Figure 2 shows one of the execution results.

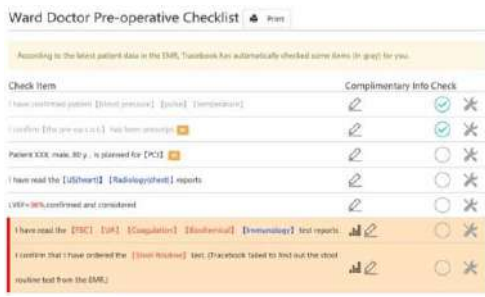

Figure 2– Execution result of the System

Discussion

According to requirements of rule expression of PCI preoperative surgery, we concluded several basic types we needed, mainly boolean expression, relational expression, logical expression, arithmetic expression, collection expression, interval expression, and data and time expression. After practicing rule construction, we found that GDL is designed to be user-friendly in expressing boolean, relation, logical, and arithmetic types; and lacking in expressing collection, interval, date and time. Collection and interval operations are important to dynamic checklist systems; keywords like foreach, where, size, contains and so on are urgently needed in cases of construction of patient safety rules. As for interval type, it can combine with data and time to express accurate date/time frame and interval without complex calculation.

The above results mainly focus on the condition part of a rule. Using GDL to fit the content of the action specification part has some shortcomings. It can hardly support our requirements totally. For example, we needed to add basic check items into a checklist template through execution of rules. As such, we needed some functions like "addTask()". Presently, we cannot find scalable functions in the action part of GDL.

Conclusions

In this study, we mainly discussed a case study about using openEHR's guideline definition language to express patient safety rules in pre-operation of PCI and its practical results. We conclude that GDL has better adaptability when constructing rules of simple expression form. At the same time, it can effectively solve the problem of data acquisition and interoperability between systems. However, the expression ability of GDL has certain limitations. Thus, it cannot completely meet requirements of dynamic checklist systems.

Future research will focus on design and implementation of a new type of guideline language to meet requirements of the dynamic checklist systems. Based on existing efforts, this new guideline language is expected to be robust, standards-based, open source tools supported, and clinically user-friendly.

Mindup: A Platform for Monitoring and Cognitive Enhancement for Patients with Alzheimer's Disease

Matheus Moreira Luna[a], Diogo Dantas Moreira[a], Fabio Abrantes Diniz[a]

[a] *Curso de Tecnologia em Análise e Desenvolvimento de Sistemas, Instituto Federal de Educação, Ciência e Tecnologia da Paraíba, Cajazeiras, Paraíba, Brasil*

Abstract

Alzheimer's Disease (AD) is an illness that degenerates an individual's cognitive functions, leaving them unable to take care of themselves. Even without a definitive cure, AD should be treated with remedies and cognitive enhancement. This article presents an application that assists in the cognitive reinforcement of AD patients through games, supports the medical follow-up of patients, and facilitates the daily exchange of information between the caregiver and the doctor.

Keywords:
Smartphone; Alzheimer Disease

Introduction

Alzheimer's disease (AD) is the most common form of dementia, characterized by being a disease that destroys nerve cells, disrupting synaptic connections, causing severe memory loss in addition to other symptoms that worsen over time [1]. Currently, AD has no cure but can be treated through medication and cognitive enhancement activities to prevent disease progression [2].

In the literature, we have found several applications that may help in cognitive enhancement in patients diagnosed with AD through games, however, none of the applications presented a dedicated platform to specialized observation of patient's performance in the games by the doctor, that is, it does not provide a form of communication between them and the caregivers.

As a way to help doctors, caregivers, and patients with the initial level of Alzheimer's disease to have better interactions, this work presents an application called "MindUp" for mobile devices and web, where it's possible for patients to have access to specific games of cognitive exercise. These exercises serve as daily reinforcement of their functions in a controlled way and the caregiver can make out daily reports of the patient and assist the doctor monitoring the evolution of the disease.

Methods

This work began with a bibliographical review of studies done by neurology experts on Alzheimer's Disease and its predictions for the next years and generations, as well as informal interviews with neurology professionals to try to validate the idea and collect system requirements. In this context, the stages of the software development process, based on the ideas of the Scrum process [8] and adapted to the text of the work, were started. The requisites collected for the system were: A) Medical account management; B) Caregiver account management; C) Patient account management; D) Cognitive reinforcement exercises (games); E) Results; F) Exercise performance monitor (for doctors); G) Caregiver's Reports history and H) Daily Report Fill.

A comparative analysis was made with 4 applications that serve the same purpose: "Fit Brain Trainer" [3]; "Lumosity" [4]; "Elevate" [5] and "Peak" [6]. These applications are the ones closest to the approach proposed by this work. The comparison can be seen in Table 1, where C indicates that the application has the associated requirement and N/C where it doesn't. When observing the collected data, the proposed system has as a differential the functions related to A, B, F, G and H requirements in relation to the related applications.

Table 1 – Applications comparison

(R)	[3]	[4]	[5]	[6]	M
A	N/C	N/C	N/C	N/C	C
B	N/C	N/C	N/C	N/C	C
C	C	C	C	C	C
D	C	C	C	C	C
E	C	C	C	C	C
F	N/C	N/C	N/C	N/C	C
G	N/C	N/C	N/C	N/C	C
H	N/C	N/C	N/C	N/C	C

Based on these requirements, the "MindUp" system, composed of three dedicated interfaces for each user role (Doctor, Patient, and Caregiver), is being implemented. Figure 1 shows the activity flow of the actors in the proposed system. Subsequent sections explain in detail each step of this flow.

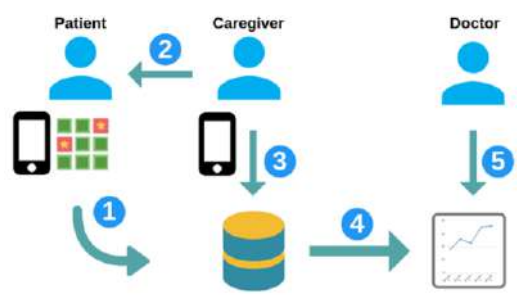

Figure 1 – Activity flow on MindUp

For the patient, the application has a simple and intuitive interface inspired by the guide to serious games for cognitive treatment [9], where the patient will have access to the game of cognitive reinforcement. In "MindUp", a memory game is used and can only be accessed at a determined time, which is

configured by the doctor, so that there is no overload of exercise and stress to the patient.

In step (1), the patient must access the platform at the time specified by the doctor and perform a round of play. Each round consists of 3 levels of difficulty, the first with 3 pairs of cards, the second with 6 pairs and the third level with 8 pairs.

For the caregivers, we used the test to catalog the daily behavior of the patient, which is observed by the caregiver in step (2), and capture details of the patient's daily life.

In step (3), the caregiver will be presented to 10 multiple choice questions that were developed by neurologist James E. Galvin, whose main purpose is to detect the level of the disease in patients, applying the questions seasonally [7].

The doctor can register their patients on the platform, giving each of them a credential, and configure the patient's times of use of the application. Subsequently, after processing the data collected by the patient's use and by the caregiver's follow-up, the system will generate data on the patient's daily income, as demonstrated in step (4).

The daily yield (Dy) is measured by the average points of each session (S) marked by the patient on a given day. The score of each session (S) is made by the average score (Pt) of each level of the game, which is calculated by the number of pairs of cards marked (x) times 10 divided by time (t). Therefore, the calculation made to gauge the yield is given by the following formulas adopted by the author 1)Ap = (10 * x) / t; 2)S = (Ap1 + Ap2 + Ap3)/3 and 3)Dy = (S1 + S2 + S3)/3

In addition, the doctor can access reports produced by the caregivers and can access the last one produced or of a certain date. This process is represented in step (5)

Results

Currently, the project is undergoing validation, prototyping, implementation, collection, and analysis of new requirements, as well as refinement of existing ones, and improvements in system architecture.

Figure 2 shows the main functionalities of the system, already implemented. The interface (1) demonstrates how its user interface (UI) is proposed by the Caregiver, who will answer the multiple choice questions; the UI (2) already demonstrates a use of the game of memory that will be accessed by the patient; Finally, the UI (3) demonstrates the proposal of the physician interface, which can be used to monitor the patient's treatment.

MindUp attempts to bring greater interaction among doctors, caregivers, and patients, collecting information onthe daily and specific behavior that may occur on sporadic days, and may encourage further research.

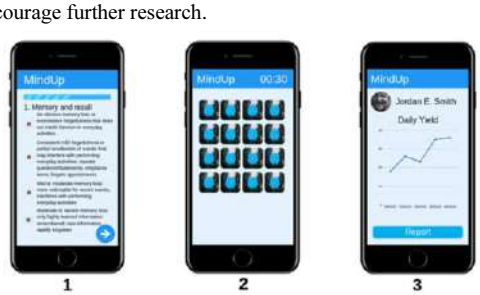

Figure 2 – UI for different roles in Mindup

Through informal interviews with neurologists, a great deal of acceptance was noted by practitioners. It was noticed that the application "MindUp" is useful those involved with Alzheimer's disease treatment, and therefore, we had a greater interaction of professionals in this project, where they were always giving ideas of what the proposed system could do.

The system proposed here differs from other related platforms in that "MindUp" proposes to be an open platform and most of the features that its competitors promise are paid. None of the related applications showed any interactivity with physicians and caregivers, showing the results of the training only for the end-user, and also does not give the caregiver the ability to record daily patient behaviors

Conclusions

The "MindUp" system still has the potential for growth, mainly because it has partnerships with professionals to understand, collect and validate requirements, which can bring new functionalities and integrating other types of cognitive reinforcement exercises.

Continuous use of the system, which has not yet been carried out, and a follow-up of a considerable number of patients can give new visions about the system and prove its relevance in the face to other available solutions.

Role of Nursing Informatics in Implementation of SNOMED-CT in India

Sweety Rai [a], Owais M Siddiqui [a], Susil K. Meher [a], A Shariff [a], Shefali Banga [a]

[a] All India Institute of Medical sciences, Ansari Nagar, New Delhi, India-1

Abstract

SNOMED-CT project under the Ministry of Health and Family Welfare is operational at AIIMS since July 2016. A team of nurses were recruited under SNOMED project who actively works for integrating existing EHR with SNOMED-CT, monitoring, training of users auditing the data, resets creation and development of National Drug Database.

This paper emphasizes role of Nursing Informatics in implementation of SNOMED-CT project in India as well as in any other country.

Keywords:
SNOMED-CT, Nursing Informatics (NIS)

Introduction

SNOMED-CT is the foundation for standardizing clinical content in Electronic Health Records (EHR) that contains concepts with unique meanings along with specific codes and formal logic based definitions organized into hierarchies.

Nursing informatics (NIS) is a field of nursing that incorporates nursing, computer, and information sciences to maintain and develop medical data and systems to support the practice of nursing, and to improve patient care outcomes.The quality of care depends on effective communication among healthcare providers, since healthcare providers communicate primarily through the notes they write in a patient's health record/in-patient chart, nurse informaticist seek to continually improve the speed, efficiency, timeliness, accuracy of patient charting, reducing costs and thereby enchancing patient care.

Methods

SNOMED-CT project under the Ministry of Health and Family Welfare is operational at AIIMS since July 2016. The team of nurses and a programmer were recruited under an exsiting SNOMED project. The programer actively works on integrating existing EHR with SNOMED-CT, monitoring, training of users auditing the data, reference set creation and development of a national drug database .

AIIMS is the premier medical institute of India and it conducts teaching programs in medical and para-medical courses both at undergraduate and postgraduate levels and awards its own degrees.

The NIS team working for SNOMED-CT at AIIMS, NEW DELHI has accomplished the following task in order to enhance the implementation of SNOMED-CT.

- Twenty six reference sets were created and validated based on the NHP (National Health Program) requirement.
- LOCAL REFSETS: Apart from these, the department wise local Refsets are also prepared in the Refset Management Tool by the AIIMS SNOMED team
- Validation of some Refsets are in process (Future Targets)
- Creation of The National Drug Library Database has been done and it includes, name of the drug with SNOMED-CT code, Manufacturer code, Drug classification which includes a SNOMED-CT code and a Medicine brand name (1,69,000 drugs have been mapped with SNOMED-CT codes)
- SNOMED-CT coding done for 4000 nationalized lab investigations given from ministry
- SNOMED-CT coding for the diagnoses collected from clinical areas of the hospital
- SNOMED Integrated EHR : Various online applications running in AIIMS have now been fully integrated with SNOMED-CT which are as follows:
  - National death registry of India (NDRI)
  - e-birth module (Online birth certificate)
  - e-MLC (Online medico legal certificate)
  - e-vitals Entry for Nurses
  - e-Hospital-Admission Discharge Transfer
  - PDS (patient display system)
  - e-Blood request
  - OT module
  - Online Admission Requisition
  - Quality Assurance Module for academics
  - Heart Transplant Registry

Results

The NIS team working for SNOMED-CT at AIIMS, NEW DELHI has been successful in creation and validation of 26 Refsets, along with Local Refset. The creation of National Drug Library Database has been done and 1,69,000 drugs have been mapped with SNOMED-CT codes, 4000 nationalized lab investigations and diagnoses have been mapped. Along with this SNOMED integrated EHR are running in AIIMS. NIS have

been successfully carrying out the ongoing implementation of SNOMED-CT.

Discussion

To make electronic health record meaningful and useful we need a standard code of terminology. SNOMED-CT provides the same, however before implementing it we need to customize it as per national requirement.

For the customization of SNOMED-CT as per national requirement comes the role of NIS.They are a neccesity in the implementation of the same .

Conclusions

Nursing informatics (NIS) is an intersection between patient care and patient health information and is emerging as the backbone for bridging the gap to implement **SNOMED-CT**. As a result, this standardized reporting helps in reducing lot of inaccuracies and thereby ensures comprehensiveness in recording the patient's entire health information.

Development of Augmented Reality in Learning for Nursing Skills

Yukie Majima[a], Seiko Masuda[a], Takeshi Matsuda[b]

[a] Graduate School of Humanities and Sustainable System Sciences, Osaka Prefecture University, Sakai, Osaka, Japan,
[b] Department of Information Security, University of Nagasaki, Nagasaki, Japan

Abstract

This study was designed to develop a wearable learning support system that enables novices to learn the skill for blood withdrawal while imitating its images displayed in front of them. For them to master "tacit knowledge," such as "proficient art" and "knacks," in intravenous injection and blood drawing techniques. This paper outlines a learning support system incorporating augmented reality (AR), which we have developed based on earlier studies.

Keywords:

Augmented Reality, Nursing Skills, Tacit Knowledge

Introduction

Along with the increasing sophistication of medical care, it is important to foster "nursing practical knowledge" with a view of nursing that gives due consideration not only to nursing skill proficiency, but also to emotional aspects of work, such as intentions of patients and their families in individual and diverse situations. Nevertheless, such practical knowledge of nursing is highly tacit in nature. It is therefore difficult to verbalize [1]. Furthermore, because nursing practice at clinical sites is conducted in a closed environment, no opportunities exist for it to be disseminated or for the information to be shared; few opportunities exist for the practices to be refined.

Other studies investigating the area of video reflexive ethnography have indicated a study method with which structural changes to clinical communication were achieved for reshaping ICU ward round practices [2]. Another study explored how clinicians used the built environment to provide safe communication in an ICU [3].

In the area of leadership education, Gordon et al. [4] reported that being able to "see" oneself at work gave participants the opportunity to discuss and analyze their everyday leadership practices and challenge some of their sometimes deeply entrenched values, beliefs, practices, and assumptions related to healthcare leadership.For those reasons, the authors have conducted research continually since 2008, specifically examining the tacit nature of nursing skills, for which efforts have been undertaken to visualize manuals for nursing skills at hospitals and to share them using an e-learning system.

Into some specific types of blood vessels, novices have difficulty inserting a needle. This study was undertaken to develop a wearable learning support system that enables novices to learn the "art" in blood vessels while imitating its images displayed in front of them. For them to master "tacit knowledge," such as "proficient art" and "knacks," in intravenous injection and blood drawing techniques, we specifically examine fingers holding no tool, those which play a supportive role, which has been a blind spot as a subject for study. To that end, we are carrying out this study using the following three approaches.

(1) Wearing sensors on supportive-side fingers for intravenous injection techniques to analyze the contact force and facilitate the insertion of a needle into a blood vessel.

(2) Consideration of a method to visualize learning contents to ease understanding of techniques.

(3) Consideration and development of a system to support real-time learning using wearable glasses.

We are now analyzing contact pressure and skin extension pressure of supportive fingers and comparing the characteristics of experts and novices in relation to (1), concurrently with the pursuit of (2). Regarding (3), we have developed a learning support system prototype using augmented reality (AR). This paper presents an outline of the system.

Earlier Studies

The authors have conducted the following studies to date, devoting particular attention to the tacit knowledge of nursing skills.

(1) We conducted an interview survey and obtained the following findings: a) Many nurses believe that, in most cases, once they have identified a vein, they are able to perform an intravenous injection. However, they just verbally express the moment when they have done it well as "feeling like entering a blood vessel 'smoothly ('kukutto' or 'sutto' in Japanese)'". It is difficult to express exactly how they feel [5]. b) Novice nursing students consider that the knack for techniques is to remember procedures [6]. It is therefore important for the process of learning support to compel novices to master procedures before their advancement to sharing the performance characteristics of experts.

(2) Having analyzed lines of sight in practicing intravenous injection techniques, we found that line-of-sight flows differed between novices (nursing students) and experts (nursing personnel) and that experts move their lines of sight to the next practice (prior treatment) [7].

(3) We developed a reflective learning support system that supports to review skills based on the procedures and the line-of-sight flows [8] and a system that can reproduce finger movements in practicing skills in computer graphics using motion capture for fingers [1].

(4) To extract tacit characterization data of nursing skills from different perspectives, we analyzed "brain waves" and "heart rate" data of practitioners and clarified the state of relaxation and that of tension in the process of practicing nursing skills. Subsequently, the characteristics of "techniques" were compared between experts and novices [9].

(5) We analyzed tuning information (pull-in effect) related to biological rhythms (brain waves and heart rate) of nurses and patients on the hypothesis that the good or bad mutual relationship between a nurse and a patient might be related to the proficiency of techniques. Results suggest the possibility that nurses' states of relaxation might cause patients' state of relaxation [10].

In injection skills education, both instructors and learners are typically highly interested in how to handle a syringe. In fact, the know-how to support the learning has been accumulated. However, only purposes such as "fixation and extension of a blood vessel" are presented in terms of the techniques of left fingers matched to the characteristics of blood vessels of individual patients for whom giving an injection is difficult. The characteristics include a rolling over-and-over ('korokoro' in Japanese) of a moving blood vessel. How to fix and extend a blood vessel has not been fully taught.

In blood drawing and intravenous injection techniques, fingers holding no tool that play a supportive role facilitate the insertion of a needle into a blood vessel. For this reason, we aim to develop a learning support system that particularly addresses those factors which play a supportive role (fingers that facilitate inserting a needle into a blood vessel) other than the main factors and processes. We compared the characteristics of experts and novices to observe the contact pressure of supportive fingers and found that experts practice skills with a more stable contact pressure [11] and skin extension pressure [12] than novices do.

Wearable AR System for Learning

In conventional education for nursing skills, novices typically first learn the purpose and procedures of the skills in lectures. Then they actually undergo training individually or as a group after having seen demonstrations in technical seminars. Because novice nursing students consider that the knack for techniques is to remember procedures, instructors have been required to try to provide easy-to-understand demonstrations. In recent years, when ICT has developed, video learning and eLearning that can be learned anywhere, anytime has become possible. Nonetheless, in actual nursing skills training, learners often practice while watching a monitor that displays video images. Real-time learning is difficult because of line-of-sight flows and other problems. No image clues are found in terms of fingers holding no tool, which might play a supportive role in a blind spot, but which might be a subject for study. It is particularly problematic to learn the "art" for blood vessels into which it is difficult for novices to insert a needle.

For that reason, we first developed a learning support system using AR (Argument Reality) in which learners can learn experts' nursing skills without moving their lines of sight.

Figure 1 portrays a specific screen for learning. When practicing skills training, learners can learn skills by following and imitating (tracing) the images of experts' techniques that are displayed transparently in front of them in real time. The prototype system verified that training is possible by overlaying images on a simulation arm model.

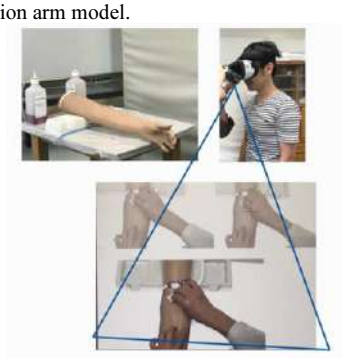

Figure 1- Wearable learning system using AR: Learners obtain skills by watching and imitating images of experts' skills projected on an actual simulation model.

Conclusions

We described the development of a wearable system for the learning of tacit knowledge of injection skills, following our research conducted to date. Future challenges include the following. Because adjustment of overlay images is necessary before training, additional efforts must be undertaken in overlaying experts' (others') images and beginners' images of skills, including the determination of object positions and how to imitate objects. Furthermore, we will compare practice performance of students using AR and those not using AR to be clearly seen whether AR makes a difference, for example, whether the time to achieve proficiency of techniques reduces by using AR.

Abstract

eHealth system users need adequate, timely access to health-related information; including the functionality of alerting and notifications on events. This was addressed through requirements engineering techniques. The analysis resulted in a requirements' list and architecture based on IHE standards. Patients, professionals and administrators were identified as main actors, core notification attributes were type and transport channel, and notifications always event-triggered. One challenge is system-based data access events, potentially leading to an invalid triggering of events.

Keywords:
Electronic health records, access to information, health personnel

Introduction

Social services and health care, are areas of welfare expected to benefit extensively from digitalization [1,2]. Both sectors require a large public investment and are areas that most citizens come in contact with over their lifetime. For eHealth system users it is crucial to be able to access health related information in an adequate and timely manner. Patients are increasingly engaged in their treatment process, transforming healthcare IT into a personalized, largely connected and patient empowering infrastructure [3]. Improving the continuity of care and establishing an effective cooperative health care is expected to reduce costs. To address this challenge, electronic health record (EHR) systems are introduced to close the gap between institution-specific patient data and a comprehensive, longitudinal collection of health related patient data [4]. Patient access to the EHR and interactive messaging functions may improve communication, patient empowerment, engagement, and self-management [5]. Those challenges and promises are drivers of many eHealth projects around the globe focusing on introducing regionally/nationally wide and connected, standards-based EHRs [6]. The underlying standards have also been endorsed and promoted by the European Union [1]. However, a recently published study on the status of EHR implementations within the European Union [7] shows that introducing the infrastructure for a standards-based EHR is not enough for a successful implementation and acceptance by the major key players in the health care system. Especially the usage by medical practitioners, and therefore the primary and secondary usage of EHR data, is in several countries an aspect receiving a low rating. One important aspect for physicians regarding the usage and acceptance of eHealth systems is the functionality of alerting and notifications on events on or within data of the EHR system [8]. Focusing on this aspect, this paper has the following goals: 1. To identify requirements for an alerting and notification system expected to be provided by a state-of-the-art EHR system; 2. To elaborate on a solution on how to incorporate such a system in an already existing IHE based EHR system.

Methods

Our approach was to address this topic by using requirements engineering techniques focusing on the business analysis and project definition phases [9]. We did not address the project execution and maintenance phase, since implementing a prototype was not within the scope of this paper. This will be a part of future research. Therefore, our research evolved through three phases leading to a list of requirements and an architecture based on IHE standards: **conception** (business analysis), **architecture and workflows** (project definition) and **validation** of the architecture against requirements.

Results

Requirements for Notification Systems in EHRs

Based on the gathered material and information, three rough types of actors of an eHealth system were identified:

- Patient: a person with a medical history. Related PHI data for the identified person is stored within the EHR. This Actor has no or limited medical knowledge and background.
- Professional: Professional user of the eHealth system connected with zero or several patients. The usage of the system is within the scope of the treatment process of associated patients.
- Administrator: Technical user with no medical background. This person is responsible for maintaining and operating the eHealth system and its functionality.

Since this paper targets the acceptance and requirements of an eHealth or EHR system for its end users, the actor "Administrator" was not considered. In contrast to our initial knowledge, the conception phase showed that the requirements on the level of which notifications are defined and received are identical for the Actors "Professional" and "Patient". For both

actors the requirements can be arranged into two core functionalities: "Define Notification" and "Receive Notification", where the latter is a consequence from the attributes defined for the former. Therefore the core characteristics of a notification are the type and transport channel.

Notification Types:

- Instant Notification: Notification of this type is submitted immediately, without non-technical delay, to the intended recipient.
- Aggregated Notification: This type of notification describes a summary of the occurrences of a certain event type. The timeframe of the summary is expected to be configured when defining the Notification.

Notification Channels:

1. In-Application: The information of the event is displayed within the application of the user. This could be a Primary System of the physician, a portal or web page. The notification is delivered as part of the application's user workflow in the user interface.
2. E-Mail: The notification is delivered in an E-Mail inbox. The transport media as well as the receiving party is expected to be insecure or not reliable.
3. Secure E-Mail: This channel is similar to the E-Mail channel, however, transport and storage are secure through state of the art security mechanisms such as encryption and receiving confirmation.
4. SMS: Delivery of the information to a mobile phone using SMS technology. Similarly to the E-Mail notification, this is not regarded as a secure channel.
5. Letter: The notification is delivered in paper form using postal deliveries. Depending on the service, this can be a secure or insecure channel.

Notification types and channels are closely related to each other since, for obvious reasons, not each Notification type can be transported through each notification channel, e.g. a Letter-based notification channel cannot transport instant notifications. Additionally, the channel has a severe impact on the notification itself. Less secure channels (e.g. E-Mail, SMS) can only transport general information events, whereas secure channels (Secure E-Mail, In-Application) are capable of transporting more detailed information such as patient names or information about the data that caused the event. This also has a direct impact on the usefulness of the notification.

Notifications are always triggered by events. Two event categories could be identified:

- User Interaction Events: Events triggered by users of the EHR (e.g. A physician accesses data of a patient)
- Data Processing Events: Events triggered by data within the EHR (e.g. a document was submitted containing critical information such as an important laboratory parameter outside its ranges)

Events are the only driver of notifications. The events are bound to the functionality of the eHealth system. In this paper, we used Siemens Healthineers eHealth Solution as an exemplary eHealth and EHR system.

Architecture for Notifications in IHE based EHR systems

As discussed previously two event categories could be identified: 1) user interaction events and 2) data processing events. In IHE based EHR systems, events are audited using the IHE ATNA (Audit Trail and Node Authentication) profile. The audit events are stored by an IHE Actor called Audit Record Repository (ARR). Our architecture uses this as the main source of triggering events. In order to generate notifications triggered by the IHE ATNA audited events, we introduce a Service called Notification Service. The ARR, acting as an Audit Record Forwarder, submits relevant events as ATNA based messages to this newly introduced service. Therefore the Notification Service is required to be capable of receiving ITI-20 transactions.

Conclusions

Based on the requirements, transaction flows and nature of IHE based eHealth systems we conclude that it is possible to enrich existing IHE based eHealth infrastructures with a notification system that is based on IHE ATNA messages and automated fetching of additionally needed information through standards-based transactions.

An Innovative Platform to Analyze Heart Failure Biomarkers in Saliva

A. Martínez-García[a], P. García-Ocaña[b], S. Rodríguez-Suárez[b], C.L. Parra-Calderón[a]

Abstract

This paper explains a methodology to improve patient safety through early detecting of HF complications and analyzing HF biomarkers in saliva obtained using a biosensor developed in HEARTEN project. A pilot study was performed in two hospitals in Spain and Italy respectively. A direct correlation was identified between TNF-alpha levels in saliva and weight. The weight gain in HF patients could predict a HF decompensation, consequently TNF-alpha could be a new biomarker of these decompensations.

Keywords:

Heart Failure, Biomarkers, Telemedicine

Introduction

Heart Failure (HF), a cardiovascular chronic disease, has been rapidly increasing, positioning this disease as a main cause of mortality and poor quality of life in western societies [1].

For this reason, in the beginning of 2015, the consortium of HEARTEN project [2] started working to develop and validate a co-operative ecosystem of tools (Clinical Decision Support - CDS- tools directed to healthcare professionals, and empowerment tools directed to patients and caregivers), with the aim to improve the HF self-management for patients, and the HF management for all the actors that participating in HF care, both regarding the adherence and compliance of drugs, diet, and physical exercise recommendations. As part of this ecosystem of tools, one of the CDS tools developed by the consortium, is a saliva biosensor to obtain cortisol and TNF-alpha HF biomarkers [3]. This couple of biomarkers are very interesting to know the HF status, and currently could be obtained taking a blood sample from the patient. HEARTEN proposal is to obtain the same biomarkers only taking a saliva sample from the patient, technique much less invasive. Our hypothesis on that subject is that a correlation between TNF-alpha and/or cortisol and HF decompensation prediction could be identified obtaining these biomarkers from saliva.

The work presented in this paper is related to the patient safety, one of the project outcomes, because the aim is to early detect HF complications analyzing saliva samples.

Methods

To validate the ecosystem of tools, a pilot study has been performed, including the collection and analysis of saliva samples. Two clinical sites participated in this study: 'Virgen del Rocío' University Hospital (VRUH) of Andalusian Health Service in Seville, Spain, and Cardiology Unit of the University Hospital (CUUH) in Pisa, Italy. Before the pilot study started, a clinical protocol was agreed between the involved partners, and approved by the ethical committees.

The pilot study started in July 2017, and finalized in March 2018. In this period, VRUH and CUUH recruited 29 and 38 patients respectively in the intervention group of the study. A 3-months follow-up was performed for each patient, validating the interactive ecosystem, and monitoring the specific saliva biomarkers. Patient used the ecosystem at home. A nurse visited patients one/two times a week, to solve doubts in the use of the ecosystem, and to collect saliva samples in a Salivette® container. The nurse carried the saliva samples to a laboratory, where a technician analyzed the samples. The laboratory technician used HEARTEN biosensors to monitor cortisol and TNF-alpha in saliva samples.

Results

There were 30 cortisol saliva samples and 28 TNF-alpha saliva samples of 15 patients (4 from Italy, 11 from Spain) analyzed with HEARTEN biosensors to find relation between cortisol and TNF-alpha samples at the beginning and at the end of the follow-up. Table 1 shows the detail of these observations.

Table 1– Cortisol and TNF-alpha Data

Biomarker	Follow-up	Nº of obs	Mean	St. dev	Min	Max
Cortisol	Begin	15	16.35	14.48	1	46.6
Cortisol	Begin	15	15.76	12.99	0.2	34.2
TNF-alpha	End	15	18.43	16.84	2.8	49.8
TNF-alpha	End	13	7.91	5.24	2	18

In Table 2, a decrease in the levels of cortisol, TNF-alpha, diastolic blood pressure (DBP) and weight can be identified, and a small increase in heart rate and systolic blood pressure (SBP). However, the only significant change can be read in the TNF-alpha levels.

Table 2– Analyzed Variables

Variable	Mean Begin	Obs Begin	Mean End	Obs End	p-value
Cortisol	16.35	15	15.76	15	0.91
TNF-alpha	18.43	15	7.91	13	0.04
SBP	129.3	15	133.13	15	0.55
DBP	71	15	69.41	15	0.74
Heart rate	71.93	15	73.27	15	0.83
Weight	81.51	15	80.64	14	0.86

The boxplot in Figure 1, a reduction in TNF-alpha at the end of the period can be graphically shown. The significance of this conclusion may be seen in the Wilcoxon signed-rank test, which shows a p-value of 0.55, allowing rejecting the null at a significance level of 10%.

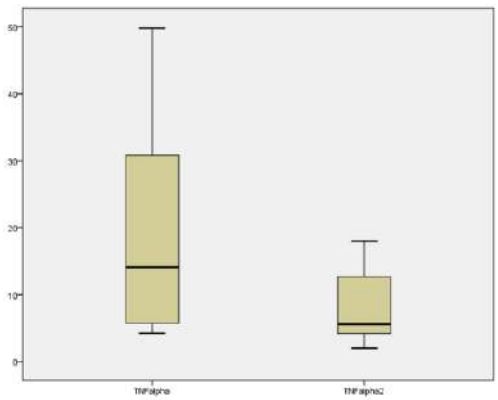

Figure 1– Reduction in TNF-alpha.

In Table 3, we can see the Spearman correlations between the two indicators and the measures of SBP, DBP, heart rate, weight, age, NYHA class and NT-proBNP at the beginning.

Table 3– Spearman Correlation Coefficient of Saliva Cortisol and TNF-alpha Samples with HEARTEN Biosensors and Biological Data at the Beginning

Variable	CORTISOL (n=15)	TNF-alpha (n=15)
SBP	-0.06	0.24
DBP	0.20	0.07
Heart rate	-0.06	0.19
Weight	0.03	0.05
NT-proBNP	0.26	-0.39
NYHA class	0.02	0.28
Age	-0.13	0.07

We cannot find any significant correlation between clinical information, although it seems to be a inverse relation between NT-proBNP and TNF-alpha, with lower levels of TNF-alpha in patiens with higher levels of NT-proBNP. This correlation is low and there is no signifficant differences (Spearman correlation coefficient 25,7% p 0,3). If this correlation is demonstrated in bigger studies patient prognostic with a non invasive sample could be predicted. Table 4 reported the same analysis considering the measures at the end of the period.

Table 4– Spearman Correlations of Saliva Cortisol and TNF-alpha Samples with HEARTEN Biosensors and Biological Data at the End

Variable	CORTISOL (n=15)	TNF-alpha (n=13)
SBP	-0.01	-0.29
DBP	0.32	0.19
Heart rate	-0.23	-0.63
Weight	0.21	0.64
NYHA class	0.12	-0.12
Age	-0.52	0.51

There is a significant negative correlation (at 5%) between TNF-alpha and heart rate. We also find a significant positive correlation between TNF-alpha and weight. We cannot analyze differences in samples at the end of the follow up because NT-proBNP has been measured only at the beginning.

Discussion

Initially in the project, the samples analysis was performed directly at patient's home. Finally, this can not be possible because the samples needed a preprocessing (for example, the saliva must be centrifuged) in a laboratory.

Although 67 patients were recruited in the pilot study, to analyze the TNF-alpha and cortisol correlation, only data from 15 patients could be used, because in some cases the patient refused to collect the sample, or the sample was corrupted. It was not possible to use all analyzed samples obtained from TNF-alpha/cortisol, since we missed data from the patient's clinical situation due to failures of HEARTEN ecosystem.

No significant correlation between cortisol and biological data has been detected, mainly due to the reduced sample size. However, it seems to have a direct correlation between TNF-alpha levels in saliva and the weight. This correlation can be used to predice HF decompensation, if the same results in bigger studies will be obtained, with a higher sample size. With higher sample size, we would like to look for a correlation between NT-proBNP and TNF-alpha, predicting patient prognostic with a non invasive sample.

Conclusions

HEARTEN ecosystem enables HF patients to achieve self-manage of their disease. The saliva samples analysis has been performed in a satisfactory way, however the sample size has been too little. Authors are interested in performing a following pilot study to obtain a higher sample size that allows to analyze in depth the correlation between TNF-alpha and cortisol in saliva and the clinical situation of patients.

The Impact for Medical Management of the Health Information Exchange Through Changes of the Number of the First Visit Patients and Admission Patients in Japan

Takehiro Matsumoto, Naota Taura, Masayuki Honda

Department of Medical Informatics, Nagasaki University Graduate School of Biomedical Sciences, Japan

Abstract

Recently Health Information Exchange (HIE) is gradually spreading in Japan. But there are few reports about the effect of the hospital management. So we examined the effect for hospital management through the number of the newly admitted patients from 2013 to 2017. In this study both the total number of the admitted patients who was reserved as first visit patients was higher than not reserved and the number of the admitted patients who visited with introduction letters was higher than without introduction letters. (p<0.01) The total number of the admitted patients who had been registered to the Ajisai-net was 624 (41.2%) for the same 5 years, and was revealed to be significantly higher than the number of the admitted patients who was reserved first visit with introduction letters. (p<0.01) In conclusion, use of the Japanese type of the HIE has a potential to increase the newly admitted patients finally.

Keywords:
Health Information Exchange, hospital administration, Electronic Health Records

Introduction

The continuous increase of the Medical costs is one of the most important national problem all over the world. It is an important problem in Japan as well. Because the income of the hospitals had been supported with the public universal insurance has been reduced, many hospital incomes are getting worse in Japan. On the other hand, Health Information Exchange (HIE) has been gradually spreading in Japan. [1,2] The Japanese Medical Association reported the number of these networks was at least 309 in 2017 all over Japan, and is increasing even now. But there are few reports about the economic and management effects of these networks in Japan[3]. The number of the newly admitted patients is one of the most influential factor of the hospital income, and this is greatly affected from the number of introduced patients from clinics or the other hospitals on the Japanese medical system. The Ajisai-net, one of the most popular HIE of Japan, has been organized and used since 2004 at the Nagasaki Prefecture located at the western end of Japan. Over 90,000 patient's medical records of 36 regional big hospitals of Nagasaki Prefecture are shared among over 370 medical institutions such as hospitals, clinics, pharmacies and other medical institutions. In this study, we evaluated the economic and management effect of HIE through the changes of the patient introduction.

Methods

The Ajisai-net is one of the HIE of Japan. The feature of this network is the type in which the whole medical information of the Electronic Medical Record of the regional big hospitals was shared among many regional clinics, hospitals, pharmacies, nursing care stations and other several medical institutions. And this type of the HIE is the most popular in Japan. Nagasaki University Hospital has joined the Ajisai-net since 2009, and almost all the medical information of the Electronic Medical record of our hospitals is shared at the clinics, pharmacies, and other medical institutions based under the patient consents. We investigated the number and rate of the newly admitted patients and first visit patients using the statistical open data and the first visit management system.And the number of registered patients to Ajisai-net and additional data were obtained from the first visit management system and the Ajisai-net registration management system of the Nagasaki University Hospital. Emergency visit cases and dental visits were excluded, and the remaining first visit patients were

divided to 3 types which are reserved visit bringing the introduction letters, non-reserved visit bringing the introduction letters and non-reserved visit not bringing the introduction letters. And 'the effective usage' in the table 2 has been defined as the case the doctor shared medical information through the Ajisai-net by themselves before introduction for this patient. Statistical analysis adopted the chi-square test.

Results

The total number of the first visit patients from 2013 to 2017 was 64,120 at the Nagasaki University Hospital, and the average admission rate was 34.7% for 5 years. (Table 1) And the admission rate had increased every year. The admission rate of the first visit patients who had been non-reserved not bringing the introduction letters was the worst of the 3 types, 17.8% in average. Conversely the highest admission rate was the type which was reserved visit bringing the introduction letters. There was a statistically significant differences between the number of the admissions of the reserved first visit and of the non-reserved first visit, ($p<0.01$) and also between the number of admission of the first visit with and without the introduction letters ($p<0.01$). On the other hand, the number of total registered to the Ajisai-net with patient consent was 5,750 for the same 5 years (Table 2). The total number of the first visit patient who had been registered to the the Ajisai-net was 3,394, and registration rate was 59.0% for the same 5 years. And the total number of the registered patients to the Ajisai-net who was introduced from clinics was 1,514. And the total number of 'the effective usage' whose Electronic Medical Records of Nagasaki University had been shared through the Ajisai-net before introduction was 1,053 (69.6%), and significantly higher than the former ($p<0.01$). The total number of the admitted patients who had been registered to the Ajisai-net was 624 (41.2%) for the same 5 years (Table 3), and was significantly higher than the number of the admitted patients of the reserved first visit patients bringing the introduction letters ($p<0.01$). And the number of the admitted patients who had been registered to the Ajisai-net as the 'effective usage' was 431 (40.9%), and also higher than the number of the admitted patients of the reserved first visit patients bringing the introduction letters ($p=0.03$).

Discussion

Recently hospital management in Japan is getting more difficult year by year because of the governmental policy of the suppression of the medical social cost. So many hospital has made much efforts to hospital management. Because in general the income of admission fee of Acute hospitals is far more than the outpatient department of the same hospital in Japan, the one of the most important factor of the hospital economic management is pointed out to be the increase of the number of the newly admitted patients. Although there are some reports about the effect to the economic and hospital management of HIE in North America[4,5], there are few in Japan. In this study the number of the admitted patients was significantly higher on the patients who had been introduced bringing the introduction letter than those who had not bringing the introduction letter ($p<0.01$) (Table 2). And the number of the admitted patients whose first visit to the outpatient sections had been reserved with FAX was also significantly more than not reserved ($p<0.01$). These results seemed to indicate the more severe patients who had been selected and introduced by the clinic doctors by means of the introduction letters and first visit reservations. On the other hand, the number of the admitted patients who had been registered to the Ajisai-net was also significantly higher than no use of the Ajisai-net. The total number and the number of the 'effective usage' of the admitted patients regsitered to the Ajisai-net was 624 (41.2%) ($p<0.01$) and 431 (40.9%) ($p=0.03$) respectively. Though the rate of the admission of the 'effective usage' patients who had registerd to the Ajisai-net before their firist visits was less than the rate of admission of the total number of the first visit who had registered to the Ajisai-net use (41.2% VS 40.9%) , these results seems to indicate the sharing medical information through the Ajisai-net which is the most popular type of HIE in Japan has clear incentive for the doctor who introduced thier patients to our hospital. In this study, although the direct increase effect of the number of hospitalized patients who had been introduced as the first visit patient after registration to the Ajisai-net is not clearly proved, at least the number of hospitalized patients who had been introduced as the "effective usage" was significantly higher than the total number of hospitalized patients who had been introduced as the first visit patients. There is 2 typical use cases on the Ajisai-net. One is for making use of the past or old medical information for the diagnosis or past history taking, etc, and the other is for the observation and evaluation of the updated patient condition or obtaining the latest medical information for the lifelong self-learing for doctors through the Ajisai-net. These results seems to indicate that there is the clearly incentives for the doctor to use the Ajisai-net through these 2 use cases when they introduce their patients to the big or professional hospitals. By the above, because the increase of the number of the hospitalized patients causes to increase the hospital income in Japan, the Japanese type of HIE is proved to be effective for the economic hospital management indirectly in this study.

Conclusions

The Japanese type of HIE like the Ajisai-net has much potential of increasing the number of the introduced first visit patients and admitted patients because of its high value in sharing medical information.

The Use of Culturally-Tailored Telehealth Interventions in Managing Anxiety and Depression in African American Adults: A Systematic Review

Terika McCall[a], Clinton S. Bolton III[b], Rebecca McCall[c], Saif Khairat[a]

Abstract

This systematic review examined studies aimed at reducing anxiety or depression in African American adults through use of telehealth interventions. Three small independent studies were identified. The findings showed significant reduction of depressive symptoms post-intervention (all p values < .05). However, effectiveness of telehealth intervention compared to face-to-face was not determined. The results highlight the need for additional research into the effectiveness of using telehealth to manage anxiety and depression in this population.

Keywords:

Telemedicine; African Americans; Mental Health

Introduction

In 2017, the U.S. Substance Abuse and Mental Health Services Administration (SAMHSA) estimated that 46.6 million adults in the U.S. experienced mental illness in the last year [1]. The prevalence rate of mental disorders, excluding serious mental illness, has remained constant since 2008 [1]. A decade later, technology has allowed us to increase the options for delivery of mental health services; however, the percentage of adults with a mental illness who received mental health services in the past year (42.6%) was comparable to the rate for most years from 2008 to 2016 [1]. The expanding adoption of telehealth in the U.S. can increase access to mental health services, improving health outcomes and reducing health care costs. Although telehealth may not work for everyone, it has the potential to help many people included in the estimated 26.7 million U.S. adults (57.4%) who have a mental illness but did not receive mental health services in the last year [1].

Anxiety and depressive disorders are among the most common mental illnesses. A report by the Centers for Disease Control and Prevention (CDC) noted that 12.9% of non-Hispanic whites and 9.3% of non-Hispanic blacks reported having received a diagnosis of anxiety in their lifetime [2]. Moreover, the estimated prevalence of depression was higher for African Americans (12.7%) than their white counterparts (7.5%) [2].

Due to underreporting of mental illness, especially in underserved populations, it is unclear if the prevalence estimates depict the true rates, and if the differences observed between racial groups are accurate; however, there is significant unmet need and racial disparity in the use of mental health services [1]. Although there is less than a 4% difference in the prevalence of mental illness among white adults compared to black adults (20.4% vs. 16.5%), African Americans utilize mental health services at less than half the rate of their white counterparts (8.9% compared to 18.1%) [3]. Barriers to African Americans receiving health services are well documented in literature.

Methods

The methods outlined in the *PRISMA Statement* for systematic reviews were followed (see Figure 1). First, a comprehensive literature search was conducted using the PubMed, PsycINFO, Scopus, and Web of Science electronic databases for relevant articles published from 1970 to September 2018. A combination of keywords relating to African Americans, depression, anxiety, and telehealth were used. Second, reference lists of the included primary articles and retrieved systematic reviews were examined to identify any relevant publications.

The criteria used for inclusion in this review were: (1) intervention targeted Black/African American adults (≥ 18 years old); (2) primary outcome(s) include either diagnosis or symptom severity of depressive or anxiety disorder; (3) telehealth-based psychological intervention; (4) intervention effectiveness evaluated using one or more standardized measures of anxiety or depression administered pre- and post-intervention; and (5) feasibility of using telehealth modality to receive psychological help, acceptability of using telehealth modality to receive mental health services, or self-management through participation in the intervention assessed post-intervention.

Covidence software was used for article screening and data extraction. Two independent reviewers (T.M. and C.B.) independently analyzed each title and abstract of articles retrieved to determine their relevance. The full text of potentially eligible studies was retrieved and similarly analyzed by T.M. and C.B. to exclude papers that did not meet inclusion criteria. Any disagreement over the eligibility of particular studies was resolved by an adjudicator (S.K.). The *Critical Appraisal Skills Programme* (CASP) checklists were used to assess the quality of the identified studies.

Significant themes and trends of the studies were identified and discussed. A quantitative analysis and comparison of treatment effectiveness across studies was considered. However, due to the limited number of randomized controlled trials (RCTs) included, comparison was not feasible.

Results

A detailed search in all databases identified a total of 622 articles. Twenty-one additional articles were identified through examining other sources. After the removal of duplicates, 529 articles were included in the title and abstract screening process. The majority of the articles that were excluded did not involve psychological interventions that targeted black adults. Fifty papers were identified as relevant to the research question and

included in the full-text screening process. Following the independent full-text screening process, three articles were identified that met the inclusion criteria and were included in the analysis [4–6].

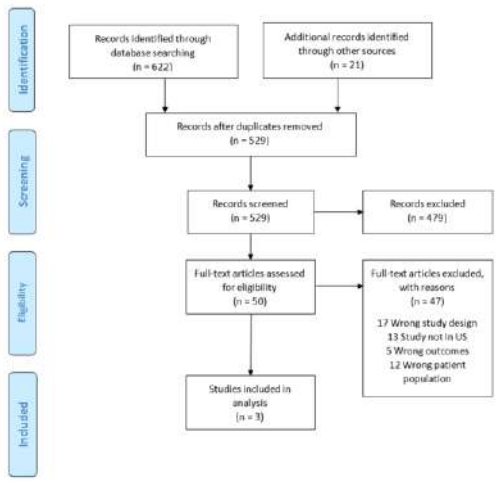

Figure 1– PRISMA Flow Diagram of Search Strategy

The three independent studies had a pooled total of 32 participants (range 6-15 per study). Telephone-based cognitive behavioral therapy (CBT) [4,6], or a mobile phone-optimized online intervention [5] was used. Only one of the studies was a randomized controlled trial (RCT) [4]. The remaining two studies were prospective cohort studies assessing the feasibility of interventions [5,6]. Two of the studies reported a majority (> 80%) of their sample were female [4,6]. All participants reported to be HIV-positive in one study [6], and another reported 60% of participants were HIV-positive [5]. All of the studies used validated assessments (the Center for Epidemiological Studies Depression Scale (CES-D) [4,5] or Hamilton Depression Rating Scale (HAM-D) [6]) to assess the primary outcome of depression pre and post intervention.

All of the studies [4–6] met a majority of the criteria used for consideration in the assessment of study quality in the CASP appraisal checklists (i.e. reviewers T.M. and C.B. answered 'yes' for > 80% of the questions). Two studies lacked control groups [5,6], and all had small sample sizes (6-15 participants) and short follow-up periods (< 6-months) [4–6]. This resulted in the reviewers rating all of the studies to be of 'fair' quality; however, all studies were published in peer reviewed journals and deemed appropriate for inclusion.

Statistically significant reduction of depressive symptoms (measured by improvement in mean CES-D or HAM-D score) was observed post-intervention in all of the studies ($p < .05$) [4–6]. In addition, one study showed a significant reduction in depression severity post-intervention ($p = .02$, measured by improvement in mean Quick Inventory of Depressive Symptomology (QIDS-SR) score) [6]. All studies reported patient satisfaction with the interventions [4–6]. Hightow-Weidman et al. also reported improvements for social support ($p = .012$) and social isolation ($p = .050$) for study participants post-intervention [5]. Furthermore, the RCT conducted by Glueckauf et al. found significant within-subjects effects for time across caregiver subjective burden ($p < .02$, measured by improvement in the subjective burden subscale of the Caregiver Appraisal Inventory (CAI)) and assistance support ($p < .03$, measured by improvement the Assistance subscale of Interpersonal Support Evaluation List (ISEL)) post-treatment [4]; however, no statistically significant effects were observed for group (telephone vs. face-to-face CBT) and the group x time interaction (all $p > .05$) on any of the measures [4].

Conclusions

Given the burden of unmet need and disparity in mental health utilization among African American adults, there is great potential to use telehealth to deliver services to this population. Telehealth is proving to be acceptable for some mental health services, such as CBT; however, to increase the likelihood of adoption among African American adults, telehealth interventions should be culturally-tailored. A "one size fits all" approach to designing telehealth interventions to help African American adults manage anxiety or depression may lead to more options but continued disparity in receiving care.

Multi-Institutional, Large-Scale, International Applied Clinical Informatics Research Through the Clinical Informatics Research Collaborative (CIRCLE)

Allison B. McCoy[a], Adam Wright[b], Dean F. Sittig[c]

Abstract

There is a critical need need for multi-institutional, large-scale, international applied clinical informatics research, given the global, widespread use of commercially-available electronic health records with different designs, capabilities, configurations, and implementation strategies. The Clinical Informatics Research Collaborative (CIRCLE) aims to identify and develop best practices for safe and effective health information technology design, development, implementation, use, and evaluation.

Keywords:
Medical Informatics, Research, Health Facilities

Introduction

The last decade witnessed dramatic growth in electronic health record (EHR) adoption, from less than 10% to nearly universal. Until recently, only large, academic healthcare organizations implemented locally developed EHRs, which enabled extensive customization and novel research but had limited generalizability [1]. Currently, 95% of EHRs are commercially-developed systems [2]. Commercial EHRs partially addressed problems related to system maintenance, long-term reliability, and variable annual costs. Nevertheless, commercial systems significantly curtail the ability of informatics researchers at a single organization to experiment with different designs, configurations, and implementation strategies, and satisfaction with current EHR performance remains low [3]. In the absence of purposeful studies, natural experiments nevertheless happen. Organizations adopting various commercially-developed EHRs choose different configurations, use systems in distinct ways, and learn valuable lessons based on mistakes during such processes [4]. These insights are rarely captured formally or disseminated widely. There is a critical need to conduct multi-institutional, large-scale, international applied clinical informatics research that can improve EHR usage and outcomes.

The Clinical Informatics Research Collaborative

The mission of the Clinical Informatics Research Collaborative (CIRCLE) is to identify and develop best practices for safe and effective health information technology design, development, implementation, use, and evaluation. CIRCLE currently has 41 collaborators representing 30 organizations across five countries. CIRCLE collaborators use many EHRs, including Epic, Cerner, MEDITECH, McKesson, Allscripts, CPRS/Vista, GE Centricity, eClinicalWorks, and others. Primary roles filled by CIRCLE collaborators include researcher, educator, physician, CMIO/CMO, nurse, data analyst, CCIO/CIO, and pharmacist. Most collaborators work in academic medical centers, though four work in community hospital settings. To date, CIRCLE collaborators have worked together to complete numerous multi-institutional research projects and have published 29 peer-reviewed manuscripts of varying types, including cross-institutional interviews and observations [5,6], surveys [7,8], system demonstrations [9,10], distributed queries [11,12], and experimental interventions [13]. Some results of these projects made available through publication in peer-reviewed journals include success factors for people involved in CDS [6], recommended practices for CDS governance [8], and guidelines for future development of user-defined CDS [10].

Future Work

To facilitate the continued efforts by CIRCLE and other research consortia, there is a need to develop standard procedures for carrying out multi-institutinal, applied clinical informatics research. Reporting guidelines improve the quality, transparency, and reproducibility of research by defining the necessary components for describing a study [14]. Some guidelines exist for health informatics research, including including STARE-HI (Statement on reporting of evaluation studies in Health Informatics) [15] and CONSORT-EHEALTH [16], but none specifically address the unique challenges posed by use of different commercially-available EHRs. Most EHRs have different local configurations across different healthcare organizations. Institutional decisions about specific implementations and configuration decisions regarding the same vendor's EHR can substantially alter their local performance [17]. External rules and regulations that can impact EHR requirements and implementations may also differ across countries [18]. Many organizations and commercial EHR vendors restrict what can be publicly shared or published regarding their EHRs [19]; thus, special considerations apply to interpreting reported results unique to the site or EHR. Improved guidance for conducting and reporting collaborative applied informatics research across varied implementations and sites may help researchers overcome such challenges. Improved quality and reproducibility of the studies would follow, ultimately increasing the effectiveness of EHRs.

Conclusions

Efforts by CIRCLE to date suggest that collaborative projects can effectively identify best practices for EHR

implementations. Future success of CIRCLE depends on continued expansion and inclusion of members from diverse healthcare settings and from sites with access to currently unrepresented EHRs, as well as established guidelines for carrying out new multi-institutional, collaborative research. New informatics research carried out through CIRCLE that is high quality, transparent, and reproducible will enable healthcare organizations to better evaluate and improve their EHR capabilities.

Abstract

The Rwandan Ministry of Health supports a countrywide installation of the Open Medical Record System (OpenMRS) to improve clinical recordkeeping and patient care. However, electronic medical records also can be a valuable source of data for observational and experimental studies. We describe the challenges and lessons learned when reusing OpenMRS data in Rwanda for global HIV epidemiology research.

Keywords:

Electronic Medical Records, Observational Study, Rwanda

Introduction

The International Epidemiology Databases to Evaluate AIDS (IeDEA) consortium includes over 400 HIV care and treatment clinics in 45 countries that pool routine patient care data to answer research questions of global scope (iedea.org). Ten HIV care and treatment clinics in Rwanda are participating in IeDEA. Clinic researchers contribute scientific expertise and their patient data extracted from OpenMRS, an open source, customizable electronic medical record system (EMR) implemented in Rwanda since 2006 to support patient care [1]. At each participating clinic, patient data are recorded on paper charts during clinic visits and subsequently entered into OpenMRS by data entry personnel. Each clinic has an Ubuntu Linux server running OpenMRS on a local area network to ensure availability without internet. The EMR infrastructure is maintained by the government of Rwanda, which supports secondary use of the data for research.

Methods

The local IeDEA data manager visits each clinic bi-annually, extracts patient data from the clinic's OpenMRS database, and runs a custom C# program that removes patient identifiers. With Rwandan government and ethics board permission, de-identified copies of the database are securely uploaded to the central Africa IeDEA coordinating center in the United States (US), which runs data quality checks and merges datasets from the entire region. Data queries are resolved by the Rwandan team. OpenMRS data are compared to paper source documents where necessary and query responses are passed back to the US data center, which then maps local data to the IeDEA data exchange standard (iedeades.org) for global IeDEA collaborations.

Results

Using this model of data preparation, the Rwanda IeDEA team has provided 60 data uploads since late 2015 and contributed 31 high quality, merged datasets for global and regional IeDEA publications. We encountered two noteworthy challenges with this approach to reusing OpenMRS data for research:

Transforming data in the OpenMRS star data model and concept dictionary to a functional research dataset is complex, with 100-130 database tables per HIV clinic. Customized data de-identification and data quality review can slow the data sharing process. However, due to the standardized OpenMRS implementation in Rwanda, we had the same concept dictionary and nearly the same database tables available at all participating care sites, which simplified the data extraction and merging.

Involving local OpenMRS experts was critical when reusing routine clinical care data. We initially used a custom OpenMRS module that generated encrypted data export files for each clinic, but this approach prevented the Rwanda IeDEA team from de-identifying the data and participating in data quality assurance. When US-based support for the module ended and there was no sustainability plan, we developed the current model. Although our current approach may be more labor intensive, it has proven secure and resilient to changes in the OpenMRS data model (due to software upgrades), and relies on a more egalitarian paradigm of shared Rwandan-US involvement with research data processes.

Conclusions

Clinical care data from OpenMRS can be utilized successfully for HIV observational and experimental research but it requires custom data de-identification, quality checks, and engaged local data teams.

Developing a Biomedical Information System for Clinical Assessments and Interventions of Mental Health and Substance Abuse Patients Belonging to YMSM of Color with HIV Using Multidimensional Scaling Analysis and Paired Comparisons Techniques

Sukrit Mukherjee[a], Eric Houston[b]

[a] *Center for Biomedical Informatics, Charles R. Drew University of Medicine and Science, Los Angeles, CA, USA,*
[b] *Department of Psychiatry and Human Behavior, Charles R. Drew University of Medicine and Science, Los Angeles, CA, USA*

Abstract

In mental health and substance abuse treatment, individualized assessments provide information on the specific thoughts and cognitive processes influencing a person's behavior, emotional responses, and psychological functioning. Given the lack of automated assessment procedures or individualized clinical interventions in the growing health disparities in the South Los Angeles of USA, we developed a novel system using idiographic techniques to automatically and quickly generate individualized patient assessment data for use in clinical interventions.

Keywords:
Mental Health, Information Systems, HIV

Introduction

Depression affects people disproportionately living with HIV and other chronic health conditions in a widesspread manner [1]. A study in the United States that was based on a nationally representative sample of people living with human immunodeficiency virus (HIV) found that 36% of participants had a probable diagnosis of major depressive disorder. This rate was nearly five times greater than that of the general population [2]. Therefore, receiving treatment for depression becomes very critical for the HIV patients. At the same time among many people living with HIV (PLH), depression continues to remain largely untreated [3][4]. This low percentage of of treatment for depression among HIV patient population have given rise to several stigmas that may include tedency of individuals to avoid engagement in treatment for depression as well as desire of non participation in depression intervention research [4][5][6][7].

In mental health and substance abuse treatment, individualized assessments provide information on the specific thoughts and cognitive processes that influence a person's behaviors, emotional responses, and psychological functioning [8]. Having information about the individual's thoughts and cognitive processes facilitates the development of clinical interventions tailored specifically to an individual patient. Research suggests that interventions based on information from such individualized assessments are likely to have greater effectiveness than those that do not [9]. Interventions that incorporate these individual-specific thoughts and cognitive processes are likely to resonate more strongly with patients than interventions lacking this focus. In addition, using individualized assessments to inform and implement treatment also heightens patient motivation and may strengthen efforts to promote their retention in treatment.

Little research has focused on how to reach and engage patients with depression and HIV who may be at the intersection of multiple social identities faced with stigma. Due to the negative impact of depression on the health status of people living with HIV, there is a need for individualized clinical interventions especially for the growing health disparities in the South Los Angeles of USA. Paired comparisons techniques and MDS analyses are two data analytic techniques that have traditionally been used in statistics and research [10]. But to date, paired-comparisons techniques and MDS have not been combined for use in either automated assessment procedures or individualized clinical interventions. We intended to fill this gap by utilizing novel use of such idiographic approaches that may be particularly valuable in clinical settings that lack staff trained in clinical interviewing or individualized assessment techniques.

Methods

We followed a mixed method research design in ths study. The study called, Project STEP ("Steps Toward Embodying Positivity") was targetted to conceive a new cognitive training intervention system to address depressive symptoms and suboptimal HIV treatment adherence among African American and Latino YMSM (ages 18-29) in the Los Angeles metropolitan area. The study received guidance and support from a community advisory board consisting of eight members for participant recruitment procedures and strategies. The Institutional Review Board of Charles R. Drew University of Medicine and Science (CDU) approved the study. Participants were recruited for a focus group session to obtain feedback on an initial version of the web-based intervention system and for a preliminary brief pilot in which individuals from the target population used the web-based intervention. Participants in the pilot were asked to use the system on a daily basis at home as well as in a clinical setting for up to four weeks. Pilot study participants also received information related to behavioral strategies for HIV treatment adherence, mood management, and alcohol and substance abuse prevention based on modules from Centers for Disease Control (CDC) of USA's evidence-based intervention. The system was accessible as web based modules that were delivered to participants via laptop computers and iPad devices during weekly visits with a study counselor. Study participants were asked to complete questionnaires to assess depressive symptoms, adherence, treatment motivation, self-

efficacy, HIV stigma, internalized homophobia, and challenges they face with regard to medication management. Pilot study participants were also asked to complete interviews regarding their views of the intervention upon completing their enrollment [11].

The system consits of 2 stages. The first stage was designed using Java Server Pages (JSP) as frontend, Java as middle tier and MySQL as backend hosted on Tomcat Web server on a Linux platform with statement session of the input data (paired-comparisons ratings) from a participant and and it processes the data using MDS analysis and transforms the data into a matrix. The combined use of paired-comparisons techniques and MDS through automated, cross-platform processes allowed for the collection of critical information from patients. We used idiographic assessment procedure to uniquely allow for this information to be obtained and processed with significantly less time and then subsequently making it available for immediate use for a range of clinical interventions and approaches, including those involving attention bias modification training, cognitive mapping techniques, and motivational interviewing which were implemented in the second stage of the system that was developed using .Net as frontend, C# as middle tier and MS SQL Server as backend hosted on Internet Information Server on a Windows platform. The primary purpose of this stage was to generate stimuli for the users in Attention Bias Modification (ABM) training interventions, particularly individualized ABM interventions. The automated nature of our assessment approach and the relative speed with which the information can be applied is novel and has much potential in addressing gaps in the delivery of care.

Results

The first stage of our 'Project STEP' system receives input data (paired-comparisons ratings) from a participant and transforms the data into a matrix followed by processing of the data in MDS analysis through a very unique and specialized algorithm that results in the automatic generation and display of a n-dimensional spatial configuration or mapping and provides stress values, a least distance measure and R values of the individual user. The second stage of this unique system that receives statements, ratings, dot location and emotion values from first stage is designed with idiographic assessment program that generates stimuli for use in ABM training interventions, particularly individualized ABM interventions. The idiographic assessment program embedded in the system could operate cross-platform using data from an elicitation task and paired-comparisons techniques. The first stage generates and displays n-dimensional configurations automatically providing data to inform and implement clinical interventions using attention bias modification training implemented in the second stage. Thus, the resulting system design is likely to have strong market potential. The customer base for such an assessment procedure would include hospitals, clinics and substance use treatment centers as well as private practitioners and agencies and organizations involved in health care delivery in the United States and abroad.

Conclusions

We have attemped to solve the problem of clinical assessment for mental health and substance abuse patients belonging to YMSM of color with HIV across the continuum of care by creating a novel system that automatically and quickly generates individualized patient assessment data for use in clinical interventions like attention bias modification training with strong market potential.

Abstract

Accurate and rapid differential diagnosis are required for personalized cancer treatment. However, owing to the numerous molecular tests used for establishing a diagnosis, pathologists need time to investigate and confirm necessary test items. We present a guideline-based decision support system for effective workflow with regards to the molecular tests for pathological differential diagnosis.

Keywords:

Pathology, Clinical Decision Support System, Practice Guideline

Introduction

A guideline-based Clinical Decision Support System (CDSS) enables medical personnel to provide improved medical care. Many CDSSs have been studied in the field of pathology. Most of these systems extract or classify free-text from pathology reports using natural language processing[3] or electronic patient data using machine learning approaches based on dictionaries and coded data[1] and International Classification of Diseases for Oncology (ICD-O)[2]. Some systems used in pathology utilize image analysis approaches that are based on morphology[4,5]. For providing personalized medicine, another type of system uses graphical models for biomarkers [6]. These are the elements of data mining, but regulatory obstacles are encountered in terms of personal data, lack of standardization, and difficulties in versatility[4]. Appropriate pathological diagnosis is important in cancer treatment, particularly in personalized medicine. Recently, the diagnostic criteria and treatment strategies for various cancer types have undergone frequent revisions. Therefore, in cancer diagnosis, a pathologist spends a large amount of time and effort to review literature such as guidelines, authorized classification books, and journals. Reducing this time and effort will enable clinicians and patients make faster clinical decisions. There is also need for a system to compensate for the chronic shortage of pathologists.The aim of this study was to construct a prototype of a decision support system that can provide effective guideline-based pathological diagnostic workflow for oncology pathologists, regardless of the pathologists' experience and knowledge.

Methods

Position of the present system in the pathological workflow

An overview of the current system is shown in Figure 1. Consideration of personal information security is the most important aspect in medical system development. However, this application completely blocked patient data from the electronic medical records.

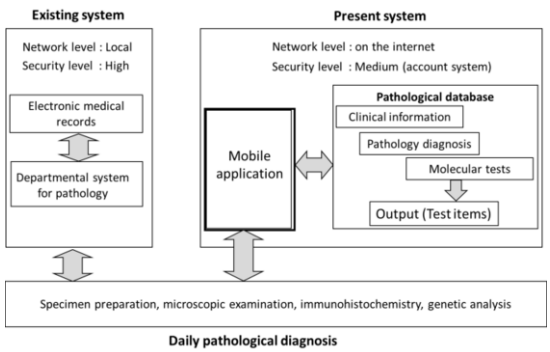

Figure 1. Overview of the current system in daily diagnostic work

Data

We collected data of each cancer type to create a comma separate value (CSV)-based master file on the local server. Data for each cancer type were extracted from "General Rule for Clinical and Pathological Record," "Japanese Clinical Guideline," "Pathology Atlas," and "WHO classification of Tumours" and coded sequentially. The following data were extracted: organ; site; method of tissue collection (biopsy or surgery); primary cancer – metastasis or un-clear; epithelial, non-epithelial, or unclear; and malignant, benign, or unclear. Diagnosis (superordinate), diagnosis (sub-ordinate), diagnosis (subordinate, English), ICD-O, target molecule for establishing the diagnosis, detection methods, expected results, and evidence (references). The expected results of molecular tests were displayed as microscopic images, because many patterns are observed in the results of immunohistochemical target molecule detection. Thus, it is difficult to understand the images based only on the text. Each photo was linked to the

corresponding text in the result. Actual immunohistochemical examination was performed for each stained sample, and the images were retrieved by the microscopic imaging software cellSense®V1.7 (Olympus Co., Tokyo, Japan).

User interface

Consideration of personal information security is the most important aspect in medical systems. This application was developed such that it could be used without inputting the IDs of patients or doctors. Therefore, this application can be used without direct access to electronic medical records of the hospital. Furthermore, considering the users and their locations, we believe that the usability of the application must not be restricted to personal computers but must also be extended to smart phones and tablets.

Decision making process

The current system was built using a web-form design with access to sequential files for making decisions regarding the molecular tests to be selected for pathological differential diagnosis. Data types were boolean nodes and guideline-based standard text nodes without free text entering. However, in addition to alternative Boolean nodes, the current system has a choice named “unidentified”. Pathology samples may not clearly indicate primary cancer or recurrence or the malignant or benign status. Sample related data, including the “unidentified” choice, are sequentially referred from the master .CSV file to help with extraction the result of candidate diagnosis. If the user selects “unidentified”, all the possible differential diagnostic nodes are extracted and displayed.

Results

On performing a demonstration test using the prototype CDSS for modeling differential diagnosis for lung cancer, we confirmed that our system operates properly in various web browser environments, including Internet Explorer, Google Chrome, Mozilla Firefox, Microsoft Edge, Safari, in each smart phone version, and in various terminals, including computers (Windows and Mac), and smart phones. Furthermore, the characteristics of the current system were studied. One of the potential benefits is that pathologists can obtain information of the latest guideline-based diagnostic terms and molecular tests, regardless of their experience and knowledge, with easy operations. The“unidentified” option will serve as an electronic dictionary and consultant to enable effective pathological diagnostic workflow. Therefore, we expect this system to promote workflow standardization, compared to the current workflow that relies on an individual's competence. Furthermore, portability to a mobile platform will allow oncology pathologists to use this state-of-the-art guideline-based CDSS in routine diagnostic workflow, without concerns about patients’ personal data breach. However, at the same time, the point of separation from personal data is a limitation of this system. If pathologists need personal patient data from electronic medical records, we will have to consider additional tools while simultaneously ensuring security of personal information. It is also necessary to increase the processing performance of this CDSS by creating a database to enable frequent revisions of the master file, in accordance to revisions of the guidelines. Furthermore, we plan to conduct a larger study with free distribution at pathology-related academic meetings in Japan to verify the utility and accuracy of this system. By increasing the number of pathologist users, accumulation of search logs will likely lead to new knowledge, particularly on rare cancer.

Conclusions

We present a guideline-based CDSS for effective diagnostic workflow for oncology pathologists. This system is expected to be more practical in terms of protecting personal data and mobile use. It is also expected to promote workflow standardization, regardless of the pathologists’ experience and knowledge.

Identify Facilitators and Challenges in Computerized Checklist Implementation

Shan Nan[a,b], Ashley De Bie[c,b], Sicui Zhang[a,b], Hendrikus Korsten[c,b], Xudong Lu[a,b], Huilong Duan[a]

[a] *College of Biomedical Engineering and Instrument Science, Zhejiang University, Hangzhou, China,*
[b] *Faculty of Industry Engineering and Innovation Science, Technical University of Eindhoven, Eindhoven, The Netherlands,*
[c] *Department of Anesthesiology and Intensive Care, Catharina Hospital, Eindhoven, The Netherlands*

Abstract

Safety checklists have been considered as a promising tool for improving patient safety for decades. Computerized checklists have better performance compared with paper-based checklists, though there are barriers to their adoption. Given previous literature, it is still unclear what assists implementations and their challenges. To address this issue, this paper summarizes the implementation of two successful computerized checklist implementations in two countries for two different clinical scenarios and analyzes their facilitators and challenges.

Keywords:

Patient Safety; Checklist; Decision Support Systems, Clinical

Introduction

In recent years, several studies have proved that process-oriented and context-aware computerized checklists can improve adherence to safety checklists and consequently improve clinical outcomes [1]. Previous studies have addressed several technical barriers to the wide adoption of computerized checklists [2]; however, it is still unclear what the facilitators and challenges are in the implementation phase.

Due to the limited amount of implementation research, it is still not possible to summarize the facilitators and challenges out of literature. However, our research team has recently implemented computerized checklist systems in two countries for two different clinical scenarios [3]. It would be meaningful to summarize and communicate the facilitators and challenges gained from these two studies.

An intensive care unit (ICU) round computerized checklist and a supporting system were developed and implemented in a Dutch tertiary hospital in 2014. The computerized checklist was connected to the electronic medical record (EMR) system in the hospital. Each item is customized to specific patient conditions by executing clinical rules. Clinical rules help intensivists to double check items, highlight items that were critical for specific patients, and tailor items to become specific for the patient. A simulation-based study was carried out to validate the user acceptance and effectiveness. Compared to the paper-based checklist, the adherence to the checklist increased from 73.6% to 100% [3].

A computerized percutaneous coronary intervention (PCI) peri-operative checklist set was developed for a Chinese tier-three hospital from 2015 to 2017. The computerized checklist was also connected to the hospital EMR. Patient data were extracted out of the EMR database. A semi-structured interview was carried out while implementing this checklist. Cardiologists reported this checklist helped them to complete the safety checklist faster, since the checklist helped them by showing relevant patient data and check items automatically.

In the remainder of this paper, we identify facilitators and challenges by analyzing our own experiences gained from these two cases.

Methods

While developing the computerized checklists in these two studies, we followed a proof-by-demonstration approach [4]. With this approach, we divided the development into several iterations. In each iteration, we demonstrated the latest software to the clinical users, interviewed them while demonstrating, analyzed users' comments, and applied validated comments to the next version of the software that would be discussed in the next iteration. Change Management Principles [5] were applied while implementing the software. After several iterations, the software was stable and brought to daily use.

In the Dutch case, two engineers and one intensivist had worked on developing checklist items and related clinical rules for half a year based on the local protocols. Another large part of the clinical rules was derived from the Clinical Decision Support System (CDSS) knowledge base.

In the Chinese case, three engineers and two cardiologists had been working on the computerized checklist for two years. The related clinical rules were based on their existing paper-based checklist and narrative clinical guidelines.

Users' comments were collected and analyzed afterward. Those comments on what they liked about computerized checklists were categorized as facilitators. Those comments on what may hinder the acceptance were considered challenges. Additionally, engineers' own development experiences were summarized into these two categories.

Results

Facilitators

Use the Established Local Standard of Care

Both hospitals already had a great amount of established local standard of care, includes existing guidelines, pathways, safety checklists, CDSSs, and other approaches that aimed to

improve quality of care. These standards were derived from published literature and adapted to their hospitals.

All providers who participated in this study suggested that this knowledge was already accepted and followed in the department level. Using this knowledge made checklist items more acceptable and reasonable to clinicians.

Make Computerized Checklists Dynamic

Providers claimed they refused to use paper-based checklists due to its static nature that did not fit in their dynamic and demanding daily workflow.

A computerized checklist that could be adapted to each specific patient made much more sense to clinicians. During the interviews, clinicians mentioned that they liked the dynamic properties as it saved time to complete the checklists and it could detect more patient-specific problems that were worth noticing.

Adaptive to Clinicians' Requirements

In both of the studies, during our implementations, clinicians also mentioned new potential clinical rules sparking their interest in computerized checklists. Especially in the Dutch case, a visualized knowledge acquisition tool was used to build clinical rules. An intensivist implemented and updated the clinical rules independently.

Provided Users Additional Value

The length of time to complete computerized checklists was a major concern for checklist users. Users claimed that the exercise of ticking boxes was time-consuming, even though it was necessary. Nevertheless, they eventually liked the idea of the computerized checklist after several iterations, because it provided additional value. While computerized checklists could help clinicians complete the checklists and worked as cognitive aids resulting in better acceptance and compliance, the additional value of the digital checklist was also their capability to extract and display relevant patient data, to analyze data automatically, and to provide evidence-based literature or local protocol.

Reuse Existing Hospital Information Systems

In our practice, we found that by reusing existing hospital information systems and their components as much as we could, we could save a great amount of time and make the computerized checklist easier to be accepted.

One example was the CDSS used in the Dutch hospital. The clinical rules in the system had been developed and tested for decades. Intensivists had all agreed on them and were familiar with these rules. Reusing these rules saved not only time for the development phase, but also made the checklist items more convinceable to the intensivists

Challenges

Users' Perception and Medical Culture

Checklists could help deliver more transparent healthcare, that people could know who did what at what time; however, some providers had their concerns. Some clinicians worried about patients and their family, who could lack medical knowledge and could misinterpret the records that they made. This could be used as evidence against them if something wrong were to happen. Therefore, these clinicians refused to use the checklists, or they ticked everything to avoid trouble.

The Right Level of Variability

Healthcare processes were highly variable. It was yet difficult for computerized checklists to cover every path of the healthcare process. In some situations, there were no checklists which could cover them or a checklist could no longer validate for those cases.

Knowledge Acquisition

The cost of knowledge acquisition was high. Knowledge engineers and clinical experts had difficulties in understanding each other. The knowledge provided by experts did not always reflect the specific problem in a specific department. It sometimes took several iterations to finalize a clinical rule.

Conclusions

Safety checklists have been considered a promising tool for improving patient safety for a decade. Computerized checklists can help implement safety checklists in a process-oriented and patient context-aware way so that they fit better in medical practices; however, due to the lack of experiences, it remains unclear what the facilitators and challenges are when implementing them in hospitals. To help accelerate the widespread adoption of computerized checklists, this paper summarizes facilitators and challenges of two successful computerized checklist implementations. Suggestions for future computerized checklist implementations and other possible research directions are considered for future research.

Acknowledgments

The research leading to these results has received funding from Chinese National Science and Technology Major Project (grant number 2016YFC0901703) and the Brain Bridge Project sponsored by Philips Research. The authors would like to thank the intensivists and cardiologists involved in this study.

A Novel Platform to Define Chemotherapy Templates and Their Prescriptions

Hernán Navas[a], María Eugenia Liva[b], Federico Rossi[b]

[a] *Health Informatics Consultant at Cloodie S.A., Buenos Aires, Argentina*
[b] *Software Engineer at Cloodie S.A., Buenos Aires, Argentina*

Abstract

Medication errors have been identified as a major type of medical errors. Chemotherapy medication errors that occur in the prescription phase appear to be related to more significant adverse outcomes. The use of pre-printed templates increases patient safety. The functionalities required for the prescription of chemotherapy are not usually part of Clinical Physician Order Entry. The implementation of electronic chemotherapy templates will reduce the prescription errors.

Keywords:
Electronic Health Records, Antineoplastic Agents, Patient Safety.

Introduction

Medication errors have been identified as a major type of medical errors. It is one of the most risky for patients. The highest percentage occurs at prescription time and its cause is multifactorial. Chemotherapy medications pose an additional risk due to the limited safety margin existing in its dosage and its high toxicity. The prescription phase medication errors appear to be related to more significant adverse outcomes.

The use of pre-printed templates on paper with complete treatment schemes increases patient safety [1]. The use of the Clinical Physician Order Entry (CPOE) also improves patient safety by generating clear, complete and accurate orders.

The implementation of CPOE in chemotherapy is related to a reduction in the risk of errors [2,3], mainly in the dose calculation, and in an improvement in administration times.

The precision of the preparation of the dilution to ensure adequate concentration is essential to optimize the efficacy and safety of the medications administered.

The aim of this paper is to describe the development of a system to create and keep electronic chemotherapy templates.

Methods

Cloodie HIS Electronic Medical Record is unique per patient. In inpatient areas, the system allows the request and visualization of complementary tests through the integration with ancillary services (laboratory, imaging, etc.), write clinical notes, and medication prescription, for general drugs.

As a requirement for a specialized Institution were conducted a joint evaluation of the prescription system for chemotherapy orders. The existent functionalities were not enough to allow the safe prescription of these medications.

They were collected and analyzed the existing paper templates. The templates filled out by the physicians were also included. In addition to the information contained in each field, all handwritten notes beside the structure of the templates were taken into account (such as marginal notes, footnotes or notes on the back). Such analysis sought to identify:

- Prescription categories, according to their structure.
- Order and relation between administrations.
- Forms of preparation/ dilution of drugs and mixtures.
- Additional variables related to administration

Results

35 empty templates and 55 complete templates were analyzed. It was possible to identify:

- Prescription categories: hydration, general and alternatives.
- Order and relation between administrations: absolute indications (as regards the time of administration), and relative to other existing ones.
- Forms of preparation/ dilution of drugs and mixtures: total and partial dilutions. Variables were also detected in terms of the dependence of the amount of solute and/ or solvent to be used.
- Additional variables related to administration: infusion rates variable in time.

A. Template Management System

The information was distributed in 4 tabs:

- General information.
- Medications.
- Preview, in calendar format.
- Signatures.

B. Parameterization of indications

The definition of the medication has been structured using an association scheme linked to two fundamental concepts. On the one hand, the conformation of a grouping entity of one or more drugs (forming a mixture), called “Drug Group”, and, on the other hand, the definition of how this group is administered over time, allowed by the template, called “Planning”. Each group of medications must have at least one plan, but it may have more than one (see Figure 1).

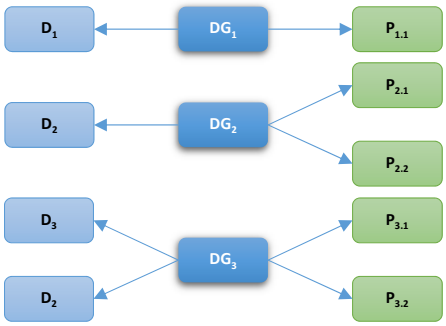

Figure 1 – Relation between "Drug", "Drug Group" and "Planning"

B1. Drug Group

It allows creating sets of medication that will be prepared by means of a mixture, if their presentation permitting, and if administered by the same route. Otherwise, only one medication per group is allowed (if the dosage form is a tablet).

B2. Definition of each plan

Each "Drug Group" may contain multiple plans. Each plan shall have as main data the dose and the time of application. In this way, the same group may be administered with a dose on certain days and with a different dose on other days.

Each plan must include:

- Basic information: the administration route must be defined (according to the selected medication), the days on which it will be administered and the temporal relation with other medications, if applicable.
- Dose: it can be defined relatively according to some anthropometric parameter of the patient; or absolutely. When expressed in a relative manner, the system will make the calculation at the prescription time.
- Method: to determine the administration frequency.
- Dilution scheme:
  - Fixed: i.e. regardless of the amount of solute (drug), it will always be diluted by the same volume of solvent.
  - Relative concentration: When a single final mixture is prepared with variable quantity of both the solute (drug) and the solvent according to the anthropometric parameters.
  - Absolute concentration: the same preparation is repeated in "n" number of bags, keeping the concentration in each of them.
- Flow: It allows specifying different rates of administration of the diluted medication.
- Observations: Free text for any relevant information.

C. Safety and control mechanisms

C1. Internal Validation

Some of the blocking validations are as follows:

- Administration days: the system will not allow values out of the range comprised by the duration in days to be entered on the template.
- Modifications from pharmacy: each time data are entered on the template, the system verifies if a change was made from the pharmacy master system on any of the attributes of each of entered medications. If so, it will alert the physician and request them to carry out the homologation.
- Maximum dose: At the prescription time, the attending physician must not exceed this value under any circumstances. If the automatic calculation resulted in a value higher than the allowed one, the physician shall adjust the parameter below the maximum established.

There are other warning that may be ignored, for example:

- Percentage of dose adjustment: for each drug on each template a percentage may be defined, within which the adjustment of the dose is recommended. If the attending physician modifies the dose beyond such percentage, a limit warning will be displayed.

C2. External Validation

A circuit was defined for the safe use of templates.

1. Creation.
2. Signature: The signing physician must evaluate the completeness and accuracy of the template.
3. Available for use by the attending physicians.
4. Template without signature: If the template was modified after the signature, it will be left out of the healthcare process, requiring the pertaining signature again. This does not affect the templates in progress.

Conclusions

The implementation of electronic chemotherapy templates will make it possible to reduce errors related to the prescription, while speeding up the prescription process by the attending physicians. It will simplify the management of such templates every time it is necessary to carry out any modification to update the treatment or removal due to obsolescence, guaranteeing the reliability of the available templates.

Incidence of Falls in a General Hospital in Southern Brazil

Aline Tsuma Gaedke Nomura[a], Murilo dos Santos Graeff[a], Lisiane Pruinelli[b], Miriam de Abreu Almeida[a]

[a] *School of Nursing, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil*
[b] *School of Nursing, University of Minnesota, Minneapolis, Minnesota, USA*

Abstract

Understanding the multifactorial dimension of fall risk contributes to the search for better preventive interventions. The objective of this study was to identify the events types and the most frequent causes related to falls in adults and newborns. In the included period, 378 falls occurred. Understanding the predictive factors for the occurrence of falls has the potential to guarantee better safety for the patient.

Keywords:

Nursing Informatics, Accidental Falls, Electronic Health Records

Introduction

Falls are the second leading cause of accidental or unintentional injury deaths worldwide [1]. A fall is defined by the World Health Organization (WHO) as "an event which results in a person coming to rest inadvertently on the ground or floor or other lower level" [2].

A study pointed to a drop rate of patients in hospitals in developed countries that ranged from 3 to 5 falls per 1,000 patient-days [3]. In addition, it pointed out that these falls resulted in damages for 30% to 50% of these cases, such as fractures, subdural hematomas, and bleeding, which can lead to death. This creates a negative impact on the mobility of patients, as well as anxiety, depression, and fear of falling again, which increases the risk of new falls.

In another study that sought to evaluate the risk and incidence of falls in hospitalized adult patients [4], authors have identified that if the patient has a high-risk score for falls on admission, this risk tends to remain high until hospital discharge. The incidence rate was 1.68%, with a higher percentage of patients classified as having a high risk for falls.

In this context, a study suggested there was an improvement in patient care practices associated with better nursing records after the implementation of specific protocols in electronic health records (EHR), and the prevention of falls is one of the greatest improvements [5].

Risks of falling is multifactorial. Among the most frequent are: disorientation/confusion, frequent urination, walking limitations, absence of caregiver, postoperative period, and number of medications administered within 72 hours before the fall (last dose of the classes: benzodiazepines, opioids, barbiturates, antipsychotics, antidepressants, antihypertensive, laxatives, diuretics, antihistamines, anticonvulsants, and sedatives) [6]. Thus, understanding the dimension of these events, through EHR, supports nursing clinical decision-making, which contributes to the search for the best preventive interventions and positively impacts patient safety [6].

The use of clinical decision support (CDS) associated with EHR has been widely used as a tool to provide the best evidence assisting physicians, patients, and other team members to achieve better care outcomes and to reduce costs in health systems [7]. According to the Office of the National Coordinator for Health Information Technology (ONC), these tools include computerized alerts and reminders for professionals, clinical guidelines, focused reports and summaries of patient data, documentation models, diagnostic support, and contextually relevant reference information, among other tools [8].

Thus, the questions are: How are the incidence of falls? What are the most common types and causes? The objective of this study was to identify the events related to, the types of, and the most frequent causes of falls in adults and newborns.

Methods

This was a quantitative, descriptive, and documental study, conducted in a private hospital in Porto Alegre in southern Brazil. The population is composed of all medical records of patients admitted to the institution from January 2011 to October 2018.

The EHR was implemented at the institution in 2008, and includes all items related to patient care, as well as decision support tools such as event management, quality, and other administrative functions. Through computerized record entries, nurses reported the falls of patients hospitalized in adult and neonatal units.

These units account for a total of 189 beds. For each notification, the Patient Safety Center (NSP) opens an event analysis form to identify possible causes, thereby generating actions to mitigate event damage. In addition, it promotes improvements targeting the prevention of other falls for the same reasons. Since the implementation of the NSP, the team has already promoted several actions to reduce the risk of falls and minimize damages.

Among the actions are: identify the patient at risk by the adoption of a bracelet, mandatory use of safety in wheelchairs, seat belts, transport of the newborn in crib or litter, placement of support bars in corridors and restrooms, and implementation of bedridden patient routines such as low beds with grids, among others. In addition, system alerts were implemented into the EHR, as a form of communication among the multi-professional health team.

Data was obtained through the EHR software database of the institution and descriptive statistics were used for analysis.

Results

During the study period, there were 378 falls, which represented 1.07 falls per 1,000 patient-days. Of these, 252 (66.66%) were falls from their own height and 126 (33.34%) were falls from a stretcher, chair, or armchair. The most frequent causes were: sensitivity deficit (24.94%), loss of balance and gait (14.40%), mental state alteration (12.08%), drugs that affect the central nervous system (6.68%), wet floor (6.43%), furniture and equipment interference (4.88%), inadequate footwear (3.60%), and bed without grid (3.34%). These numbers represented 76.35% of all events.

Conclusions

The study allowed the identification of the characteristics of events related to falls using a large EHR system with the aid of a clinical-decision tool specifically designed for the identification of the risk of and the event of falls. With the adoption of electronic systems and the systematization of care, it was possible to understand the predictive factors for the occurrence of falls in this field of study. From the data generated, it is possible to obtain resources to evaluate, plan, and implement actions aiming to reduce falls in the hospital environment in order to promote greater patient safety.

Although multifactorial, the findings determined the main factors that led to falls. Through critical thinking and clinical judgment, it is possible to implement a preventive care plan that is more attentive to related causes. A preventive care plan includes: to plan a safer environment with the physical structure and furniture, to evaluate the need for greater human resources, to implement patient, family, and professional educational programs, and to make use of specific instruments and protocols to prevent falls. These are some strategies to be implemented and/or optimized.

It is important to highlight the important role of the nurse in management, risk control, and hospital safety. It should also be emphasized that prevention processes should be systematically analyzed and reviewed, guided by best care practices. EHR and the standardization of nursing records, combined with information systems improvement, can contribute to the development and management of quality indicators, promoting decision-making and patient safety.

Acknowledgements

We would especially like to thank colleagues at the Patient Safety Center for their support in planning and conducting this study. We also give special thanks to the technicians of the information technology who provided technical support during the data collection.

The authors have been developing research projects on Nursing Processes and electronic health records, based on Computer Science.

Midwives' Perception of Using a Knowledge Base on Fetal Impact of Drugs

Ulrika Nörby[a,b], Tero Shemeikka[a], Birger Winbladh[b,c]

[a] *Health and Medical Care Administration, Stockholm County Council, Sweden*
[b] *Center of Reproduction Epidemiology, Department of Clinical Sciences, Lund University, Sweden*
[c] *Department of Clinical Sciences and Education, South Hospital, Karolinska Institutet, Stockholm,* Sweden

Abstract

A non-commercial knowledge base providing assessments of fetal risks of medicinal drugs is a useful tool in the everyday work of midwives. The information is freely available on the internet, and according to a questionnaire study, nearly 95% of the midwives are familiar with the database, 30% use the information weekly, and 80% express that it affects their medical decisions. A vast majority of the midwives also state that it is time-saving.

Keywords:
Knowledge Bases, Risk assessment, Midwifery

Introduction

The midwife has a central position in perinatal care in Sweden with its own responsibility for normal pregnancy, delivery, and care after birth [1]. As a result, the midwife is usually the primary contact person for the pregnant woman. The midwife must assess whether there are any complications that have to be referred to a physician.

Over the years, drug treatment during pregnancy has become more and more common [2; 3], probably due to the fact that pregnant women are older nowadays and because effective therapy of chronic diseases allows more women to give birth. Hence, most women use drugs at some point during their pregnancies [4-6]. A common question is thereby whether exposure to different medicinal drugs might harm the unborn baby. Often, both pregnant women and health care professionals believe that the fetal risk of drug exposure is higher than the actual risk [7; 8].

To support health care professionals, the non-commercial Swedish knowledge base *Janusmed Drugs and Birth Defects* provides assessments of fetal risks of the approximately 1450 drug medicinal substances on the Swedish market. It is available at www.janusinfo.se/fosterpaverkan, as well as integrated into several electronic health records [9].

The contents are based on substances and in most cases one document deals with one substance. Each document is after that linked to a medical products register via a combination of unique substance identifiers and ATC codes (Anatomical Therapeutic Chemical classification codes), which allows the users to search for both substances and drug products. The texts are written in a structured way with short risk assessments, background, and references. They are also classified according to the 3-tier system dependent on the risk level.

The medical contents are better adapted to clinical decision making than the official summaries of product characteristics for the drug products, which are not seldom inconsistent and sometimes even incorrect [10; 11].

The knowledge base has previously been shown to be useful for pregnant women, even though it is not adapted for lay people [12]. In this survey, we have evaluated how midwives as key persons in antenatal care, use and perceive the web-based version of the database.

Methods

An electronic questionnaire focusing on the use and value of the database was sent by e-mail to 960 midwives in Sweden. The e-mail addresses were provided by coordinating midwives who have regional responsibility for training, routines and quality control of antenatal care. The questionnaire consisted of multiple-choice, scaled and open-ended questions. We used the survey tool Easyresearch provided by Questback to set up and collect the data.

Results

In total, 408 midwives answered the questionnaire which corresponds to a response rate of 48% among respondents with a valid e-mail address. 93% of the midwives were familiar with the database: among them, 4% used it daily, 26% weekly, 35% at least once per month and 35% more seldom. They used the information both during the pregnant woman's visit at the clinic (80%) and before/after the consultation (74%) and to a lesser extent for teaching and own studies (17%).

The most common situation was when a pregnant woman already had used a drug, in which case 96% of the midwives consulted the database. However, 46% used it to choose suitable drug treatment for a pregnant woman. Overall, the midwives perceived that the knowledge base provided answers to their questions and that it had an impact on their medical decisions (Table 1). They also often read the texts together with the pregnant woman and perceived that the information is useful to decrease the woman's anxiety of teratogenic effects, see Table 1. Finally, 76% of the midwives answered that the knowledge base saves time.

The following answers to open-ended questions illustrate the opinions of the midwives:

"Typically, I am able to calm down a worried patient who used a medication during her pregnancy"

"I use the database to collect facts concerning a drug and provide the woman with proper information. Sometimes, an appointment with a physician is made."

"Saves a lot of time. It is tremendously useful!"

Table 1– Midwives' use of the knowledge base – key questions

Question	Response option	n	%
To what extent does *Janusmed Drugs and Birth Defects* provide answers to your questions?	Very high extent	258	54
	Rather high extent	178	38
	Neither high nor low	15	3
	Rather low extent	3	1
	Very low extent	3	1
	Don't know	17	4
How often do the risk assessments in *Janusmed Drugs and Birth Defects* affect your medical decisions?	Very often	96	27
	Often	99	28
	Sometimes	83	24
	Seldom	12	3
	Never	3	1
	Not relevant	58	16
How does the information in *Janusmed Drugs and Birth Defects* affect the pregnant woman's anxiety for negative fetal impact?	Decreases to a high extent	120	34
	Decreases to some extent	184	52
	Neither high nor low	2	1
	No impact	2	1
	Increases to a high extent	2	1
	Not relevant/can not judge	81	17
Do you read the texts together with the pregnant woman or advice her to use the knowledge base?	Yes, often	84	24
	Yes, sometimes	178	51
	No	88	25

Discussion

By using the knowledge base *Janusmed Drugs and Birth Defects,* midwives are able to handle many questions independently, which unburdens the work-load of the physicians and provides the pregnant women with evaluated advice in an efficient way. It is an advantage that the database benefits both health care professionals and pregnant women. Using the same primary information resource likely facilitates communication and prevents misunderstanding.

Conclusions

The knowledge base *Janusmed Drugs and Birth Defects* is extensively used and appreciated by midwives in Sweden. Further, it has a direct impact on their medical decisions and advice at the point of care.

Acknowledgements

The authors would like to thank the coordinating midwives for providing the
e-mail addresses to the respondents.

Development of Albumin Analyzer with Whole Blood and Application to Telemedicine for Patient Nutrition Management in Home Health Nursing

H. Nozaka[a], H. Sazawa[b], S. Shiroto[a], M. Nakano[a], H. Takami[a]

[a] Hirosaki University Graduate school of Health Sciences, Hirosaki city, Aomori, Japan
[b] Department of Clinical Labolatory, Hokkaido Cancer Center, Sapporo city, Hokkaido, Japan

Abstract

Albumin level is q significant indicator of patient nutritional status. However, Point of Care Testing (POCT) devices and telemedicine system that nurses can operate easily in-home medical care is not developed. The aim of this work is the development of a POCT device for Albumin level and application to a telemedicine support system. The operability of our system was simple and easy for the nurse or patient. We believe our method is useful for Nutrition Support Team activities in-home medical care.

Keywords:
Telemedicine, Home Health Nursing, Nutrition Status

Introduction

Albumin (ALB) level is a significant indicator of a patient's long-term nutritional status[1,2]. Nutritional management is reported as strongly related to patient prognosis, recovery period, and survival rate. Nutrition Support Team (NST) activities become more important not only in hospital but also in home health nursing. Biochemical analysis with Point of Care Testing (POCT) in home health nursing is useful for the understanding of patient nutritional status, but measuring principle of albumin level with whole blood specimen has not been developed[3]. The aim of this work is the development of a POCT device for albumin test with whole blood specimen and application to a telemedicine support system for patient nutrition management in home health nursing.

Methods

We designed a POCT device that can measure hemoglobin and albumin level with whole blood from the fingertip. The hardware consisted of two photo-transistor units, LED units, and "NI-USB DAQ" (Figures 1, 2). The SLS-hemoglobin method was adopted for hemoglobin testing, and the BCG method was adopted for albumin testing. We improved the BCG method for whole blood test specimens and devised the data convert algorithms from whole blood result to serum result (Figure 3).

Tele-medicine system for patient nutrition management

We used the iPad and telepresence robot "Kubi" as the telemedicine support system. Web conference system "Zoom" was used for face-to-face coaching between nurse and patient. Also, we developed a chatbot system, "e-nutrition" as an automatic response system in non-face-to-face (Figures 4, 5).

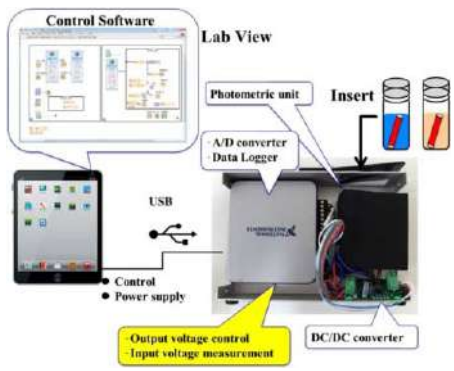

Figure 1– Whole blood albumin analyzer

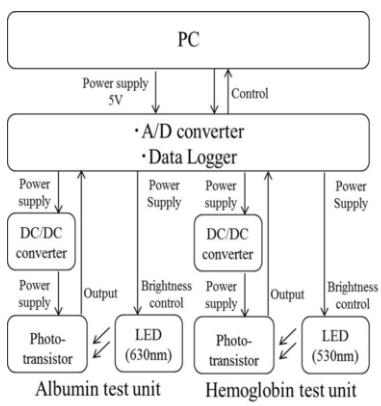

Figure 2 – System Block Diagram

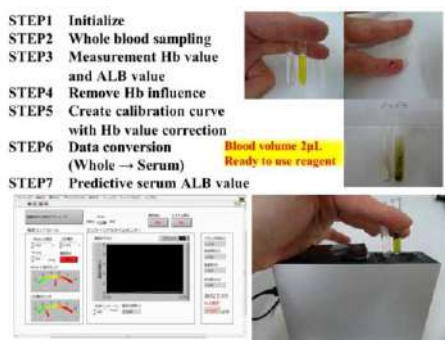

Figure 3– Prototype system of ALB POCT device

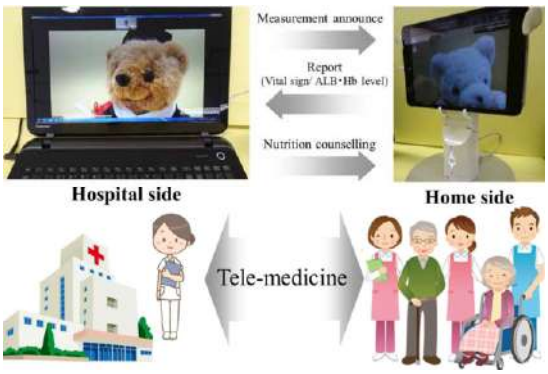

Figure 4– Face-to-face coarching between nurse and patient

Figure 5– Automatic response system by chat bot system

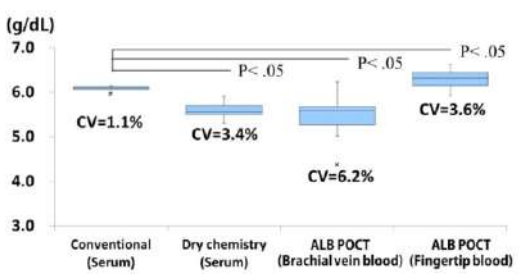

Figure 6– Repeatability and Accuracy

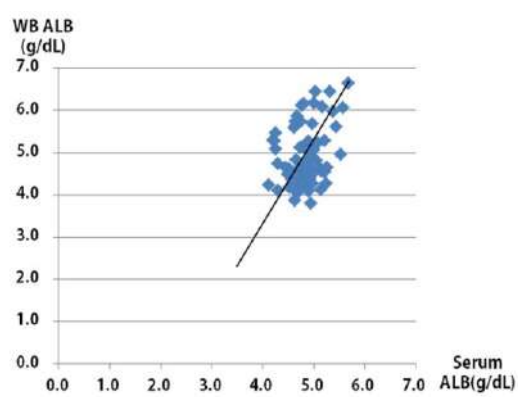

Figure 7– Correlation between actual measurementserum ALB level and estimated ALB level with whole blood

Clinical trial

We evaluated the correlation and accuracy of ALB level between the hospital and the home. Evaluation of the telemedicine system was carried out by patients survey. 1) Study subjects: fifty normal healthy persons. 2) Home side: Patients draw fingertip blood with lancet by themselves, and collected into a microcapillary. ALB level was measured with whole blood by our POCT system. 3) Hospital side: We draw peripheral blood from a brachial vein and collected into a blood collection tube. Serum was recovered after centrifuge. Albumin level was measured with serum by biochemical analysis.

Results

Analytical repeatability showed C.V. 6.2% or C.V. 3.6% with whole blood method, and it was sufficient in clinical fields use (Figure 6). Approximate levels were obtained between estimated ALB level and serum ALB level in about 70% of cases. Deviation between estimated ALB level and serum ALB level was caused in high Hb level cases (Figure 7). Automated response system by chatbot scored high in operability on input. It was also excellent that patients could respond at any time, and it was useful for the report when the nurse is absent.

Conclusions

Our POCT showed a good correlation between whole blood and serum. The correction with Hemoglobin level was effective for the albumin level data convert from whole blood to serum. Our system is possible to measure estimated ALB level with a small amount of blood collection, and operability is simple and easy for home health nursing. Our POCT method with liquid reagent is low cost and the chatbot system contributed to labor-saving of hospital nurses. We believe this system can contribute to home health nursing in telemedicine.

From Fax to Blockchain: Sharing Health Information Democratically and Safely

David Parry

Department of Computer Science, Auckland University of Technology, New Zealand

Abstract

Information sharing in healthcare remains an unsolved problem despite a plethora of standards and architectures. Effective information sharing is difficult because of the heterogeneity of health information users and data sources, organisational, ethical and legislative constraints and the very demanding requirements of clinical practice. This paper argues that the key requirement of a viable sharing architecture is to support trust in the system and between stakeholders. It uses the concept of a "democratic " approach where citizens can control and verify the use and sharing of data about them and identify ways that some of the value extracted from the data could be assigned to the patient themselves. The reasons for the survival of obsolescent methods are used to inform the design of a proposed citizen-centric architecture using blockchain technology.

Keywords:
Health Information Exchange, Privacy, Communication

Introduction

Sharing medical information between healthcare providers is a key task in improving healthcare to avoid over testing, and misdiagnosis.. At the same time access to, and value extraction from data by citizens, governments and machine learning agencies is becoming ever-more prominent. Many current data sharing approaches are not universal and have led to the perhaps surprising survial of older technologies such as the fax machine.

Review

Clinical information is often described as residing in "silos"- separate and sealed repositories of data that are generally aligned around a clinical service rather than the needs of the patients. Before any information sharing can take place, the location of possibly relevant information must be identified and systems must have semantic interoperability.

A low-overhead, relatively flexible means of transferring time-sensitive information is attractive. Fax's continue to meet this need in many part of the health system [1].

A major reason why data is not routinely and effectively shared is a lack of trust between providers [2]. Centralized systems such as the *Myhealth record* in Australia [3] have had particular problems in getting both clinical and patient support, with privacy being seen, sometimes perhaps more than is warranted, as a major barrier. Health information exchanges are one approach to addressing this problem, and although often successful when implemented within regions, costs and boundary issues remain a major problem [4]

The middle-out approach [5] involves setting interface standards and allowing users and vendors to build systems that can interface with this. The effect of adding new systems to a standards-based middle-out system is to add value to the network without increasing complexity.

Key technologies and standards

Blockchain is a technology derived from the underlying principles of crypto currency. It is attracting increasing interest as a medium for health data exchange [6]. Issues of file-size have bedevilled early implementations – the blockchain gets larger with every interaction- but this is being addressed with newer approaches [7].

SNOMED CT can be used for storing vocabulary information and *open*EHR architypes can be used to incorporate metadata about clinical information. Semantic web approaches can be used as an universal directory, for both the transfer of data and the location of data stores. Blockchain-based messages using FHIR or other low-overhead interfaces may be added to health systems and devices. Practical approaches to doing this have been described in Peterson et al. [8].

Methods

A system must allow the patient to know who is sharing information and why There must be an accessible and non-repuduiatable audit trail showing use, change and viewing of the data. However the the patient may want to restrict access in some cases and both aspects must be supported. People are increasingly aware of such issues and developing models that go beyond simple privacy and control.

Ownership of financial and other benefits of use of the data must be clear and a process for negotiation around such income must be possible [9]. As much as possible, the data shared should be atomic – only including as much data as needed . Interfaces to the transfer system, directory and audit system must be relatively simple and based around standards that are scalable. Network value increase with the number of connections, and blockchain-based networks appear to be following Metcalfe's law [10] that the value of the network increases exponentially with the number of nodes. The payload of data transfer should be stored efficiently but with fully integrated metadata. Non-traditional forms of medical information – e.g personal electronic health records, data from wearables etc. must be able to be integrated into the system

Results

Architecture of a block chain-based health information exchange

An outline design for such an approach is shown in Figure

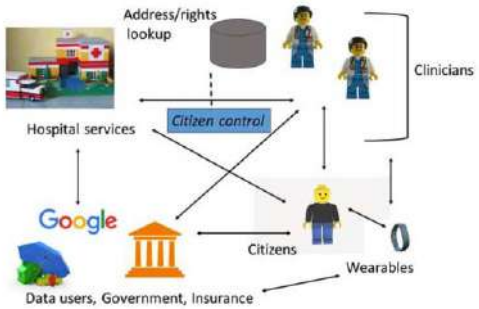

Figure 1: Architecture - each connection is made using block chain-based messaging

Use-case example.

Patient A has high blood pressure and prediabetes. She communicates her wellness data from here wearable devices via the blockchain architecture to her family doctor. The specialist in internal medicine is on a pre-agreed "whitelist" of data receivers so the family doctor adds clinical observations and the result of blood tests to this information as part of a consultation process. A pharmaceutical company has interest in patients with similar characteristics, so the specialist sends a request to the patient, including an estimated fee, to the patient to allow the pharmaceutical company to extract some data from the blockchain-based message. The original patient has complete visibility of both who has viewed and who has changed the data. If there is a delay in the specialist reviewing the data, this can be communicated to the family doctor and a reminder sent.

Discussion

There exists a growing gap between the expectations of citizens that they are to have control of their data – for example the recent general data protection regulation in the EU [11] and current practice. Verifiable control of personal data hsa become very important to large numbers of individuals. However onerous privacy policies, are unpopular and may be used as an excuse to not share data between health providers where appropriate [12]. Granular sharing of data – that is data being shared with certain entities for defined reasons- is popular in principle but difficult to implement in conventional models [13]. Attitudes to data sharing and use have become more citizen-centric – as demonstrated by the EU adoption of GDPR.

Conclusions

Blockchain approaches are at an early stage of development and are certainly suffering from a great deal of "hype" and unrealistic expectations [14]. The democratisation and simplification of health information exchange and value extraction is an important and continuing challenge for health professionals and citizens and other users of health data.

To replace the Fax, the healthcare system and citizens need to be able to understand and trust systems that transfer information safely and fairly apportion the value extracted from that data.

Application of Process Metrics to Compare Children's Asthma Diagnostic Pathways in 30 EU/EEA Countries

Fabrizio Pecoraro, Daniela Luzi, Oscar Tamburis

National Research Council. Institute for Research on Population and Social Policies, Rome, Italy

Abstract

The paper presents the results of the application of the business process approach to analyse and compare healthcare pathways performed in 30 EU/EEA countries focusing on children's asthma care. The adoption of process metrics allows the identification of different levels of fragmentation across countries resulting from the interactions among primary and secondary healthcare professionals as well as from parents' involvement in the process.

Keywords:

Business process modelling, Bronchial Asthma, Child health

Introduction

Asthma is the most common chronic disease among children [1], representing one of the top 20 conditions for global ranking of disability-adjusted life years (DALY) [2]. Although different international widespread guidelines [3] provide criteria to diagnose, manage and monitor asthma in children and young adults, this disease is still one of the most difficult disease to diagnose and control [4]. A correct, timely and early diagnosis of asthma is necessary to improve its control. This requires speeding up the provision of diagnostic tests, such as spirometry, to confirm asthma diagnosis and its severity, as symptoms alone are not enough to assess the presence and the severity of this respiratory disease [5]. In some countries this is achieved performing spirometry in the primary care setting. Moreover, communication procedures have a crucial role to improve the continuity of care in the management of patients with asthma [6].

This study is part of the MOCHA (Models of Child Health Appraised) project1 that aims to compare and appraise existing national models of primary care for children. Within this project the objective of this paper is to analyse the efficiency of the diagnostic pathway carried out in 30 EU/EEA countries focusing on the communication among professionals and parents as well as on the performance of the spirometry test.

Methods

The communication procedures between primary and secondary care as well as the provision of the spirometry test in each MOCHA country are captured analysing the answers provided by local experts in child health services, i.e. Country Agents (CAs), in an ad hoc questionnaire. In particular the analysis is focused on the following questions, as reported by 22 CAs: 1) is the spirometry usually performed by a primary care (PC) provider?; 2) how does the secondary care (SC) specialist provide the results of the spirometry test to the primary care provider?; 3) which are the usual procedures to refer the child to secondary care?. Moreover, the CAs were asked to report the availability of the medical record in PC setting and whether the record is shared among other professionals. The result of this analysis has been represented using the Unified Modelling Language (UML) diagrams that facilitate the comparison between the different business processes performed in the MOCHA countries in the delivery of child care [7]. In particular, the UML use case diagram has been developed to provide an overall picture of the activities performed as well as of the actors involved in each activity of the care process. This diagram represents the starting point to group countries that have similar procedures, used similar services, and are based on similar caregivers for the provision of care. Responses reported in each use case can help to cluster countries that have a similar behaviour to complete the process. A set of UML activity diagrams have been then developed to summarize the behaviour of each group of countries describing activities performed and messages exchanged by the different actors as well as triggering conditions taking also into account their location and timeline. The process flows adopted in each group of country is analysed to detect differences and similarities among countries in the performance of the different parts of the diagnostic pathway. This analysis requires the identification, quantification and application of business process metrics [8]. Considering the purpose of this paper and giving the high-level description captured from the questionnaire, in this paper we focused on the straightforwardness versus the fragmentation of the care process considering two main aspects: 1) the number of interactions among actors (i.e. professionals, child and parents); 2) the points of the process in which time (waiting for appointments, referral, etc.) has a role in getting the diagnosis and monitoring child health status. Finally, to carry out a performance analysis the activity diagrams were mapped using the NETIMIS process simulation tool. This tool supports the representation of possible bottle necks in a clinical pathway, describing the patients' journey through a series of nodes (e.g. activities) that can be associated with a time and/or a cost for their execution [9].

Results

For space reasons the UML diagrams are not reported in this paper. Starting from the UML use case diagram, countries have been classified and clustered as reported in Table 1. From the cluster analysis three countries have been selected

[1] MOCHA website available at http://www.childhealthservicemodels.eu/

and analyses to capture the level of complexity of the process in terms of its straightforwardness: 1) Spain; 2) Italy and 3) Lithuania. Each activity diagram was subsequently mapped in the NETIMIS simulation tool to represent the differences in the execution of the process, where the probability of the alternatives of the diagnostic pathways decision points is reported in the relevant branches. Figure 1 reports the NETIMIS representation of the activity diagram of Italy.

Table 1– Cluster of countries considering the referral (columns) and communication procedures (rows) and the availability of spirometry in PC (= available; # = partially available). The presence of a shared EHR is reported in brackets (E)*

		PC refers to SC

	Parents		Belgium # Latvia #	Poland * Bulgaria Lithuania Romania *

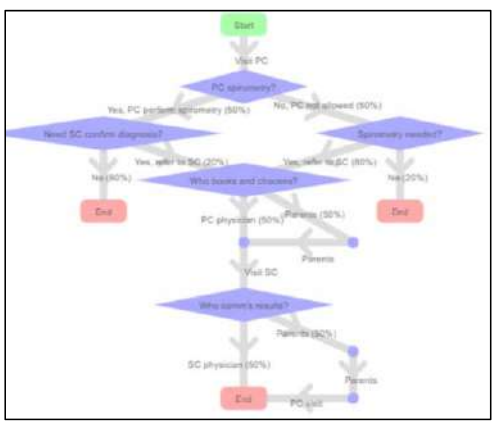

Figure 1– NETIMIS process diagram

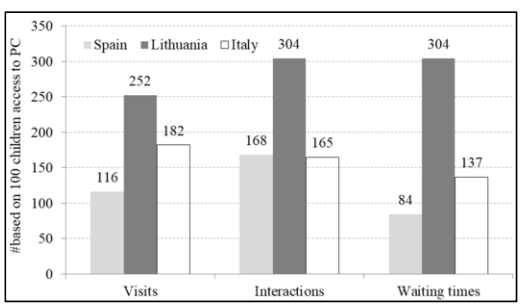

Figure 2– Simulation results reporting the number of visits, interactions and waiting times occurred in each scenario

Discussion and Conclusions

Our approach supports the analysis of the different diagnostic pathways that represent a mix of organisational solutions adopted at local level to address childcare needs [10]. In the present example of asthma, the analysis considered number of encounters, interaction transactions, presence and use of EHR and waiting times across countries. It contributes to outlining the efficiency of organizational models of asthma diagnosis for children on the basis of process metrics highlighting bottlenecks and - through cross-country comparison - possible solutions to improve the process. The need of an early and appropriate diagnosis speaks in favour of spirometry done at PC encounters, especially in cases of exacerbations, when the major focus is posed on the organisational efficacy. Under the business metrics' perspective this resulted in the reduction of the number of visits and interaction between PC and SC physicians and consequently waiting times. In the countries where this is not allowed, the presence of shared EHR and/or close collaboration between primary and secondary care can support both accurate and timely diagnosis (decrease of number of interactions) as well as provide relief of parents' burden in childcare with asthma. The mapping in the NETIMIS simulation tool provides further insights in the analysis of the organisational process, as time and costs of resources can be evaluated. The association of these indicators with children health outcomes could contribute to evaluate the efficacy in the adopted diagnostic process outlining optimal pathways of childcare.

The Impact of Hybridisation on the Accuracy of Fluid Balance Documentation: A Retrospective Cross-Sectional Analysis of Intravenous Fluid Order and Administration Documentation Using a Partly-Computerized Medical Record in an Australian Tertiary Teaching Hospital

Samuel Perotti[a], Angus Ritchie[b]

[a] *M.D Student, The University of Sydney School of Medicine, Sydney, Australia*
[b] *Health Informatics Unit, Sydney Local Health District, Sydney, Australia*

Abstract

Inaccurate intravenous (IV) fluid documentation remains a major cause of fluid-related adverse health outcomes in hospitals. In this study, we characterise the integrity and documentation completeness of a hybrid paper-computer documentation system for IV fluids and explore how inconsistencies within it are associated with adverse patient health outcomes. We highlight key areas of weakness specific to IV fluid documentation that need to be addressed in moving to a fully computerised system in the future.

Keywords:

Infusions, Intravenous; Medical Order Entry Systems; Electronic Health Records

Introduction

IV fluids are the most commonly prescribed intervention in Australian hospitals and are responsible for more adverse reactions than any other single drug alone. It is estimated that up to 20% of patients experience some complication from their use [1]. A major contributor to this issue is incomplete and inaccurate documentation, with studies finding that 20% of fluid orders are incorrectly documented [2,3]. To tackle this, documentation is shifting towards electronic platforms. In 2014, Concord Repatriation General Hospital (CRGH) in Sydney, Australia implemented a "hybrid" model whereby IV fluid orders and administration were documented on paper, and the fluid balance charts were documented in the hospital's electronic medical record (eMR) database. To date, no study has explored the integrity of such a system on IV fluid documentation completeness and how it relates to patient health outcomes. This study sought to address this by: assessing documentation completeness of paper IV fluid orders at CRGH, exploring how well these match their corresponding electronic eMR entries in the hybrid documentation system, and establishing whether inconsistencies between the paper and electronic platforms are associated with poorer health outcomes.

Methods

This study consisted of a retrospective cross-sectional analysis of nearly all inpatients at CRGH between October and December 2016 who received more than 100 ml of crystalloid IV fluids during their admission (excluding paediatric, intensive care and emergency department admissions). Eligible patients were extracted from the hospital's eMR database, and a representative sample was randomly selected for inclusion in the study. For each patient, paper IV fluid orders were examined for completeness of fluid order and administration details (as listed in Table 1). Each paper documentation was then compared with its corresponding eMR fluid balance chart entry. To be assessed as being correct and consistent, the paper and eMR entries needed to record the same fluid type, volume, and infusion duration. The incidence of calls for Clinical Review (CR; i.e., an escalation system for deteriorating patients [4]) made for each patient during their hospital stay was used as a marker of poor patient health outcomes (Figure 1).

Results

A total of 1679 patients met eligibility criteria, of which a random sample of 91 was included in the analysis. A total of 360 IV fluid prescriptions were made for these 91 patients and were assessed for completeness of order and administration details (Table 1). Our findings demonstrate high completeness of IV fluid identifiers and start time, but low completeness for documentation of delivery site (35.6%), time ceased (24.7%) and total volume delivered (18.9%). When compared with their corresponding eMR documentation (Figure 2), it was found that 35.8% of orders were correctly documented, 38.1% were incompletely documented, and 26.1% had no electronic entry at all. The most common inconsistency between paper charts and fluid balance records was showing a different volume of IV fluids delivered on the eMR compared to the paper order (Figure 2). Twenty-two patients received at least one CR call during their admission, which was associated with twice as many documentation inconsistencies between the paper and electronic records (median of 3 vs 1.5 per patient; P=.0007; see Figure 3).

Discussion and conclusions

Paper documentation completeness at CRGH was generally higher than that the 60% completeness reported in the literature [5,6]. However, this study found a significant issue relating to inacurate documentation of total volumes delivered, which is essential information for guiding clinical decision-making and likely to contribute to IV fluid-related adverse events. This is the first study to assess the documentation consistency in a hydrid paper-electronic documentation workflow for IV fluid management. This analysis identified a

high rate of documentation inconsistencies. Possible contributors include poor staff adherence to recommended workflows, difficulties in managing the hydrid interface, time pressures and interruptions in a busy clinical environment, and failure to document changes in fluid orders contemporaneously. Our results also support a strong association between documentation inconsistencies and poorer patient outcomes, as measured by CR call incidence. Though it remains difficult to contextualize these results due to the lack of similar studies in the field, it is clear that hospitals must carefully evaluate the implementation of hybrid documentation platforms as they transition to fully computerized systems in the future.

A Study Design to Model Clinical Management Process for the Health and Wellbeing of Patients with Alcohol Use Disorders

Siyu Qian, Ting Song, Ping Yu

Centre for IT Enabled Transformation, School of Computing and Information Technology, Faculty of Engineering and Information Sciences, University of Wollongong, NSW 2522, Australia

Abstract

Public hospitals are often plagued by patients with unexpected acute alcohol withdrawals because of failure of diagnosis at the time of their presentation. To address these problems, this study will develop models to predict the risk of alcohol withdrawal and recommend corresponding management processes to optimize patient safety using health data analytics.

Keywords:

Alcohol-induced disorders, public hospitals, patient safety

Introduction

Public healthcare systems face the challenge of providing safe and cost effective services to patients with alcohol use disorders. Internationally, alcohol is the most commonly abused substance and causes preventable morbidity, mortality and related behavioural risks [1, 2]. In North America, Europe and Asia there is high prevalence of alcohol use disorders in patients presenting to hospitals [3-5]. Likewise, in Australia, 27% of the patients presenting to hospitals have alcohol use disorders and require certain level of intervention [6]. It is estimated that the annual hospital cost for patients with alcohol use disorders is $19.8 billlion in the US [7]. These patients are often unidentified due to other seemingly unrelated presentation problems such as abdominal pain [8]. Consequently, public hospitals are often plagued by unexpected acute alcohol withdrawal developed during management processes [9]. Our preliminary study found that 73% of the patients with alcohol use disorders were not identified at the time of presentation and the clinical management for these patients was inconsistent and unsafe.

To address these challenges, this study aims to investigate the clinical identification and management processes for patients with alcohol use disorders in Australian hospitals. Multiple research methods, including clinical guidelines review, expert panel discussions with clinicians, machine learning and data mining of the routinely collected inpatient data in the electronic medical records (EMR), will be corroborated to maximize output. Specific research questions (RQs) are:

RQ1. How can we effectively identify patients with alcohol use disorders at the time of presentation?

RQ2. What are the recommended clinical management processes for these patients according to the clinical guidelines?

RQ3. What are the actual clinical management processes for these patients?

RQ4. Do these actual processes comply with the recommendation of the clinical guidelines?

RQ5. What are the optimal processes for safe and cost effective management for these patients?

Methods

This study is designed with two research components: 1. Development of a prediction model to identify patients with alcohol use disorders at the time of presentation (addressing RQ 1); 2. Development of optimal process models for clinical management for these patients (addressing RQs 2-5). Figure 1 illustrates the research components, tasks, methods and theoretical frameworks that guide this research.

The following research theory and frameworks will be adapted to guide this research:

Activity theory [10] will provide an overarching framework to guide our identification of clinical actors and actions from clinical guidelines review and panel discussions with clinicians. This theory provides a systematic approach to inspect a clinical activity from six aspects: who (e.g., clinicians) conducts the activity for what purpose (e.g., to manage alcohol withdrawal symptoms), using what tools (e.g., alcohol withdrawal scale), following what rules (e.g., clinical guidelines), supported by which community (e.g., healthcare team) and the roles of community members (e.g., clinician, nurse) [10]. The usefulness of this theory to our project is drawn from its successful application to study activities of patient discharge and maternal data collection [11-13]. We have successfully applied this theory in a previous study for medication management processes in a residential aged care facility [14].

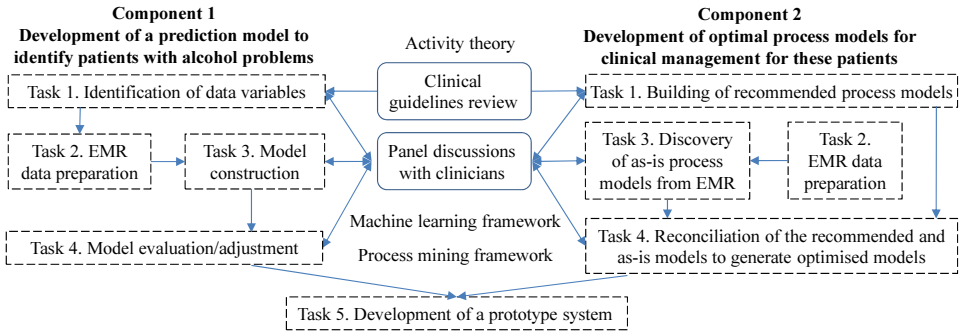

Figure 1– Research components, tasks, methods and theoretical frameworks.

Machine learning technique will be applied to deliver Research Components 1 and 2 [11]. Four steps will be followed to deliver Research Component 1: identification of data variables as model predictors, EMR data preparation, model construction, and model evaluation and adjustment. Whereas a process mining technique [15] will be applied to Research Component 2. The technique will be applied to discover as-is process models from the EMR. The key steps include — EMR data preparation, discovery of as-is process models, and model evaluation.

Conclusion

This paper presents a study design to model the clinical management process for the health and wellbeing of patients with alcohol problems in hospital environment. It addresses the practical challenges of identification and management of patients with alcohol problems in hospitals.

HomeCoRe: Bringing Cognitive Rehabilitation at Home

Silvana Quaglini[a], Silvia Panzarasa[a], Anna Alloni[b], Michele Sacchi[a], Elena Sinforiani[c], Sara Bottiroli[c], Sara Bernini[c]

Abstract

CoRe is a system for cognitive rehabilitation that has been successfully used for several years in hospital settings. Leveraging on the positive survey results from the potential final users (patients and their home caregivers), we developed HomeCoRe. This new version of the system will allow discharged patients to continue the rehabilitation treatment at home.

Keywords:

Home care services; neurological rehabilitation; therapy, computer-assisted therapy

Introduction

CoRe is a program for computer-supported cognitive rehabilitation. Since the development of first CoRe version over ten years ago, we have enhanced the through several iterations. It has been used in different clinical settings for face-to-face rehabilitation sessions between patients and their therapists [1]. A recent clinical study on hospitalized patients affected by Parkinson's disease [2] showed that patients undergoing one month of rehabilitation through CoRe outperformed control patients in the standard battery of neuropsychological tests administered at the clinical cognitive assessment before discharge. However, this advantage was less evident at the six months follow-up after discharge. This observation motivated the development of HomeCoRe, a version of the system that allowed patients to continue rehabilitation at home, after becoming familiar with the program during the hospital stay. We propose that a longer rehabilitation period will maintain the benefits achieved in the first month.

Methods

For the first stage, we interviewed and surveyed patients to investigate their willingness to continue rehabilitation at home. Home caregivers were also study participants, due to their role in both supporting and motivating patients.

The technical stage had the HomeCoRe architecture embedded into two main components, therapist-side and patient-side, and communication channels between them. Consideration was given to addressing the lack of availability of internet connection at home, and particularly for the elderly. The two components communicated through XML files that, from case to case, were either automatically sent using the internet (online mode) or manually shared (offline mode) through flash memories like usb drives, at the control visits.

From the functional point of view, to increase the patient motivation for the rehabilitation treatment, we exploited a unique characteristic of CoRe that was capable of generating "ever new" exercises, due to a stimuli ontology composed by thousands of images, words and sounds, and relationships among them. Moreover, HomeCoRe was able to generate patient-tailored exercises, by adding to the ontology a "private", patient-specific set of stimuli representative of his daily life (pictures from his house, his relatives, sentences related to his job, hobbies, etc.). To monitor a patient's progress, the system calculated an "overall weighted score (OWS)", taking into account the correctness of the answers, the execution time, and the difficulty of the exercises. A temporal abstraction algorithm informed the therapists about the OWS trend. All components were developed in Java.

Results

Out of 21 patient participants, 15 (71.5%) had definite positive responses, 2 (9.5%) had definite negative responses, and 4 (19%), although appreciating HomeCoRe, expressed a refusal to have a further home commitment. Even better results were obtained from caregivers. We were able to interview 16 of them, and 15 (94%) answered positively. The study results encouraged us to start the HomeCoRe project.

Discussion

The therapist's view, migrating from CoRe to HomeCoRe implied to add some functionalities to the therapist's interface. Figure 1 details the top (a) and lower (b) left panel of therapist's interface for creating/selecting patients, managing patients' data and therapeutic plans, and the system dashboard. Figure 2 illustrates the therapist's interface for visualizing the details of the active and expired therapeutic plans for the selected patient.

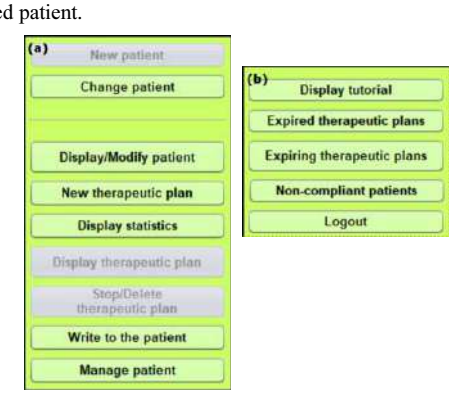

Fig. 1 – Details of the Therapist's Interface with all the System Functionalities

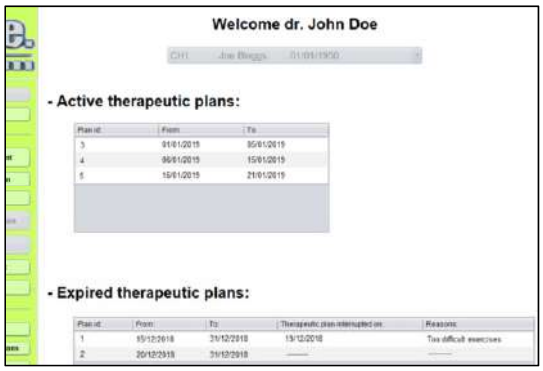

Figure 2 – The Therapist's Interface for Viewing the Active and Expired Therapeutic Patient Plans

The psychologist was able to prepare an entire rehabilitation plan, personalized to a specific patient (see Figure 3). As mentioned, the plan was represented through a XML file that, according to the clinicians' requirements, described (i) the type of exercises for each rehab session, (ii) the duration of the plan in days and daily frequency of execution, (iii) the difficulty level, and (iv) a set of parameters defining some other details, such as the automatic modification of the difficulty level according to the patient's performance, the feedback for the patient, the stimuli exposure time, etc.

The therapist was also able to set a *goal*, i.e. a score that the patient should achieve at the end of the plan execution. The idea was that, if a patient achieved OWS_{disch} at discharge, the goal could be OWS_{final}= OWS_{disch} +y at the end of the plan, with y>=0, decided according to the estimated potentialities of the individual patient. Similarly, goals could be defined for the neuropsychological tests scores (even if they were not continuously measured as the OWS, since they required a face-to-face visit).

Fig. 3 – The Therapist's Interface for Setting the Requirements for the Exercise Plan

At any time, the therapist could check a patient's progress, and the system showed him the percentage of goals achieved. Accordingly, the therapist could modify the rehabilitation plan or update (upgrading or downgrading) the goals.

On the patient's/caregiver's side, the interface was very simple to use (Figure 4). Patients were able to view the exercises of the day, read the message from their therapist and exit. The caregiver could access his private area with a username and a password. The caregiver had a restricted area, where he could upload the XML file and download the results (offline mode) and see all the messages sent by the therapist.

Figure 4 – Home Page of the Patient/Caregiver

All the exercises were performed through a touchscreen (Figure 5). The interface always showed information about the completion percentage of the tasks.

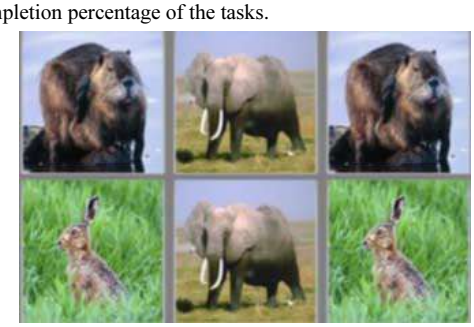

Figure 5 –Memory Exercise Example in the Therapeutic Plan

Conclusion

HomeCoRe is a tool for personalized cognitive rehabilitation that allows patients to continue a rehabilitation plan, which is often abandoned after discharge, due to scarcity of healthcare personnel for homecare. The limitation of the presented work is the lack of a clinical study to show the users' acceptance and efficacy of our proposal. We plan to start a pilot study to refine the system functionalities, in particular communication among patients, caregivers and therapists, and training modalities. Possible next steps include installation of in-hospital workstations to allow patients and caregivers to simulate future home sessions and assessment of the organizational changes that occur with the introduction of technological innovations [3].

Abstract

Medical geo-informatics allows the Health world to address major challenges thanks to attractive concepts, methods and user-friendly IT. PoleSat-web-2018 presents a decision support system – a modelling "variable geometry" IT tool for simulation of hospital spatial planning. The outputs enable quasi-instantaneous analytic visualization at several geographic levels. PoleSat-web-2018 provides prospective views of hospital catchments (by grouping, closing) and proves to be relevant for the French planners of the Ministry of Health.

Keywords:

Health Services Accessibility, Hospital Planning, Expert Systems

Introduction

Geo-informatics has become an important science and faces deep challenges to assist the medical policy makers through attractive concepts and methods. Among them, 1-spatial accessibility is paramount within the framework of a gravity model in order to provide the most valid measures [1-3]. 2- Decision Support Systems (DSS) as management tools through geospatial applications [3]. The main objective is to deliver a user-friendly Information Technology (IT) simulation environment that enables studies and test assumptions [4] and provides immediate strategic spatial views. PoleSat-web-2018 is based on a Graphical User Interface (GUI) with an embedded optimized geometric algorithm (an article was submitted to JOMS on March 2019) for simulation modelling hospital spatial planning. The algorithm, related to a refined gravity model [2; 5], has evolved in order to be completely automated inside a spatial DSS and is intended for the non-geomatician, i.e. non-Geographic Information System (GIS) specialists. An online demonstration (alpha version) is currently available for both specialties: traumatology – total hip prosthesis (PTH)) and Clinical Onco-Hematology (COH) on four geographical scales/levels including 1- former regions, 2- new regions, 3- Territory Hospital Grouping (GHT), 4- France.

This article presents the modelling results (by specialty) through the Advanced 1st Order Simulation **(A1OS)** and the Advanced 2nd Order Simulation **(A2OS)** examples, which are based firstly on "a grouping of hospitals" and secondly on "a suppression of hospitals followed by a conditional-based grouping of the remaining hospitals".

Materials and methods

PoleSat-web-2018 uses sources from the French Diagnosis-Related Group "DRG"-based information system (PMSI). This database (DB) is derived from aggregated data retrievals and represents private-public sectors in 2014. The specialties concern "rare and onerous diseases – OH", and "common and less expensive illnesses" – traumatology-PTH. Patient identification is rendered impossible. More details on the geographic DBs can be found inside the GUI aid.

Software access, architecture and algorithm process

An online PoleSat-web-2018 access is given by https://thymine.univ-lille2.fr/polesat2018/ with a log-in (ID: demo3/PW: polesat4). As of now, no scalability management has been made. Clients and server machines communicate in a request-response messaging pattern. All human-computer exchanges are made in a secured environment. The client can check the progress of the process. The calculation takes 2-3 min (per region) and 45 min (for France coverage). The algorithm workflow can be depicted through the succession of four main steps. 1- Keep all or delete hospital services (P5, default setting: keep all services = 0). 2- Group the hospitals with an expert distance (P8, default setting: 15,000 m). 3- Create referring hospital poles after relocating hospitals in "hospital and hospital-basket poles". 4- Deliver outputs detailing hospital catchment areas (CAs) in maps (.pdf, .shp) and spreadsheets (.csv).

Results

The modelling results derive first in "the A1OS" by grouping hospitals for the region: "Hauts-de-France". Next, the A2OS represents a removal of hospitals followed by grouping of the remaining hospitals. The GUI is intended either for a basic user (with a video guide and a pre-recorded default setup) or for a more advanced user (knowledge of the planner and setting adjustment).

The A1OS: grouping hospitals – COH DB

The A1OS represents (Figure 1) with 53 hospital services, a grouping of 12 services and a final number of 41 referring poles.

Figure 1– The A1OS: Grouping Hospitals (a CA map with black administrative census (IRIS) & white PMSI limits). The main settings: D5: COH, P1: New regions, P2: 32, ***P5: 0****, P8: 15,000 m, checked boxes of CHUs, label, ID, IRIS & PMSI*

The A2OS: removal & grouping hospitals – COH DB

The A2OS (Figure 2), with 53 hospital services, is based on A: removal of 26 hospitals (mass < 2) followed by B: grouping of the 3 remaining hospitals (inside a radius <= 15,000 m), into simple or basket poles, which are 24 final referring poles.

Figure 2– The A2OS by Closing & Grouping (a CA map with black IRIS & white PMSI limits). The main settings: D5: COH, P1: New regions, P2: 32, ***P5: 2****, P8: 15,000 m, checked boxes of CHUs, label, ID, IRIS & PMSI*

Discussion

The results provide both a quasi-instantaneous visualization thanks to ready-to-use maps and spreadsheets, and other format files suitable for geomatic use. To note that the related symbology, used in hospital CA maps, is distinguished by random and contrasting automatic colors. Also, a non-administrative numbered circle is assigned for each referring pole.

The advanced simulations: A1OS & A2OS

After launching the A1OS, maps and spreadsheets are available for verifications and adjusting the settings (Figure 1) and before launching A2OS if hospital closing is desired. This time, there are removals of services followed by a grouping of remaining hospital poles (Figure 2). However, the hospital closing insight (even by specialty) may be terrifying (for citizens), but that should not lead planners to give up this idea. It is why a tailored-made version could be focused to specifically start on hospital supply view and grouping modelling. Only after deeper simulation analyses, a new option proposal of service closing could be adopted by planners & public because of the objective, detailed and clearly analyzed proofs.

Besides, catchment area differences for specific border hospital pole could appear if we use a former or a new region. In consequence, the geographical analysis level choice must take place according to the initial problem of the planner and with full background knowledge.

Obviously, future versions should allow the processing of all PMSI and other health DBs over long periods. A tailored-made version has just begun for the French Health Ministry. The future updates are not yet specified since we are in a preliminary test period.

Conclusions

PoleSat-web-2018 is an effective and easy-to-use web-based GUI (alpha version), with an embedded optimized and automatized algorithm for prospective hospital spatial planning. PoleSat offers practical simulations for studying different scenario effects. It aims at helping planners in predicting the hospital provision reorganization. It proves to be a modelling "variable geometry" IT tool and appears to be relevant for planners with a productive and impartial foundation for strategic decisions. It can therefore be generalized.

[d] *HESPER EA 7425, Lyon, France*

Abstract

EBMPracticeNet is a Belgian website of guidelines translated and adapted from the Finnish EBM guidelines. During the experimentation of the EBMPracticeNet website in France, physicians globally got an accurate answer and found the information provided by the website reliable and useful for practice. They perceived its ergonomics as good and wished to continue using it. Improvements should focus on the indexation and adaptation of the guidelines, and on physicians' training.

Keywords:

Point-of-care system, practice guidelines, general practice, France

Introduction

Web-based medical compendia are point-of-care tools specifically designed to deliver pre-digested, rapidly accessible, comprehensive, periodically updated and evidence-based information to clinicians, which could be a solution to facilitate the use of clinical practice guidelines [1]. More of 20 systems have been developed worldwide, including BMJ Practice in the UK, Dynamed and Uptodate in the USA, which have been assessed in the top three according to their volume, editorial quality and methodology [2].

EBM Guidelines is a collection of 1000 clinical practice guidelines for primary care, produced by the Finnish medical society. It has been translated into French, adapted to the Belgium context and made available to all Belgian physicians on the website *EBMPracticeNet* [3].

As no such web-based point of care information summary was available in France, we have experimented this Belgian website. This aim of this study was to assess physician's participation and searches' effectiveness and users' global evaluation of *EBMPracticeNet* in French general practice.

Methods

A sample of French physicians experimented the Belgian website from March to September 2017. We contacted the approximately 2000 members of the French College of General practice and 50 post-graduate trainees from two medical schools. We collected data from three sources: 1) The website logbook where all searches were recorded with the following fields: user ID, timestamp(s), query(ies), guideline(s) opened; 2) a search-specific assessment questionnaire, evaluating searches effectiveness, periodically activated online; 3) a global assessment questionnaire, evaluating the website ergonomics (System Usability Scale, SUS) and content, and the participants' global satisfaction, sent by mail at midtime and at the end of the study. The frequency of use by each participant was defined as the number of clicks performed into the website, either for entering a query or for opening a guideline.

Results

Among 417 physicians registered, 262 (62.8%) performed at least one search on the website. The participants clicked into the website on average 5.9 folds per month (2.9 queries entered, 3.0 guidelines opened). The number of monthly users decreased during the study period from 168 to 53. In the meantime, the mean number of clicks per monthly user decreased from 17.0 to 11.3. We collected 194 search-specific questionnaires from 85 (32.4%) physicians. Most of them had performed their search out of the consultation (61.3%) and got an accurate answer (74.2%) (Table 1).

We collected a global assessment from 158 (60.3%) physicians at midtime and 103 (39.3%) physicians at the end of the study. At the end of the study, most physicians found the information provided by the website rather reliable (92.2%) and useful for practice (78.6%), were rather satisfied (63.1%) and wished to continue using the website (95.1%) (Table 2).

Table 2 - Final global assessment (n=103)

		At the end n (%)	
Information reliability	Rather reliable 95 (92.2%)	Medium 5 (4.9%)	Rather unreliable 3 (2.9%)
Information adaptation to the French context	Rather adapted 82 (79.6%)	Medium 17 (16.5%)	Rather not adapted 4 (3.9%)
Website usefulness for practice	Rather useful 81 (78.6%)	Medium 14 (13.6%)	Rather useless 8 (7.8%)
Global satisfaction	Rather satisfied 65 (63.1%)	Medium 31 (30.1%)	Rather not satisfied 7 (6.8%)

The mean SUS score was 70.3 at the end of the study. No change was observed for these variables between midtime and the end of the study. On the 183 comments collected, the main barriers reported by respondents concerned the time and the effort required to find an accurate answer and the uneven relevance of the information retrieved.

Conclusion

Before implementing EBMPracticeNet at large scale in France, improvements should focus on the indexation of the guidelines and their adaptation to the French context, and on physicians' training in searching medical databases.

Acknowledgements

The French experimentation and assessment of *EBMPracticeNet* has been funded by the French public health insurance system (Assurance Maladie).

Design and Evaluation of an Automatic Speech Recognition Model for Clinical Notes in Spanish in a Mobile Online Environment

Alejandro Renato, Hernan Berinsky, Mariana Daus, Miguel Fantin Dachery, Oscar Jauregui, Fernando Storani, María Laura Gambarte, Carlos Otero, Daniel Luna

Department of Health Informatics, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

Abstract

Clinical documentation in healthcare institutions is one of the daily tasks that consumes most of the time for those involved. The adoption of mobile devices in medical practice increases efficiency among healthcare professionals. We describe the design and evaluation of an automatic speech recognition system that enables the transcription of audio to text of clinical notes in a mobile environment. Our system achieved 94.1% word accuracy when evaluated on pediatrics, internal medicine and surgery services.

Keywords:

Speech Recognition Software, Mobile Applications, Electronic Health Records.

Introduction

Clinical documentation is an important task, but also time consuming, often taking up 50% of the total time of health professionals [3]. This is where the need arises for new support technologies such as speech recognition, which could allow professionals to free up time and resources. Professionals could then focus more attention on the relationship with the patient. In addition, speech recognition technology maintains the quality of clinical documentation carried out and applied according to the workflow of the professional [4].

In this work carried out in the Hospital Italiano of Buenos Aires, we describe the development and implementation of an application of automatic speech recognition (ASR) oriented to medical domain in a mobile environment.

Methods

In 1998, the Hospital Italiano de Buenos Aires (HIBA) began implementation of its Health Information System (HIS), integrating the administrative and clinical workflows with the applications in use. This system handles all clinical and administrative information, from capture to analysis. Currently, the Electronic Health Record (EHR) is a software in web format, with problem oriented architecture and is focused at the patient level.

Automatic Speech Recognition System

The ASR system was developed internally by HIBA using the open source Kaldi system [2]. For the construction of the system, both the acoustic and the language models, and the acoustic dictionary were developed as part of our work, as well as a reverse text normalization module.

The acoustic model was trained with approximately 800 hours of audio from Spanish speakers from different locations in Argentina. At the end of the training period, we obtained a Neural Networks model (NNET3 in terms of Kaldi, based on sequential models with an I-Vectors module).

The language model used in this work was constructed from the clinical notes performed at HIBA for 5 years, a total of 12 million. The notes comprise 800 million tokens, and a vocabulary close to 80,000 terms. More than 60 medical specialties were represented in the notes. For the construction of the model, the text was standardized and normalized. With this textual database, we built a trigrams model consisting of 62,000 words.

The pronunciation of the 80,000 words of clinical notes was obtained automatically by the grapheme to phoneme converter and then supervised manually. Finally, a module was built to perform the inverse normalization.

The ASR System architecture is shown in Figure 1. ASR Service supports full-duplex communication based on websockets in a scalable architecture: HAProxy distributes incoming requests on multiple independent Kaldi GStreamer Servers [1]; each server supports concurrent processing running multiple workers. GStreamer plugins (GST plugin), installed on Kaldi, executes the decoding task. This task transforms input audio signals to text transcription output based on the ASR Model. The Mobile application for Android is built with Ionic 1 framework and AngularJS (using Cordova plugins to access to the microphone).

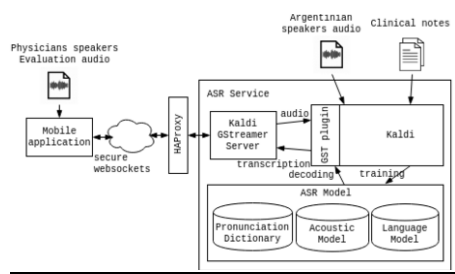

Figure 1– Automatic Speech Recognition (ASR) System architecture

Results

Over eight hours of audio recorded from the reading of clinical notes were used to assess the performance of the system.

The texts were selected from clinical notes of three specialties: internal medicine, pediatrics and surgery. The objective of the selection of texts was that several dimensions of the texts were represented: length of clinical notes measured in words, coverage of the vocabulary and less frequent phonemic combinations. To fulfill this objective, a random selection was made with the following requirements: length between 100 and 200 words, containing one of the 20,000 least frequent words, and containing at least one of the less frequent triptones found during acoustic model training. Following these criteria, 12 batches of data were obtained, each consisting at least 60 clinical notes, and were given to read to HIBA physicians who knew the vocabulary of each specialty.

The speakers were selected from the set of resident physicians at HIBA. Of the twelve residents, eight were women and four were men. One of the speakers was not a native Spanish speaker (Brazilian Portuguese), while another is a native Spanish speaker, but with a different dialect (Colombia). From the remaining speakers, nine speak Rio de la Plata Spanish as their native dialect.

The texts were read in a silent environment, using the mobile client designed for the final application. The logs of the system were collected, along with the original transcription and the audios of the system.

The results of the system without tuning were 91.7% Accuracy, 8.3% WER (Word Error Rate), and 93.4% Percent Correct.

Table 1 shows the results obtained after tuning the system. WER is determined by subtracting Accuracy from 100. Accuracy is different from Percent Correct Word, since it includes both inserts and deletions. The second column in Table 1 gives the percent values while the third column shows absolute values.

Among the serious errors, which are the most difficult to control, are the numerical quantities. Of the 5666 numerical expressions that appear throughout the recorded corpus, there were 307 errors in recognizing numbers (5.41%). Although it seems that the error rate is not high, the occurrence of one of these errors in some contexts can threaten the patient's safety.

Finally, a comparison was made with a set of typed clinical notes of similar characteristics extracted randomly from the set of notes. An analysis of the errors found was then made. The analysis shows that the degree of correct words is 89.2%, versus 95.8% obtained by the ASR system.

Table 1– Results Evaluation

Measurements	Percent	N Words
Word Error Rate	5.9%	2745
Percent Correct	95.8%	44406
Substitution	2.9%	1354
Deletions	1.3%	607
Insertions	1.7%	784
Word Accuracy	94.1%	

Conclusions

We conclude that our mobile ASR system for taking clinical notes has been shown to perform acceptably. Other studies are underway to verify parameters such as: tool safety, clinical applicability, performance compared to the traditional method and quality of the record.

Abstract

Clinical decision support systems (CDSS) are widely used to improve patient care and guide workflow. End users can be valuable contributors to monitoring for CDSS malfunctions. However, they often have little means of providing direct feedback on the design and build of such systems. In this study, we describe an electronic survey tool deployed from within the electronic health record and coupled with a conversation with Clinical Informaticians as a method to manage CDSS design and lifecycle.

Keywords:
Clinical Decision Support, Feedback, Quality Improvement

Introduction

Clinical decisions support systems (CDSS) are widely used in electronic health records (EHR) and have been shown to improve patient safety, increase adherence to guideline-based care and decrease healthcare costs. However, increasing adoption and reliance on CDSS can have unintended consequences that can negatively impact patients [1-3] and lead to increased and inappropriate alerts for healthcare workers when CDSS malfunction.

In addition to automated monitoring systems to prevent CDSS from malfunctioning or quickly remedy errors, EHR users are a potential source of important feedback about the functioning and usefulness of the systems. Engaging the large number of end-users to comment on and report issues with CDSS related to differing workflows and errors in logic can allow malfunctions to be identified more quickly. Further, designing systems to directly alert Clinical Informaticians on an organization's Clinical Decision Support Team can accelerate the remediation of a malfunction. End-users may also have ideas about strategies to optimize a clinical workflow or changes to the EHR build to address a clinical problem without resorting to interruptive alerts.

We developed and implemented a user feedback tool embedded within our CDSS and assessed the impact of user-feedback on our ability to recognize malfunctions, improve CDSS design and manage the CDSS lifecycle.

Methods

In our EHR (Epic Systems v2018), there were no dedicated methods of eliciting user feedback. Healthcare workers were able to leave comments on alerts received at the point of care, but this feedback was limited because the end-user was unclear who read the comments and comments were generally directed towards concerns related to patient care, rather than system functioning. In addition, comments entered in this manner are stored in the patient's permanent medical record, which is not ideal for describing errors in the alerting logic or suggestions for EHR improvement.

To address these limitations, at our institution have we leveraged an external survey tool (REDCap) to collect feedback about how alerts were functioning. We placed a "provide feedback" link to the survey in every alert (Figure 1) and created a single question survey asking for user feedback about the alert they had just received (Figure 2). The link contained associated metadata about the alert such as time, patient medical record number, identity of alert displayed and alert ID. The survey encouraged users to leave any sort of feedback through the alert. Whenever possible, a member of the Clinical Informatics Team responded directly to the user with explanations about the current-state CDSS build and encouraged them to engage in direct discussion about what, if anything, would be changed based on their survey feedback or why it could not be changed.

Results

Over the past year, we have received 983 user feedback comments. Of those, 112 (11%) were blank or single character responses; 321 (33%) related to clinical care (i.e. not feedback on the alert) and 550 (56%) were feedback about the alerts. We received feedback on 89 different alerts (~19% of our CDSS inventory) from 415 unique users (highest user left 35 responses); 304 (55.3%) responses related to 10 alerts.

We responded to 152 (27.6%) user feedback comments that were not about patient care or were blank. We categorized the comments into 6 categories: Unclear Why Alert Fired (27%), Suggestion for Improvement (24%), Error in Alert (21%), Frustration (19%), Clinical Misunderstanding of Alert (6%), Positive Feedback (2%).

Based on the feedback received, we made changes to 43 alerts ranging from updating display text to adjusting errors in logic to creating entirely new version of the alerts. In addition, the user feedback system alerted us to 3 abnormal firing rates before detection by our automated daily monitoring system and we were able to correct those errors on the same day.

Discussion and Conclusions

Launching the REDCap survey tool from within the CDSS alert workflow provided important real-time feedback on the design and build of our CDSS. User adoption took place seemlessly and without specific training. We were able to identify malfunctions in our system, as well as improve workflows. Ad hoc feedback from users leads us to believe that direct conversation between the Clinical Informatics staff and users can provide both groups with new information to be used for system design and result in an improved sense of partnership. In the future, we plan to expand the feedback and user engagement to include a response to all comments. We also plan to incorporate routine review of aggregated comments regarding individual alerts as part of our routine CDSS review and life cycle maintenance.

Abstract

Electronic Health Records (EHRs) constitute evidence of online health information management. Critical healthcare information technology (HIT) infrastructure facilitates health information exchange of 'modern' health systems. The growth and implementation of EHRs are progressing in many countries while the adoption rate is lagging and lacking momentum amidst privacy and security concerns.

This paper uses an interrupted time series (ITS) analysis of OECD data related to EHRs from many countries to make predictions about EHR adoption. The ITS model can be used to explore the impact of various HIT on adoption. Assumptions about the impact of Information Accountability are entered into the model to generate projections if information accountability technologies are developed. In this way, the OECD data and ITS analysis can be used to perform simulations for improving EHR adoption.

Keywords:

Electronic Health Records, Intervention Study, Information Accountability.

Introduction

The health sector plays a significant role in any country's productivity and economic development. Health sector expenses are astronomical, and factors associated with service deliveries and healthcare products, directly impact on quality of life. The health sector is also an information intensive sector in that information is generated and consumed in enormous quantities by healthcare professionals, patients, managers, and other stakeholders. In this information, intensive sector, the research challenges include discovery of ways that health information can be integration that linked and, measuring appropriate use of health information under the given privacy and security constraints (e.g., Information Accountability) [1, 2].

Electronic health records (EHR) capture healthcare information prior to the inception of an individual's birth, through the life span until after death. These records are either captured in paper format or are electronic in nature and, should and would empower the consumer and their families care. It is indeed the comprehensive, unified, longitudinal records that aid in improving 'quality of life'. With technological maturity, EHRs constitute evidence of online records from interactions between professionals (e.g., Physicians and GPs), the public (Consumers and Patients) and healthcare service providers (healthcare policy makers and funding agencies). Furthermore "EHRs consist of patient information such as demographics, medications, laboratory test results, diagnosis codes, and procedures" [3].

Realization of the health information flow and contextual awareness of EHR sharing capabilities are vital to have meaningful and quality healthcare decision making [4]. This socio-technical, information accountability driven, conceptual EHR knowledge-based information sharing model is considered for this study [4], illustrated in Figure 1 below.

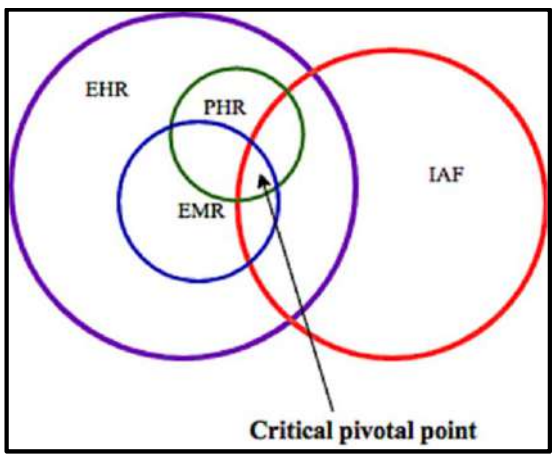

Figure 1– Information Accountability Driven EHR Model [4]

A brief description of Figure-1 elements are presented below:

1. **EMR** (electronic medical record)– information is amended; updated personal health records (**PHR**s) are managed by authorized clinicians and healthcare organizations (the professional view). While the information stored in this area is vital for the clinical decision-making process, at the same time the **PHR** will be managed to link the "Patient" for specific information sharing.
2. **PHR**– is recognizable; where individual information is stored, collected, shared and controlled by the individual (the public view). This set of information supports the individual "Patient" healthcare journey. The Healthcare Information Exchange (**HIE**) requires meaningful linkage of the **EHR** to complete the "Patient" journey.
3. **EHR**– is a key element of the model that is recognizable [1, 2]; and "*a comprehensive interconnected health information record that can capture and share a variety of information about people's health status, their history of encounters with the healthcare system, the results of all diagnostic and therapeutic interventions, and (ideally) their key social and demographic characteristics*".
4. **IAF**– is the Information Accountability Framework, the principle defined and implanted [1, 2] for the model. The governing principles of Information Accountability is "*that information usage should be transparent so it is possible to determine whether a use is appropriate under a given set of rules*".

5. Ω–this pivotal point is a significant balance [4] between healthcare services providers (policy makers and practitioners) and consumers ("Patient") to be maintained transparently when sharing the EHR.

The aims of this paper are to establish a socio-technical, information accountability driven, conceptual EHR knowledge based information sharing model demonstrated in preceding sections. The following sections present the data set retrieved based on infodemiological discoveries, organized and analyzed using an intervention study using Interrupted Time Series Analysis [6 & 7], as well as a discussion of the findings.

Methods

The OECD has assessed the Technological Readiness of countries (TOR) and the Data governance readiness through a series of surveys and assessments between 2015 and 2017. A Quasi–Poisson model was used to determine the variances. The statistical analysis was carried out using the **R** function ***glm*** and necessary adjustments were accommodated to estimate time seasonality.

Results

The dispersion parameter for the ***quasipoisson*** family is taken to be 0.1841. The ITS generated post 2015 projection illustrated that some countries are within the acceptable range while others are not. This illustrates that by using assumptions about the impact of Information Technology, some countries are ready to accommodate this HIT whereas others are not.

Discussion

An adoption of EHR associated technologies provides sustainability of healthcare systems and enables population-based outcomes. Furthermore, 'modern' healthcare systems affordability and equity depend on its performance. The proposed model (Figure 1) allows consumer-directed exchange of health information. With the patient–empowerment principle in the background, it is reasonable and practicable to search for the coexistence of HIT infrastructure that facilitates the model capabilities, possibilities and opportunities to establish the patient controlled EHR system.

This study describes an *infodemiological* exploration of patient empowerment measured through EHR adoption using OECD data analyzed through ITS models. This approach would help and "*could shed light on unmet medical needs and research priorities for the future, and provide guidance for the decision making in public policy*" [7]. An alternate approach would be to employ a randomized control trial (RCT), however this exercise would be impractical and difficult to generalize to "real world" settings.

Conclusions

Use of personal health data creates opportunities for health system improvement, research and disease surveillance, but requires the right governance frameworks to realize these benefits while managing risks. Patient–empowerment facilitates and provides HIT factors including sharing electronic health records providing functional data interoperability and meaningful use to minimize the security and privacy concerns. This paper investigated potential and opportunities for shared EHRs in Patient–empowerment from a sociotechnical perspective. The intervention study used an interrupted time series analysis (ITS) of the publicly available data, and its prediction diagnosis for opportunities and usefulness are based on recent developments of the EHR on two readiness factors: Technical and Operational (TOR), and Data governance (DGR), which are part and parcel of the socio-technical interactions.

This makes better use of health data in this exponential growth of digital technologies, which is warranted to establish the support of Patient–empowerment. Sharing data under a thoroughly functional data interoperability regime would support other community benefits like migrant inflow to the health watch of the communities. Establishing 'quality of care' among such community elements should also be supported. The Healthcare expenditure and health policy implementation is controversial and a troubling location. Healthcare spending might be managed and reduced by use of HIT however, long–term planning on studies like this and longitudinal experiments on the use of **shared EHR** should benefit most counties that require immediate healthcare support.

Based on the information available from OECD countries, employing and implementing an intervention study of interrupted time series regression analysis (ITS) on available and practicable HIT infrastructure information is a promising start.

Acknowledgements

The authors acknowledge that this paper neither analyses the situation per country nor provides predictions for a country. This analysis is out of the scope of this paper since the granularity of the data is complex and unknown.

Data sources for the work was obtained from the OECD iLibrary and we appreciate the support rendered by the iLibrary team. There is no financial transaction involved in this endeavor.

Analysis of the Stay Time of Patients in Gunma University Heavy Ion Medical Center (GHMC) Using RFID Technology

Partha Protim Hazarika, Kota Torikai, Rei Noguchi, Yuichiro Saito

Department of Medical Informatics, Gunma University Graduate School of Medicine
Maebashi City, Gunma, 371-8511 JAPAN

Abstract

We observed the stay time of patients and staff in Gunma University Heavy Ion Medical Center. The stay time of patients with the prostatic cancer and the facing time with radiotherapy technicians in treatment rooms were significantly reduced as times goes by. This decreasing in time has an implication in scheduling algorithm development: for patients. RFID technology can be a potential method to track both staff and patients and thereby to assess the resource utilization efficiency.

Keywords:

Radio Frequency Identification Device (RFID), heavy ion therapy, prostatic cancer.

Introduction

Radio Frequency Identification Device (RFID) technology is a short-range wireless electromagnetic field technology used to communicate digital information between a stationary location and a movable object or between movable objects. Use of RFID-based unique identification of objects is presently being explored in many sectors, including health. We have reported that RFID technology was found to provide feasible and accurate means for capturing and evaluating nursing time spent in patient rooms [1]. We checked feasibility of this system to evaluate resource utilization of our Gunma University Heavy Ion Medical Center (GHMC). It is available only in 12 centers across the globe, as its installation necessitates huge infrastructure cost and skilled manpower resources [2]. Appropriate treatment scheduling of patients at a medical office in a hospital using RFID system has the potential to reduce patient's waiting time [3]. It will have implications in improving patients' satisfaction and better compliance to treatment, in addition to optimizing utilization of precious heavy ion treatment facilities.

Methods

The RFID system at GHMC (by TOPPAN FORMS, Tokyo, Japan) used a frequency band of 93.75 KHz and 300 MHz. All patients and staff at GHMC were issued a specific semi-active integrated circuit tag (MXAT-MV-14, MATRIX, MATRIX, Osaka, Japan) which was activated by two trigger coils during movement to/from a room. To perform this retrospective study, we retrieved all the time stamp information stored on the server from September 2010 to November 2013. The data were initially sorted out and separated based on tag ID holders – patients, doctors, and radiology technicians. Clinical data (age, diagnosis, and performance status) of all the available patients is retrieved from the hospital information system. All the statistical analysis of this study was done using statistical data analysis package of Microsoft Excel 2016. Statistical significance indications were $p < 0.05$ by using unpaired, two-tailed t-tests. This study was approved by the Institutional Review Board (IRB) of Gunma University (reg. no. 2016-030).

Results

In patients with the prostatic cancer, we observed a significant decrease in the average stay time on 2nd, 4th, 5th, 8th, 9th, 11th, 12th, 13th, 14th and 15th days of treatment as compared with the first day of treatment during the early period. On the other hand, in case of patients with the liver cancer and the lung cancer, there was a decreasing trend in stay time on subsequent days, although the reduction was not statistically significant because of small number of patients (n=32 in 3.6 years). When the respective treatment days on the early period were compared to other periods in patients with the prostatic cancer, the stay time was significantly reduced in a later period (Figure 1). Next, we analyzed the stay time of radiology technicians to confirm if a reduction in patients' stay time is associated with parallel reduction of radiology technicians stay time in treatment unit. We noticed that there was statistically significant reduction in stay time of radiology technicians on 2nd, 3rd, 6th, 9th, 12th, and 14th days in the early period. Furthermore, the stay time of radiology technicians in the later period was significantly decreased as compared with the early period (Figure 2). On the contrary, the stay time of patients inside examination unit with doctors was similar throughout the time independent of the treatment unit installation status. Based on the analysis of tracking results, we developed a radiology information system to book a treatment schedule of our patients in GHMC. The number of patients treated in GHMC increased from 266 in 2013 to 574 in 2018

Discussion

We observed that the stay time of the prostatic cancer patients in treatment unit was considerably reduced in the last several days as compared to the 1st day of treatment. It was noticed that stay time of patients as well as the face time with radiotherapy technicians in the treatment unit was significantly decreased in most of the days of the later period. This suggests that the radiotherapy technicians took comparatively lesser time during pre-treatment setting up and post-treatment patient removal and it proves their increasing efficiency with time. Generating a transparent information flow and using it for coordination

between healthcare workers and patients is an effective way to minimize waiting times, which is possible by tracking patients as well as staff by using RFID technology. We had a few limitations in our study. In 3.51% of patients, there was no data recorded in server, due to missing signal capture from the tag readers. Vakili et al. found that an RFID system's event record rate was 83.7% in the rooms of an ambulatory clinic in Johns Hopkins University School of Medicine [4]. Our data were better than their rate, however we need efforts to improve accuracy of RFID systems in future. Long waiting time for treatment is a very important but overlooked infrastructural problem [5] and it can lead to poor adherence to prescribed treatment schedule especially in case of elderly cancer patients, thereby compromising possibility of cure [6]. Patient experience and/or outcome measure will be topics for future study.

Conclusions

Our study suggests that RFID technology can be a potential method to track both staff and patients and thereby to assess the resource utilization efficiency.

Abstract

This article describes the development of a prototype application for obstetric telemonitoring of hypertensive syndromes during pregnancy. A workflow was elaborated with the conduct for gestational hypertensive syndromes. Subsequently, prototyping was performed using Balsamiq. The prototype presents daily monitoring of blood pressure, signs and symptoms, displays accompanying charts, and generates alerts when there are changes to more or less the normal values, which are sent to the pregnant woman and the health professional.

Keywords: Mobile applications; Hypertension, Pregnancy; Obstetrics.

Introduction

Pregnancy is a physiological and dynamic process that occurs most often without complications. However, a considerable number of women develop gestational problems or some health impairments during the gestational period. Gestational hypertensive syndromes (GHS) represent a high risk for maternal and fetal health [1, 2]. In addition to diseases such as hypertensive encephalopathy, cardiac and renal failure, GHSs are associated with severe perinatal complications [2].

GHSs are considered the second cause of maternal mortality [3]. They can often be avoided by screening family, personal, habits and lifestyles, as well as controlling and monitoring blood pressure levels. Thus, early screening of risk factors for the development of SHGs becomes essential in assisting the pregnant woman so that early detection of injuries to the mother-baby binomial is possible.

There are several strategies that the health professional can use to monitor the possible gestational risk factors for GHS. With the increasing use of the internet by pregnant women and family members for gestational follow-up, the use of applications for this purpose has shown to be a great potential [4]. As the Internet has become a tool of support for pregnant women in seeking information about pregnancy, the websites and applications available do not guarantee to provided the basis of scientific evidence [4].

Considering the importance of the screening of risk factors, monitoring pressure levels and detecting warning signs of complications due to hypertensive syndromes, as well as the increasing and positive use of technology in health by pregnant women and health professionals for maternal, this study aims to describe the development of a prototype of care application for obstetric telemonitoring of hypertensive syndromes during pregnancy.

Methods

The pressent study was conducted in the period from January to October 2018. This study describes an application prototype related to gestational hypertensive syndromes, which will be incorporated into an obstetric telemonitoring system.

First, a literature review of international guidelines, manuals and protocols of the Brazilian Ministry of Health (MS), the World Health Organization (WHO), health institutions and scientific evidence was conducted, followed by a search in the Play Store of gestational applications that deal with blood pressure monitoring and hypertensive syndromes. Then, a workflow for SHGs using BPMN in the Bizagi Modeler software was created with the specification of a clinical protocol with all the information. A prototyping of the GHS service module from Balsamiq software was developed. In this preliminary study, no usability testing has been performed, limiting only to prototyping. Thus, no ethical appreciation was required.

Results

The data collected from the materials were unified in a single flowchart that encompasses different aspects including screening, diagnosis, prevention, and management of hypertensive syndromes during pregnancy.

The search in the Play Store showed that only one application presented a feature of monitoring blood pressure. Regarding health education, 6 applications presented general educational information about the changes in blood pressure in pregnant women. None of them evaluated aspects related to antecedents and risk factors or allowed to fulfill obstetric telemonitoring data by health professionals.

A protocol was created containing the signs and symptoms, risk factors, explanations, possible diagnoses, behaviors for pregnant women and health professionals, as well as warning messages for both, when necessary.

The prototyping of the application was performed based this protocol using Balsamiq, a medium fidelity prototyping software, which allows the elaboration of functional interfaces and gives the user an initial impression of the application's operation.

Regarding the main functionalities, the prototype presents space for insertion and daily monitoring of the pregnant woman's blood pressure (BP) (Figure 1). The pregnant woman not only can insert the BP from a external device at home, but

also can register the data recorded on her prenatal card or follow the data recorded by the health professional.

Figure 1- Prototype screens: data record of health and symptoms

The alerts are sent to both the pregnant woman and her health professional in prenatal care. The prototype also presents educational information on hypertensive syndromes in gestation, including gestational hypertension, preeclampsia, preeclampsia overlapping with chronic hypertension, eclampsia and hellp syndrome, emphasizing health education for pregnant women and health professionals.

Discussion

Blood pressure is a vital sign and thus needs continuous monitoring, especially during pregnancy. It is an indicator that allows the monitoring of health parameters that, when present or altered, predispose pathologies responsible for a large part of maternal and neonatal deaths and morbidity, such as pre-eclampsia and eclampsia [3, 5, 6].

The data entered are available for both personal and professional conferences, allowing for continuous monitoring of pregnant women's blood pressure values and early intercurrent screening, as well as better screening for high-risk pregnant women. To assist the health professional, the prototype of the hypertensive syndromes module, flowcharts and protocols on screening, diagnosis and management of SHGs are available.

The use of digital resources in preventive health presents itself as an opportunity to gather pregnant women, family and health professionals in a virtual and safe environment so that they can seek correct and relevant information and obtain a safe and continuous assistance among health professionals.

Conclusions

In this study we developed a prototype application that aims at hypertensive syndromes during pregnancy. The application will be incorporated into an obstetric telemonitoring system for prenatal follow-up. It is understood that the early identification of potential gestational complications through low cost and high impact interventions can reduce the number of morbidity and mortality among pregnant women worldwide.

Terminology Gap in Continuous Care Between Acute and Long-Term Care Hospitals

Ryoma Seto[a], Toshitaka Inoue[b,c], Suemi Katayama[c]

[a] *Division of Healthcare Informatics, Faculty of Healthcare, Tokyo Healthcare University, Tokyo, Japan*
[b] *Department of Social Welfare, Nishi-Kyushu University, Saga, Japan*

Abstract

This study aimed to elucidate the gap in terminology between acute and long-term care (LTC) hospitals. Fifty-seven hospital documents were analyzed using text mining. Each document contained a mean 194.2 terms. Acute care hospital documents often contain pharmacological information. LTC hospital documents often contain information related to patients' lives. Documents from both settings used local, non-standardized language. Our results suggest that expanding the national standard of nursing terminologies has potential for enhancing continuity of care.

Keywords:
Long-Term Care; Electronic Health Records; Standardized Nursing Terminology

Introduction

In a rapidly aging society, continuous care is becoming more and more important. Acute care hospitals are actively working to shorten the length of stay owing to health service reform initiatives. Acute care hospitals should provide patients with information using a "document for continuous care (DCC)" regarding the transition to long-term care (LTC) facilities (e.g. rehabilitation hospitals, nursing homes, and home care). Unfortunately, many LTC facility residents are readmitted to acute care hospitals because of changes in their general condition (e.g. loss of body water or inability to consume meals). LTC facilities therefore have to prepare DCCs for use by acute care hospitals.

The DCC content is not dictated by the Japanese government, but rather by local governments or public associations (local DCCs). However, local DCCs widely differ owing to the use of various formats, terminologies, or other items. Some DCCs are implemented as a component of the electronic health record (EHR).

In some areas, the DCC in the EHR is an effective means of sharing patient information with other settings [1-3]. Conversely, paper-based DCCs are more popular than electronic DCCs because most LTC facilities do not use EHRs. Most public sectors (e.g. local governments and/or public associations) prefer paper-based documents and forms compared with electronic documents, although paper-based documents are often generated using computer applications (e.g. Microsoft Office™).

Some public sectors provide a DCC template on their websites. These templates may prevent the expansion of the use of electronic DCCs as the national standard. This study aimed to elucidate the terminology gap in DCCs used in acute care and LTC hospitals.

Methods

1) Data collection

Twenty-five local areas in Japan that provided a DCC template on their websites were enrolled in the study. We therefore collected and examined 57 DCC forms from these areas.

2) Data analysis

First, the 57 DCCs were classified based on document user (sender/receiver). Next, each DCC was analyzed using a text-mining tool (*KH-Coder 2.00f*, Japan), and terms contained within each DCC were numbered. These terms were then categorized and analyzed to elucidate the terms that were most often used, relative to each setting (acute care or LTC hospital). Finally, frequently used terms were matched with those in nursing practice standardized terminology (NPST). NPST was approved to contain national standard terminologies in Japan by the Ministry of Health, Labor and Welfare in 2016. The NPST, as the national standard, covers the widest range of terminologies.

Results

1) Type of DCC forms

As for the sender of the DCCs, 26 of the 57 DCCs originated in medical settings (e.g. acute care hospitals), 22 originated from "care managers" (CM), and 21 in LTC settings. The total number includes common-use forms for both settings; thus, the total number is actually more than 57. A CM is a specialist who builds each patient's care plan under LTC insurance.

As for the receiver of the DCCs, 9 of 57 DCCs were CMs, 42 were acute care hospitals, and 17 were LTC settings (*Table 1*).

Table 1 – Sender and Receiver of DCCs (n=57)

User of DCCs	N	(%)
Sender		
Medical Settings (e.g. Acute hospital)	26	45.6
Long Term Care Settings	21	36.8
Care Manager	22	38.6
Others (e.g. Dental, Pharmacy)	4	7.0
Receiver		
Medical Settings (e.g. Acute hospital)	42	73.7
Long Term Care Settings	17	29.8
Care Manager	9	15.8
Others (e.g. Dental, Pharmacy, EMS)	5	8.8

2) Character of each DCCs

Each DCC form averaged 194.2 terms. The number of terms in DCCs from acute care hospitals or other medical settings, CM, and LTC settings was 187.8, 248.0, and 224.2, respectively. DCCs from acute care hospitals or other medical settings tended to contain pharmaceutical information (e.g. ability for drug self-management). DCCs from LTC settings and CMs tended to contain information related to patients' lives (e.g. having meals, toileting, etc.) (*Figure 1*).

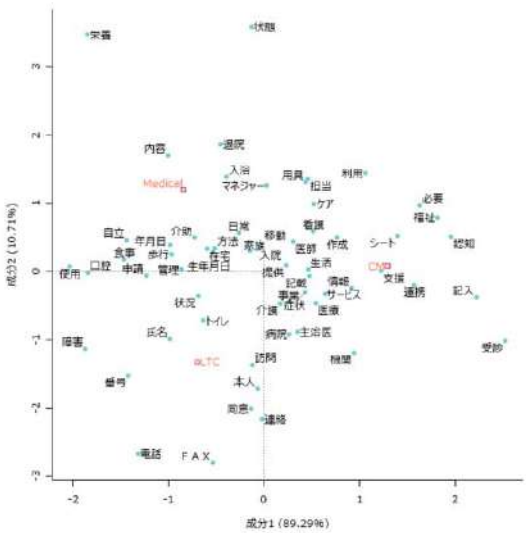

Figure 1. Character of each DCCs by correspondence analysis

3) Matching DCCs to NPST

The top 30 recurrent words found in each type of DCC were matched to the NPST. The match rate was 96.7% for DCCs from acute care hospitals or other medical settings (exception: "unnecessity"), 93.3% from CMs (expection: "smooth", "filling up"), and 86.7% from LTC settings (exception: "at a fine［nice, pretty, sad］pass" etc.).

Discussion

Some DCC forms have multiple functions, e.g. guiding the transition between (1) acute care hospitals to LTC settings, and (2) LTC settings to acute care hospitals. However, multi-function DCCs are not specialized, so the number of words was not enough. These forms tended to include free-text areas and were less structured.

DCCs from acute care hospitals contained some structured terms, but DCCs from CM and LTC settings tended to be unstructured. Unstructured DCCs are labor-intensive, and require senders to fill out the forms, possibility preventing future implementation of electronic DCCs [4].

DCCs from all settings (acute care hospitals, LTC facilities, and CMs) contain mostly local language and contain much standardized text. Even while working with paper-based DCC forms in the future, DCC terminology should consist of standardized terminology completely.

Conclusions

We found a terminology gap in the transition between acute care and LTC settings by analyzing DCC forms.

Our results suggest a need to use common terminology by expanding the NPST to cover terms that are frequently used in LTC settings. This is a realistic plan for improving the quality of continuous care in Japan.

Preconditions for Enabling Advanced Patient-Centered Decision Support on a National Knowledge Information Infrastructure

Line Silsand[a], Gro-Hilde Severinsen[a,1], Rune Pedersen[a,b], Gunnar Ellingsen[a,b]

[a] *Norwegian Centre for E-health Research, University Hospital of North Norway, Tromsø, Norway*
[b] *Telemedicine and E-health Research Group, The Arctic University of Norway, Tromsø, Norway*
[1] *Gro-Hilde has changed her surname from Ulriksen to Severinsen*

Abstract

In Western healthcare, an important goal is to provide clinical decision support "for the right healthcare personnel, in the right situation, at the right time". In this poster, we use a qualitative approach to outline the preconditions for enabling such advanced patient-centered decision support. This study indicates that establishing a national knowledge information infrastructure demands well-defined national standards, codes, and terminologies, as well as structured clinical data. An extensive governance structure is also required.

Keywords:

Knowledge bases, decision support systems, clinical

Introduction

In most developed countries, the demand for improved e-Health information and communication technology (ICT) solutions such as electronic patient record (EPR) systems has grown enormously [1; 2]. Well-designed EPR systems have the potential to support complex healthcare processes and subsequently raise the quality of treatment and improve patients' outcomes [3; 4]. In addition, it is important that healthcare personnel actively use evidence-based knowledge to ensure quality healthcare services. In the Norwegian context, the National eHealth Strategy (2017 – 2022) [5] emphasizes that EPR systems must be able to provide clinical decision support (CDS), where evidence-based knowledge is used to support patient treatment and care. Today, however, CDS capabilities are not widely used [1]. One reason for this is the lack of a central or national repository [1; 6] that enables access to evidence-based guidelines, procedures, and treatment protocols. Currently, the knowledge bases in Norway are scattered among different organizations. In addition, healthcare workers only have access to knowledge support through external publishing channels, which makes the process of finding and using the newest evidence-based knowledge complex and time-consuming [6].

Therefore, a national initiative has been started to explore how to establish a standardized "knowledge platform", the overall goal being to enable high quality knowledge support "for the right healthcare personnel, in the right situation, at the right time". In this poster, we explore the preconditions for establishing a national knowledge platform. We raise the following research question: How can a national knowledge information infrastructure be organized, and what are the preconditions to enable advanced patient-centered decision support?

We conceptualize the national platform for evidence-based knowledge as an information infrastructure (II) in order to analyze the complexity of organizing and using a large-scale knowledge base. The notion of II addresses how technology, like the "knowledge platform", is intertwined with users, work practices, and organizational structures. Therefore, standardization is an important prerequisite for communication within an II [7].

Methods

The study applied a qualitative approach based on literature searches and semi-structured interviews with EPR vendors, knowledge-base providers, and healthcare personnel and managers (see Table 1). The interviews followed a hermeneutic approach where we considered the informants' different viewpoints. All of the interviews were transcribed and systematized through thematic coding based on terms from the literature search [8], aiming to answer the research question and provide further recommendations for the national work with a "knowledge platform" [9]. When analyzing the data, II theory was used as a lens to make the findings relevant for other organizations beyond the Norwegian healthcare context [9].

Table 1 – Overview of the Data Collection

Organization	***Duration***	***Category***
EPIC	60 min	System provider
Cerner	90 min	System provider
DIPS AS	120 min	System provider
Inter Systems	60 min	System provider
Duodecim	60 min	Knowledge provider
Elsevier	60 min	Knowledge provider
UpToDate	45 min	Knowledge provider
Catalonia, Hospital	120 min	Clinical field
Finland (Pegasus)	60 min	Clinical field
HIMMS	45 min	

Results

This study presents three different categories of clinical knowledge support determined by the extent of the integration between different sources of evidence-based knowledge and the EPR system. Based on the empirical data, it is clear that the structure of and access to knowledge support varies extensively.

External passive knowledge support

In this most basic form of knowledge support and CDS, healthcare personnel are only able to access knowledge through external publishing channels outside of their EPR.

This makes the process of finding and using the newest evidence-based knowledge complex and time-consuming [6]. There exist both national knowledge sources, like the National Directorate of Health and the Norwegian Institute of Public Health, and international commercial knowledge providers that offer passive evidence-based knowledge support for healthcare. A representative from an international commercial knowledge provider stated, "We mainly provide external passive knowledge support and the knowledge is based on the best available evidence out there, without being tailored to specific countries, needs, or markets".

Almost every Norwegian healthcare organization has its own quality system which includes clinical procedures and guidelines. The knowledge content in these systems is developed and governed by the organizations themselves. Healthcare organizations abroad also work to develop and govern their own knowledge support systems. The CTO from Hospital A stated, "We have integrated some regional guidelines and procedures into the EPR system and work on a regional solution for real-time knowledge and decision support". This knowledge support provides such services as drug allergy warnings and advice on when to order blood tests.

Integrated passive knowledge support

In integrated passive support, CDS solutions are integrated with the EPR systems. However, the clinicians have to decide actively when to access the knowledge base. In Norway, there are platforms of medical treatment and care procedures that can be accessible directly from the EPR system or through a link to the procedure attached to a document or care plan. In addition, commercial knowledge providers deliver systems for integrated passive support. These CDS systems are not integrated directly with the EPR system. The clinicians have to decide which patient data from the EPR they want to combine with the CDS motor, whereupon the data is mapped and returned to the EPR system. This is particularly useful for patients with comorbidities because it is possible to combine different symptoms, medications and pathways to provide healthcare personnel with the best overall recommendations.

Active knowledge support

The most advanced form of evidence-based knowledge support is active knowledge support, where the knowledge systems are embedded in the EPRs. Health professionals automatically receive active notifications and recommendations, as well as access to patient-specific decision support in various clinical situations. Knowledge support may be triggered, for instance, when the clinician needs to choose between different treatment methods for a certain patient.

All four of the system providers interviewed are able to integrate their systems with any knowledge source or CDS. However, they argue that most healthcare organizations are not ready for active knowledge support. One system vendor stated, "The healthcare organizations must organize work processes and organizational structures like governance organizations in order to make use of effective knowledge and CDS". Neither the knowledge providers nor the system vendors offer governance related to regional or national knowledge support and CDS. In addition, knowledge and decision support are not automatically included in EPR systems. Some have partial support included in their EPR systems (e.g. for medication administration) but adjustments based on local conditions are always required. The degree of support also depends on how the healthcare organizations manage to organize and govern their knowledge base.

Conclusions

It is important to establish a national knowledge information infrastructure in order to enable advanced patient-centered CDS. Establishing a national knowledge information infrastructure demands an extensive governance structure spanning multiple organizational levels. There are three important preconditions necessary to achieve an active level of support. First, clinicians need to change their registration practice and document in real time in the EPR. Second, the EPR system must be based on structured clinical information, since CDS engines only extract structured data elements. Third, a national knowledge II requires a definition for what standards, codes and terminologies to use in order to integrate different knowledge sources into an II at a national level, as well as to ensure effective communication between the EPR and other healthcare ICT systems. This standardization encompasses both technical and organizational elements as a prerequisite for communication within the II. Finally, it is of great importance to involve the clinicians in the governance and standardization work, in order to ensure that the knowledge is updated and trustworthy to the clinicians.

CDSS for Documenting Blood Glycemia Critical Values at the POC

Camila Sofía Galván[a], Mariana Daus[a], Oscar Ignacio Jauregui[a], Matías Alejandro Álvarez[a], Carlos Otero[a], Daniel Luna[a]

[a] *Department of Health Informatics, Hospital Italiano de Buenos Aires*

Abstract

When a critical blood glucose value is detected, then it is necessary to inform, advice, communicate, act and document it in the patient´s medical record. We sought to describe the development of an alert system for glycemia values at the point of care integrated with an EHR, both in desktop and mobile devices.

Keywords:

Closed-loop communication, Point-of-care, Patient safety.

Introduction

A critical value is defined as an "indicator or result of a pathophysiological state, so far from normal that it can endanger the patient's life if it is not acted quickly, and for which it is necessary to adopt corrective measures" [1].

The emission and the reception of the critical value are equally important so the communication in the healthcare team is carried out effectively and safely [2]. The JCI and others organizations have made references to this communication, highlighting the need to notify critical results and readback of the professionals, and receiving the result; in this matter, standards and guidelines have been published. [3, 4].

When a blood glucose critical value is detected in this context, it is necessary to have a defined process to identify, advice, communicate, act and document it in the patient's clinical record [5]. EHR and CDSS represent an important tool in which patient safety oriented guidelines can be implemented throughout the organization. The Hospital Italiano de Buenos Aires (HIBA) intends to continue acquiring tools that facilitate the user experience, focusing on improving the quality of care and patient safety, adhering to current JCI recommendations, including the report of the critical value of blood glucose.

The objective of this article was to describe the design and development of a clinical decision support for documenting blood glycemia critical values at the point-of-care (POC).

Methods

The HIBA is a university hospital that covers the entire spectrum of healthcare. The institution holds a JCI certification since 2014, being re certified in 2018. Since 1998, it runs a homegrown Health Information System, that supports all the organization´s clinical and administrative operations. It has been certified by HIMSS as level 7 in the EMRAM model in 2017.

Glycemic critical value interface design and develop

For the prototyping, the usability area worked under the methodological framework “User-centered design” (UCD), adapted to the format and interface templates established in the design of EHR. The prototypes, both desktop and mobile were first designed in low fidelity reproducing the workflow and recording the critical values, and testing sessions were

performed with end users with qualitative analysis being done by members of the team. Then high fidelity prototypes were built, and again tested with users with same methodology (Figure 1).

Results

Process analysis and optimization

Some key findings were achieved in the pre-implementation process:

1. Nurses didn´t have a specific place in the EHR to register the glycemic value as critical.
2. The documentation about the communication of the critical value was registered asynchronously, most of the times after the 5 minutes stated in the policy.
3. Not all the information needed by the policy was present in the registries (e.g. physician communicated, read back, action taken).
4. Nurses had difficulties in finding the physician in charge to whom communicate the critical value.

Some modifications were suggested to address these difficulties and to comply with the organization's critical value policy, and the optimized process was plotted. The improvements consisted in having a real time documentation of the critical value communication; having a CDSS in which a number of rules were coded to interpret glycemic values and trigger the alert if a value was of range; create mandatory fields in the form to satisfy all required information by the policy; and offering the nurse information about the attending physician for the patient together with his contact number.

Also some modifications were done in the eMAR, highlighting the glycemic values recorded as critical in red for better information retrieval (Figure 1).

Interface design and development

The alert system should comply with four objectives:

5. Identify critical values of glycemia by glucometer.
6. Alert health professionals.
7. Communicate effectively and timely to the health team to provide a joint treatment.
8. Record the critical findings of blood glucose controlled at the POC.

A low fidelity mockup was built, and after user testing sessions a number of improvements were made when designing the high fidelity mockup, like adding the measured value to the pop up menu, showing specific fields like contacted physician and read back only if the option selected in the first field is affirmative, and changing the sides of the “save” and “back” buttons (Figure 2).

The final system had the following elements:

- **Input:** the trigger for the alert was the entry of the critical value in point of care glucose meter in the eMAR system.
- **Trigger:** rules were developed for the alert system to identify and alert health professionals of critical value when it is less than 40 mg/dL or greater than 500 mg/dL.
- **Output:** consisted in a pop up menu with identification of attending physician through Master Professional Index, a radio buttons for registering effective communication, and proper read back process.

Since medication administration and vital sign control are processes that are supported by our homegrown mobile eMAR application, android native interfaces were also designed and developed with the same methodology, objectives, and having the same elements as the desktop platform. Also, as both systems run in the same production environment, critical values recorded in one of them were seamlessly read in the other one.

Conclusions

This study presented the description of an iterative development with the objective of complying with the recommendations of the JCI that included, identify, alert, communicate and record the critical values of blood glucose by hemoglucotest, involving stakeholders in the validation of each of the tests. Establishing a protocol of action before critical values is a recommendable quality practice. Although there is a varied bibliography about the effective communication of these findings in areas such as clinical laboratory or diagnostic imaging, no literature was found that reports the development of blood glycemia critical values at the POC. This project only made the description of the glucose alert system in the electronic medical record, future lines of research could focus on the measurement of before and after implementation, and monitoring the tool.

Expectations in the Development of Computer Technology in Primary Care: A Multidisciplinary Delphi Study Among 23 French Experts

C. Sors[a], A. Bermes[a], J-B. Kern[a,b]

[a] *Department of General Practice, Grenoble Alpes University, Grenoble, France*
[b] *TIMC-IMAG Laboratory, CNRS UMR 5525, Grenoble Alpes University, Grenoble, France*

Abstract

The goal of this study was to determine a consensual proposition for the development of computer tools in primary care. A Delphi study using colored abaci was conducted among 23 French experts, some of whom were patients. The tools expected by the experts were: a customizable knowledge database integrated into an efficient clinical support system, a follow-up calendar designed as a collaborative patient-focused tool, and an information exchange data system.

Keywords:

Primary Health Care; Health Information Systems; Electronic Health Records

Introduction

Information and communication technologies are precious tools in dealing with present day health care challenges [1,2,3] but practical uses are often less efficient than expected. Their current use lies far below their potential and future possible applications.

In French primary care, general practitioners (GP) often use an electronic medical record but only in minor functionalities. A national e-health record is having difficulty getting off the ground. Patient portals are beginning to be deployed [4]. Health data is only partially collected using social insurance data, and just beginning to be opened with the "Système National des Données de Santé" (French health data organization) [5].

The purpose of this study is to determine a consensual proposition for expected computer tools to be used in primary care between different expert profiles. Three directions were explored: assisted systems for medical decision making, care coordination and communication, health data exploitation and the ethical issues involved.

Methods

A Delphi method associated with Regnier colored abaci [6] was conducted using an online written survey with the website *colorinsight*® (http://www.colorinsight.fr/).

Experts in medical and paramedical practical fields, care coordination, health project management, medical IT (information technology) systems, or patients' experts in health system use were recruited. Their expertise was assessed by their training and professional experience.

The first propositions were built from literature analysis supplemented by discussion with experts during recruitment. The second and third surveys were devised from analysis of the previous surveys content, to explore non-consensual points and find new ideas in view of obtaining a consensus. Finally, global answers were analysed by theme and summarized.

Surveys were given to experts with a glossary explaining technical words and the summarized personalized answers of previous survey when necessary. Experts were invited to express their opinion about each proposition by a colored vote, with an optional comment section, to enable them to justify their position. A comment was systematically requested in case of disagreement.

For each survey, the analysis was quantitative, with measurement of agreement rates, and qualitative, with the colored vote distribution analysis on the abaci and subsequent comments.

The primary objective was achieving a positive consensus, defined by an agreement rate of over 75%. The distribution of the other votes showed strength of consensus.

Expert consent was collected throughout the survey. French data protection authorities were notified (CNIL – "Commission Nationale de l'Informatique et des Libertés").

Results

Panel of experts and proceedings

Twenty-three experts, among thirty-seven originally contacted, agreed to participate. Refusals were related to lack of time for volunteer contribution. They were 8 primary health care professionals, 2 coordination professionals, 5 physicians involved in IT health projects, 3 medical IT experts and 5 patients promoted to patient experts.

Three surveys with 21, 20 and 18 propositions were given to experts between March and August 2018. Answers from respectively 23, 21 and 17 experts were collected.

Answer content

Main consensual **propositions** are presented in figure 1.

Clinical support system

The use of a knowledge database to gain access to organized information in order to support clinical decisions was consensual. It had to be integrated into professional workflow and to be personalized by using comments and personal documents.

The possibility for professionals to use a follow up calendar (including prescriptions, complementary investigations, secondary and tertiary health care feedbacks) for each patient was consensual. The calendar had to function collaboratively (between health professionals, social workers, other concerned parties and patients) and include major life events.

Data exchange

The need to consider interoperability in a global environment including health care facilities, the electronic health record, the pharmaceutical record and social facilities, was consensual. As

far as data standardization was concerned, experts suggested that standardized data was not accurate enough to be used as a means of supporting decisions and the only consensus was around consultation assessment.

Health data access by the patient and the possibility to exchange and share the data with other health professionals in a secured, structured way was a consensual point. Data exchange using a secured mailbox was consensual as was that he different data exchange methods be centralized around a single online access. Experts expressed the need for health professionals to manage electronic exchange in order to limit legal risk and preserve data treatment capacity.

Other communication systems seemed consensual: online prescription transfer to a designated pharmacist, an instant mailbox to communicate between health professionals and access to electronic exchange from the patient's electronic record in work IT software.

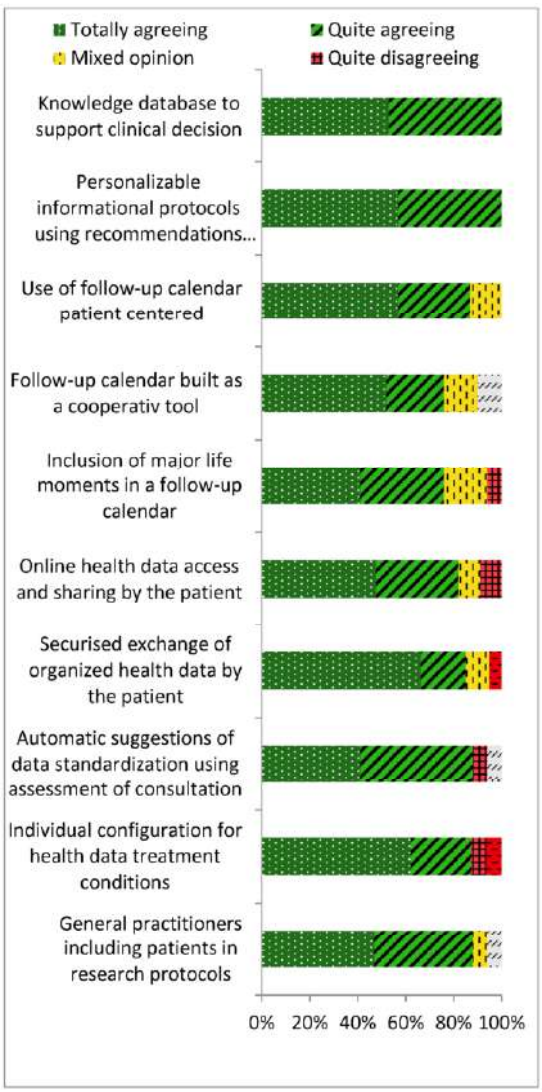

Figure 1 - Main results of Delphi rounds

Data treatment

Health data utilization and regulation was not agreed upon. Use of the data for research purposes and to improve health quality was not consensual. Some experts wanted a regulated control of data anonymization and a limitation of their utilization to pre-selected projects. Other experts were in favor of free access to the data to foster further research. Having a separate organization handle health data use was not consensual. Analysis of the data was described as difficult, because of disparity in electronic health record quality and in data collection.

The necessity for each patient to give his/her consent to the use of his/her health data was consensual.

That GP's should be able to offer the research protocol to a chosen patient was consensual.

Conclusions

This study shows common expectations for computer tools developing patient focused work. It highlights the need for a single and sharable medical record, thought around the patient, adapted to professional health needs and including training and communication features. Application of the consensual propositions of this study could have a major impact on primary health care organization. It should foster further research and question French national policies for e-health development.

Electronic Image Documentation of Patient Reported Outcomes Using Mobile Technologies

Iñaki Soto-Rey[a], Tobias Hardt[a], Luca Hollenberg[a], Philipp Bruland[a], Sonja Ständer[b], Martin Dugas[a], Michael Storck[a]

[a] *Institute of Medical Informatics, University of Münster, Münster, Germany*
[b] *Center for Chronic Pruritus and Department of Dermatology, University Hospital Münster, Germany*

Abstract

Patient Reported Outcomes (PROs) provide essential clinical data for the diagnosis and treatment of patients. Mobile technologies enable rapid and structured collection of PROs with a high usability. MoPat is an electronic PRO system developed at the Münster University that enables patients to complete PROs in multiple languages. This research reports the further development of MoPat and the inclusion of features to document images electronically that will be evaluated in a multi-site clinical research.

Keywords:

Patient-reported Outcomes, Mobile Health, Electronic documentation.

Introduction

Patient-reported outcomes (PROs) are information provided by patients without any interpretation by a clinican or anyone else. Electronic systems and specially mobile devices provide a fantastic opportunity for the collection of these. In recent years, initiatives such as ResearchKit [1] have modified the way how PROs were being collected and also the kind of data that can be documented including new question types such as reaction time and tapping speed among others.

The Institute of Medical Informatics in Münster (Germany) has developed its own electronic patient-reported outcome system (ePRO): the Mobile Patient Survey (MoPat) [2]. MoPat is an interoperable and multi-lingual web-based ePRO that enables clinical data collection in clinical settings and at home.

The Translational Pruritus Research Group[1] aims to identify clinical and therapeutical relevant mediators for chronic itch, as well as related anatomical and functional neuronal changes. To achieve these aims, patient data regarding the regions where pruritus and pain appear need to be collected. A similar functionality is required by the McGill-Pain index PRO [3], where patients also need to mark painful regions on the image of a human body.

The objective of this research is to integrate an applicable way of reporting parts and individual marks in arbitrary images within the MoPat ePRO.

Methods

Before starting the implementation of the new features, it was necessary to perform a system analysis in order to define the software architecture of the new features and plan their integration into the existing code. At the same time, the development team identifyed available libraries that could be re-used to fulfill the requirements.

The major updates needed were the following: on the one hand, it was necessary to create and save the question data such as the images and the predefined body parts. On the other hand, it was crucial to display the new question types in a user-friendly way within a survey.

The image marker question uses an HTML5 <img>-tag that allows setting base64 strings as source of the image. This tag is embedded in a canvas element that facilitates the drawing of marks. The marks are stored in a list together with an additional pointer that indicates which marks should be displayed.

The body part question type was implemented using a class that contains an enum 'BodyPart', which defines the selectable regions. This class includes the multilingual message code, the path element, which defines the body region to be selected, and the enum ImageType that links the body part to the corresponding image. The path element is represented by an XML string that defines the region inside of a scalable vector graphics image.

The images in both question types are transmitted in a data transfer object to the client as base64 encoded strings. The new functionality was internally tested using automatic (JUnit) and semi-automatic tests.

Results

Image marker

The image marker question type enables MoPat administrators to upload arbitrary images to the MoPat server. When an image marker question is created, the file type, the dimensions and the resolution of the uploaded image are validated. If the size is unfitting or the resolution too low, warning messages are displayed. During a patient survey, image marker questions show the uploaded images together with a brushtool to select the color of the marks and the buttons to revert and redo changes (see Figure 1). Patients can then tap (or click) on the screen and draw "X" marks in black or white on it.

As MoPat enables answering questionnaires offline, the images had to be transfered at the beginning of the survey to the client without reloading it from the server, which explains why base64 encoding was chosen.

[1] www.prusearch.net

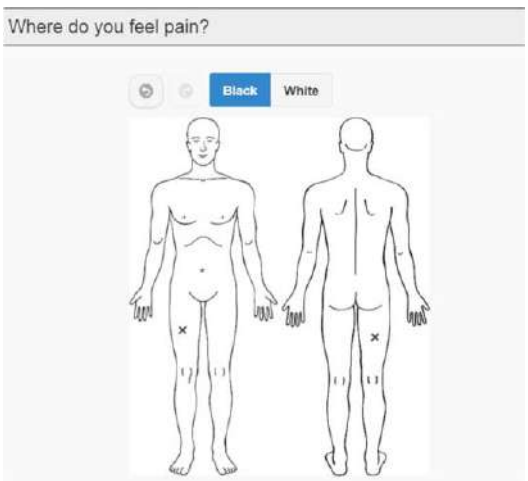

Figure 1– Snapshot of an image marker question with two marks on the right front and right back thigh

The marks included by the patients are stored as a percentage of the image width and height to ensure correct positioning if the survey is stopped in one device and restarted on another one with a different screen size or resolution.

The image marker question type was informally evaluated including 15 testers who completed a test script and filled out the System Usability Score questionnaire reaching an average score of 90.

Body Part

The body part question type enables MoPat administrators to include a predefined body part question and its selectable regions in a MoPat questionnaire. The administrator decides which body parts can be selected and these are displayed in light blue for the surveyed patient. When a body part is selected, the part's color is displayed in dark blue (see Figure 2).

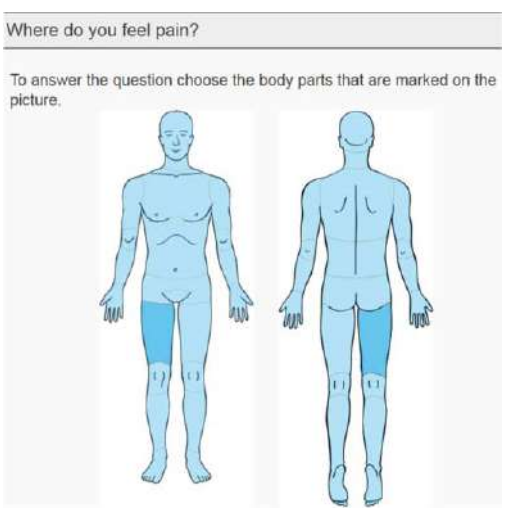

Figure 2– Snapshot of a body part question with two body parts selected (displayed in dark blue)

The implementation of body part question answering is similar to the multiple choice questions' one. The selectable regions are treated like multiple choice answers and can be exported as a nominal variable.

Discussion

The question types "Image Marker" and "Body Part" have been sucessfully implemented and tested within MoPat. This functionality will be evaluated in the context of a large multi site clinical study, the Translational Pruritus Research Group.

These two new question types entail some limitations: The image marker coordinates (where marks are included by patients within image marker questions) are not exported; however, they are being stored. This means that it would be straightforward to implement a coordinate export if required. The image marker question brushtool is limited to X marks and black and white colors. The colors were initially restricted in order to avoid possible categorisation of the marks, e.g. green marks are positive and red ones are negative. The body part question images and the parts that can be selected are hardcoded and can only be modifyed within MoPat's source code. The images are transmitted in base64 format, which represents a considerable amount of data. This could be an issue when mobile devices use network data.

The development of the image marker and the body part questions is an ongoing task. A new version of the image marker module should include a more complete brushtool enabling drawing of circles or elipses as well as a wider variety of colors. Likewise, the body part question type could be enhanced with the possibility to include images and define body parts within the administrators graphical user interface.

Conclusions

MoPat has been enhanced with two new question types: an image marker and a body part selector. These types will be tested and evaluated in the context of a multi site clinical study. The new question types will be further developed to improve their usability.

Configuration of Input Forms in EHR Systems Using Spreadsheets, openEHR Archetypes and Templates

Erik Sundvall[a,b], Annika Terner[c], Helen Broberg[d], Carrick Gillespie[e]

[e] Omniq AB, Stockholm, Sweden

Abstract

Differences in structure and semantics of data captured using screen forms in different Electronic Health Record (EHR) products and configurations is the root cause of many interoperability problems. We present a workaround enabling reuse of openEHR archetype and template semantics to configure forms in four surveyed, insufficiently standardized, EHR-products used in Sweden (Cerner Melior, Cerner Millenium, Cambio Cosmic and CGM TakeCare). Data from EHRs was then exported and queried using standardized query mechanisms.

Keywords:
electronic health records, semantics, medical record linkage

Introduction and Background

EHR systems provide both hardcoded non-configurable structures and other customer configurable parts. A significant part of EHR configuration is the creation of custom input forms, sometimes called templates, which consist of headings. However, the predefined headings are only to a small extent shared between the professional groups [1] within a healthcare provider or shared between providers [2]. This variation makes it hard or impossible to share structured information in an interoperable way. If the information is too different then it cannot be safely converted/mapped to structured exchange formats. Instead unstructured versions of exchange formats or telefax-transmission of printouts are often used, combined with time consuming reinterpretation and restructuring of the information by (already too busy) healthcare staff in order to fit into the receiving organization's IT-system and routines.

Standards targeted for EHR content standardization such as openEHR, HL7 CIMI, EN ISO 13606 combined with EN ISO 13940 can, if wisely used, contribute to support similar data capture at the source (data entry) making conversion processes unnecessary, simpler, or at least possible. In Sweden the implemented support for such standards in present and recently acquired EHR systems is limited. Customer-configurable forms do however exist.

The idea of using openEHR archetypes to configure input forms in a proprietary system by making limited modifications to the EHR System software has been described by Chen et.al. [3], and would likely have been useful if it had been implemented beyond research pilot. The work described here builds on similar ideas, but only uses (the more limited) mechanisms available in the studied current systems without vendor modifications of the software.

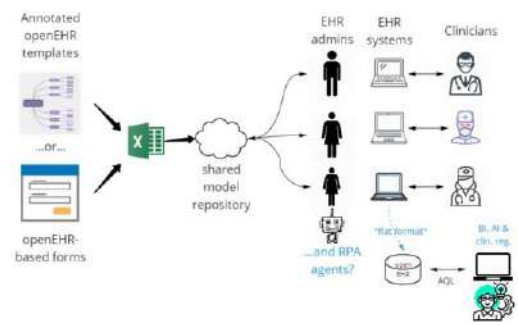

Figure 1 – Usage Context of Suggested Workaround

Several regions have signaled interest in using shared archetypes and openEHR-templates as building blocks when creating and maintaining configurable EHR input forms also in non-openEHR systems. That is the path explored here.

Methods

We asked what methods different healthcare regions employ when formalizing requirements and configuring EHR systems. Excel spreadsheets or documents with tables were received from six of the 21 Swedish healthcare regions. A new combined spreadsheet was compiled to fit all studied vendors' main datatypes for configurable input forms, see *Table 1*. A smoking-related spreadsheet example can be found in the "ehr-form-config" directory of https://github.com/modellbibliotek/standin/

A detailed description of openEHR-based modelling is out of scope, but a brief summary is that an openEHR template for a specific use-case can be constructed by joining and configuring/constraining and combining several (possibly repeated) archetypes (and terminology subsets/lists). Any node in such a template has a unique archetype based "path" and can also carry arbitrary "annotations" (key+value-pairs). We used annotations to mark which template nodes to expose in non-openEHR systems' forms and at what "indentation" level. The annotations could also allow automation of the (now manually executed) algorithm to convert from annotated template to the suggested spreadsheet format or ideally directly to control configuration APIs or interfaces. As part of the algorithm the paths of the used nodes are also written into corresponding spreadsheet rows (to enable later storage in the EHR system's or EHR-data export toolchain's data or metadata). The ID of the openEHR-template is also written into the spreadsheet.

Table 1 – A simplified view of the main datatypes found to be used for configuration in the four studied systems. In addition to the described datatypes the spreadsheet file, where applicable, contains descriptive help text intended to be easily available upon user request in form systems. Also columns relating the rows to openEHR templates and "paths" based on openEHR-archetypes were added to support openEHR based post-processing and potential querying of data. HL7 FHIR mapping guidance can also be manually added to the spreadsheet if available. A header level "depth" column is used for systems that support headings in hierarchical levels.

Datatype/ System	Free text	Date & Time	Numeric value	Calculation	Selection list	Coded term	Link
Cambio Cosmic	Yes	Yes, §F	Yes, §F, 1…2	Yes, §F	Yes, §F, +N, 2	Yes, 1…*	Yes
Cerner Melior	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Cerner Millenium	Yes	Yes	Yes, +F	Yes	Yes, +F, 1S	Yes, 1...*	Yes
CGM TakeCare	Yes	Yes	Yes	Yes	Yes	Yes	Yes

Abbreviation legend: +F = Free text field for comments can be added (configurable); §F = Free text field is always available for comment (not possible to turn off in configuration); +N = Numeric value can be added to the respective choices and can be used for calculation, e.g. for assessment instruments.; 2 = The number of choices in the selection list can be delimited to two choices by single selection, e.g. when using checkboxes for 'Yes' and 'No', respectively; 1...* = One to several code systems can be made available, e.g. both ICD-10 and ATC.; 1...2 = One or two numeric values can be specified in the same datatype. E.g. for blood pressure, two numerical values can be specified; 1S = If a special choice (in an otherwise multiple-choice type of) selection list is selected, then no more choices from the list can be made, e.g. if you choose 'No diseases' in a selection list that in addition to the choice 'No diseases' contains a selection of diseases.

Results

The combined spreadsheet format has seven different main datatypes, see Table 1. *Free text* implies narrative text without any additional structure. *Date & Time* (possibly partial) dates and times. *Numeric value* includes the value itself, unit, maximum value, minimum value and reference values. For *calculation*, a formula is given, combined with unit, maximum value, minimum value and reference values of the calculated value. For the *selection list*, the choices available to be selected are defined and whether single or multiple choice is allowed. *Coded term* carries codes that can be numeric or alphanumeric, and a meaning/display label of each code in a plain text. *Link* references other information, within or outside the EHR system

The spreadsheet method is suggested to be used as a way to "translate" annotated openEHR templates (or forms) based on archetypes to a form that resembles what current EHR system administrators are familiar with and using today. The configuration of the templates, in current EHR systems that lack an import mechanism, then has to be made manually based on the spreadsheets (as usually done today) or potentially assisted by RPA (Robotic Process Automation) tool scripts.

If/when openEHR modelling tools become more familiar in the regions and more automation is desired, then the spreadsheet step could be skipped and either annotated openEHR templates or form definitions could be used for configuration information. Templates were currently chosen instead of the form definition format already used by a couple of openEHR products, since there is not yet an official openEHR standard for that format. When standardized, it could potentially be used instead of (or as a complement to) annotated templates.

Figure 1 illustrates the workflow; templates of shared interest are collaboratively created and annotated (using normal openEHR toolchains) to fit use-cases and then algorithmically converted to the suggested spreadsheet format and uploaded to a shared repository (e.g. on GitHub) When the EHR administrators configure forms based on the spreadsheet they make sure to also carry over information regarding which openEHR template-ID the form is based on into the EHR. Information about which archetype-based path each spreadsheet row is associated with also needs to be stored in the EHR configuration or some other place that export mechanisms later can use to re-associate the EHR data with the path. Exact association mechanism may vary between systems, shorter Dewey-compressed [4] or hashed paths an also be used instead of full paths in EHR data.

The data in the (non-openEHR) EHR systems will not need to contain the full openEHR tree structures. As long as the openEHR-template-IDs and paths can be reconstructed during data export then e.g. an openEHR "flat" JSON format (https://github.com/ethercis/ethercis/blob/master/doc/flat%20json.md) can be used as import mechanism into an openEHR-compliant system and for example be queried using AQL [5].

The whole approach was tested by using an openEHR-template-derived spreadsheet to configure a CGM TakeCare EHR system. Export mappings to openEHR based "flat format" were then easily created and used to export data to an openEHR based open source EtherCIS EHR. The data (originating from the TakeCare system) could then be queried in the EtherCIS system using AQL (Archetype Query Language).

Conclusion

The described "spreadsheet" approach will of course not make existing non-standardized EHR content any easier to share in a structured way (no matter if it is user configured content or non-configurable content designed by the vendor). Organizations with an existing operational EHR installation will likely not suddenly switch all configurable EHR-entry forms from non-standardized to standardized, but can do it incrementally combined with other process and information change management and maintenance work.

Relationship Between Very Cold Outside Weather and Surgical Outcome: Integrating Shallow and Deep Artificial Neural Nets

Ahmad P. Tafti[a], Yue Dong[b], Elizabeth Habermann[a], Hongfang Liu[a], Vitaly Herasevich[b]

[a] Department of Health Sciences Research, Mayo Clinic, Rochester, MN, USA,
[b] Department of Anesthesiology, Mayo Clinic, Rochester, MN, USA

Abstract

Patients' hospital length of stay (LOS) as a surgical outcome is important indicator of quality of care. We used EMR data to build artificial neural network models to better understand the impact of cold weather on outcome of first surgeries in a day in comparison to a matched cohort receiving surgical treatment in warm days. We found that LOS for first-in-a-day cardiac and orthopedic surgical cases are longer in very cold days.

Keywords:

Length of Stay, Machine Learning, Association Learning.

Introduction

High-quality surgical care is of paramount importance to the public health community as the volume of surgery has remarkably increased all across the world. Successive assessment of surgical outcomes (e.g., LOS, readmission rates, functional health status, patient satisfaction) improves the efficacy of hospitalization, keeping LOS to a minimum, and helps health care providers build effective programs to patient care [1; 5]. Baseline heath status, condition lead to surgical intervention and procedural factors that can impact surgical outcome; however, no knowledge exists to study exterior factors, such as weather conditions impacting the hospital LOS of surgical patients. The availability of large-scale multi-modal data along with artificial intelligence algorithms make it possible to estimate association of different factors in measuring surgical outcome. In the present study, we develop machine learning-based, data-driven models to analyze the impact of cold and freezing outside weather on LOS after surgery. Our hypothesis is that freezing outside weather can affect the first surgical case in a day as operating room (OR) staff could have cold hands and be rushing to work. We compare hospital LOS after similar surgeries in freezing and summer days. Our main contributions are three-fold: (1) Inspired by shallow and deep artificial neural networks, we integrate daily temperature data with surgical data, and begin to understand how does the cold weather affect LOS for a cohort exposed to cold weather in comparison to a matched, non-exposed to cold weather cohort; (2) We turn a descriptive analysis problem into a classification pipeline, and develop a deep-stacked, contractive auto-encoder to learn useful data representation and extract relevant features from the combined clinical and weather data; and (3) The present study is expected to open several research avenues to incorporate more data and more multi-modal data to inquiry of surgical outcome.

Methods

The present study was reviewed and approved by the Mayo Clinic institutional review board. The Mayo Clinic OR Datamart was used to identify first-in-a-day surgical cases between January 2005 and December 2017. All patients admitted during the study period to the OR in the Rochester campus of the Mayo Clinic were eligible for inclusion. The Rochester (MN 55902) temperature data was obtained using a publicly available data source, namely NOAA, the National Oceanic and Atmospheric Administration [2]. To ensure consistency, we cross-checked the temperature data using an alternative source, called Weather Underground [4]. Our proposed workflow and the software tiers we developed are shown in Figure 1. After data cleaning, we had 132,095 unique surgical cases to perform the analysis. 45 data fields across 4 different categories (e.g., patient data, surgical data, intervention data, weather data) were used. Although the temperature data were originally obtained in Fahrenheit in the format of decimal numbers, an additional field namely "Temperature_Ordinal" was added to the dataset, in which to also account for a categorical representation of temperature. We employed the facts demonstrated in [3; 7] to turn temperature data from continous to ordinal values, as follows: {Temperature $< 14\ ^{o}F$ ➔ '*Very Cold*'**;** $14\ ^{o}F \leq$ Temperature $< 50\ ^{o}F$ ➔ '*Cold*'**;** $50\ ^{o}F \leq$ Temperature $< 68\ ^{o}F$ ➔ '*Mild*'**;** $68\ ^{o}F \leq$ Temperature $< 85\ ^{o}F$ ➔ '*Normal*'**;** Temperature $\geq 85\ ^{o}F$ ➔ 'Warm'}. In regard to LOS, the minimum and maximum values among all surgical cases were 0 and 31 days, respectively. To turn LOS to a nominal value and have it as the target class, median and mean of daily basis LOS were separately calculated for each surgery procedure. We thus defined short-term, mid-term, and long-term LOS for every surgery procedure as: {LOS < LOS_median ➔ '*Short-Term*'**;** LOS_median ≤ LOS ≤ LOS_mean ➔ '*Mid-Term*'**;** LOS > LOS_mean ➔ '*Long-Term*'}. All surgical data records have been combined with temperature data (decimal and ordinal) and stored in a single data repository, called Aggregated Dataset (see Figure 1). Once we had all data records and variables (*X* in Figure 1) available, we fed the deep-stacked, contractive auto-encoder with the data (each record represented as a vector X), in order to better capture the local relationships and directions of variables dictated by the surgical data records. The stacked contractive auto-encoder [6] is an unsupervised learning strategy that automatically discovers useful data representation models out of the given data. As a mathematical function, it maps an input vector $X \in R^{dx}$ to a hidden representation $h(x) \in R^{dh}$, as: $h = f(x) = S_f(W_x + b_h)$, where S_f is a non-linear activation function, and it is parameterized through a $d_h \times d_x$ weight matrix W, and a bias vector $b_h \in R^{dh}$, and decoder function will map hidden

representation h to a reconstruction y as: $y = g(h) = S_g(W'_h + b_y)$. The contractive auto-encoder training tries to find parameters $\Theta = \{W, b_h, b_y\}$ that minimize the reconstruction error on a training set of instances D_n as follows [6]:

$$\delta(\Theta) = \sum_{x \in D_n} (L\left(x, g\left(f(x)\right)\right) + \lambda ||J_f(x)||_F^2) \quad (1)$$

Having LOS nominal variable as the target class [short-term, mid-term, long-term], we then utilized three different classifiers, namely Neural Network (NN), Decision Tree, and Random Forest (RF), to learn how relevant features could be associated to a class. We split all data records into different segments to first train the classifiers, and then validate and test how those classifiers are accurate. If the F-measure and ROC area we obtained using the classifiers plus those relevant variables that automatically extracted through stacked contractive auto-encoder were promising, then we took association rules with the help of Apriori algorithm to extract patterns and rules across the data. Otherwise, we were back to the stacked contractive auto-encoder and re-configured the internal parameters (e.g., penalty term for the reconstruction cost function, number of epochs) to iterate the process.

Results

We used 50% of the data records to train the contractive auto-encoder, 25% to validate, and 25% to test. For classification purposes, we used 5-fold cross validation to evaluate the models. We ran into learning curves and calculated the F-Measure and ROC area to see the performance of the supervised method (shallow nets, RF, and Decision Tree), and then iteratively tuned and refined the entire parameters (e.g., penalty term) of the feature extraction component, the deep-stacked, contractive auto-encoder. The best F-Measure and ROC area were achived by NN, with F-Measure of 0.831 and ROC area of 0.847. Table 1 presents some temperature-related rules that automatically extracted using the system. The current study showed some relationship between cold weather and LOS for cardiac and orthopedic surgeries. We are 95% confident that the cold and very cold day cardiac surgeries which classified as long-term LOS have fallen between 68.59% and 71.41%. We are 95% confident that the mean LOS difference between cold and very cold versus not cold and very cold day cardiac surgeries is between 2 and 2.2 days, and we are also 95% confident that the mean LOS difference between Long-Term LOS versus not Long-Term LOS for cardiac surgeries is between 6.5 and 6.7 days. For orthopedic surgeries, we are 95% confident that the cold and very cold day orthopedic surgeries which classified as long-term LOS have fallen between 71.37% and 74.63%. We are 95% confident that the mean LOS difference between cold and very cold versus not cold and very cold day orthopedic surgeries is between 1.7 and 2.3 days. We are also 95% confident that the mean LOS difference between Long-Term LOS versus not Long-Term LOS for orthopedic surgeries is between 6.5 and 7.0 days. Our study did not find any relationship in data between cold weather and some surgeries, including gynecology, plastic, general, and urology.

Discussion

In this data mining study, we found associations between LOS patients undergo surgeries, including cardiac and orthopedic as first case in a day and very cold outside weather. Some previous studies were done studying association between hot climate and perioperative outcome in elderly patients. But this study is first to investigate the impact of very cold weather. Besides the large number of surgical cases and 12-year observation period, our study has limitation as this is association study affected by number of biases.

Conclusions

We found that LOS for first-in-a-day cardiac and orthopedic surgical cases were statistically significantly longer in very cold days. In this study, we only matched type of surgeries. This was designed as an exploratory study that required more fundamental epidemiological approaches to eliminate biases and confounders. Traditional epidemiological research is required to support this conclusion behind simple association.

Table 1 – Temperature-Related Patterns and Rules, Automatically Extracted Using the Proposed System

Patterns/Rules	Support [Confidence]
Procedure = "Cardiac" AND {Temp_nominal ="Cold" OR Temp_nominal="Very Cold"} ➔ LOS_Nominal = Long-Term	68.59% - 71.41% [95%]
Procedure = "Orthopedic" AND {Temp_nominal ="Cold" OR Temp_nominal="Very Cold"} ➔ LOS_Nominal = Long-Term	71.37% - 74.63% [95%]

Abstract

The digitization of health records and cross-institutional data sharing is a necessary precondition to improve clinical research and patient care. The SMITH project unites several university hospitals and medical faculties in order to provide medical informatics solutions for health data integration and cross-institutional communication. In this paper, we focus on requirements elicitation and management for extracting clinical data from heterogeneous subsystems and data integration based on eHealth standards such as HL7 FHIR and IHE profiles.

Keywords:
Data sharing , engineering

Introduction

The SMITH project [1], along with three other consortia, is part of the Medical Informatics Initiative (MII), funded by the German government. The aim of MII is to improve patient-oriented clinical research through optimized intra- and inter-institutional data exchange [2]. Therefore, a core dataset [3] and innovative medical informatics solutions for health data integration and cross-institutional data sharing are developed within the scope of MII. The SMITH consortium unites several university hospitals and medical faculties as well as industry partners in order to implement Data Integration Centers (DICs) at each hospital. These DICs are responsible for health data sharing and interoperability issues in the MII. Essentially, the implementation of such a trans-institutional health information system that enables the integration of heterogeneous data from various local hospital information systems (HISs) is a very complex and challenging task. In this paper, we focus on requirements elicitation and management for implementing this challenge.

Methods

We have adopted a generic approach that enables a collaborative requirement elicitation and a continuous refinement of the user requirements. Essentially, there were two conditions, among others, guiding the method selection for requirements documentation. 1) The team members belong to different institutions and have different levels of experience in requirements engineering. Consequently, they adopt different perspectives for requirement elicitation. 2) There was no specific tool for collaborative requirement engineering available and familiar to all team members. Hence, we decided to use a widespread word processor tool to create our technical requirements documents (TRDs). To support collaboration on the documents, we used SharePoint as a tracking system and repository. We additionally applied the method of Balzert [4]. This method helped us to structure specific requirements for heterogeneous data sources in the participating hospitals. Moreover, we modified this method by adding and linking local TRDs to a generic document that specify the core technical requirements (core TRD). Furthermore, conceptual models that describe the architectural requirements were included. They had been developed based on a DIC reference model [1] and the local TRDs, which take into account the local IT architecture and the resulting requirements. Finally, we adopted an ontology-based specification of the data requirements using Excel spreadsheets. To enable semantic interoperability, standard ontologies such as SNOMED CT and LOINC were used to code the data items required to implement SMITH use cases.

Results

We analyzed all functional requirements for data integration and validated them in cooperation with the participating hospitals. The resulting requirements of core business processes (BPs) were specified in the core TRD. Table 1 illustrates the core BPs. The code WP1-Core:BP50, for example, identifies UC data extraction as a generic BP requirement. The first three characters indicate the work package (here WP1). Table 2 illustrates an example that provides a generic specification for UC data extraction. Analogous to this example, we also defined requirements for all other core BPs. The implementation of this core process in DIC Leipzig differs from other locations. At the University Hospital Leipzig, i-Solutions LabCentre is installed as a laboratory information system whereas at the University hospital Jena Roche Swisslab is installed. For this reason, we also defined sub BP requirements specific to the local HISs. These

requirements were described in the separate local TRDs, which were linked to the core TRD. The TRD specific to DIC Leipzig contains, for example, five sub BP requirements that provide a detailed specification for the data extraction pipeline in DIC Leipzig. Each sub BP defines the relevant requirements for extracting UC data from different data sources such as LabCentre and i.s.h.med. I.s.h.med is a clinical documentation system provided by Cerner. To meet the requirement described in Table 2, a LabCentre interface has to be implemented. This interface extracts the UC data from LabCentre and transfers them to the data integration engine (DIE) using HL7 v2 [5]. The DIE is responsible for transforming the extracted data into interoperable standards such as HL7 FHIR [5] and CDA templates [5]. Finally, the Health Data Storage (HDS) stores the generated CDA documents in an IHE XDS [6] repository and loads the created FHIR resources into an FHIR server for discrete data.

Table 1– Core business processes

BP-Code	Core business process
WP1-Core:BP10	Extract calibration data for the UC tools and make it available for users
WP1-Core:BP20	Configure the DIE and activate DIC connectors to IHE-based components
WP1-Core:BP30	Configure the interface of DIE to clinical subsystems and establish connections to data sources
WP1-Core:BP40	Extract the MII core dataset
WP1-Core:BP50	Extract the UC data
WP2-Core:BP60	Transform extracted data into eHealth standards and integrate it in DIC HDS
WP9-Core:BP70	Supply UC data via standardized external interfaces such as IHE-profiles [6]

Table 2– An example of core business process requirements

/WP1-Core:BP50/ Core business process: extract the UC data	
Purpose	UC data can be extracted from clinical subsystem
Precondition	The DIE is ready for use and a connector to subsystem interface is established. The UC data are available in the subsystem to the extent necessary for the UC tools
Postcondition	UC data was successfully extracted from clinical subsystem and transmitted to DIE via a standard HL7 interface
Description	A connection to subsystem data source has to be established (see WP1-core:PB30) in order to extract the necessary data. The user can restrict the data quality and volume by certain parameters such as the number of patients and date. The user must also be able to sample the required data in a given time period (for example every 20s).

Once the data transformation and integration is finished, the next business process is data sharing. This core process requires IHE based data sharing services that connect all SMITH DIC information systems in order to provide access to anonymized clinical data stored in the local HDS.

Furthermore, we interviewed healthcare IT experts of the participating hospitals to get information about the primary data and to specify UC data requirements such as communication interfaces, source clinical subsystems, local IDs, local coding systems, and sampling rate. As a result, we created a spreadsheet file that combines all data items required to implement SMITH use cases. This file contains one spreadsheet for every partner hospital. To enable semantic interoperability, all data items specified in these spreadsheets were coded using standard ontologies such as SNOMED CT and LOINC. These spreadsheets will be used as a base for a metadata repository that represents all the data used and provided in SMITH.

Conclusion

We have adopted a generic requirement engineering method for supporting collaborative requirement elicitation and management in the SMITH consortium. This approach provided in our project a generic solution for aligning various requirements specific to different local hospitals. The resulting TRDs provide the basis for planning the system tests and future evaluations. Essentially, the resulting requirements are used to identify dependencies and to support the project management task.

In addition, the resulting spreadsheets provide a detailed specification of data items that should be extracted from local electronic medical records. Hence, our future work will include the development of corresponding FHIR profiles and the transformation of extracted UC data into FHIR resources.

Sweet Talking: Voice Technology and Virtual Assistants in Clinical Diabetes Management

Samuel Tan[a], Farhad Fatehi[b]

[a] *Centre for Online Health, Faculty of Medicine, The University of Queensland, Brisbane, Australia*

Abstract

Voice technology offers a range of novel and promising strategies for clinical diabetes management. Incorporation of voice-powered virtual assistants (such as Apple Siri and Microsoft Cortana) into diabetes care programs has the potential to improve patient awareness and adherence; facilitate comprehensive provider-patient integration and data collection; and expedite consultations, procedures, and meal preparations. This study will present a qualitative literature review on existing and speculative applications of voice technology in diabetes care.

Keywords:

Diabetes Mellitus, Mobile Applications, Speech Recognition Software

Introduction

Diabetes encompasses a number of related conditions chiefly characterized by dysregulations in glucose metabolism and resultant hyperglycemia. It is a globally recognized health issue with an estimated prevalence of over 400 million people worldwide [1]. Diabetes is primarily represented by two main subtypes: Type 1 diabetes mellitus (T1DM), an autoimmune condition; and Type 2 diabetes mellitus (T2DM), caused by deficient insulin secretion and/or insulin resistance [2]. Both forms of diabetes are lifelong and associated with increased mortality, largely due to cardiovascular and cancer-related causes [3].

Clinically, there are many issues that impair contemporary diabetes management. As diabetes is a chronic condition, patient education and adherence are closely intertwined with overall outcomes [4]. However, long-term adherence remains low, largely due to the complexity and consistency demanded by comprehensive management plans [5]. Surgery represents a prominent challenge in the diabetic population, both due to its fasting requirement and a greater rate of cardiovascular and infectious complications [6]. Additional issues in diabetes management include underdiagnosis, polypharmacy, drug interactions, wound care, and healthcare delivery [7].

Recent advances in digital and online technologies have presented a novel avenue to overcome these challenges [8], though reports on adoption and efficacy remain variable [9]. Smartphone applications have demonstrated efficacy at improving patient adherence and reducing blood glucose levels [10]. Similarly, artificial intelligence systems may allow patients and healthcare providers to better navigate the complexity of diabetes [11].

Voice technology, including virtual assistants such as Amazon Alexa, Apple Siri, and Google Home, offers a highly personalized and accessible approach to diabetes management. This study aims to summarize the current state of voice technology in diabetes management, as well as report on upcoming and potential applications.

Methods

A review of the literature was conducted to identify relevant peer-reviewed articles, conference abstracts, and technical reports. Databases searched included PubMed, Scopus, ACM Digital Library, and IEEE Digital Library. Google Scholar was used to identify relevant grey literature. The eligibility criteria for this study included English-language articles published from 01/01/2010 to 31/12/2018, as well as assessments of topical relevance, reliability, and data quality.

To find studies involving both diabetes and voice technology, a two-pronged search strategy was developed. Diabetes-related search terms included “diabetes”, “blood glucose”, and “blood sugar”. Voice technology search terms included “Amazon Alexa”, “Amazon Echo”, “Apple Siri”, “Microsoft Cortana”, “Google Assistant”, “Google Glass”, “Google Home”, “interactive voice”, “virtual assistant”, “voice assistant”, “voice intervention”, “voice recognition”, “voice interface”, and “voice response”. Overall, 28 peer-reviewed publications and 2 grey literature articles met the eligibility criteria for this study.

Results

Patient Adherence and Education

Interactive voice response (IVR) systems provide automated phone consultations through the use of voice recognition software [12]. Multiple studies have shown that IVR improves medication and lifestyle modification adherence in T2DM patients, ultimately resulting in HbA_{1C} and outcome reductions [12; 13]. By providing personalized advice and a range of answers to common medical questions, voice-driven technologies are also effective at educating and informing patients [14].

Insulin therapy is considered to be clinically underused in T2DM, largely due to difficulties in manually calculating one’s bolus dose [15]. In conjunction with a machine learning algorithm for nutrient determination [16], Foltynski et al. report on a smartphone application that can synthesize verbal descriptions of meals and accurately return the corresponding insulin bolus dose [17]. A similar voice-activated initiative was successfully trialled in patients with diabetic retinopathy [18]. Further development and distribution of these programs have the potential to greatly expedite insulin therapy for existing users, as well as promote its adoption in current non-users.

Healthcare Delivery

IVR and virtual assistants allow patients to easily book health appointments, as well as rapidly notify care providers about hypoglycemic and cardiovascular events [14]. Voice recognition software has successfully been used to transcribe endocrine consultations, improving healthcare efficiency and continuity [19]. Taken together, these systems allow for

doctors' advice and recommendations to be repeated at home, improving patient recall and adherence [14].

Surgeries in diabetic patients are often complex and demand significant expertise [6]. Armstrong et al. document the use of proprietary Google Glass software during diabetic limb salvage surgery to facilitate clinician communication and consultation, reducing errors and improving patient outcomes [20].

Surveillance and Diagnosis

Notably, voice recognition software appears capable of identifying early diabetic [21] and acutely hyperglycemic [22] patients from alterations in their vocal characteristics. Basatneh et al. additionally propose integrating virtual assistants with wearable sensors, such as foot mats and 'smart' wound dressings. This would facilitate wound self-care, early notification of risky behavior, and timely alerts to health providers [14].

Conclusions

Voice technology is swiftly gaining traction in contemporary diabetes management, with studied applications in intervention adherence, medication guidance, healthcare access, intra-operative consultation, and surveillance. Future expansions include the potential for further integration with existing diabetes technologies and machine learning systems, improving symptom detection and reducing intervention complexity. While voice technology currently holds a relatively niche role in diabetes management, the rapidly increasing prevalence of virtual assistants and speech recognition software heralds far greater adoption in the years to come.

The Evaluation of the Medical Information Exchange on 24-Hour Operation at North Kyushu Area in Japan

Naota Taura[a], Takehiro Matsumoto[a], Masayuki Honda[a]

[a] *Department of Medical Informatics, Nagasaki University Graduate School of Biomedical Sciences, Japan*

Abstract

We report on triage before transportation by sharing patient information between hospitals, making it possible to use the Ajisai-net for 24 hours. Fifty-six times hospital collaboration was conducted during the period from start of hospital cooperation operation until October 2018. Transportation cost reduction of 3,935,000 yen (34,620 dollars) was estimated. It is expected to contribute to improvement of efficiency of emergency medical care in North Kyushu.

Keywords:
Medical information exchange, triage before transportation.

Introduction

Health Information Exchange (HIE) has been gradually spreading in Japan [1]. The Japan Ministry of Health, Labour and Welfare reported that the number of these networks were spreading to 26 prefectures (55%) in Japan. Ajisai (hydrangea)-net, one of the most popular health information exchange (HIE), has been used since 2004 [1]. The electric medical records of 35 large hospitals of North Kyushu area (Fukuoka, Saga and Nagasaki prefecture) are shared among hospitals, clinics, pharmacies and other medical institutions. However, since regional collaborating room of each information provision hospital which implements access right setting cannot respond outside weekends, public holidays and weekday hours, it is difficult to operate for 24 hours, and lack of function has been pointed out in emergency medical care. We report on triage before transportation by sharing patient information between hospitals, making it possible to use Ajisai (hydrangea)-net 24 hours a day, 7 days a week.

Methods

The electric medical records of 84,332 patients were shared with their consent in Ajisai (hydrangea)-net from 2009 to 2018. This network system when utilized at the right setting is required to carry out strict protection of personal information of each patient.

The regional collaboration room of the information provision hospital's inability to set access right outside weekends, public holidays, weekday hours and lack of function in overtime medical examination has been pointed out. In addition, despite acute phase hospital collaboration with secondary and tertiary hospitals, spoil cases have been found to be appropriate for patients who really need transport outside of the indication. For these problems, it was decided to outsource weekends, public holidays and outside of weekday hours access right setting. To obtain written consent from the patient or a representative at the hospital, fax is sent to outsourced facility and consent form is confirmed by outsourcer. It performs setting of access right by outsourcer and makes completion report to requesting facility. Outsourcing facility further sends work report and consent form to regional collaboration office of each information provision hospital. The work of outsourcer is then terminated. Fax is sent to regional collaboration room of each hospital from the outsourced facility and work of outsourcer terminated. In addition, associated outsourcing costs were 1.2 million yen (10,909 dollars) per year. We examined triage before transportation using Ajisai (hydrangea)-net by cases where hospital-to-hospital cooperation was utilized.

Results

Fifty-six times hospital collaboration was conducted during the period from start of hospital cooperation operation until October 2018. Details were 39 cases (70%) before hospital transfer, 9 cases (16%) consultation, and 8 cases (14%) unknown (see Table 1).

Table 1 – The reason for between hospital cooperation

	Number	Proportion (%)
All	56	100
Before hospital transfer	39	70
Consultation	9	16
Unknown	8	14

Further investigation revealed that of the 39 cases conveyed before triage, 27 cases were transported [16 cases by helicopter (41%) and 11 by ambulance transportation (28%)], and 12 cases (31%) were not transported (see Table 2). We examined cases that were not transported further, and we found 7 cases scheduled to be conveyed by helicopter and 5 patients scheduled to be transported by ambulance.

Table 2 – Hospitalty transfers by between hospital cooperation

	Number	Proportion (%)
All	39	100
Transported:	27	
Helicopter	16	41
Ambulance	11	28
Not transported	12	31

According to previous reports, we estimated 530,000 yen (4,660 dollars) for helicopter transportation per case and 45,000

yen (395 dollars) for ambulance transportation in Japan [2,3]. Estimated total transportation cost reduction was 3,935,000 yen (34,620 dollars), helicopter transport cost reduction of 3,710,000 yen (32,640 dollars), and ambulance transport cost reduction of 225,000 yen (1,980 dollars).

Discussion

The medical network system started from paper media and has shifted from the fax using telephone communication network to the internet system. With these advances, it has become possible to confirm patient information in real time, which has greatly contributed to telemedicine and medical treatment support [4,5]. However, protection of patient's personal information, response at time of remote medical care, response to overtime, and so on still often must be solved.

We reported that to construct a method for registering out of time to the online system. By using outsourcing to solve the problem posed by holidays and weekday outside hours, it is possible to share information at emergency medical scene by enabling the use of hydrangea 24 hours a day, 7 days a week.

In Japan, several hospitals in the region cooperate with each other for emergency medical care. It is important to share imaging findings and laboratory data when linking between hospitals. In our study, by establishing a 24-hour hospital-to-hospital linkage, these results could be shared to allow treatment decisions to be made prior to transport, thus reducing emergency ambulance or helicopter transport by 31%. As a result, cost savings estimated at 3,935,000 yen (34,620 dollars) was reported. The role sharing of hospitals by triage before transportation, and reduction of medical cost is expected to contribute to improvement of efficiency of emergency medical care in North Kyushu.

Conclusions

It was possible to review the trial and treatment method before transporting by confirming the medical information in the receiving hospital before medical examination.

Improving Postural Balance in Dentoalveolar Malocclusion Patients Using a Vibrotactile Posture Trainer Device

Bhornsawan Thanathornwong[a], Siriwan Suebnukarn[b]

[a] *Faculty of Dentistry, Srinakarinwirot University, Bangkok, Thailand,*
[b] *Faculty of Dentistry, Thammasat University, Pathumthani, Thailand*

Abstract

The biomechanical relationship between the body and teeth suggested that posture imbalance can lead to dentoalveolar malocclusion. A randomized crossover trial was conducted to compare body posture measure using tilt angles of the neck and center of pressure of the malocclusion patients that received vibrotactile biofeedback from the posture trainer device with those who received no feedback. The results showed that the system is associated with quantitative improvements of the body posture in malocclusion patients.

Keywords:

Malocclusion; Postural Balance; Cross-Over Studies.

Introduction

Occlusion is a term used to refer to the alignment of teeth. Deviations from an ideal occlusion are called malocclusion. Orthodontics is a branch of dentistry that treats malocclusion. Some patients can maintain satisfactory conditions long after the treatment. However, in some patients, the symptoms reappear. Relapses can be interpreted as a return to an earlier posture expressing the patient's initial postural pattern [1]. A number of studies have been conducted on body structures affecting occlusion, focusing on genetically abnormal and unvaccinated body structures. The results of these studies indicate that, in general, individuals with unusual body structures are also associated with abnormal facial structure and occlusion [2, 3] due to the fact that both structures are connected by muscles. To be in a balanced position both statically and dynamically, it is necessary to balance the neck as well as the facial muscles and the occlusion plane [3].

Studies on the relationship between biomechanical and neurological aspects of the oral cavity and jaw have continued to multiply in the literature [4-6]. The study of body balance in patients with malocclusion using the equilibrium platform showed that it was instability in patients with severe class II or III malocclusion [5]. Body inclination has been found in cases of severe malocclusion, such as prominent protrusion or short jaw [6].

The use of biofeedback has been offered in the past as an instrument for training that enables an individual to learn how to change physiological activity or behavior for the purposes of improving performance. In therapeutic applications, biofeedback training of balance and posture has shown to be effective for posture control in adolescent scoliosis [7], and has also decreased the fall rate in elderly patients with peripheral neuropathy [8]. In patients with bilateral vestibular loss [9], biofeedback training was also found useful in enhancing postural stability even under challenging standing conditions, beyond the effect of practice alone.

This study evaluated the effectiveness of a vibrotactile posture trainer device that comprised of a wearable device containing an accelerometer sensor for measuring the tilt angle of the body (input) and provided real-time vibrotactile biofeedback (output) when the body is unbalanced measured using center of pressure (COP), the point where the total sum of a pressure field acts on a body, causing a force to act through that point.

Methods

The wearable device developed by our group consisted of an ADXL345 3-axis accelerometer sensors with high-resolution (13-bit) measurement at up to ±16g and a 12.5-400Hz bandwidth response. An accelerometer sensor was used for tracking body tilt angles. The accelerometer sensor presented two reading outputs, one for the X_{out} and another for Y_{out}, and a power supply voltage input of 2.0-3.6V. The expected values for X_{out} and Y_{out} were in the digital IO voltage range of 1.8-2.5V. The sensor consisted of a structure with a capacitive sensing cell (g-cell) and signal conditioning to detect small displacements. The signals from the accelerometer sensors were amplified and converted into digital signals through a data acquisition card (13-bit resolution) connected to a computer. The accelerometer mounted on a circuit card was used as an inclinometer to calculate body tilt angles. The vibrotactile biofeedback was provided to the user via a wearable device when the tilt angles were higher than 15 degree (Figure 1).

Figure 1– The wearable device containing an accelerometer sensor and vibrotactile biofeedback module was attached to the participant to measure the tilt angles of the body.

A randomized crossover trial was conducted to compare COP of the participants that received vibrotactile biofeedback from the system with the control group who received no feedback. The COP (Newton meter) was measured using Bertec forceplate (BERTEC, USA). We recruited eight Class II malocclusion (Maxillary protrusion) and eight Class III malocclusion (Mandibular protrusion) patients aged between 20-30. The study was approved by the institutional Ethical Review Board. A written consent form was provided by all participants.

Participants in the experiment group received vibrotactile biofeedback from the system after standing for 20 second, while those who were in the control group received no feedback. The primary outcome measures were the mean values of COP. The effects of a vibrotactile posture trainer (control vs. feedback group) were evaluated using the Paired t- test and were assumed to be significant at $p < 0.05$ (two-side). All analyses were conducted with the statistical package for the Social Science version 21.0 (SPSS, Chicago, IL).

Results

Participants who have Class II and Class III malocclusion that received feedback from the system had lower center of pressure which were statistically different ($p < 0.05$) from those who received no feedback from the system (Table 1).

Table 1– COP of feedback and no feedback group

Mal Occlusion	*n*	No Feedback Mean COP±SD	Feedback Mean COP±SD	*p*
Class II	8	21.14±6.92	17.08±14.38	0.007
Class III	8	20.76±11.09	14.74±3.04	0.005

Discussion

The findings indicated changes or modifications of the parts that affect any other body parts connected with muscles ensure a reaction by the nervous system as well, which influences the center of pressure and gait stability as exhibited through different body postures [10, 11]. A study by Lippold et al. [12] found a relationship between class II molar relationship occlusion and the balance platform. The children in the group had a poorer balance platform than other children. It was therefore recommended to observe occlusion during childhood so as to prevent future disorders of the body structure.

Several studies have used vibration-type feedback data and found it to be highly effective. For example, a study by Gopalai and Senanayake [13] conducted an experiment on a group of 12 people, comprising 6 males and 6 females. Vibration-type of feedback data was used by attaching a sensor on the back of participants while they were standing. The results indicated that the group with feedback data had a better balance platform with less movement. This was reiterated by a study carried out by Alahakone and Senanayake [14], who found that feedback data with vibration could help improve the walking patterns of patients who were unable to walk in a straight line because of tandem gait, and was better than letting the patients practice alone.

Conclusions

The results presented here demonstrate that the vibrotactile posture training system is associated with quantitative improvements of postural balance. This may be viewed as a promising first step to implement the system to minimize unbalanced posture that cause relapses in orthodontic treatment.

A Descriptive Review: Six Pediatric Personal Health Records

Cori Thompson[a]

[a] *Global ICT Consulting, Victoria, British Columbia, Canada*

Abstract

This descriptive review narratively synthesized themes and concepts from academic studies on pediatric personal health records (PHRs) from Medline EBSCO and CINAHL published January 1, 2007 to April 7, 2017. Reported features were summarized into a frequency table. Six studies in four countries reported PHRs for children with special health care needs, well-children, and adolescents. All studies advocated further development of such tools to improve healthcare. Such development might include children in the design phase.

Keywords:
Child, Personal health record, Review.

Introduction

This poster presents main findings from a descriptive review of academic literature on personal health records (PHRs) for children and adolescents (children) as a first step towards summarizing the evidence. PHRs have the potential to improve patient health outcomes by supporting patient interaction with and management of their own health care. PHRs may be defined as "a record controlled by the individual and may include health information from a variety of sources, including multiple health care providers and the patients themselves. The PHR is separate from, and does not replace the legal record of any health care provider… and may be stand alone or connected" (Office of the National Coordinator [ONC])[1].

Methods

A descriptive review methodology was chosen to identify any "trends or patterns" from published academic empirical studies, to "collect, codify and analyze numeric data" for frequency in pediatric PHRs, and to review a "representative sample" rather than being comprehensive [2]. For further rigour, the review relied on additional items from the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) (i.e., rationale, eligibility criteria, information sources, search, study selection, data collection process, data items, synthesis of results, study characteristics, limitations) [3]. The topics were the reported key information types and functionalities - or features - in pediatric PHRs. From the included studies, reported features were abstracted into a frequency table and the themes and concepts were narratively synthesized. The concept of pediatric PHR using terms "child" AND "personal" AND "health record" was searched in Medline EBSCO and in the Cumulative Index to Nursing and Allied Health Literature (CINAHL) from January 1, 2007 to April 7, 2017. Excel tables were used to screen the returns, identify duplicates, and abstract and summarize findings from included studies. Inclusion criteria were (1) on patient-controlled integrated or non-integrated PHRs as defined by ONC, (2) designed for or tailored to children, (3) reported on key information types and functionalities, (4) primary studies or used secondary data, and (5) in English. Exclusion criteria included (1) PHRs designed and/or used for adults, (2) records not controlled by patients such as school health records, (3) pediatric medical records to avoid skewing the frequency counts, (4) commentaries, grey literature, and policy statements, and (5) although a formal qualitative assessment was not conducted to avoid excluding any of the few studies, an informal assessment excluded studies that reported too few features to avoid skewing frequency counts.

Results

Of 49 results, 3 duplicates were excluded, and 36 articles did not meet the eligibility criteria. Ten articles were reviewed in full. Subsequently, four were excluded: three reported too few key information types and one was not about a PHR. Table 1 compares key study characteristics of the six included studies from four countries. The studies were found to use 15 different terms for pediatric PHR. The frequency analysis listed forty-eight features: all six studies reported on reminders or notifications, privacy (confidentiality), and security; five reported on patient demographics, immunizations, problem list/diagnosis, medications, and secure messaging; and four reported on lab results, calendaring/appointments, and ability to grant limited access. Evidence from the six studies was synthesized into four main themes and concepts for pediatric PHR design and usage. First, the main value of a PHR was the potential for communication and care coordination with the care team. Many children have multiple care providers in different locations and specialities [4-7, 9]. Parents used the PHR as a tool to support care coordination. Second, intrinsic motivation to use the PHR is needed for empowerment. Empowerment includes a balance of taking and relinquishing control (e.g., a patient may choose not to view a test result prior to the visit, a patient may review the record for any missing information) [7]. Third, the adoption, usage, and usability of the records depended on the parents' coping ability with the child's condition [5-7]. The PHR could also be a vehicle for knowledge transfer about the child's condition between provider-parent and specialist-primary care provider, as well as a means for parent-parent support and identifying parents as experts in their child's condition [4-7, 9]. Pediatric PHRs also need to support parental responsibility for their child's health decisions, right to reliable, complete health information, parental control and accountability of the record, and the need for understandable information [6]. While there was mixed evidence for PHR adoption by parents [7], most studies provided evidence of PHR adoption. Further research is needed as PHR adoption might be

by "parents more engaged in their child's care" [9]. Last, privacy (confidentiality) and security were key especially for adolescents' PHRs where both legislation and meaninful use criteria needed to be met. Organizational policies may help ensure these criteria are met in the PHR design and use [8].

Table 1 – Characteristics of the six reviewed studies

First author (Year) ***Country*** **[citaton]**	**Study type** ***Data source***	**Record name (Stage)** ***Integrated or Stand alone***	**Population/ Condition (Record control)**
De Graaf (2014) *NL* [4]	Evaluative *Primary data*	huidhuis.nl PHR with treatment plan (Implemented) *Integrated*	Congenital conditions (Patient owned, provider accessible)
Popkin (2009) *CA* [5]	Evaluative *Primary data*	eFOSTr PHR (Prototype) *Stand alone*	Organ transplants (Partially by parents)
Rocha (2007) *USA* [6]	Descriptive *Primary data*	PedMHR – medical home record (Design) *Stand alone*	Special health care needs (Partially by parents)
Schneider (2016) *UK* [7]	Descriptive *Primary data*	Patient Knows Best (PCEHR) (Implemented) *Stand alone*	Serious chronic conditions (Partially by parents)
Thompson (2016) *USA* [8]	Evaluative *Secondary data*	MyUFHealth Portal (Implemented) *Integrated*	Adolescents (Adolescent controlled, proxy granted to parents)
Tom (2012) *USA* [9]	Evaluative *Secondary data*	Kaiser Permanente child PHR (Implemented) *Integrated*	Well-child (visits, immunization) (Parent proxy via own PHR)

While four studies described participatory design with parents, providers, and/or organizational representatives [5-8], none reported involving children or adolescents in the design phase. This maybe an area for future research [8]. Future recommendations also include providing training and real-time technical support within a supportive health care organization environment, and tailoring information to the parents' ability to cope with their child's condition [6-7]. There may be differences in PHR use for well-children compared to PHR use for children with complex health care needs [5-6, 9]. Further research is needed.

Conclusions

This review attempted to synthesize academic literature on pediatric PHRs. Limitations included: one researcher designed and conducted the review, the studies' findings might not be generalizable to other jurisdictions, it is possible the studies did not report all features, and, last, only one expression of the key concept and two databases were searched. https://www.crd.york.ac.uk/prospero/display_record.php?RecordID=75346 has been registered to address the limitations. All six studies advocated future research of pediatric PHRs.

Is Teledermoscopy Improving General Practitioner Skin Cancer Care?

Femke van Sinderen[ab], Esmée Tensen[ab], Job P. van der Heijden[b], Leonard Witkamp[ab], Monique W.M. Jaspers[a], Linda W.P. Peute[a]

[a] *Amsterdam UMC, University of Amsterdam, Department of Medical Informatics, Amsterdam Public Health Research Institute, Meibergdreef 9, Amsterdam, the Netherlands*
[b] *Ksyos Health Management Research, Prof. J.H. Bavincklaan 2-4, Amstelveen, the Netherlands*

Abstract

Skin cancer incidences have tripled in the Netherlands for the last twenty years and are expected to increase even more in the coming years. Teledermoscopy (TDsc) is implemented in Dutch practice to support and enhance early skin cancer detection by general practitioners (GPs) through remote consultation with dermatologists. This study assesses the effect of TDsc consultation on the quality and efficiency of skin cancer care in the primary setting by analyzing 10,184 TDsc consultations.

Keywords:

Telemedicine, Dermatology, Skin Cancer

Introduction

Incidences of the most common skin cancer types have tripled in the Netherlands for the last twenty years [1]. Skin cancer accounts for 15% of all newly diagnosed cancers. Specifically, melanoma incidences are the highest in the Netherlands compared to other European countries, thereby likely increasing the burden on the general practice [1; 2].

Teledermoscopy (TDsc) has been suggested as a method to enhance the quality of care by supporting patient treatment and/or referral decisions. TDsc is defined as the provision of a consultation with a remote dermatologist based on digitally available dermatoscopic images [3]. As a result, TDsc could support GPs in primary dermatology healthcare in early diagnosis and referral of patients with skin problems, thereby augmenting their expertise in melanoma detection. Also, it can improve the efficiency of primary dermatologic care by preventing unnecessary referrals to secondary care, as well as accelerate the time to diagnosis.

Store-and-forward TDsc has been reimbursed and integrated into the Dutch healthcare system as a regular health service since 2009 by Ksyos Telemedical Center. Earlier studies in the Netherlands mainly focused on regular teledermatology [4; 5]. The aim of this study was to assess how TDsc affects the quality and efficiency of Dutch general practitioner dermatology care.

Methods

TDsc consultations data performed between February 2009 and March 2017 from routine clinical practice sent between GPs and dermatologists in the Netherlands using Ksyos Teledermoscopy services (Ksyos, Amstelveen, the Netherlands) was analyzed descriptively. The TDsc flow can be seen in Figure 1.

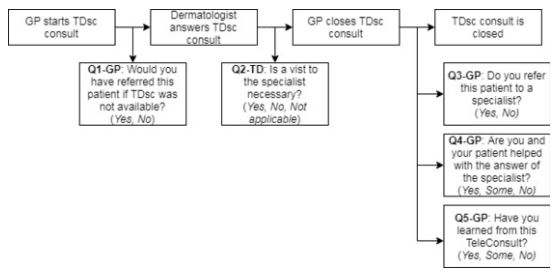

Figure 1. Overview of the five evaluation questions in the TDsc service. Q = Question, TD = teledermatologist.

Patients gave oral informed consent for a TDsc consultation. A TDsc consultation included among others, a maximum of four (dermatoscopic) pictures, an anamnesis, differential diagnosis by ICD-10 classification, and medical history. Questions to the dermatologist were asked in a free text field. As a result, the teledermatologist provided the diagnosis by providing an ICD-10 code and advice on diagnostic management by free text.

Five mandatory evaluation questions implemented in the Ksyos teledermoscopy service were asked to the GP and dermatologist (Figure 1). Answers to these evaluation questions were translated to indicators to assess the quality and efficiency of TDsc. Several of these indicators have also been used in a prospective study on the quality of general teledermatology [5]. In this study, dermatologists' response time was seen as an efficiency of care indicator related to the efficiency in the 'time to diagnose' process. The following indicators were subject in this study:

Quality of Care

1. Extra dermatologic advice requests: when Q1 = No.
2. Additional required referrals: when Q1 = No AND Q3 = Yes.
3. GP valuation of TDsc: when Q4 = Yes, Some. And when Q5 = Yes, Some.

Efficiency of Care

1. Prevented physical referrals: when Q1 = Yes AND Q3 = No.
2. Overall percentage of prevented physical referrals: 1 – (numerator is Q3 = Yes and the denominator is Q1 = Yes) * 100%.
3. Median dermatologists' response time: this was measured based on working days (8.30 am to 5.30 pm) from a 5-day working week.

Results

A total of 10,184 TDsc consultations performed between 26th February 2009 and 27th March 2017 was analyzed. Those were sent by 730 GPs from 555 practices and answered by 95 dermatologists. TDsc consultations with missing responses were excluded from the analysis (N = 2,345). Table 1 represents the interpretation of those outcomes concerning the indicators described below.

Table 1. The TDsc quality and efficiency indicator outcomes.

TDsc quality of care indicators	
Of the TDsc consultations:	
1.	**30.3%** were performed by GP due to the availability of TDsc, to gain extra dermatological advice.
2.	**17.3%** led to physical referrals of patients otherwise not referred by the GP, these included pre-diagnosed skin cancer cases.
3.	**97.4%** was reported as helpful by the GP and **95.3%** were considered educational/instructive.
TDsc efficiency of care indicators	
Of the TDsc consultations:	
1.	**69.6%** prevented a physical referral, decreasing the number of patients needed to be seen face-to-face by the dermatologists.
2.	Overall **62.1%** physical referrals were prevented.
3.	**2.23** hours was the median dermatologist response time increasing efficiency of the diagnostic process (mean; 6.58h, standard deviation; 26.8h).

Quality of Care

Regarding the first indicator, 7,839 of 10,184 of the TDsc consultations were included and had responses on both Q1 and Q3. Of the included consultations, 2,379 (30.3%) were requested by the GP to gain supplementary dermatological advice (Table 1).

Concerning the second indicator, 411 patients (17.3%) who would otherwise not have been referred were physically referred after a TDsc consultation to the dermatologist (Q1 = No and Q3 = Yes). Teledermatologists provided an ICD-10 code for 149 of those consultations, including skin cancer diagnosis. In 7,637 TDsc consultations (97.4%) GPs reported that they and their patients were helped by the dermatologist's response (Q4 = Yes, Some). Assessment of the reported learning effect by GPs showed that 7,474 consultations (95.3%) were considered instructive (Q5 = Yes, Some).

Efficiency of Care

Of the included consultations 5,460 (69.7%) were intended to prevent a physical referral (Q1 = Yes). Of these, 3,800 (69.6%) were actually prevented (Q1 = Yes and Q3 = No). Without TDsc 5,460 patients would have been referred to the dermatologists. After TDsc 2,071 patients were referred, resulting in 62.1% of prevented physical referrals overall.

Timestamps have been stored since July 2011. Hundred-eighteen consultations were excluded due to missing timestamps. The median response time of the dermatologist was 2.23h (Figure 2).

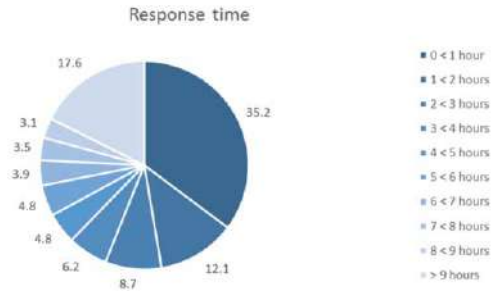

Figure 2. The distribution (%) of response times of TDsc consultations (N=10,066)

Conclusions

The results from this study give a strong indication that TDsc is improving Dutch dermatologic general practitioner health care regarding its quality and efficiency. TDsc availability is valued by GPs in gaining additional and helpful dermatologic advice and prevented a high percentage of physical referrals. Moreover, TDsc resulted in the detection of potential skin cancer cases of patients who would not have been referred if TDsc had not been available. TDsc also improves the efficiency of GP dermatology healthcare by obtaining dermatological advice within one working day.

Conflicts of Interests

E.T., F.v.S, and J.P.v.d.H. are employed (part-time) by Ksyos, and L.W. is the director of Ksyos. The remaining authors state no conflicts of interest.

Standards, Processes and Instruments for Assessing Usability of Health Mobile Apps: A Systematic Literature Review

Francisco Vera[a], René Noël[a], Carla Taramasco[a]

[a] *Escuela de Ingeniería Civil Informática, Universidad de Valparaíso, Valparaíso, Chile*

Abstract

mHealth applications have had sustained growth in recent years. However, there is scant and disorganized scientific evidence of methods for evaluating their usability and adoption. We conducted a systematic literature review to describe standards, processes, methods, and tools for evaluating mobile health software. We analyzed ten studies: two identify standards for evaluation, and seven specify tools or instruments for supporting assessment. PSSUQ, SUS, and MARS were the most referenced instruments for usability and adoption evaluation.

Keywords:
Mobile Applications, Information Systems, Review Literature as Topic

Introduction

The World Health Organization defines mHealth as "the practice of medicine and public health supported by mobile devices such as mobile phones, patient monitoring devices, personal digital assistants and other wireless devices" [1]. Mobile applications have proliferated in recent years, addressing health education, patient monitoring, or as part of health information systems. It is estimated that there are more than 325,000 mHealth applications for the most popular mobile platforms (iOS and Android) [2]. One of the challenges associated with the large number of applications is quality. In health, usability has been considered quality factors related to patients' safety and care quality [3-5]. There are specific instruments for the evaluation of usability in mobile applications [6] and recommendations of global organizations, such as HIMMS of processes and instruments [7]. Secondary studies have also been conducted looking for evidence of usability processes for mobile applications, identifying that the majority of usability evaluations are based on questionnaires [8]. Although these initiatives are varied, there is scant and disorganized scientific evidence of the standards, processes, and tools used in real life for the evaluation of quality from this perspective. We conducted a Systematic Literature Review (SLR) regarding the use of quality assessment standards, processes, methods, and tools with respect to the usability and adoption, from the point of view of the researcher in the context of trending scientific publications on health and information technologies.

Methods

Based the purpose of this review, we defined three research questions:

RQ1. What standards and norms are used for the certification of the attributes of quality in usability, for the development of mobile applications for health?

RQ2. What processes or methodologies have been used in the development of mobile applications for health in which they include elements of usability?

RQ3. What tools to assess the usability of mobile health applications have been used by software developers?

The search string was created according to the "Population, Intervention, Comparison and Output" (PICO) structure [9,10]. We defined population as mobile health, intervention as use and usability of health information systems, and ommitted comparison and outcomes due to lack of prior studies in the same context. The final search string was: *((Mobile OR smartphone) AND (app OR application) AND ("mHealth" OR "health software")) AND ("Adoption" OR "Usage" OR "Usability" OR"Assessment" OR "Evaluation" OR "Study" OR "Standard" OR "Metric")*. We selected two main scientific databases as sources: SCOPUS and Web of Science (WoS). The search string presented in the previous section was modified according to the syntax of the search engines of each database. Studies with at least one of the below exclusion criterion were not selected:

- Assessment target was not related to mobile apps,
- Domain of mobile apps was not related to health,
- Assessed quality attributes were not related to usability nor quality in use,
- Documents type is different from article, non-English, or published before 2000 or after 2017, or
- Article does not present experiences, processes, methods, tools, instruments, surveys, or literature reviews related to assessment of usability or quality.

Results

Figure 1 presents the results of each stage. Ten studies were included in the final analysis and classified according to the proposed protocol. Regarding RQ1, only two studies [11,12] mentioned standards for the evaluation of usability of health information systems, including ISO 9241-11: 2018 [13], ISO 9241-12:1998 [14], and ISO / IEC 9126-1) [16]. Regarding RQ2, 50% of the articles specified a process or methodology, while just 10% specified an ad-hoc approach. Regarding RQ3, 70% informed the use of tools and instruments; PSSUQ[18], mHIMMS[7] and MARS[4] were the most referenced.

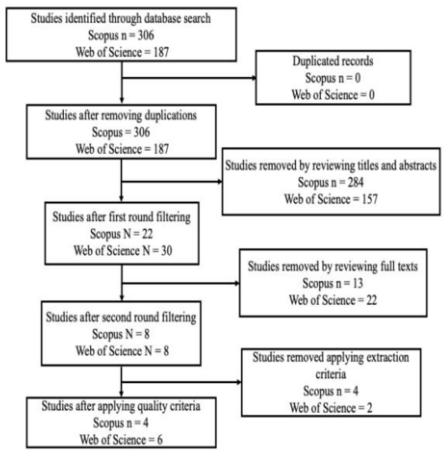

Figure 1 – Flow Diagram for the Study Selection Process.

Conclusions

We performed a SLR regarding usability assessment in mHealth mobile apps. From 493 initial articles, 10 were included and analysed. Main findings are consistent with previous similar reviews: usability assessment is mainly based on polls or questionnaires (only two studied report the use of standards), although specific mobile platform guidelines [19] and specific evaluations frameworks [11,17] were also found. All of the studies mentioned usability as a quality characteristic, 30% specified other attributes such as security and efficiency, and 30% reported a usability sub-characteristic (memorability). Given that selected studies are recent (3 were published in 2014, 4 in 2016, and 3 in 2017), it is likely that the evaluation of usability of mobile applications is in an incipient period.

Oncotherapy: A Decision Support System to Validate Oncological Treatments

María Laura Vera Righi[a], Pablo Martinez[b], Alcides Silva[b], Cati Umpierrez[c], Robinson Rodriguez[d]

[a]Department of Medical Informatics, National Cancer Institute, Uruguay
[b]ADN Engineers, Uruguay
[c] National Bank of Cytostatic, National Cancer Institute, Uruguay
[d]Medical Oncology, National Cancer Institute, Uruguay

Abstract

Making therapy decisions in oncology is a challenging task in the medical precision era. Oncotherapy is a decision support system that provides oncologists with suitable therapies for the patient within the national guidelines. The system is capable, on the one hand, to help the oncologist to maximize fitting therapy to the patient and, on the other hand, to provide control tools for the country´s sanitary authorities.

Keywords:

Clinical decision support system, Decision making, Medical oncology

Introduction

A clinical decision support system is a technological tool to help the physician to make decisions. Nowadays, choosing the best available therapy for a patient is a difficult task. We wanted to make an information system to help physicians to select the best option for each particular case, taking information from the accurate knowledge of the expert in the field enriched by the opinion of the oncologic community. It is a valuable assistance to reduce the occurrence of errors [1] in the physician's decision making process. This type of error is not the most frequent, but surely one of the most serious, because in most cases it does not allow the possibility of correction before any damage occurs. Oncotherapy also guarantees patients receive therapies in equal terms in the public health system. Besides, it allows the authorities to model the available therapies in the National Health System.

The objective of this study is to show a decision-making process in the prescription of oncological protocols assisted by a clinical decision support system called Oncotherapy, version 1.9.6.2.

Methods

Until June 2016, the National Cancer Institute collected, processed and sent by hand more than 2500 requests of series of therapy protocols every month. We have created an oncologic therapy engine with the guidelines of oncology therapies, based on the knowledge provided by the Guidelines Committee, guided by state-of-the-art oncology therapies. This engine will provide the available therapies according to the following three types of data: clinical diagnosis, clinical stage, and therapeutic criteria. The requests go through a designed workflow and may be automatically approved by the system if they match the criteria established by the engine. If the data do not match, the request is submitted to the consideration of a Therapy Committee and may be either approved or rejected. If it is rejected, the petitioner could resend this petition to the Coordinator of the Therapy Committee, who could approve or reject it definitely (see Figure 1). The main reason for rejection is to have another similar therapy in progress. Patients could receive more than one treatment at the same time or at different times, requested by either the same doctor or a different one. The procedure is allowed and controlled by the system. Each request is processed, by computing drugs, presentations, doses by patient which are packaged and sent to the medical centers where the patients receive oncological medical treatment. The request comprises a complete treatment and not one treatment cycle as it used to be done before. Every treatment is modeled within a period of time and it is required to confirm the request at certain intervals. The doctor receives an alert signal to proceed. In this way we are certain to send therapies that are still needed by the patient. The request could be ordinary or express depending on the timing that the treatment is needed according to the clinical situation. To date, we have processed 2260 urgent requests. The treatment could be suspended if it has already begun or cancelled if it has not been sent yet. In case the treating oncologist should be unable to find the intended therapeutic protocol by using the engine, a request to the Guidelines Committee could be sent, which may then enter new knowledge into the engine to enable the new option. In this way, the system allows a dynamic interaction between the Guidelines Committee and the country's oncologic community, providing the engine with feedback. One messenger service is activated inside the system to facilitate the communication among the oncologic community members, as well as with the Guidelines Committee. The Administrator profile is allowed to model the engine, feeding it with permits and constraints depending on the existing therapies in the National Health System. The solution is presented in oncological language and is assisted by colors and images to help the physicians to reach the desired function promptly.

The sanitary authorities could control the procedure and indirectly they also control the expenses in medical oncology.

Oncotherapy is made in a distributed environment, using web-based technology, supported with Java development and uses the PostgreSql® database engine. The application is supported and administered on a TomCat ® server.

Results

The decision-making about oncology therapy is a very challenging aim to achieve. Physicians participate in Tumor Committees, but these are not always possible in places far from the oncology centers. This type of clinical decision support system brings the knowledge universally in the same conditions wherever the patient is.

From July, 2016 to August 2018, Oncotherapy processed 14905 requests for 9300 patient made by 78 medical oncologists

distributed throughout the country. The workflow of the requests is shown in Table 1. 80.5% of requests follow the automatic approval without human intervention. Therefore, the administrative manual work has been eliminated and the number of members in the Therapies Committee has been reduced. More than 2000 therapies are currently in progress in the whole country and the medical request error is nonexistent (see Table 2). The diagnostic area of therapeutic intervention was distributed as Table 3 shows. The Guidelines Committee has a continuous intervention in the update of the engine model. The administrator sets the model depending on the Guidelines Committee resolutions and the sanitary authorities criteria. Indirectly, the cost of therapies was reduced by almost 20%, in the same period of time the number of patients increased due to the possibility to request therapies across the whole country. The medical informatics solution will contribute to creating a robust procedure to request oncology therapies according to the national guidelines in the National Health System.

Table 1 - Summary of Requests

Status	Request
Request	14905
Automatically Approved	12020
Requesting	145
Under Evaluation	10
Approved by the Therapies Committee	2475
Rejected	130
Temporary Rejection	15
Request after temporary rejection	12
Rejoinder awaiting answer	19
Approved by the Coordinator of the Therapies Committee	60
Rejected by the Coordinator of the Therapies Committee	40
Guidelines Committee Request approved	100

Table 2 – Summary of Therapies

Status Therapies	Sum
Under therapy	2105
Awaiting confirmation	525
Finished	7060
Suspended	120
Cancelled	705
Confirmed	3670

Table 3 – Summary of Diagnostic Area

Area	Sum
Gynecological cancer	7312
Urological cancer	3923
Digestive cancer	1585
Lung cancer	350
Head and Neck cancer	239
Skin cancer	66
Brain cancer	49
Soft Tissue cancer	41
Primitive unknown	10

Discussion

It is not an easy goal to create an IT (Information Technology) tool that helps physicians to do part of their technical job. Finding the suitable windows where the information system could be part of the routine without interrupting the clinical process is a very challenging work for medical informatics. It requires deep knowledge of the business and the technology to make it part of the clinical process. In order to reach this objective, it is very important to understand that technology is not the most important thing. It is better to focus on the involvement with the clinical situation with the doctor.

Until now we were working in terms of different dimensions such as patients, treatment, drugs, protocols of therapies and guidelines. However, our work has not finished yet. We are working on user profiles to use the physician´s dimension as a new filter to expand the use of the software to other cancer specialities and to other medical specialities, because the engine is useful in some other diseases. This will be included in the new version before the end of 2019.

The next step is to create the interfaces of the software to talk with other IT solutions in the national information system.

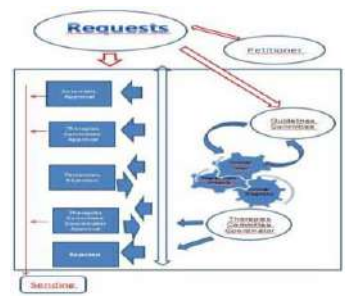

Figure 1 – Workflow of Request

Conclusions

We have created a clinical support system, where the oncological therapies engine is the most important input to the systematization of the decision-making process. This has been working successfully for 2 years in the control area of the National Cancer Bank of antitumor therapies. At the same time it is beneficial for the oncologic community to eliminate prescription errors. We have created a tool for the authorities to control the cost of the therapies, controlling the model and the spread, avoiding the waste of drugs.

Acknowledgements

To the authorities of the National Cancer Institute, specially to the director, Dr. Alvaro Luongo.
To Roche Industry Laboratories which contributed part of the cost of the development of the system.
To the Oncologic Community for contributing to the best usefulness of the engine.

Age and Nationality: Two Variables That Challenge the Univocal Identification of People in the Health System of the Autonomous City of Buenos Aires

María Victoria Risoli, Mora Ruffo, Manuel Rodríguez, Belén Islas, Micaela Zapata, María Victoria Giussi, Analía Baum

Health Information Systems Office, Ministry of Health, Buenos Aires City, Argentina

Abstract

The univocal identification of people is fundamental for the longitudinal monitoring of health status. The impossibility of all people to credit their identity via their identity document generates temporary records that make it difficult to record the continuity of care. This paper analyzes the Patient Index of the Ministry of Health of the Buenos Aires City and describes how the age and nationality variables influence the creation of temporary records.

Keywords:

Health Information System, Health Plan Implementation, Data Collection.

Introduction

The univocal identification of a patient in the health information systems is key to guarantee the continuity of care [1-4]. The situation of the Autonomous City of Buenos Aires is not replicable to other places in the world where accreditation is a common and indisputable fact. In our context, the accreditation of identity is not a mandatory requirement since it is imperative to comply with current health laws. Law 153 “Basic Health Law of the City of Buenos Aires” implies the obligation to provide care to all citizens, residents or persons in transit within the City of Buenos Aires (CABA) [5]. There are many reasons that make it difficult to prove the identity of the entire population attending the facilities of the public system: without documentation [6], no identification at the time of contact or not willing to present it to State institutions.

In any case, it is known that the problem is not simply finding a unique patient identifier and its attributes, but the creation and maintenance of a Master Patient Index (MPI) with an associated patient identification service that supports and maintains [1-3]. In Buenos Aires City, the procedure through which the opening of an Electronic Health Record (EHR) is generated is called “registration” and is based on specific standards for the univocal identification of people [6]. These standards imply the search of candidates in the MPI before entering a new patient to avoid duplicates [1, 2, 6]. When the patient cannot prove identity, an EHR called “Temporary” is created. This condition should be exceptional in order to proceed to the patient's care and then be rectified by an admission process that identifies the patient and captures a document that enables the EHR to be “Permanent” [1]. The aim of this poster is to investigate the variables that are linked to the opening of EHR in a Temporary state and the characteristics of its use, particularly in cases where it does not act as a temporary situation and it is extended over time crystallizing the risks of the longitudinally of a non-valid record.

Methods

The Buenos Aires city healthcare network is conformed by Ministry of Health, 35 Hospitals, 74 Primary Care Centers (CESAC, CMB), 1 Ambulatory Reference Medical Facility (CEMAR), 2 children's dental centers, 2 health mental centers, It is structured into 12 geographical areas in order to organize health care delivery. Since June 2016, an EHR has been gradually implemented in the outpatient setting [7].

A mixed, quantitative and qualitative methodology was designed. In the first phase, data were requested and collected to confirm or rule out variables that could influence the creation of temporary EHRs provided by the Information and Statistics Management sector of the Ministry of Health.

We analyzed the nationality, the place of residence (divided into the Autonomous City of Buenos Aires, the Province of Buenos Aires and others), the age range, plus the place where it was registered (Primary Care Center or hospital). In addition, the amount of EHRs in the temporary state and the percentage of temporal registers rectified were analyzed.

Results

Among temporary records, the variables nationality and age range present differences in relation to the total number of registered patients, while patient's address and the type of facility did not show significant differences in terms of the percentage of temporary registrants.

Nationality

In August 2018, the proportion of temporary records for people with a foreign document was 19.49% compared to 9.07% of records with an Argentine document.

Age

In the last six months, an increase in number of the temporary records has been observed, especially in children under one year of age. In the last six months there has been an increase in Temporal EHR (Figure 2): in August 2018 the percentages of registered as temporary in children under 1 year, children between 1 and 6 years, children in 6 and 18 years and over 18 years old, were 18%, 7.14%, 9.59% and 8.72%, respectively.

This coincides with the implementation of SIS in acute general hospitals that have maternities.

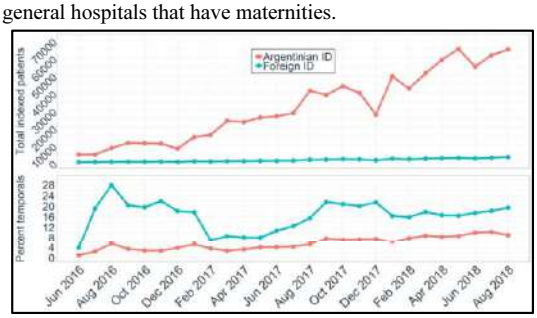

Figure 1: Total number of patients registered as temporal and percentage of the total number of registered patients per month and nationality

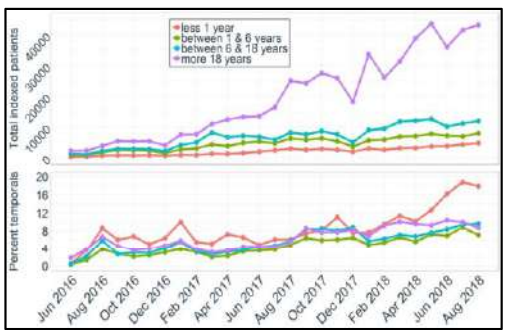

Figure 2: Total number of registered patients and percentage of temporal records per month and age range.

Of the total number of patients registered as temporary (N = 65734 = 6.6%), 10.3% was rectified (N = 6751). 36.4% had at least one clinical note in their Temporary EHR (Table 1).

Table 1 - Amount of temporary and rectified records without clinical notes, with one note and two or more notes

	Temporary		Rectified	
Consultations	**n**	**%**		**%**
0	41,809	63.60	3485	8.34
1	11,169	16.99	1131	10.13
>2	12,767	19.41	2135	16.74
	65,734		6,751	

Conclusions

Regarding age, children under one year usually do not have a document because the parents have not yet completed the process or sometimes because they do not bring it with them to the pediatric outpatient clinic [7]. In order to minimize this fact, the administrative staff were asked to register the child with a permanent status using the parent's document. Regarding the temporal-nationality relationship, it may be due to the fact that in our country, immigrants are in a very vulnerable social situation, but the true cause should be deepened. We were not able to explain the fact that some temporary records are not associated to a visit, but we believe that the creation of a temporary records could be shortcut used by the administrative staff to expedite attention times, since this process is faster than creating a permanent patient record [1-6].

Limitations and future directions

We need to perform qualitative explorations that allow us to determine and better understand why the temporary records are created. Understanding the causes will allow us to develop communication strategies and training or modification in the processes so that these obstacles are not an impediment that lasts over time. Further qualitative explorations are needed to better understand this phenomenon.

Design, Implementation and Adoption of an Electronic Dental Record Within an Electronic Health Record in the Public Healthcare System of Buenos Aires City

Stok Capella JF, Zubillaga MJ, Nero FG, Muguerza P, Lanuza J, Alassia L, Rodriguez Tablado M, Giussi MV, Baum A

Health Information Systems Office, Ministry of Health, Buenos Aires City, Argentina

Abstract

This paper describes the development and implementation of a Dental Record within an Electronic Health Record in the public Primary Health Care network of Buenos Aires City. In the five months of implementation, the adoption was progressively increasing but with a great deal of variability among the health facilities. Pediatric population was the most common assisted and the most frequent oral health problem was caries.

Keywords:

Dental Health Services, Electronic Health Record, Dental Record

Introduction

Oral health has been an issue of great concern for many years. Reduction of risks to oral diseases is only possible if services are oriented towards primary health care and prevention [1-2].

Control of oral disease depends on availability and accessibility of oral health systems. In developing countries, oral health services are mostly offered from regional or central hospitals of urban centers and little, if any, priority is given to preventive or restorative dental care. Even more, many countries in Latin-America have a shortage of oral health personnel, and by and large, the capacity of the systems is limited to pain relief or emergency care [1].

International statistics indicate that the main problem of oral health in underdeveloped countries is dental caries, 60% and 90% of young students and 92% of the adult population [3].

There are no known studies that provide data on the oral health status of the adult Argentinian population [4].

A dental electronic health record has become a priority in many countries. However, experience shows that any dental electronic health record system cannot be subordinate to, or a subset of, a medical record.

Optimal, oral health care needs integrated dental, medical, and behavioral health information into an electronic health record and be readily available to health providers [2-4]. The Buenos Aires City public healthcare network has a unique opportunity for the integrated Electronic Dental Record because oral health professionals work at a primary care level where an Electronic Health record has been implemented for the last two years [5].

Methods

Setting

The Buenos Aires city healthcare network is conformed by a Ministry of Health, 35 Hospitals, 74 Primary Care Centers (CESAC, CMB), 1 Ambulatory Reference Medical Facility (CEMAR), 2 children´s dental centers, 2 health mental centers, and its structured into 12 geographical areas in order to organize health care delivery. Since June 2016, an Electronic Health Record (EHR) has being gradually implemented in outpatient. [6] Until October 2018, 60 healthcare facilities have been using EHR and more than 2.5 million of clinical notes had been registered. This EHR incorporated dental record capabilities in June 2018. The dental network [7] delivers care in 44 primary care facilities, 26 general hospitals and 3 specialized dental care hospitals which provide emergency services 24 hours a day. There are approximately 250 dental care professionals supporting health care in this network.

Software Development Process

There was an interdisciplinary team focused on designing a tool based on the professionals´ needs. Then, three iterative cycles of design, development and testing of the electronic dental record took place. The Electronic Dental Record (EDR) was developed within the Electronic Primary Care Health Record System.

In order to know the users' needs, interviews of dentists and observations of dental practices were carried out in primary care facilities. Then, a tailor-made implementation plan was designed taking into account the dental care processes within the different facilities of the network.

Results

Between January and June-July of 2018, three iterative cycles of design, development and testing of the electronic dental record were completed. The design and development of the tool was divided into three phases. The first phase required two full iterations. In the first iteration, the goal was to complete the minimal required functionalities needed by dentists to replace a paper based, dental record, allowing the registration of the current and historical status of the denture as well as the

planned treatment. As a result of this first iteration, an alpha version was released and evaluated by an interdisciplinary team and a backlog of minimal required corrections and improvements were defined. A second iteration was completed in order to incorporate these changes, resulting in a production-ready version by June 2018.

In the second phase, which required one full iteration, non-blocking but desired features were added to the EDR: the possibility to register supernumerary teeth and the live calculation of epidemiological indicators for dental cavities.

The third phase, which is under development, is aimed to the specific registry of oral mucosal health.

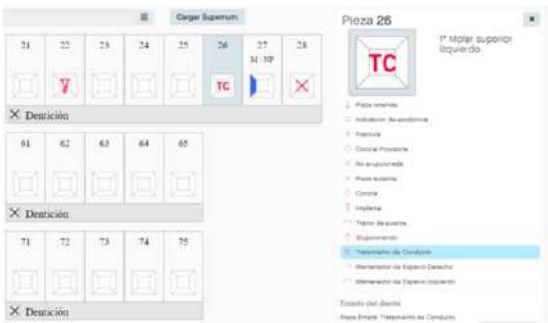

Figure 1. Dental Record Interface

Interdisciplinary team and implementation strategy

Participation in the interdisciplinary team included 2 computer scientists and 3 specialists in health informatics with different disciplines (sociology, dentistry and medicine).

In order to understand the needs of the oral health registry and gather information of importance for the design and development of the electronic dental registry, 30 interviews with dentists were conducted.

Chiefs of the primary care centers and dental network coordinators also participated in the interviews to find out what information was critical for public policy decision-making.

Fifteen implementers were trained to give instructions about the use of the dental record to 100 primary care dentists from June to October 2018. The trainings were carried out in a personalized way with each professional and a passive support time was destined to evacuate doubts from the use of the tool.

Electronic Dental Record Adoption

Between June and October of 2018, the EDR was implemented in 30 Primary Care Facilities (CESAC).

Conclusions

Oral disease is a health care problem and not solely a dental one. This is why the dental record cannot be isolated from the health record. Optimal, oral health care needs integrated dental, medical, and behavioral health information into an electronic health record and be readily available to health providers. We did that integration but future investigation is needed to understand causes associated with oral health and design policies that improve the oral health care of the population in this sense.

Development of a Virtual Reality System for Early Mobilization of Critically Ill Patients

Jiani Wang[a], Chunyan Zhang[b], Yanrui Jia[b], Chenxi Shi[b], Thomas Choi[c], Qian Xiao[a]

[a] *School of Nursing, Capital Medical University, Beijing, China*
[b] *Beijing Chaoyang Hospital, Capital Medical University, China*
[c] *Centre for Smart Health, School of Nursing, The Hong Kong Polytechnic University, HKSAR, China*

Abstract

More and more researchers have recommended critically ill patients to start mobilization as early as possible. However, the clinical utilization rate of early mobilization remains low for patients in the intensive care units (ICU) because of various factors. In order to promote the rehabilitation of critically ill patients, a multidisciplinary research team, including academic researchers, ICU head nurses, respiratory therapists, and a software engineer, has developed a virtual reality system for early mobilization in ICU. This system has four main features-the diverse forms of mobilization based on muscle strength, the integration of exercise and cognitive training, the visualization of the mobilization process and the record of the trajectory during mobilization exercises. This paper presents and discusses the development process of this system.

Keywords:

Critical illness, early mobilization, virtual reality

Introduction

With the advancement of medical technology, researchers concern not only the increase in survival rate with technology, but also the quality of rehabilitation of critically ill patients[1]. Traditionally, rehabilitation begins after patients are discharged from ICU, which could be too late for the recovery of physical and cognitive functions, causing a majority of ICU patients to lose their ability of independent living and the quality of life[2]. In recent years, researchers have suggested that early mobilization for critically ill patients during treatment in ICU can circumvent many complications, reduce the hospitalization length and improve their quality of life[3]. However, the current implementation of early mobilization in ICU is not well administered. The main reasons are due to the shortage of medical staff, equipment and other resources, and more importantly, patient's unwillingness to exercise. Therefore, it is necessary to explore methods to improve the motivation and compliance of critically ill patients towards early mobilization. Recently, many researchers have used information technology to assist patients in the rehabilitation process, where virtual reality technology, as novel information technology, has the potential to meet the needs of promoting early mobilization concerned with this research. Hence, our team has developed a virtual reality system to assist ICU patients and record their progress in early mobilization. The system is presented and discussed in this paper.

Methods

A multidisciplinary research team including academic researchers, ICU nurses, respiratory therapists, and a software engineer was set up. The team had been involved in designing early mobilization strategies for ICU. ICU nurses and respiratory therapists have rich experience in critical care and early mobilization.

Stage 1: Alpha Version of the System

After reviewing literatures on ICU early mobilization and making reference to clinical experience, our research team came to the conclusion that early mobilization of ICU patients would be administered based on the muscle strength of their upper and lower extremities as measured by the MRC Muscle Scale; and that mobilization would be performed step by step. Then, the functions of the system were determined, which included diverse forms of mobilization based on muscle strength, integrating exercise and cognitive training, the visualization of the mobilization process and the record of the trajectories during mobilization exercises.

Stage 2: Beta Version of the System

The alpha version of the system was refined based on the result of stage 1. It was re-programmed to increase the ease of use by providing a user-friendly interface. The fidelity of the system was also improved by modifying the algorithms and parameters of the computer program so as to better capture the motion of the lower limbs.

Results

The virtual reality early mobilization system for critically ill patients has been developed after several rounds of discussion and modification. Before using this system, the medical staff is required to assess the patient's basic vital sign and muscle strength. In the first page of the system, medical staff should fill in patients' name, age, gender and muscle strength (Figure 1). Based on the inputs, they are provided with suggestions on the form of early mobilization, the dosage, and intensity that are suitable for the patients. The four basic functions of the system are described as follows.

Figure 1– First page of the system

Function 1: Diverse forms of mobilization based on MRC

This function is to identify the best form of early mobilization for patients according to their muscle strength, which is depicted in Figure 2. For example, patients with an MRC Score

of 2 for their upper extremity muscle strength need to complete plane movement, fisting activity, and wrist flexion.

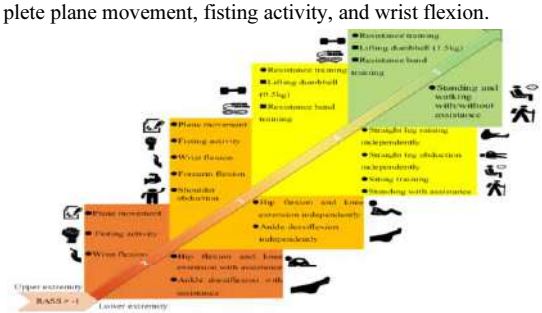

Figure 2–Different mobilization strategies

Function 2: Integration of exercise and cognitive training

With this system, every patient is suggested to receive various physical and cognitive training. For instance, patients with an MRC Score of 2 for upper extremity muscle strength need to complete plane movement integrated with cognitive training, in which patients are guided to write or draw using a visual sensing device. When the MRC Score for the upper limb is greater than 3, a variety of exercise games are recommended for the patients to choose. The games require patients to make a decision and stimulate their thinking while motivating them to exercise more and making it an enjoyable process as a whole.

Function 3: Visualization of the mobilization process

After adjusting the devices and computer, data about the movement of the critically ill patients can be transmitted to a laptop, where all the processes of the mobilization can be visualized. In some games, the virtual person appearing on the screen could follow the actions of the patient. Standard exercise indicators are displayed on the screen to assist patients to judge by themselves whether their movements are correctly performed. Furthermore, in the games of playing piano, jumping frog and others, patients can gradually increase the intensity of exercise and target at the higher game score, which is helpful to increase the interest and motivation of early mobilization. By adding algorithms into the program, the ability of patients in meeting the criteria of mobilization can be judged and the frequency of exercise can be recorded.

Function 4: Record of trajectory during exercises

The trajectory during mobilization exercises can be recorded by the system by capturing the patient's movement with a camera. In the later stage, the trajectories of daily mobilization exercises can be compared, which can fully reflect the rehabilitation trend of the patient.

Discussion

This is the first study to develop a virtual reality system on early mobilization for critically ill patients. It is well known that there are many barriers in implementing early mobilization for patients in ICU, such as patient-associated factors, structural issues, process factors, and cultural factors. Among these factors, patient's willingness is the most important factor that is difficult to deal with. According to clinical investigation, patients with critical illness often show frailty, indifference, and melancholy, which are partly due to the physical diseases and the psychological status of the patients. Medical staff should recognize the true state of patients, and then remove the discomfort from patients, and actively encourage them to exercise as early as possible. However, ICU medical staff already have a heavy workload. It is difficult to carry out early mobilization for the patients. The development of this system can help improve compliance of critically ill patients on early mobilization. The usual care in ICU could make patients feel boring, making it difficult to adhere to and achieve the effect of rehabilitation. The proposed system utilizes virtual reality technology to enable patients to gain interesting experience with various forms of exercise, making them more willing to participate actively in rehabilitation therapy. This system can also reduce the workload and pressure on the medical staff.

One of the innovations of the system is the integration of exercise and cognitive training. Although some studies tried to combine early mobilization and cognitive training, the two interventions were separate and patients have to receive them independently. In addition, exercise games are goal-oriented, giving patients a good sense of achievement when they achieve their goals. More importantly, the usage of the system does not require patients to wear or carry any objects. Patients can use their fingers as a pen to interact with computer programs, thus making them feel more natural when doing the exercises.

Another innovation of the system is to record the trajectory of exercises for critically ill patients. The dynamic changes of patients' movement are often difficult to capture and describe clearly. This system allows for the visualization of patients' movement during the whole process, which can also be recorded for analysis. With this function, the patient can understand their progress and the effect of rehabilitation more intuitively, which is beneficial to enhance their belief and confidence in early mobilization. For medical staff, the system provides more detailed data and record about the progress of recovery.

A limitation of this study is that it targets only at patients who are awake and with moderate muscle strength, For patients in coma or with lower MCR Score, medical staff is still required to perform passive or assistive exercise intervention for the patients. We will conduct research on this aspect in the pursuit of research breakthroughs.

Conclusions

This study described the development process of a virtual reality system by a multidisciplinary research team for early mobilization in ICU. The system is developed with novel design concepts and practical features. It can be applied to promote early mobilization of critically ill patients. This system motivates patients to exercise with engaging designs and records the trajectory of mobilization and rehabilitation. A further improved version of the system will be developed after addressing the comments from clinical experts and patients. The system has the potential to enhance the rehabilitation and the quality of life for ICU patients. It is expected to play an important role in clinical applications.

Twenty Plus Years of Distance Learning: Lessons Learned

Elizabeth Weiner[a], Ryan McNew[a], Jeffry Gordon[a], Patricia Trangenstein[a], Keith Wood[a]

[a] *Frist Nursing Informatics Center, Vanderbilt University School of Nursing, Nashville, TN, USA*

Abstract

Private institutions of higher education in the United States were hesitant to institute programs of distance learning for fear that they could not maintain the quality of the education they had delivered in face-to-face programs. Vanderbilt University allowed their School of Nursing to embark on such an endeavor in 1996, as long as quality measures were incorporated. The result has been a comprehensive resource support team using Quality Matters and an increase in program rankings.

Keywords:
Distance Education, Online Learning, Online Education

Introduction

In the 1990s, the Masters of Science in Nursing (MSN) program at Vanderbilt University School of Nursing (VUSN) was a relatively small, high quality, boutique program solely aimed at students within commuting distance of the campus. Growing the program required steps to accommodate a different type of student—the distance learner—who in turn brought about a completely new set of challenges.

The first specialty to implement a modified distance option was the Psychiatric Mental Health Nurse Practitioner program in the fall of 1996. They started by video streaming classes while simultaneously recording sessions for later distribution. Bandwidth in many of the rural areas prohibited quality viewing, so the IT support staff of five resorted to pressing CDs and mailing them out within 24 hours of the class.

Dean Colleen Conway-Welch determined that leadership was needed to guide the school through the various barriers to deliver quality online education. She had the vision to hire a Senior Associate Dean for Informatics. That individual assumed the responsibility of guiding the expansion of the program using "at a distance" tools and then identified and hired the additional staff needed for support. Support and quality became the cornerstones of all subsequent planning, implementation, and evaluation.

While the initial intent was to expand enrollments because the regional area had been saturated with nurse practitioner graduates, it soon became clear that other programs were seeing rising student satisfaction studies with online learning as faculty became more skilled with the online learning environment [1]. Furthermore, the quality of online courses was becoming the same as, or better than, traditional face-to-face courses [2].

This poster will explore the lessons learned during this 23-year journey. The design of the poster will be completed using innovative interactive software that will allow users to use smartphone technologies to further explore various subjects using augmented reality to visualize additional multimedia materials.

Methods

Staffing

When the Senior Associate Dean for Informatics was hired, she shared her vision for a comprehensive technology and informatics support team. As a condition of her employment, she received institutional commitment that a team approach would be employed to provide the best support model, prepared in a range of skill sets from networking to instructional design.

Technology Tool Set

Each year the informatics support team has chosen the hardware and software solutions that best meet the needs of the faculty. Decisions are made on which tools will be supported so that duplicate videoconferencing solutions, for example, do not exist. All software purchases have been centralized under the informatics area, including grant purchases. This decision has resulted in more effective support and more efficient purchasing.

Student and Faculty Orientation

Orientation activities are crucial to every academic year, and are presented both online and during the face-to-face sessions at the beginning of the academic year. Configuration sessions are critical so that all devices are equipped with the appropriate software tools and can attach to the university network. Once students are at home, they need to be able to make the appropriate connections so that they can successfully use their technology tools for learning. Students are instructed to call or email for any support or connection issues once they are back in their home environment.

Quality Standards

For the last ten years, VUSN has subscribed to the Quality Matters (QM) framework. Skiba describes this framework as being built upon eight standards derived from current research [3]. The framework is based on the assumption that quality online education is represented by institutional commitment to quality. Two instructional designers trained in the QM framework work with faculty to help them meet the criteria incorporated in the QM rubric [4]. The rubric is used to examine eight general standards for course design. The rubric also incorporates the concept of alignment, which refers to several essential course components working together to achieve desired outcomes.

Results

Staffing

Five technology support people were at VUSN when the Senior Associate Dean for Informatics was hired in 2000. Implementing her vision for comprehensive support, the team has now grown to 28. Positions include classroom support, computer lab coordinator, network manager, web developer, graphic artists, general IT support, instructional designers, program coordinator, videographers, materials coordinator, videographers, media services, programmers, simulation staff, and informatics faculty. Enrollments have more than tripled, reaching as high as 1000 students in the MSN, DNP, and PhD programs.

Technology Tool Set

In order to effectively manage on-site delivery of the technology, the network infrastructure was strengthened with all classrooms and offices having wired and wireless connections. Electronic classrooms have been updated to include the Crestron control system [5]. Hardware guidelines are agreed upon annually and communicated to students along with the software.

Software solutions include:

- digital video streaming via Mediasite,
- web conferencing via BlueJeans,
- clinical log via Medatrax,
- secure large file exchange via Box, s
- ecure testing via Remote Proctor,
- video case studies via ReelDx ,
- simulation software via B-Line Medical,
- instructional design software via Lectora,
- plagiarism checker via Turn-It-In,
- digital signatures via Adobe Acrobat,
- remote support via Team Viewer,
- course management via Brightspace, and
- Microsoft Office Productivity suite.

Student and Faculty Orientation

VUSN teaches courses year-round so that the August orientation starts the beginning of all classes. During this time, each program has week-long orientation activities. Reviewing technology standards is important to all programs, along with the configuration of all their devices to connect back to VUSN from anywhere in the world. New faculty are oriented online via technology support and solutions, and returning faculty are updated at the annual Fall Faculty meeting. Further support is provided online including a Tech Tools section of the VUSN website along with a Knowledge Base.

Quality Standards

The Institute of Medicine defines a learning healthcare system as a system in which "science, informatics, incentives, and culture are aligned for continuous improvement and innovation, with best practices seamlessly embedded in the delivery process and new knowledge captured as an integral by-product of the delivery experience [6]." The Learning Health System Cycle is further described by Friedman as being cyclical in nature with the steps of "assemble, analyze, feedback, and change [7]." This same process has been used by VUSN through course evaluations at the end of each course, curriculum evaluations through course portfolio reviews across all programs, and surveys regarding distance learning support completed by faculty and staff every two years.

All MSN and DNP courses have introduced an interactive course template that guides them through the appropriate planning stages that maps the objectives with outcomes. Current efforts are on increasing course interactivity, and the QM rubric is being used internally to help all faculty improve the quality of their courses. Feedback from students is received via standardized course evaluations along with a survey sent out to students every other year about the technology support. All evaluations have been extremely positive (4.95 on a 5 point scale) with minor suggestions for improvement.

Program rankings have all risen during the 23 years of online learning. Rankings in 2019 for VUSN were eight for the MSN program, and five for the DNP program, marking the first time that both programs have been in the top 10 [8]. In addition, throughout the 23-year period all VUSN programs have maintained accreditation by national nursing bodies, demonstrating that by offering education in an online fashion quality was at least equal to, if not higher than, face-to-face delivery of programs.

Conclusions: Lessons Learned

The lessons learned from over twenty years of experience can be summarized by the following important considerations. Quality (from an organizational commitment and framework), comprehensive support team, leadership at the Senior Associate Dean level, a strong network infrastructure, standardized hardware and software, student and faculty orientation activities followed by web tools, and feedback from users including both faculty and students followed by revision of activities. Late lessons included the need for a remote proctor tool with browser lockdown, the addition of a searchable knowledgebase, and the need to be active participants at the university level for campus-wide selection of online tools. Maintaining faculty engagement continues to be a challenge due to a number of off-site classes rather than being taught from faculty offices.

A Precision Post-Operative Wellness Monitoring Solution

Nilmini Wickramasinghe[a,b], Vijay Gehlot[c], Elliot Sloane[c], Phil Smart[b,d] and Jonathan Schaffer[e]

[a] *Swinburne University, Australia*
[b] *Epworth HealthCare, Australia*

[d] *The Austin, Australia*
[e] *The Cleveland Clinic, USA*

Abstract

Multiple orthogonal challenges around escalating costs and providing quality care plague healthcare delivery, especially in OECD countries. This research in progress paper addresses the post-operative discharge phase of the patient journey and proffers a technology-enabled model that both supports a quality care experience post-discharge but also prudent management to minimise costly unplanned readmissions and thereby subscribe to a value-based care paradigm. The chosen context is stoma patients but the solution can be easily generalised to other contexts. Next steps include the conduct of clinical trials to establish proof of concept, validity and usability.

Keywords:

Patient Readmission, Patient-Centered Care, Patient Monitoring

Introduction

Given the challenges facing private healthcare today, there is an increasing pressure on private healthcare organisations to provide high value, high-quality patient-centred care across the acute-care continuum (Australian Commission on Safety and Quality in Healthcare 2010 [1]). While the recognition for the need of care delivery to be patient-centric is growing, the appropriateness of the approaches adopted to achieving this endeavour remains questionable [2].

An integral enabler is without question Information Technology (IT) solutions (see for example [3]). The limitation with many current systems is their limited coverage across the acute-care continuum [4], where both pre-admission and post-discharge phases are not seamlessly connected to the hospitalisation phase in the patient journey.

In Australia, as in other OECD countries, most notably the US, unplanned readmissions are now becoming more carefully scrutinised. In most instances in Australia, unplanned readmissions are considered to be readmissions for issues relating to the primary diagnosis within 28 days of the initial treatment for that primary diagnosis. We believe that it may be possible to reduce the number of unplanned readmission by developing a precision post discharge wellness monitoring solution and the following serve to outline this solution.

We select stoma patients as a pilot study for this solution because we note that based on hospital data gathered from a large not-for-profit tertiary institute in Melbourne, Australia a common and avoidable unplanned readmission relating to stoma patients is around lack of hydration. This is particularly problematic during the hot dry Australian summer months.

This study proposes a generic, open-source-based starting point for a customizable modeling, simulation and testing framework for mobile Patient Care Devices (PCDs) that can support relatively complex coordination of care for post-surgical patients. This system uses an architecture that can be modified to suit each patient's precise needs or widely differing clinical protocols. These tools allow simulation of expected ranges of safe and reliable performance, and can also be used to explore or simulate likely failure modes and potential safety or health risks due to communication system or staffing overload, errors, or other complications

Clinical Use Case

In order to provide proactive patient care post-discharge following stoma surgery, several remote medical devices can be employed. For example, elevated patient temperature or pulse can indicate an emerging infection at home which might easily and inexpensively be treated by early intervention with an appropriate antibiotic. High blood pressure and pulse might be an indicator of patient pain or discomfort, which might be initially treated with basic over-the-counter anti-inflammatory medications. Low blood pressure and elevated pulse might be predictors of dehydration, which might readily be treated by drinking more fluids and electrolytes. The stoma bag may also be monitored with simple sensors that keep track of filling and emptying rates, providing an indication of inadequate food and liquid intake.

In all cases, the monitored patient wellness parameters can be routed to a central patient homecare coordination team. The care coordination team can invoke appropriate rules and treatment actions. For example, a care coordinator could call the patient/family, provide remediation guidance, education, and/or prescriptions. If needed, a visiting nurse or physician could be dispatched to provide in-home care.

In addition, the monitors and the data monitoring systems can have an alarm and/or alert level triggers pre-set or remotely adjusted. Thus, if a low-grade fever appears to be emerging, the patient, family, or care coordination team could increase the temperature alarm by one degree, to notify them if/when the fever becomes more severe. Similarly, a high and low blood pressure alarm could be pre-established based on the patient's

discharge condition, in order to alert caregivers of unusual emerging risks.

Once a patient's physiological data is available to the care coordination system and team, clinical decision support algorithms and systems can be used to enhance, accelerate, and escalate emerging patient risks to staff who are appropriately trained to support high-quality, safe home care for discharged patients. Intervention at the home will usually be far less expensive than re-admission to the hospital, and care plan changes can often occur quickly. The care coordination team will be able to arrange emergency care or transport if home-care turns out to be inadequate for a specific patient situation.

Because many physiologic monitoring devices are now becoming rather inexpensive and ubiquitous, and they rely on consumer-grade internet or cellular communication channels, the incremental cost of deploying such systems is falling rapidly. In addition, many of these devices can be cleaned and re-used for subsequent patients.

In the following sections, we illustrate the system design and simulation of a flexible home-care monitoring and care coordination system. We identify representative monitoring devices, but the model is extensible. Additional monitoring devices and data can easily be added. e.g., in some cases, patient weight may be a valuable indicator of dehydration, or of congestive heart failure complications. Adding a patient scale and decision support rules is very easy with this system.

In addition, this system could easily be extended to include patient co-morbidities. For example, a severe industrial or automobile trauma patient could conceivably be sent home with both a stoma bag and a hip replacement. If that were the situation, additional physiologic channels may be added, such as gait and PT/exercise/mobility tracking and analysis.

Results and Discussions

The previous section has served to proffer an appropriate solution leveraging the capabilities of various technologies. The aim is to monitor patients as unobtrusively as possible so that alerts can be triggered to inform the designated healthcare professional if a trigger incident has occurred that should be addressed. In this way, the patient is able to navigate the post-discharge phase of their treatment effectively and efficiently and with the highest level of a positive patient and caregiver experience. In addition, by having alerts triggered no sooner a trigger situation arises, it is also possible to act as quickly as possible, thereby averting a more complicated, dangerous, and/or expensive problem further down the track. In this way, we believe we are addressing two critical objectives of healthcare delivery simultaneously; namely providing a high-quality patient experience as well as providing a high-value solution as we are trying to mitigate the need for unplanned readmissions by catching trigger situations as early as possible and then addressing them.

The next step is to run a two-arm non-blinded clinical trial to test the full benefits of the proposed solution. The control arm will continue to have patients exposed to standard practices around discharge and post-discharge follow up and monitoring while the intervention arm will focus on utilising the developed technology solution in addition to standard care practices around discharge and post-discharge. In particular, we plan to monitor levels of hydration, using triggers of blood pressure, pulse and weight to trigger levels going below an appropriate threshold. In addition, patients will receive via their mobile phones, education, reminders and other important information about maintaining appropriate levels of hydration. We focus on hydration as this has been identified as the singular most frequent reason for unplanned readmission with stoma patients at the chosen healthcare facility. We have secured ethics committee approval, and plan to run this trial as soon as final clinical post-discharge protocols are complete, validated, and approved and patient recruitment is complete.

Conclusions

This research in progress has served to proffer a solution to address the post-discharge phase of stoma patients. The proffered technology-enabled solution support both a high-quality patient experience as well as supporting a value-based care paradigm. We contend that such solutions are not just useful in the context as we have presented; i.e., stoma patients, but can be applied more generally so that the post-discharge phase of the patient journey is also monitored and managed, enabling both a high-quality patient experience as well as prudent management of likely trigger situations that may if not addressed lead to unplanned readmissions. Given the challenges faced by all OECD countries with respect to the exponential costs to provide quality care and the increasing pressures on healthcare organisations to deliver high quality and high-value care, we believe such technology solutions are strategic necessities and must be carefully considered. Our future work will focus on conducting clinical trials to establish the validity, usability and proof of concept of the proffered solution.

Acknowledgements

We acknowledge the healthcare organizations who have assisted us in the work to date and will continue to assist us as we move forward with planned clinical trials.

Continuous Video Recording of Electronic Health Record User Sessions to Support Usability and Safety

Adam Wright[a,b,c], Skye Aaron[a], Gianna Zuccotti[a,b,c]

[a] *Brigham & Women's Hospital, Boston, MA,*
[b] *Harvard Medical School, Boston, MA,*
[c] *Partners HealthCare, Boston, MA*

Abstract

Electronic health records (EHRs) have been shown to improve safety and quality. However, usability and safety issues with EHRs have been reported. The current state of the art in usability testing is to have clinicians conduct simulated activities in a usability lab. In this poster, we describe our experience with continuous recording of real-world EHR use to improve safety and usability.

Keywords:
Electronic Health Records, Patient Safety

Introduction

There is ample evidence that electronic health records (EHRs), when implemented and used effectively, are associated with increased quality of care and safety [1]. However, significant usability and safety issues [3] with EHRs have been reported, including instances of patient harm [4]. Usability has been found to play a major role in the exacerbation and prevention of health information technology (HIT) hazards, and has been identified as a critical component of safe HIT use [3]. Poor usability has been shown to put patients at risk by impeding HIT adoption and workflow, decreasing clinician satisfaction and productivity, and directly causing clinical errors [2].

The current state of the art for usability evaluation of clinical information systems is to have clinicians conduct simulated activities in a usability lab. Less commonly, a usability researcher observes the clinician during routine care. These approaches are useful, but limit the amount of data that can be collected. This is particularly challenging for assessing the usability of infrequently used workflows (such as organ transplant or cardiac arrest documentation) that are unlikely to be observed naturalistically.

Citrix provides application virtualization services and is used with many EHRs, also offers session recording software. This feature allows for efficient capture and archiving of full-screen videos of applications running through Citrix. We describe a pilot study to assess the usefulness of this functionality for usability and safety research.

Methods

We installed and configured session recording on our Citrix environment, and enabled recording for a group of pilot users. Videos are captured whenever users use our Epic EHR. Only Epic activity is recorded; local application activity such as email or web browsing is not captured. A system diagram is shown in Figure 1.

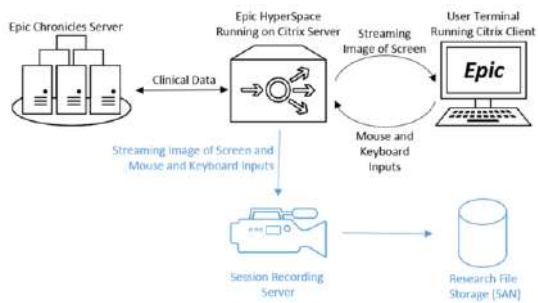

Figure 1– System Diagram of Screen Capture

Results

In early pilot testing, we found the videos to be useful, and there was no measurable impact on system performance or reliability. Videos consumed 14 megabytes per hour, which exceeds Citrix's published estimate of 4 megabytes per hour but is still reasonable. Extrapolating across Partners HealthCare system, there are approximately 22 million Epic sessions per year, with a typical session lasting about 10 minutes (with considerable variability). This would yield 3,704,458 hours of video per year, hence a year's worth of videos would require approximately 51.8 terabytes of storage. We currently pay 12.96 cents/gb/yr for storage, yielding a cost of $6,713 to store videos internally. If we used an archival storage system, costs would fall to a third of this amount.

Figure 2 shows our current approach for identifying videos to review, indexing, and analyzing them. Our approach adopts a series of general and EHR-specific usability tools, standards, and processes. In pilot testing, videos were manual retried, and could be tedious; we are in the process of developing indexing tools to make video retrieval more straightforward.

Discussion and Conclusion

In early pilot testing, we found Citrix session recording feasible and useful. Special challenges included system upgrades and dual monitors. We plan to extend our pilot to additional users and collect more data. We are also planning to

improve indexing capabilities to make it easier to retrieve videos that correspond to specific events in the EHR transaction log. When complete, we will be able to launch directly to the video of a workflow under investigation. For example, the video of a user adding a particular allergy or using a particular function. We anticipate this functionality will have broad-based application for quality and safety, as well as for usability and system redesign.

Acknowledgements

The authors appreciate the assistance of the Partners HealthCare Citrix team in implementing the tool, as well as valuable feedback from usability personnel at Partners, who have provided feedback on the tools, processes and videos.

Abstract

Intelligent conversation agents (ICAs) have been used for patient self-management and support in recent years. This study systematically reviewed ICA resarch and innovation in academic and industrial institutions using bibliometric and patent analysis. We reported the types of diseases and patients, and the ICAs delivery approaches for patient-self-management. We identified the gaps in the productivity and focused areas.

Keywords:
self-management, patients, conversational agent

Introduction

The Intelligent conversational agent (ICA) (e.g., Amazon Alexa and Apple Siri) is an application that enables natural language communication with users [1]. The human-like communication nature of ICAs is making themselves very popular. Clinical analysts foresee that ICAs can potentially improve patient care in terms of symptom management, caregiver engagement, and patient support [2]. A recent systematic review on conversational agents in healthcare has shown that ICAs has addressed health issues related to psychotherapy support, education, self-monitoring, and data collection for consumers (e.g., patients), caregiver, or healthcare professionals [3]. However, no study to-date has explicitly focused on how ICAs support patient self-management in a non-clinical setting.

Patents are associated with research and mirror technology development and investment trends in a particular domain [4]. Analyzing patent records, thus, will help understand the state of the art of technology development and the landscape of the innovations. This study aimed to use data from both publications and patents to systematically investigate ICA research and innovation for patient self-management in home settings.

Methods

Data Collection

The research publications were retrieved from five citation databases (i.e., PubMed, Scopus, CINAHL, EMBASE, ACM D-Library). The granted patent and published applications were retrieved from the Derwent Innovation Index (DII) which has a comprehensive coverage of 40 worldwide patent-issuing authorities. The searches in citation databases and DII were executed with the same search strategies in August 2018. The search term consists of three parts, the ICA related terms, self-management related terms, and patient related terms. The ICA related terms included about 100 synonyms and term variations (e.g., voice-activated interface, conversational assistant, chatbots). The self-management related terms included about 20 synonyms and term variations (e.g., self-management, self-care, self-efficacy, supportive care). The patient related terms included 13 synonyms and term variations (e.g., patients, caregivers, sufferer, and survivor). In addition, this study collected publications identified through citations of retrieved research papers and from grey literatures.

Screening Critiria

The title and abstract fields of the retrieved publications and patent were screened by three of researchers (i.e., ZX, FY, & YQ) via Covidence [5]. Disagreement was resolved among researchers in group discussion. A publication or patent was included if it 1) adopted natural language interaction either in written, graphical or voice-activated communication modality, 2) was designed for patients, caregiver or customers. A publication or patent was excluded if it 1) discussed only partial techniques of ICAs such as automatic speech recognition, natural language understanding, dialogue management, response generation, or text-to-speech synthesis; 2) had limited and predefined interaction model (e.g., Voice-Activated-Dialing which only allows number as input); 3) had missing titles or abstract.

Data Abstraction and Analysis

For publications, we extracted the following data fields: authors, publication year, affiliation, title, and abstract. For patent, we extracted the inventor, priority date, assignee, title, and abstract. All included patent applications were filed before 2018 because patent applications are generally published 18 months after the earliest priority date.

In this study, VOSviewer [6] was employed to extract and visualize the key terms from both the title and abstract fields for included publication and patent records. We set the threshold of minimum key term occurrence as 3 for publication records and as 1 for patent records in mapping graph, for appropriate visual effects. In addition, the synonyms and variations of an extracted key term were merged and controlled for visualization using a thesaurus (e.g., "child" and "kid" merge to "child").

Results & Discussion

Data Description

We retrieved a total of 1835 publications from PubMed (N=751), EMBASE (N=137), CINAHL (N=29), Scopus

(N=687), ACM Digital Library (N=231), 535 patent records from DII, and 12 additional records from the citations of the patents. We included 91 publications and 21 patents in the analysis after title-abstract screening and removal of duplicate records. The publications were contributed by 128 institutions from 28 countries, whereas the patents were from 22 patent assignees (i.e., 16 companies and 6 individuals) from 5 countries. The United States is the leading country in the numbers of publications and granted patents. Particularly, the Northeast University and Boston University have had the most research productivity. Regarding the patents, Koninklijke Philips N.V. from Netherlands had three patents and each of the rest assignees have had less than three.

Topic Mapping

The key terms extracted from the publications and patents were visualized and compared based on types of diseases and patients and delivery approaches to patent self-management.

The Types of Disease and Patient

Compared with patents, the publications reported more types of diseases and patients (Fig 1). The publications reported that ICAs were developed to address chronic conditions (e.g., "diabetes", "cancer", "stroke", "hypertension"), mental disorders (e.g., "autism", "dementia", "post-traumatic stress disorder"), and emotional issues (e.g., "depression", "anxiety", "stress", "mindfulness"). The targeted users included "child", "elderly", "young", "woman", "mother", and "pregnant (women)". As displayed in Fig 2, the patents have focused on health conditions such as diabetes, communication disorders, and skin issues (e.g., "lesion"). Patterns have not specified the types of targeted patients but used a general term "user" instead.

The Delivery Approach of Self-Managment Support

The topics related to health interventions in the publications included "psychotherapy", "neurorehabilitation", "virtual interviewer" whereas the patents tended to be uniquely designed with customized support (e.g., "interaction plan", "first conversation", "user profile", "patient relationship model") based on user data ("user data", "medical record") and dialogue context (e.g., "dialogue context", "context pattern"). This customized support has not been observed in publications.

Nevertheless, the publications and patents under review demonstrated common interests such as patient's decision-making support (e.g., "patient coaching" and "health consultation") and user/patient behaviors (e.g., "behavior change", "behavioral intervention" in the publication and "dialogue behavior" in the patents). They also discussed multi-modal interaction modality in ICAs. Specifically, publications described "multimodal interaction", "embodied agent" and the patents discussed "graphical interface", "voice interface", "animation".

Conclusions

To our knowledge, this is the first study that has systematically examined ICA research and innovations for patient self-management using data extracted from both publications and patents. We have found that the ICA research and innovation in patient self-management is in its infancy. The total numbers of publications and patents are small. The ICAs to-date have mostly focused on patient coaching, consultations for decisional support and behavioral changes. In addition, the academia and industry have focused on different types of diseases and patients, and on various delivery approaches to self-management support by ICAs. However, they also share some common topic interests, such as multi-modal interaction ICAs. The diversity may lead to a broad spectrum of ICA applications in health care whereas the commonality may indicate the topical trends in the near future.

Abstract

We investigated problems concerning medical imaging management using PACS in medical settings through text analysis. We conducted a questionnaire survey in Hokkaido, Japan, where PACS related problems were described by radiological technologists. After analyzing the descriptions in response to the questionnaire, we detected four main problems in PACS using a word co-occurrence network; i) image management, ii) image fetching error, iii) DICOM violation and iv) name notation.

Keywords:

Management Information Systems, Educational Measurement, Computers

Introduction

DICOM (Digital Imaging and Communications in Medicine) standard, which is the standard in the medical information field, provides a seamless connection, clinical image, and data sharing when introducing new devices to medical institutions. However, the details of the functions of PACS (Picture Archiving and Communication Systems) depend on the specifications of each medical equipment manufacturer. In Japan, especially in local cities, medical professionals, such as radiological technologists, who are not specialized in medical information, often struggle to manage PACS during their professional work. Occasionally, serious problems with the PACS system occur when medical staff are unable to confirm the interface with image scanners or hospital information systems. When such an incident occurs, it disrupts the delivery of routine examinations. Several studies about the introduction factors of PACS have been analyzed [1]. However, there are few studies investigating problems concerning medical imaging management using PACS in medical settings.

The purpose of our study was to identify problems of image transfer and storage related to PACS specifications to avoid any serious trouble.

Methods

261 hospitals have introduced PACS in Hokkaido prefecture, which is the northern part of Japan. We sent questionnaires by mail to presidents and leaders of radiologic technologists in all of the hospitals, and they input the answers on the specialized web site we developed (from February to March in 2018). In the questionnaire, there were some questions about the hospital (Table 1) and we made open-ended statements (seeking arbitrary endings) about troubling cases related to the operation of PACS and critical points of operation. Table 1 shows examples of items in the questionnaire.

Table 1 Items of the questionnaire in hospital attribution

Items
The number of beds
Having or not medical information system correspondents in radiology department
Who are PACS correspondents in the hospiral
Introduction time of PACS
Capacity of PACS
Problem cases and issue related to operation of PACS

After collecting questionnaires, we added up numbers and analyzed the open-ended statements by natural language processing (NLP). In NLP, we conducted morphological analysis using ChaSen [2] at first. Since ChaSen is a dictionary-based morphological analyzer, words that are not included in the dictionary are output as unknown words. In this study, we used ipadic-2.4.4 as Japanese dictionary for morphorogical analysis. Then, the number of words were counted. Next, we developed a word co-occurrence network using the co-occurrence of the words that appeared more than twice, to clarify the problems related to image transfer and storage in PACS. Jaccard index was used as a co-occurrence index.

$$\text{Jaccard index} = \frac{a}{F_1 + F_2 - a}$$

Where, F_1 represents the total number of sentences where word "A" appears, F_2 represents the total number of sentences where word "B" appears, a represents the total number of sentences where A and B both appear.

We used a free software KH coder 2 [3] for a series of procedures from morphological analysis to developing the co-occurrence network. The questionnaire survey was conducted with the approval of the Hokkaido University of Science Ethics Committee.

Results

There were 94 responses (collection rate: 36%). The number of completed opened ended responses was 39.

About half of the hospitals had fewer than 100 beds. The number of radiological technologists in each hospital was 1~58 and 20% of the hospitals had fewer than 10 technologists. 84% of the hospitals had radiological technologists who manage PACS.

In the results of morphological analysis, we extracted 441 words. Regarding the high frequency of words, image (34), PACS (12), fetching (9), DICOM, (6) and data (6) were recorded (Table2).

Table 2 Example of word appearance in each part of speech

noun	n.	verb	n.	Unknown word	n.
画像 (image)	34	行う (conduct)	7	PACS	12
取り込み (fetching)	9	取り込める (can fetch)	4	DICOM	6
データ (data)	7	取り込む (fetch)	3	CD	3
患者 (patient)	6	異なる (differ)	2	ID	3
情報 (information)	6	含む (include)	2	Tag	3
モダリティ (modality)	5	考える (consider)	2	CS	3
管理 (manegement)	5	困る (difficulty)	2	PC	2
医師 (doctor)	4	思う (think)	2	RIS	2
サーバー (server)	3	取り交わす (exchange)	2	パブリッシャー(Publisher)	2

We represented the word co-occurrence network using 105 words to visualize co-occurrence relations among words. Common problems reported were regarding "image management," "image fetching error," "DICOM violation," and "name notation".

Table 3 items of the questionnaire

Category	Example
image management	Best storage period Defect of storage, education about virus Fetching video data
image fetching error	Can not import patient's data from CD made by other hospitals
DICOM violation	Patient data from other hospitals are DICOM violation
name notation	Handling of names of international people in kanji and kana characters which are Japanese characters

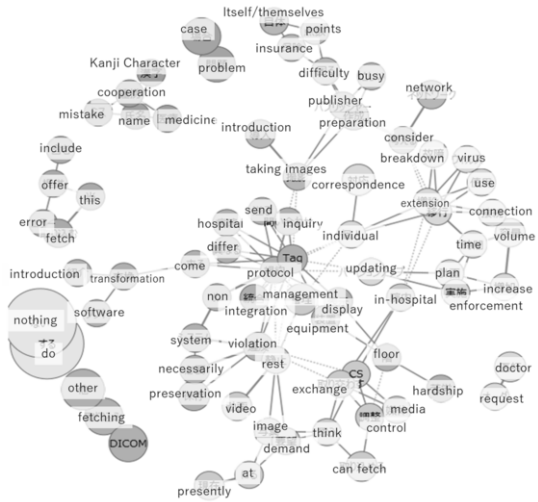

Figure 1 word co-occurence network

Conclusions

We clarified that radiological technologists engaged in PACS management in most of the hospitals, and there were four categories of problems when applying the guidelines in the medical setting; image management, image fetching error, DICOM violation and name notation. This study will contribute to developing user-friendly systems and consider making and revising guidelines or standardization.

[c] Department of Clinical Laboratory, University of Fukui, Fukui, Japan,
[d] Carecom co.,ltd, Tokyo,Japan

Abstract

As one of the countermeasures against infection at medical institutions, thorough hand hygiene is extremely important. In Japan, these controls are not sufficient. In order to do this management, it is necessary to track the hand washing situation. *Therefore, we decided to monitor the condition of hand washing by utilizing IoT.* Since there are environments where we can use IoT in our hospital, we decided to follow up using these environments. *As a result, it is possible to collect data continuously for 24 hours, 365 days, and evaluate infection risk based on data. In addition, our hospital can also obtain location information on smartphone, so we can also track work. We are considering support for medical staff by utilizing smart devices.*

Keywords:
Hand Hygiene, Infection Control, Medical Staff

Introduction

The World Health Organization (WHO) created hand hygiene guidelines in 2009. It saught compliance with hand hygiene at five timing. However, in the announcement of the Japan Society for Environmental Infections in 2017, our hand hygiene compliance rate is 38% on average, which is lower than much of the world, and the occurrence rate of resistant bacteria is very high compared to the Northern Europe such as Sweden. For this reason, we consider it necessary to reduce the infection rate.

Nurses who have many contact opportunities with patients are actively engaged in nosocomial infection prevention. They always carry disinfectants and maintain cleanliness of fingers, are cooperative in countermeasures against nosocomial infections, and the compliance rate of hand hygiene is higher than other medical treatments It shows a high price compared with the person. However, medical personnel other than doctors and nurses do not adequately comply with the WHO hand hygiene guidelines and are low consciousness.

Since Internet of Things (IoT) devices using Bluetooth and others can be used cheaply, the use of radio wave networks has begun to spread to solve medical problem problems. In our hospital, we can also use it for patient observation, and the positioning of medical staff is possible in the whole hospital as well. Using this kind of communication environment, we attempt to solve the problem of nosocomial infection control using hand hygiene disinfectant with IoT.

By visualizing the present state of hand hygiene using IoT and supplementing the management of infection control by utilizing the collected data, it is believed to lead to the creation of a safer medical environment. In addition, by evaluating hand hygiene for each medical doctor and giving feedback to individuals of medical personnel in real time, if there is a risk, educational effect can be obtained, and expectation can be expected for habitualization of behavior change of handicap and hand hygiene. Furthermore, we decided to aim for a method to use on a daily basis with smartphones and others.

Methods

In our hospital, we are strengthening the use of wireless communication as part of promoting medical ICT. Therefore, communication such as Bluetooth and ZigBee can be used. We have created and installed modules so that these communications can be used in hospitals. The configuration of the IoT gateway module is for converting from communication such as Bluetooth, Zigbee etc. to a Wifi connection to Wi-Fi. (Figure 1)

We developed this IoT gataway to acquire data and location information including alarms from medical devices and various sensors. We have already installed 1,500 IoT gataways in the hospital. In addition to this device, the staff distributes the smartphone as an extension, so this smartphone is used for location detection and personal identification.

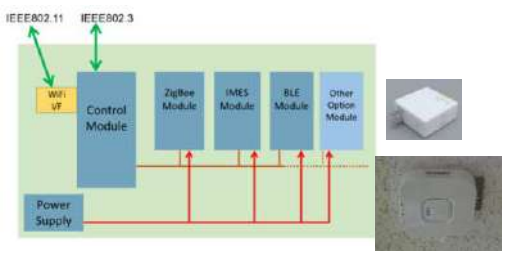

Figure 1 – Structure of IoT Hateway

We use a combination of smartphones and IoTgateway to detect medical staff locations. As a positioning method, Bluetooth low energy (BLE) beacon is performed by position calculation from multiple RSSI radio wave intensity measurements. In order to detect hand hygiene, it is necessary to detect the operating state of the disinfectant. For this reason, we created a mechanism to output a signal when the disinfectant was operated (Figure 2).

Figure 2 – Disinfection Pump Operation Detection Sensor

By combining the staff's flow line and disinfection pump operation, it is possible to detect the hand disinfection situation. In this way, it is possible to detect the hand disinfection situation at the time of entering the area or approaching the patient. By collecting these data continuously, it is possible to measure the required hand hygiene performance.

Results

In this system, positions and flow lines of staff are acquired with accuracy of approximately one meter (Figure 3). For this reason, we are making it possible to receive multiple BLE beacons at any location.

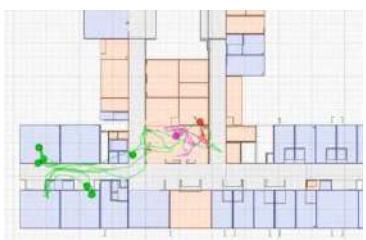

Figure 3 – Acquisition of Position and Flow Line of Staff

The fixed disinfection pump maps the coordinates of the installation position, and the carried disinfection pump is made to correspond to the person. Timing is determined by matching the operation signal of the disinfection pump with the position information. As a result, continuous measurement is possible , and it is possible to present collected hand hygiene data.

One result is the measurement result of the ICU. The status of hand hygiene compliance when entering the ICU and entering the patient area was (94.5%, 21.3%) by nurses (37 people), (64.3%, 12.5%) by anesthesiologists (5 people), (28.0%, 13.5%) by cardiac surgeons(6 person), (48.0%, 15.7%) by circulatory physicians (1 person), (100%, 18.2%) by physiotherapists (1 person), (100%, 100%) by nurse assistants (6 persons).

This is an ICU situation, but similar measurements are possible in hospital wards. By feedback the results of hand hygiene measurement, the hand hygiene action of the medical staff has improved. However, we believe that infection control is an inadequate condition.

Discussion

With this method, the compliance rate of hand hygiene can be measured steadily. However, simply presenting this compliance rate is insufficient for continuous improvement. Although there are advantages in terms of visualization of compliance status, there are many cases where it is limited to presenting data. In order to make this improvement, we need to develop a method that reflects our actual behavior. we think that real-time assistance should be provided in important situations for infection control.

Conclusions

By using this method, it is possible to measure the behavior of medial staff in real time, so it is necessary to consider a method to utilize this result. In our hospital, one staff member uses smartphones, so we believe that hand hygiene can be improved by adding a mechanism to notify warnings when hand hygiene is needed. In the future, we will consider implementation with smartphone notification function. We plan to develop from the location of the medical staff's smartphone to a system that can provide appropriate assistance notifications. This method can be used in the same way as patient monitoring in the future, so it can be used together with these devices. We are also considering combining it with the sensor used in the nurse call system. In such a combination, we believe that this method is widely available.

A Survey on Health Care and Health Concerning Workers for Considering Appropriate Personal Health Record Service

Mayumi Yoshida[a], Ryuichi Yamamoto[a]

[a] *Medical Information System Development Center, Tokyo, Japan*

Abstract

To prevent worsening of diabetes mellitus, we conducted a developmental research of personal health record (PHR), whereby affected individuals, medical staff and an insurer cooperate and manage effective treatment. Medical expenses can be suppressed by preventing the onset of lifestyle-related diseases. Companies can benefit from improved employee productivity by promoting healthy and efficient working styles. We conducted a health and medical consciousness survey to examine PHR models that are attractive for both employers and employees.

Keywords:
Personal Health Record, Survey

Introduction

In Japan, there is a universal insurance system that allows most people to have one health insurance. [1]. Company employees engage in corporate health insurance and mutual aid insurance coverage that are affiliated by employers. In addition, retirees and individual business owners subscribe to the National Health Insurance. Till date, the social security of Japan has been substantial, with the citizens receiving equally high-quality treatment, regardless of which medical institution they attended. However, with an increase in lifestyle diseases and acceleration of the ageing population, medical expenses are increasing and insurers are also being dealt with.

To prevent worsening of diabetes mellitus (DM), we conducted a developmental research of personal health record (PHR), whereby the affected persons, medical staff and insurer cooperate and manage effective treatment by themselves [2,3]]. In the case of mild diabetes, there is not much burden on patients and insurers. Patients can visit medical institutions once a month and receive appropriate treatment after examination and through medication at hospitals. However, when diabetes becomes severe, it results in renal failure, blindness, etc. For example, it is inevitable for patients to worsen their quality of life owing to the requirement of artificial dialysis. The burden of medical expenses is increased on both the patients and insurers. Alternatively, in Japan, companies tend to be concerned about their employee's health management.

Companies are also believed to contribute towards the improved productivity of their employees by promoting healthy and efficient working. To investigate the development of an attractive PHR model for both employers and employees, we conducted a preliminary survey on health and medical attitudes of 10,000 people residing in the country.

Methods

The survey included questions regarding the current health status, status of medical examination attendance, meals and sleep pattern, lifestyle habits, job types, working hours, preferred leisure activities and consciousness of own health. This web questionnaire survey was conducted in March 2018 after acquiring the consent of 10,000 workers aged >20 years in Japan. We allocated participants to different groups based on their age and sex. For each sex in their 20's, 30's, 40's and 50's, as a unit of 1,000 at the age of 10, >60's were taken as a group of 1,000 each, and total 10,000 people were targeted.

Results

Respondents included 41.7% children and 28.5% single people, with 32.7% involved in office work, 23.3% in professional and technical work and 12.9% in the service industry. Approximately 72.4% of the participants worked for 5 days a week and 13.5% for 6 days a week. Of 28.5% individuals currently undergoing treatment, 47.3% had confidence in their own health, 22.9% smoked regularly, 57.5% consumed alcohol and 46.8% preferred to sleep to rest. The main questionnaire results are listed below. When N is not displayed, N = 10000.

1. Regarding discomfort in the most concerned body part, the following was found: stiff neck in 36.1%; headache in 27.8%; lower back pain in 25.7%; and obesity in 10.8% patients.
2. Diseases under treatment included: hypertension 25.4%; dyslipidaemia 12.5%; lower back pain 11.1%; DM 10.7% patients (N = 2851).'.
3. For illness prevention, 70.4% received medical check-ups conducted by companies and municipalities.
4. The reasons for not receiving medical check-ups included the following (N = 2,959): 'Proceedings are troublesome' for 26.5%, 'Because I do not want to spend on such things' for 16.2% and 'I was unaware of health check-ups as such' for 12.0%.
5. Regarding whether paper inspection results or prescriptions were preserved, 51.4% said 'We have not kept it at all or I do not know', 13.8% said 'all are kept', 10.5% said 'I have stored test results on chronic disease', 24.4% said 'I keep results of important test results and prescription'.
6. Approximately 59.8% of persons retain the results of past health check-ups for the following reasons: 'Because it is custom' by 38.7%, 'I want to use it when

I become sick in the future' by 32.8% and 'to review my own lifestyle' by 24.6% (N = 5989).

7. Approximately 60.4% persons regularly measure their weight (daily); 21% (N = 6041) preserved records of their weight.
8. Of the 27.9% participants that used pedometers and activity meters, 38% (N = 2787) record their results.
9. Regarding physical exercising, 35.8% said 'I always liked exercising', 23.5% said 'I do not dislike exercise, but I enjoy it' and 40.7% said 'I do not prefer to exercise'.
10. Regarding regular physical exercise, 21.9% responded with 'I do it' and 78.1% with 'No, I do not'.
11. Regarding eating habits, 'meals considering physical condition and nutrition balance are important to them' was responded by 59.3%, 'Meals that are balanced and nutritious are not fun' by 21.1% and 'I am not interested in meals' by 19.6%.
12. About using a healthcare application in smartphones (such as applications for blood pressure and diet management), 1.6% said 'I use paid apps', 13.3% said 'I use free apps' and 85.1% said 'I do not use apps'.
13. On things necessary for maintaining health, 26.4% voted for 'strong will', 25.1% for 'target with deadline', 14.5% for 'everyday encouragement' and 'Healthcare IoT (Internet of Things) device that automatically measures weight and step count' by 14.2%, and 'Comrade' by 13.8%.
14. As for PHR using a smartphone that holds all data on health and medical care, such as daily weight and blood pressure as a result of examination result and prescription, periodical health check-up and can be used when necessary; 65.6% responded as 'I want to use it for free', 4.5% as 'I want to use it for a fee' and 29.9% as 'I am not interested or do not want to use it' (multiple answers).

Discussion

Based on the survey results, most participants worked for 5 or 6 days in a week and 70% of the participants were healthy. The participants who were suffering from illnesses tended to have more number of lifestyle diseases and pre-diabetes mellitus. Stiff shoulder, headache and back pain were believed to be caused by labour and lifestyle habits.

More than 50% of participants had drinking habits and 20% were smokers. In addition, half of the participants did not get enough sleep and half were not confident about their health.

Approximately 70% of the participants underwent periodic health check-up for prevention, with more than half of them preserving health check-up results. In addition, 60% of the participants weighed themselves regularly and 20% of them recorded their weight.

The results showed that diet for nutritional balance was considered to be important.

Despite 60% of the participants believing that physical exercise was important, only 30% exercised daily. Regarding the necessary factor in maintaining health, 'strong will' and 'goals that decided the deadline' were rated higher than 'the need for convenient healthcare IoT devices'.

Approximately 25% of the participants who used health applications, 65.5% wanted to use PHR service by smartphone for free, whereas 4.5% were willing to use it for a fee. Companies can thus consider providing health apps and PHR to employees as an effective step towards health management.

Conclusions

Based on the results of our questionnaire survey, workers suffering from illness had lifestyle diseases and pre-diabetes mellitus. Approximately 70% of the workers had mild disabilities and several of them had bodily malfunctions owing to stiff shoulder, headache and back pain, which are believed to be caused by labour and lifestyle habits.

Based on the results of the questionnaire survey, it is expected that the development of PHR using an appropriate Healthcare IoT device can help prevent or delay the onset of lifestyle diseases. For employers, it is expected that employees who work in a healthy and efficient manner show improvement in productivity and face reduced burden of medical expenses and bear a part of the introduction cost of PHR.

[f] Department of Preventive Medicine, School of Medicine, Chungnam National University, Daejeon, Republic of Korea

Abstract

The purpose of this study was to develop an ICT-based care-management support system and to assess its validity and applicability through pilot testing. The system links users' health and social needs to community resources. Users and care managers participated in each step of care management through an interactive decision support system. The system contributes to facilitate person-centered community care.

Keywords:
Case management, community health Services.

Introduction

Care systems in Korea face significant challenges due to an aging population and the increasing complexity of the health care system. Needs continue to grow for services and care from an integrated and coordinated system that is easy to navigate, efficient, and communicates well.

According to KISA (Korea Internet Security Agency), all households in Korea are able to access the Internet through mobile devices. To respond to these changes, we developed an Information Communication Technology (ICT)-based care-management support system for care managers and citizens in the community.

The purpose of this system is to support efficient care management and to provide tailored service information, based on the individual health and social needs of citizens. The main study objectives were to develop a care-management support system based on ICT by modifying the case-management to be more user-centered and to test the suitability and validity of the developed system.

Methods

The study developed a prototype of an ICT-based care-management support system. The system involved the following modules: 1) Engagement and relationship building with users; 2) Basic information collection and assessment; 3) Patient decision to participate in care management; 4) Comprehensive assessment, including physical condition and health, activity and engagement evaluation, and environment evaluation; 5) Comprehensive profile of users' needs based on standardized ICF classifications on functioning, disability, and health; and 6) An individualized service plan.

This ICT-based care-management support system will help service users and care managers collaborate in each stage. In addition, the user-friendly diagrams and infographics guided each decision step. A pilot test of this system was performed with 30 older citizens.

Results

The majority of users were positive about the usability of the ICT-based care-management support system. Users responded that they felt actively involved in the care-management process by sharing health and social care information on the web. The ICT solution enabled efficient collection of data through standardization and individualization of care management and provided user-friendly individualized recommendations for users.

Discussion

The ICT-based care management support system was developed for the Korean community case management users and reflected feedback from the case management users and community residents to assess its usefulness and feasibility. As the results show, users actively engaged in care management through a user-centered care-management system. However, various incentives are needed to keep ICT-based case managers involved. Further training is needed to make it easier for users to use the ICT system.

Conclusions

The overall prospect was that the ICT-based case management system would enable service recipients to become involved in the decision-making process of care management. Therefore, the care-management system using ICT can serve as the basis for person-centered community care.

Implementation of a Novel User Interface for Review of Clinical Microbiology Results

Gianna Zuccotti[a,b,c], Skye Aaron[a], Adam Wright[a,b,c]

[a] *Brigham & Women's Hospital, Boston, MA, USA,*
[b] *Harvard Medical School, Boston MA, USA*
[c] *Partners HealthCare, Boston, MA, USA*

Abstract

Compared to other laboratory data, microbiology data are a complex mix of quantitative and qualitative results that return iteratively over time. Commercial electronic health records (EHR) frequently have limitations in the manner in which they manage microbiology data, not attempting to codify data but rather displaying it as text. This contributes to time- consuming and error-prone clinical workflows. We developed a microbiology viewer application to aggregate results and implemented it in our EHR.

Keywords:
Electronic Health Records, Manage, Workflows

Introduction

Microbiology data is a critical component for care delivery in Infectious Diseases. Availablity and accuracy of such data facilitates appropriate antimicrobial therapy, guides duration of therapy, can limit the spread of drug-resistant organisms and can enable detection of outbreaks.[1] Comprehensive review of microbiology results is a time-consuming and complex activity made more challenging by a high volume of tests, time delay to test positivity, co-existence of clinically significant and insignificant organisms within a single specimen, and complex antimicrobial susceptibility patterns. [2]

Commercial electronic health records (EHR) generally have limitations with regards to clinical workflows for review and management of microbiology data. EHRs generally do not attempt to codify microbiology data at all, instead displaying it as text. This prevents searching, grouping, and other functions that streamline clinical workflow and instead shifts the cognitive burden of assessment and summary to the clinician. [3] Despite its complexity, microbiology data does have an underlying hierarchical structure of specimens, organisms, tests and susceptibilities that, if preserved, can facilitate electronic summarization and decision support. We developed a tool that reviews text data and displays it in a manner that permits rapid assessment and trending.

Methods

We developed a microbiology viewer application that contains two views; a tabular view, that displays all microbiology and other Infectious Disease-related results and an organism view that displays all results by organism. The tabular view supported the activities of searching, sorting and filtering. It also allowed access to the full text report. The organism view facilitated rapid assessment of all organisms in a patient's history, which allowed a user to see data organized by organism rather than chronologically.

The original prototype of the microbiology viewer was developed as a standalone web-based Java application, outside of our EHR. The prototype viewer used web services to authenticate users, retrieve patient identity from our enterprise master patient index, clinical team assignments from our enterprise patient list, and structured microbiology data from our comprehensive clinical data repository (CDR). After demonstrating the value of the system with usability testing [4], we integrated a hardened version of the application into our EHR (Epic Systems v2018), which permits seamlessly embedding external web applications.

Results

We successfully coded our microbiology viewer to launch within Epic and to coexist within the vendor-supported clinical workflow. Figure 1 shows the tabular view. A key feature of the viewer was the novel organism-specific (i.e. Bacteria, fungus etc.) view (Figure 2) that allowed the user to see data organized by organism rather than chronologically. This view has been particularly useful for patients with complex, multi-year histories, such as those undergoing hematopoeitic stem cell transplant. In addition, we have developed the ability to filter/sort data to permit clinical review to focus on a subset of information, further enhancing user experience. User adoption took place seamlessly and without specific training, further supporting the usability principles that we observed when the product existed outside of the EHR.

Discussion and Conclusion

We have demonstrated successful integration into a commercial EHR of a tool that was initially built entirely outide of our legacy EHR system. Information systems that can aggregate, synthesize and present data are well-suited to improvement of the management of microbiology test results.

Acknowledgements

The authors appreciate the assistant of the Partners HealthCare Clinical Data Repository Team in building and implementing the tool. We also that the Partners eCare Clinical Content Team and Epic Integration Team for designing and supporting the clinical workflow within the Epic Electronic Health Record.

Abstract

The goal of the Precision in Symptom Self-Management (PriSSM) Center is to advance the science of symptom self-management for Latinos through a social ecological lens that takes into account variability in individual, interpersonal, organizational, and environmental factors across the life course. Informatics and data science methods are foundational to PriSSM's research activities including its pilot studies and research resources. This work highlights three areas: Latino Data Repository, Information Visualization, and Center Evaluation.

Keywords:
Precision Medicine, Nursing Informatics, Self-Management

Introduction

The goal of the Precision in Symptom Self-Management (PriSSM) Center is to advance the science of symptom self-management for Latinos through a social ecological lens that takes into account variability in individual, interpersonal, organizational, and environmental factors across the life course. Informatics and data science methods are foundational to PriSSM's research activities including its pilot studies and research resources. The PriSSM Center is a Center of Excellence funded by the National Institute for Nursing Research (NINR) and a member of its Center Directors Network, which collaboratively works to advance symptom and self-management science. [1,2,3] The purpose of this work is to highlight three areas in which informatics and data science methods have been used to facilitate the goal of the PriSSM Center: Latino Data Repository, Information Visualization, and Center Evaluation.

Methods

Setting

Columbia University Irving Medical Center is an academic medical center in a primarily Latino neighborhood in Northern Manhattan and is affiliated with NewYork-Presbyterian Hospital.

Approaches

Methodological approaches including procedures, data sets, sample size, and analytic plans that where relevant are summarized within each research activity.

Latino Data Repository

All PriSSM Center pilot studies include collection of genomic and phenotype data including a set of NINR-designated common data elements (CDEs) related to patient-reported symptoms. We received supplemental Center funding from NINR to create a Latino Data Repository that integrates genomic data, CDEs, and other phenotypic and environmental data from PriSSM pilot studies as well as our other Latino data sets. We processed, transformed, and integrated all data into a Research Electronic Data Capture (REDCap) database.

Information Visualization

Information visualization is a methodological focus in the PriSSM Center. We convene a monthly interdisciplinary Visualization Design Studio, support a doctoral level course in information visualization for research synthesis, and conduct participatory design research to create information visualizations for returning individual research results.

Center Evaluation

To examine co-authorship patterns and grant and publication topics for PriSSM Center investigators (n=22), we apply network analysis and topic modeling, respectively, to publication and grant corpora created from online sources (PubMed, NIH RePORTER, Federal RePORTER, Columbia University Scientific Profiles).

Results

Latino Data Repository

The Latino Data Repository contains sociodemographc data, NINR CDEs, other patient-reported data such as diet and physical actiivty, Ancestry Informative Markers, and a selected set of common variants and rare mutations. We also store participants consent for data sharing, data linkage, and willingness to be contacted for future research along with medical record number if available. The latter facilitates access to clinical data for particpants who have consented to data linkage. Columbia researchers can request access to both samples and data as demonstrated in a recent Cell publication.[4]

Information Visualization

Through the Visualization Design Studio, we have provided guidance on the design and creation of a broad variety of information visualizations including those for returning

research results, patient-provider communication tools, mHealth apps, and clinical dashboards. We are offering the doctoral-level information visualization class annually. Figures 1 and 2 display information visualizatons for returning results to research participants.

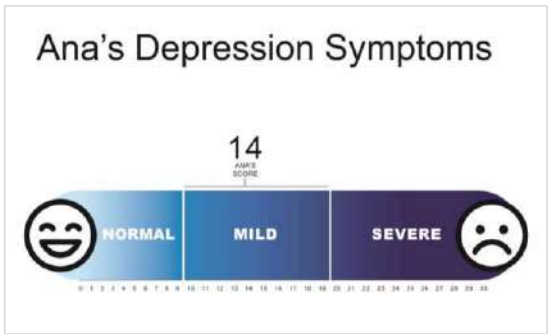

Figure 1. Depression Common Data Element Visualization

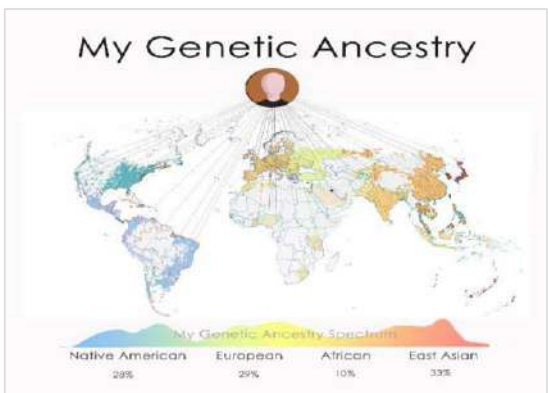

Figure 2. Ancestry Informative Marker Visualization

Center Evaluation

The co-authorship network (Figure 3) shows that Pilot Project principal investigators (PIs) have developed publication networks that distinguish them from the PriSSM Center PIs. The topic model (Figure 4) illustrates the clinical application areas as well as informatics and data science methods in grants (n=44) and publicatons (n=121).

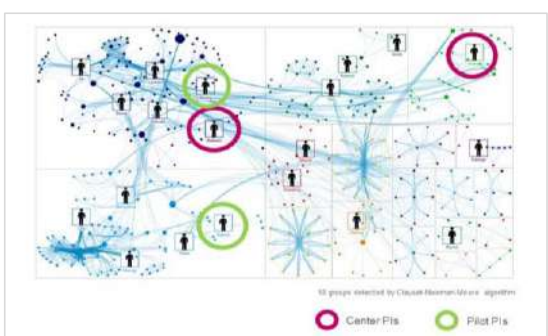

Figure 3. Network Analysis Showing Co-Author Patterns of Center Investigators

Conclusions

Our results demonstrate the important role that informatics and data science play in enabling the PriSSM Center to achieve its scientific goal as well as to evaluate Center performance.

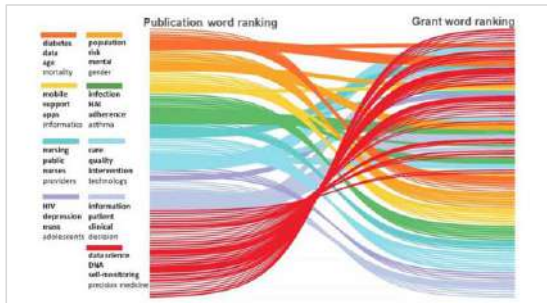

Figure 4. Topic Models of Grants and Publicaitons. Thicker lines mean higher frequency.

Acknowledgements

The PriSSM Center is funded by the National Institutes of Health/National Institute of Nursing Research (P30NR016587, P30NR016587,-02S1, Bakken, Hickey, Merrill, Arcia, Koleck). We thank Dr. Janet Woollen for Figure 2 and Dr. Sunmoo Yoon for the data analysis and visualizations in Figures 3 and 4.

Information Systems, Statistical Information Availability and Decision Making in the Primary Health Care Level of the City of Buenos Aires

María Belén Islas[a], Cecilia Palermo[a], Micaela Zapata[a], Santiago Esteban[a]

[a] *Health Information Systems Office, Ministry of Health, Buenos Aires City, Argentina*

Abstract

The availability of statistical information is usually associated with 'better decision making', fundamentally within the paradigm of evidence-based decisions. Thus, it is interesting to understand the demands and expectations, interpretations and effective use of statistical information by decision-makers at the primary health care level, considering the implications of the recently implemented Information System in Public Health (Buenos Aires, Argentina).

Keywords:

Attention, Decision Making, Statistics

Introduction

The introduction and development of information systems has an impact on the way in which significant data is generated for decision-making at the clinical, institutional, organizational and resource management levels. The implementation of an Information System (IS) in health -including an Electronic Health Record (EHR) cluster- began, in Buenos Aires City, in the year 2016. This process brought certain transformations in the way in which information is generated, available for and used by decision-makers: previous statistic information was merely descriptive and resulted of hand-filled forms, and the implementation of an EHR lead to the development of new strategies to collect and obtain information.

Within the introduction of an IS, the information sources are unified. This is considered an advantage, because "decision making by health care professionals is often complicated by the need to integrate ill-structured, uncertain, and potentially conflicting information from various sources" [3]. Thus, it is important to understand the way in which decision-makers work with and use the available statistic information. Even though statistical information is referred to be used for either management and clinical aspects, this poster analyze the use of statistical information for decision-making involving the collection, systemization, structuring, storage, combination, distribution and provision of valuable information - considering the impact of the IS introduction in the resulting access to information.

In the field of public health, decision-making is defined by Cediel Becerra as *"the process that implies being able to continuously respond to changing circumstances, anticipating emerging threats and identifying ways to control them"* [1]. It implies decisions that affect the health of entire communities or populations. The decision-making process in managerial roles is a fundamental mean to promote the achievement of objectives set by managers in every institution; in this sense, its exercise cannot depend on the sole experience or intuition of the decision-maker. It should be based on knowledge and interpretation of the best available evidence and local data.

With the implementation of the Electronic Health Record in the first level of care, we aspire to obtain high quality statistical data to support these decision-making processes. Actually, the information resultant of the use of EHR by professionals of the primary health care level is been processed with the aim to develop a dashboard with extensive sets of information. Nevertheless, it is not clear how managers at the primary care level make actual use of the available information.

This work aims to analyze the use of statistical and(or) scientific information in the decision-making process carried out by health center managers of the primary health care level.
Thus, it is necessary to identify the decision-making main topics, the different agents involved through the process, and the difficulties and issues that may arise along it. The main decisions topics and specific demands of information were identified, according to the experiences of Managers of Primary Health Care Level Centers.

As well, it analyzes the impact of EHR concerning the access and availability of information and specific information requirements issued by managers at the primary care level. In light of the little reliable evidence quantifying the extent to which research evidence is used in public health decision making processes [4], in the specific case of Buenos Aires city, the question on which this work relies is: an increased availability of information, necessarily involves an upgrade in decision-making? This question is significant to conduce local analysis, considering background information refers to international settings [5].

Methods

Setting

The Buenos Aires city healthcare network is conformed by a Ministry of Health, 33 Hospitals, 81 Primary Care Centers and it is structured into 12 areas in order to organize health care delivery. The health system employs a total of 41,000 people. Since June 2016 an Electronic Health Record (EHR) is being gradually implemented in the outpatient setting. [2] Until October 2018, 60 healthcare facilities are using EHR and more than 2.5 million of clinical notes had been registered.

Through a qualitative approach, 9 (nine) managers of the Primary Care Centers participated in individual semi-structured interviews. Throughout these interviews, the following dimensions were explored: circuit and current flow of information; personal experience as decision makers; influence of the available statistical data in the decision-making process; and the expectations about information available on dashboards.

Results

During the interviews, managers were asked about their decision-making governance areas. They defined three key dimensions:

Management: this item involves supplies, personnel and infrastructural demands.

Activities: refers to specific activities that are designed according to general prevalence of health problems and characteristics of the population.

Prevention: on one side, this is bound to identify health-trends in order to plan interventions. On the other, it relates to comparative studies between actual and historic information, to identify health-fluctuations in the population.

By processing the content of the interviews conducted, we were able to identify a 'theoretical' and a 'practical' dimension, associated with the importance of statistical information availability. On a theoretical level, the interviewees said that a greater amount of statistical information would contribute to characterize and typify health problems and identify epidemiological tendencies along the city territory. They also mentioned that if typification is not correctly achieved by the use of data, it might be misled by intuition or personal-biases of the healthcare teamwork, and it would generate erroneous planning and diagnoses. On the other hand, on a more practical level, the interviewees revealed that the usefulness of statistical information in decision-making is post-factum, as decisions are not necessarily based on statistical evidence.

Conclusions

The analysis of the decision-makers' perspective points out that there is not a detailed proposal related to the content and availability of statistical information. The demands usually refer to specific topics, such as patient absenteeism, amount of consultations according to each professional, chief complaints and concerns. Even though professionals point out the strong potential of data resulting of EHR, there is still uncertainty over the access and usefulness of information associated to decision-making. Also, there is no specific or structured notion regarding the ideal way to make information available: the electronic format generates a perception of potentiality but at the same time it is not clear to them how data is generated and processed.

Ideally, actors with decision-making power in public health providers should incorporate scientific evidence to make decisions, develop policies and implement programs. However, in reality, these decisions are often based on short-term demands.

Statistic information availability is not sufficient on its own if there is not a clear view of which data is needed, what for, and the how is these data interpreted. Even though the analysis presented on this poster is exploratory, it intends to show the professional's expectations over the use of information regarding decision-making processes.

The importance of the availability of information is not exclusively at the central level or in decision-making positions, but it is also extremely important for professionals (who in turn are the ones who generate it) and the use they can make of it.

Standardized Observational Cancer Research Using the OMOP CDM Oncology Module

Rimma Belenkaya[a], Michael Gurley[b], Dmitry Dymshyts[c], Sonia Araujo[d], Andrew Williams[e], RuiJun Chen[f], Christian Reich[g]

Abstract

Observational research in cancer requires substantially more detail than most other therapeutic areas. Cancer conditions are defined through histology, affected anatomical structures, staging and grading, and biomarkers, and are treated with complex therapies. Here, we show a new cancer module as part of the OMOP CDM, allowing manual and automated abstraction and standardized analytics. We tested the model in EHR and registry data against a number of typical use cases.

Keywords:
Oncology, Research, Standardized

Introduction

Observational research utilizes secondary use of observational healthcare databases for pharmacoepidemiology, health outcomes, and health services research. A variety of statistical and epidemiological methods produce estimates of desired or adverse effects caused by medical interventions and associated statistical artifacts such as confidence intervals and p-values. Cancer research is no different from general observational research. However, cancer characterization requires much more details such as: histology of the tumor tissue, anatomical sites affected by the disease, tumor size, affected lymph nodes and metastases, tumor markers (conventional and genomic aberrations), and standardized disease grade and staging.

The treatment of cancer is also more complex than most other conditions since it involves surgery, radiotherapy, chemotherapy, targeted therapy, and immunotherapy. Many of these are administered in cycles. In addition, chemotherapy compounds are applied in predefined regimens.

Cancer diagnosis and treatment interventions are complicated healthcare interactions stretching over longer periods of time. To perform observational cancer research, low-level events need to get abstracted into higher level disease episodes, treatments, and outcomes such as initial diagnosis, drug regimen, radiotherapy, surgical resection, response to treatment, overall and disease-free survival, etc.

Systematic and standardized analytics requires data harmonization, which also enables distributed research networks [1]. Both data format and representation (coding) need to be standardized for true federated analytics. Currently, there is no comprehensive data model or standard semantic terminology system covering the cancer domain available in the public domain to support this approach.

ICD-10 is the most common coding scheme for defining the condition in observational data. However, it details mostly anatomical sites of cancer, while histology and tumor attributes are poorly covered. ICD-O-3 is a classification with explicit topology and histology domains, but it is not connected to other terminologies. The two coding systems are not combined to form meaningful conditions and it lacks detailed tumor characteristics. The CAP Cancer Protocols solves the latter problem by defining a mandatory and specific set of data elements for each cancer type, called synoptic reporting. However, this resource does not have a freely available computer-readable representation and does not have a properly defined terminology. The NAACCR Data Dictionary is addressing this issue and also contains terminologies for treatment. However, its data elements are not conceptualized to carry a distinct meaning independent from context, and for most of its data elements, it does not utilize or map to any external existing coding system. For clinical trials, CDISC developed comprehensive Therapeutic Area Standards, but it covers only four cancer types and also lacks relationships to external standards. HL7 FHIR is developing cancer-specific profiles, but only Breast Cancer Staging is available today. The Nebraska Lexicon addresses all of the above issues, creating a freely available ontology embedded in SNOMED-CT, but it is a work in progress, and currently only covers breast, colorectal, lung cancer, and malignant melanoma.

For cancer treatments, the situation is equally inconsistent. RxNorm is the standard vocabulary for the OMOP drug domain, but it is not specific to oncology and does not contain regimens. Both the NCI List of cancer drugs, the SEER*Rx, and the NCI Metathesaurus contain cancer specific drugs and their indication, but not regimens with constituent ingredients normalized to RxNorm. The NCCN has comprehensive drug and regimen information, but nothing is available in the public domain. The SEER OROT contains a comprehensive cancer drug repository with maps to NDC and HCPCS. Finally, HemOnc contains a rich drug and regimen ontology, including indications and links to RxNorm but requires proper life cycle of their concepts.

Here, we introduce the OMOP Cancer Module. It consists of a comprehensive hierarchy of cancer conditions, including topography, histology and tumor attributes, as well as treatments with regimens. It also contains the data model for abstracted

episodes and a mechanism to link them to the lower level clinical detail. We converted four cancer databases into this model and tested it for a number of typical use cases.

Methods

We used the following standardized vocabularies:

1. Cancer diagnosis: We incorporated all ICD-O-3 histology and topography codes and created equivalent or "uphill" links to SNOMED. We combined all histologies and topologies to create standard conditions. Instead of instantiating the entire Cartesian product, we only used reported combinations derived from ICD-O-3 site, ICD-O-3 SEER Site/Histology Validation List, Columbia University Medical Center (CUMC) Cancer Registry, and Northwestern University (NU) Tumor Registry. We mapped the resulting conditions that existed in SNOMED, and connected the rest of the conditions to their histology and topography and linked them to the higher level SNOMED concept.
2. Modifiers: We incorporated and instantiated both the NAACCR Data Dictionary and the Nebraska Lexicon and de-duplicated the resulting corpus. For ambiguous NAACCR concepts, we pre-coordinated the data elements with its site-specific context.
3. Treatment episodes: We instantiated NAACCR surgery and radiation concepts. We incorporated HemOnc drug regimens and classification. We used OROT to connect drug concepts to the underlying source codes.

Episode model

We introduced new Episode and Episode_Event tables to represent disease and treatment episodes and their connection to lower level events (Figure 1).

Database instantiation

We converted Electronic Health Records (EHRs) and registries from four participating institutions into the new model.

Abstraction

We used an automatic abstraction algorithm to derive disease and treatment episodes [2]. We also performed manual abstraction and compared it to the automatic abstraction.

Empirical Model Testing

We compared the manual to the automatic abstraction and characterized the results. We then tested the following use cases using either abstractions.

- Complete history of cancer disease for patients cohort
- Complete list of modifiers for cohort of patients
- Stratification of therapy by high level classes based on vocabulary hierarchy

For each use case, we distributed a standard query through the network of databases and experts validated the results.

Results

We successfully generated the Standardized Vocabularies and converted the data from four participating institutions: NU, CUMC, Maine Medical Center Research Institute, and IQVIA.

We achieved 95% of coverage for the diagnoses reported in the source data by the Standardized Vocabularies, the remaining 5% represented rare cancers. The positive predictive value (PPV) of the automatic abstraction compared to manual chart review and Cancer Registry was 96% for any cancer diagnosis for four cancers, 100% for chemotherapy, 98% for hormone therapy, 100% for immunotherapy, and 86% for radiotherapy.

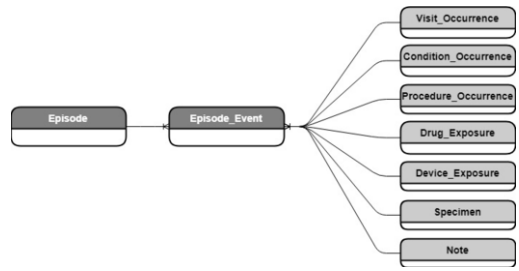

Figure 1– New Episode and Episode_Event tables

Conclusions

We successfully standardized the key aspects of cancer diseases required for observational research. Further work will include: extending Standardized Vocabularies to provide complete coverage of diagnoses and diagnostic modifiers, modeling of genomic data and outcomes, and creating automatic abstraction algorithms that would be utilized in an Open Network of cancer databases.

Measuring Healthcare-Associated Infection Outcomes: Enhanced Surveillance to Include Process Adherence for Quality Improvement

Simon J. Burrell[a], Ann L. Bull[a], Leon J. Worth[a, b]

[a] Victorian Healthcare Associated Infection Surveillance System (VICNISS) Coordinating Centre, Doherty Institute, Melbourne, Victoria, Australia,
[b] Department of Medicine, University of Melbourne, Melbourne, Victoria, Australia

Abstract

To prevent healthcare-associated infections, there are a range of clinical practices that should be followed. For example, appropriate administration of prophylactic antibiotics [process] is essential to reduce risks of surgical site infections post-operatively [outcome]. Monitoring adherence to these processes provides insights into potential causes of infection. The Victorian Healthcare Associated Infection Surveillance System (VICNISS) captures process data in the same system as outcome data, thereby providing integrated data to support quality improvement within healthcare and reduce the burden of healthcare-associated infections.

Keywords:

Cross Infection, Antibiotic Prophylaxis, Population Surveillance

Introduction

The Victorian Healthcare Associated Infection Surveillance System (VICNISS) was established in 2002 with the primary aim of reducing the incidence of healthcare-associated infections (HAI) in the Australian state of Victoria [1].

While the initial program was targeted towards large acute hospitals (greater than 100 acute beds), subsequently a smaller hospitals surveillance program was established and more recently residential aged care facilities have commenced the HAI surveillance program. There are currently approximately 460 participating facilities.

Surveillance activities through the VICNISS program can be classified into three types: infection outcomes, preventative process, and vaccination compliance/immunity.

When facilities have an increase in infection rate/s, clinicians, quality improvement staff and hospital executives seek to understand how to lower the rate and improve patient outcomes [2]. A sole focus upon monitoring infection outcomes does not enable relevant factors contributing to risk to be identified. It has been demonstrated that clinical processes (or multimodal processes, 'bundles of care') can be implemented to reduce the risk of acquiring a range of infections in healthcare settings [3].

The importance of process adherence in the prevention of surgical site infections is documented in a World Health Organisation (WHO) guideline [4].

Table 1– Examples of processes that are integrated with infection surveillance in the VICNISS program

Infection (outcome)	Associated clinical practice (process)
Surgical site infection	Antibiotic prophylaxis (choice, duration and timing)
Staphylococcus aureus bloodstream infection (s)	Hand hygiene compliance, Central line insertion practices
Central line-associated bloodstream infections	Central line insertion practices
Surgical site infections following colorectal surgery	Colorectal surgery process adherence (multimodal bundle)

Process monitoring requires additional data collection and therefore resource allocation. In our experience, additional data required to monitor the prevention process of antibiotic prophylaxis can be quite easily collected in tandem with surgical site infection data.

This paper describes how we integrated process adherence monitoring, namely surgical antibiotic prophylaxis, with surgical site infection surveillance.

Methods

The VICNISS SSI surveillance program is based on the U.S. Department of Health & Human Services - Centers for Disease Control and Prevention (CDC) National Healthcare Safety Network (NHSN) [1]. In Australia, national medication prescribing guidelines, including recommendations for surgical antibiotic prophylaxis, are widely available and utilised within healthcare [5].

Surveillance for post-operative surgical site infections (SSI) requires the collection of demographic and surgery details for every patient undertaking the surgery under surveillance. Many of these data elements are routinely captured by hospital IT systems and are extracted for infection surveillance use.

Additional data are required to monitor concordance of antibiotic prescribing with the national guidelines [5]: antibiotic agent, time of administration, and if the antibiotic is continued for greater than 24 hours.

Hospital infection prevention staff extract data from their hospital system and either upload a batch file or enter the data onto a web form in the VICNISS secure portal. Validation and

quality checks are processed at time of entry. Data are stored in a relational database structure.

We expanded our web form to allow the collection of additional antibiotic fields at the same time as the surgical procedure data are entered. These fields were also added to the bulk upload process.

To enable reporting of antibiotic prophylaxis compliance the national antibiotic guidelines are transcribed into single business rules that can be applied to each surgical procedure and antibiotic combination. As such, there are four possible results of applied rules: optimal, adequate, inadequate and unknown.

Business rules are stored in a database table and code written to run on a nightly schedule that applies the rules to incoming data. Results are saved into a subsequent table. Once data have been uploaded to VICNISS, individual hospitals are able to run reports showing their infection rates together with process compliance over time [6].

Results

Figure 1 summarises the time-trend for appropriate antibiotic choice for surgical antibiotic prophylaxis. Over time, 'optimal' choice has increased while 'inadequate' choice of agents has diminished. The surgical procedures included in Figure 1 are CAGS, cardiac, hip prosthesis, knee prosthesis, and colorectal surgery.

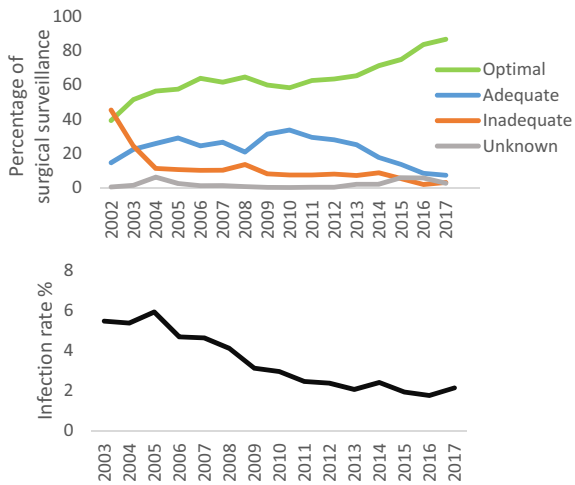

Figure 1– Top: Assessment of appropriateness of prophylactic surgical antibiotic choice over time (high-risk procedures). Observed increase in optimal prescribing. Bottom: Reported surgical site infections following surgery over time (high-risk procedures). Observed reduction in infections outcomes.

In addition to antibiotic choice, the timing of administration and duration of prophylaxis are captured. For prolonged procedures, the administration of repeat doses of antibiotic for prophylaxis, are also recorded.

At a hospital level, these data allow clinicians to identify key areas for quality improvement and education. Antibiotic stewardship teams may opt to focus upon choice, timing or repeat dosing in strategies to enhance quality of prescribing.

Conclusions

While it is well-documented that infection surveillance activities are associated with a reduction in healthcare-associated infections, we demonstrate that a small increase in captured data (to include relevant processes) is an efficient way to gain greater insight into possible opportunities for practice improvement to reduce infection risk[7].

We are achieving our aim of reducing healthcare-associated infections and very efficiently answering the first question that front-line hospital staff ask: 'What should we do when we have an increased infection rate?'

Acknowledgements

VICNISS is funded by the Victorian Department of Health and Human Services, is a Service of the Royal Melbourne Hospital and located at the Peter Doherty Institute for Infection and Immunity. We acknowledge the work of infection prevention and control staff in collecting the surveillance data at each healthcare facility participating in the VICNISS program.

Toward CDSS Benefiting Elderly Patients with Olfactory Disorders

Xiaoqiu Chen[a], Chao Shang[b], Fan Li[c], Zhiwei Cao[a], Yang Gong[d]

[a] *ENT Department of Shengjing Hospital, China Medical University, Shenyang, Liaoning Province, China,*
[b] *Department of Network Center, China Medical University, Shenyang, Liaoning Province, China,*
[c] *School of Medical Informatics, China Medical University, Shenyang, Liaoning Province, China,*
[d] *School of Biomedical Informatics, University of Texas Health Science Center at Houston, Texas, USA*

Abstract

Patients with olfactory disorders are often encountered with a complex workflow and unsatisfied results. This article explores an informatics application to manage olfactory disorders with clinical decision support. Evidence from PubMed was used to analyze and extract the workflow, according to the "five rights" CDS framework. Five focus points and corresponding tips were identified. This work provides disease analysis and life guidance for prediction of the occurrence of more serious diseases.

Keywords:

Olfactory disorders, elderly, clinical decision support

Introduction

Olfactory disorders (OD) are common diseases in ENT clinics. The elderly are the main population affected by OD and are sometimes unaware of risky circumstances. It has been proven that OD are also early signs of neurodegenerative disorders [1].

The current treatment of OD is far from satisfactory. Doctors suffer from only a limited number of methods that can be used for treatment. Patients have to accept unsatisfactory results after complicated examinations and treatment.

The clinical decision support system (CDSS) is typically an effective application of electronic health records (EHR) [2]. Osheroff's "five rights" of clinical decision support are a good summary of what needs to be done in design, development, and implementation of CDSS application [3].

This poster explores how we apply the "five rights" CDS framework to effectively manage OD, from the perspective of all spectrum of OD participants including doctors, patients, patient family members or caregivers, aiming to create personalized informatics prescriptions, and thus improve patients' quality of life.

Methods

Articles related to senile OD were captured from the PubMed database between 2008~2018. MeSH terms "olfactory disorders" and "age 45+ years" were used in the literature search strategy. A total of 1047 articles were retrieved. 73 articles were included and further reviewed based on the titles and abstracts, once the following information was extracted from each article: the morbidity, onset characteristics, inducing and prognostic factors, hazardous events, treatment methods and cure rates of OD. Using the "five rights" as a CDSS theoretical framework, three professors of otolaryngology were consulted, and combined with the application data of the EHR system in the nasal clinic where the researcher worked (more than 40,000 outpatient visited per year), the entire OD workflow was analyzed.

Results

In the EHR system, there are five focus points found to intervene with the treatment workflow of OD as the workflow progressed.

The 1st focus point: age over 50

The incidence of OD in the elderly is extremely high (*Table 1)*. The growing aging population will inevitably surge the OD incidence accordingly.

Table 1— Epidemiologic Surveys of OD Patients in Different Countries

	Age Group			
Country	**≥50ys**	**≥60ys**	**65-80ys**	**≥ 80ys**
2002 U.S	25%[4]			
2004 SWE	19.1%[5]			
2009 U.S			50%[6]	75%[7]
2011 U.S		12.5%[8]		

The 2nd focus point: lasting more than 1 year

The basis for OD treatments relies on the identification of the cause. In a latest systematic review, OD commonly origin from five causes: naso-sinal disease, head trauma, upper respiratory infection [URI], age-related loss, and congenital disorders [9]. Within a year, all of them can be treated accordingly and get a stable therapeutic effect.

Other than the above-mentioned causes, the National Health and Nutrition Examination Survey (NHANES) self-reported olfactory function index appears to offer 12 months to screen for anosmia (loss of olfaction) in the community [10].

The 3rd focus point: hazardousevents caused by OD

The hazardous events caused by OD are not rare. In 2004 and 2014, two scientists separately published the results that the incidence of experienced any hazardous event (*Table 2*) is progressively increased with degree of impairment and there is significant differences based on age [11][12]. The questions about hazardous events are simple indicators for assessing the impact on patients' previous life, and are warnings and reminders for their future life.

Table 2 Ratio of hazardous events among OD patients

OD pts	**Pts with events**	**events**	**Cooking related**	**Spoiled food**	**Neglect gas leak**	**Neglect fire**
340	124(37%)	165	45%	25%	23%	7%
543	179(33%)	266	47%	30%	12%	11%

Figure 1- Five Focus point intervention towards CDSS

The 4th focus point: questionnaire of OD (QOD)

The QOD is widely used in clinical and field surveys since it was developed by Thomas Hummel and Johannes Frasnelli in 2005 [13]. Due to its high degrees of reliability and validity, the QOD is a self-reporting and systematic questionnaire implemented at the national level in the United States. Meanwhile the QOD score comparison before and after treatment can be used to evaluate the patient's life status, ease communication barriers caused by information asymmetry, and resolve the contradiction between doctors and patients.

The 5th focus point: Family history and early manifestations of neurodegenerative diseases.

About 20 years ago, neurologists observed that OD are a cardinal feature of several neurodegenerative diseases such as Alzheimer's Disease (AD) and Parkinson's Disease (PD). In both diseases, the deficit is present in 85~ 90% of early-stage patients. Subsequent research suggests that OD in first-degree relatives of PD patients is associated with at least a 10% increased risk for developing clinically defined PD within 2 years [14]. The EHR is an ideal location where the above five points can be found easily.

During the regular workflow, how the 5 focus points to intervene in the follow-up treatment of OD patients intervened is shown in Figure 1.

Conclusion

The current OD workflow is often incomplete for the following reasons: (1) No one has explained the correlation between age and course with prognosis; (2) No one pays attention to the family history of neurodegenerative diseases and whether dangerous events occur in the patient's life; (3) The main purpose of current OD diagnosis and treatment is still to find the cause, often without accurate quantitive indicators; and (4) Almost no one gives a valid informatics prescription. With the help of EHR, the OD diagnosis and treatment process under the intervention of CDSS can help reduce medical errors, clear referral, predict the possibility of ND, and improve patient life treatment.

A Generic IT Infrastructure for Identity Management and Pseudonymization in Small Research Projects with Heterogeneous and Distributed Data Sources Under Consideration of the GDPR

Hauke Fischer[a], Rainer Röhrig[a], Volker Sebastian Thiemann[a]

[a] *Division of Medical Informatics, Carl von Ossietzky University, Oldenburg, Germany*

Abstract

Each year, millions of rescue operations occur in Germany. Despite rising numbers, there is a shortfall of systematic quality management (QM). Focusing on finding the required quality parameters, this work aims at linking heterogeneous and distributed data sources on the patient-level. Presented here is necessary IT infrastructure for linking patients' data records properly and efficiently. The focus of the IT infrastructure is to provide a lightweight and easy applicable solution with an utmost generic approach.

Keywords:

Privacy, Health Services Research, Emergency Medical Services

Introduction

"*About 14 million emergency runs take place annually in Germany. However, little systematic quality assurance (QA) that includes the course of the patient, medical outcomes and interregional comparisons is conducted*" [1]. Founded to address this shortcoming, the *Inno_RD* [2] research project investigates parameters necessary to establish a systematic quality management for German emergency medical service operations. In order to evaluate the medical outcome of these, medical data of patients from different sources needs to be linked. In Germany, health service providers and health insurances share specific data sets, consisting of billing information needed for later reimbursement. For each case, the data sets contain the health insurance number of the respective patient. Connecting the data sets from multiple service providers and health insurances allows for the tracking of the patient course beyond single contacts to a specific service provider. Thus, there is the need for an IT infrastructure to link the data on a patient-level.

One must consider the recent changes in regulation induced by the general data protection regulation (GDPR), especially regarding sensitive information such as health data. When following the GDPR, it is a requirement to link data without directly sending and using the patients' names or identifying information, as the use of pseudonymization is encouraged if not mandatory when processing personalized (health) data. The GDPR defines pseudonymization as "*the processing of personal data in such a manner that the personal data can no longer be attributed to a specific data subject without the use of additional information, provided that such additional information is kept separately and is subject to technical and organizational measures to ensure that the personal data are not attributed to an identified or identifiable natural person*" (Article 4 (5)).

We developed a data protection concept, determining the technical requirements for the implementation of the IT-infrastructure. Our goal was to deliver a lightweight and easy-to-handle IT infrastructure for identity management and data linkage in small, distributed research networks. This IT infrastructure must meet the needs of offering local file processing and batch processing of data.

State of the Art

Different approaches for the given challenge can be found in literature. The *ToolPool Gesundheitsforschung* [3] has provided an overview of established solutions for the German health care system. The *ToolPool* contains approaches like the *Mainzelliste* [4] or *MOSAIC* [5]. The *Mainzelliste* is an identity management system based on pseudonymization and REST-Services for distributed data warehouses developed by the University of Mainz. *MOSAIC* is a modular approach for data management in epidemiological studies, which provides identity management as well as pseudonymization tools. The University of Greifswald developed MOSAIC. Most of the existing solutions process identifying patient data consisting of names and additional personal information for identity management. These systems employ complex algorithms to convert strings into phonetic codes or use word distance techniques to ensure proper linkage [6]. The latter approaches provide identity management in the form of federated IT infrastructures. Medical research registers or data warehouses with continuous data flow often use these techniques. The investigated tools are not designed for local file processing and fast batch processing of large data sets.

Concept

Based on the data protection concept and the project's context, we performed a requirement analysis for the IT infrastructure. We prioritized these requirements according to the MoSCoW prioritization [7]. We base the core concept for data linkage within the project on a cryptographically secure identifier generator and pseudonymization service that is supposed to be able to translate the health insurance number used as a pseudonym by health service providers and health insurances into a new pseudonym. The direct usage of the health insurance number is not possible. A pseudonym should minimize the possibility to identify the respective patient, and the health insurance number identifies the patient on each provider site. Thus, we need to build cryptographically a new pseudonym. One can assume, that the quality of the data of the health insurance

number is quite high due to its purpose as key value in the billing process.

Using these concepts the data is processed based on a two level pseudonymization approach in our IT infrastructure. On the first level of the pseudonymization process, we generate a permanent identifier (PID). For generating the PID, we used the personal identity data (IDAT, being the health insurance number) of each patient. The PID is sent to a pseudonymization service (PSS). The PSS performs the second level of the pseudonymization process. For each deposited PID the PSS generates a unique permanent pseudonym (PSN).The data analyst receives this PSN in place of the original IDAT, enabling the linkage of different datasets. Each IDAT and thus PSN is linked to specific medical data (MDAT).The MDAT is not touched as it routed through to the PSS in encrypted form [8]. With the PSN, the data analyst can link data from different data providers on a patient-level. With this approach, none of the three participants hold enough information to single-handedly trace the research data back to a patient or vice versa (c.f. Fig. 1).

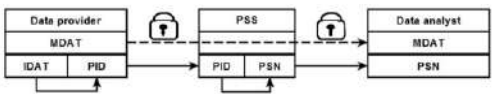

Figure 1: Pseudonymization and transmission of encrypted data

We base the PID generation on a pepper-based hash method. Hashing with pepper is a cryptographic process that adds a secret phrase serving as a password to any input. This method shares the phrase between all data providers and keeps it away from identity management, pseudonymization and the data receiver. The aim of this approach was to minimize the possibility of reconstructing the health insurance number of a patient. Using our IT infrastructure, we then send the PID to the identity management, which generates a PSN for each PID and a temporary ID (tempID). Identity management sends the tempID to the data provider, to replace the health insurance number in the original data set. The data receiver then collects the data set with the tempIDs. The receiver of the data set sends the tempID to receive the respective PSN replacing the tempID.

We base the IT infrastructure on a client-server-architecture where the PSS functions as a server. It provides and manages the allocation of PIDs, tempIDs and PSNs. A software-application, or the so-called pseudonymization software, manages the client-side. The PSS acts as a passive service provider reacting only to send requests from the pseudonymization software. Designed to be firewall-friendly, this approach gives full control of all connections to the client software. Also based on the GDPR principle of data minimization (Article 5 (1) (c)), this system offers full control over the data delivery process to each data provider. The pseudonymization software contains a module for data receivers and a module for the data provider. An access management via authentication keys decouples the different functionalities of the two user groups.

Implementation

On the server-side of the IT infrastructure we are using Java Enterprise Edition for a lightweight server application. On the client-side, we employ an executable Java desktop application with a graphical user interface able to process data in CSV format. The desktop application offers encryption of the pseudonymized data based on a hybrid encryption process using AES and RSA encryption. The software also supports the transfer of files via a separate FTP file server. This option simplifies the process of pseudonymization and sending the data in an encrypted way for the user to a user interface that is similar to a simple file upload graphical user interface.

Lessons learned

The designed and implemented IT infrastructure delivers a generic tool to link data records for small research projects with distributed data sources. The main prerequisite is a unique identifier that identifies the subjects across all data sources. The approach encapsulates the data provider, the data analyst and the trusty agency through our pseudonymization concept. This is reached through the use of the client-server architecture and locally executable client software.

During the development process, the need for a toolbox combining multiple methods needed for small research projects became obvious. This toolbox needs to integrate the developed tools and offer further instruments, which we need to identify. There is a need for potential solutions inter alia for encryption, pseudonymization, record linkage, and data preparation as well as legal requirements, such as the data protection concept. These could save research projects time and gives the possibility to focus more on research itself.

PRO (Patient Reported Outcomes) Implementation: From Vision to Reality

Alex Galper[a], Ora Shamai-Rosler[a], Dr. Varda Stanger[a], Dr. Eyal Zimlichman[a]

[a] Department of Medical Quality, Sheba Medical Center, Ramat Gan, Israel

Abstract

Patient-reported outcomes measure patients' views of their health-related quality of life. With the increasing interest and usage of PRO's in the world, Sheba Medical Center is the pioneer in the field in Israel looking at the potential value in PRO implementation in routine practice as a quality improvement tool together with the opportunity to help drive changes in healthcare delivery.

The PRO implementation process involves the multi-disciplinary ward or clinic staff in order to engage them and transform the process into a work routine. The collection methods and usage differ from one clinical area to another and require cultural adaptation in each area. Adjusted reporting and usage during patient encounter assist to improve patient enrolment and provide better and more accurate outcomes for the patient and the medical center.

Keywords:
Patient Reported Outcome Measures, Health-related Quality Of Life, Quality of Health Care

Introduction

Objective clinical outcomes are highly valued by healthcare professionals, but may not reflect the disease impact on the patient's life. Patient-reported outcomes (PROs) are of any health report or indicator given directly by the patient, without an external interpretation by a physician or researcher. This tool can be especially useful following medical procedures and interventions.

PROs were initially developed for research use, which has culminated in some regulatory bodies mandating their use. From there, PROs were adopted by a limited number of doctors to enhance the clinical management of individual patients. In recent years they have been used in order to assess and compare the outcomes achieved by healthcare providers.

Patient-reported outcomes (PROs) ask patients to evaluate the features of their health, including symptoms, quality of life, mental and functional status following healthcare treatment. The resulting data provides valuable information on how healthcare interventions affect critical aspects of an individual's life[1].

An ongoing PRO program launched at the Sheba Medical Center in 2015, based on the pioneering work at the Boston-based Partners HealthCare network. The pilot stage began with three clinical areas – prostate cancer, acute coronary disease, and cataract surgery.

The project aims to improve the quality of medical care and service by identifying and collecting outcomes that are significant for treating patients by reporting the results back to clinicians and the patients and by thus enhance patient engagement, adherence and shared decision making [2].

Methods

The PRO process begins with an initiative that usually comes from the ward head or clinician inside the ward or clinic. At the initial meeting, a clinical and patient profile is built in order to later adopt the required questionnaires, implementation method and work routine to the unique clinic culture and regime. Primary work with the clinical staff is required to choose the correct tools and questionnaires according to the clinician, patient preferences, language barriers, and relevant literature. In Sheba Medical Center each adult questionnaire contains the PROMIS Global Tool in addition to disease-specific reliable and validated questionnaires.

The information is gathered from patients during the waiting period in outpatient clinics when the patient is asked to fill out a questionnaire consisting of questions regarding his quality of life, functional and mental status and symptoms related to his medical condition. The set is completed on a tablet using a dedicated applet or with a manual questionnaire, which is later transferred to the PRO dedicated database. Then, on specific periods, the patients are tracked, using the same toolset, during the follow-up meeting, directly via the patient portal (Sheba Connect) or using a phone operator. Each tool set is processed by the dedicated PRO system and its results are presented in an easy to read PDF format that was developed using both clinicians and patients. While the patients can access the report via the patient portal, the report is embedded into the EMR and accessible to the clinicians.

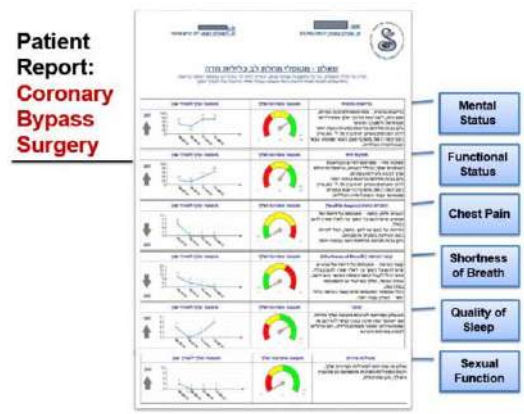

Figure 1 – patient report

In the initial implementation period, the primary focus is put on staff involvement and education. Clinical staff is educated about the collection process method and outcomes, especially report structure and benefits in routine work. The administrative staff is involved in adopting the process into their work routine.

Results

The program began in 2015 in three areas, developed into 20 active clinical areas and 40 additional areas in different stages of information gathering and implementation. From an active managerial approach focused on area recruiting it transformed to dealing with ward and clinic request for PRO program enrollment. The main volume is relying on the early areas, cataract (30%) and acute coronary disease (26%) together with oncology (14%) and orthopedics (21%) while other disciplines, including chronic illness, are being integrated into the program.

Program growth and collection methods improvement intend to double the number of questionnaires collected between 2017 and 2018 and almost triple in relation to 2016. Similarly, the number of participating patients raised in 63% between 2017 and 2018 and rose by 115% against 2018. The use of the patient portal had a significant impact and involved 11% of all complete tool sets and 30% of the follow-up questionnaires.

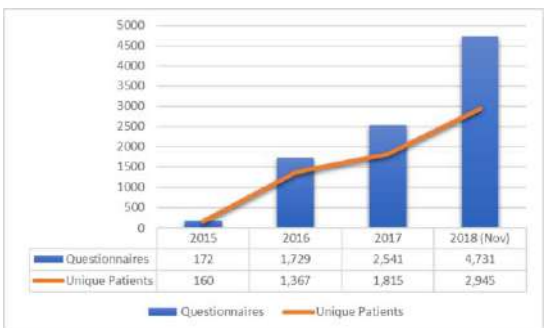

Figure 2 – PRO collection

Discussion

Current basic collection tools and methods that depend on man-power should be replaced with electronic collections methods such as IVR and automated messaging.

Constant project growth and deep clinical implementation, as part of medical quality improvement, require constant efforts and increasing resources as the foundation for a much elaborate system for Sheba Medical Center and the future of medicine using international collaboration.

Shared big data combined with socio-demographic, genomic and other EMR existing data can be used to create and measure outcome benchmarking as well as construct patient predictive tools for patients to make informative treatment decisions and to perform as clinical decision support tool for both patients and clinicians, at a hospital or home setting.

Conclusions

The PROs program expansion in the past three years shows success in patients, clinicians and managers recruitment to the program. Understatement of the process and its benefits of all involved parties increases the patient responsiveness and continues to generate interest among wards and clinics towards an accelerated expansion expected in 2019. However, many challenges still exist, such as educating clinicians to use the tools in routine clinical encounters, collecting and reporting processes as part of the routine clinical environment and implementing the use of tools by the online portal system.

Ethnic Difference in Skin Infection Rates: An Analysis of Electronic Health Records

Yulong Gu[a], John Kennelly[b]

[a] School of Health Sciences, Stockton University, Galloway, New Jersey, United States of America
[b] Department of General Practice and Primary Healthcare, University of Auckland, Auckland, New Zealand

Abstract

Diagnosis and prescription data in the electronic health records (EHR) of a New Zealand primary care clinic are analyzed to identify skin infection occurrences in support of a public health initiative. High prevalence of this disease and substantial differences in the prevalence and occurrence rates among ethnic groups are identified. The findings indicate application potential of the analysis algorithm in public health for identifying the population groups with high needs and assessing intervention impact.

Keywords:

Electronic Health Records, Infectious Skin Diseases, Ethnic Groups, Public Health

Introduction

Skin and Soft tissue infections (SSTI) are highly infectious diseases caused by *Staphylococcus aureus* and/or *Streptococcus pyogenes* bacteria. The SSTI rates are rising in New Zealand, with significant health disparity among ethnic groups [1]. SSTI are easily treated in individuals but the blood borne spread of the infection carries a serious threat to survival with the development of osteomyelitis, septic arthritis, pneumonia, and cerebral abscesses. This suggests that SSTI treatment should be considered from a public health perspective. As a part of the public health initiative (The Whakakotahi Initiative), The Happy Skin Project aims to improve SSTI management in the community, particularly among Pacific people. In support of this project, we analyzed baseline electronic health records (EHR) from an Auckland primary care clinic to identify SSTI occurrences.

Methods

The participating clinic serves predominantly Pacific people in West Auckland. Anonymized EHR data of recent 12 months (September 2017 – August 2018) were extracted from this clinic using Structured Query Language (SQL) queries on demographic, diagnosis, and prescription data. The patients of 24 years of age or younger who are registered at this clinic are included in this study. Three ethnic groups are considered in the analysis as Tuvaluans, other Pacific people (including Samoan, Tongan, Cook Island Maori, Niuean, Tokelauan, Fijian, and Pacific people not further defined), and non-Pacific people.

The SSTI identification algorithm was developed based on previous research that validated the use of EHR data in automatic detection of SSTI occurrences [2]. In this study, the diagnosis records of cellulitis, abscess, boil, impetigo, infected eczema, folliculitis, furuncle, and other skin infections were identified by examining the EHR-recorded READ codes (READ Version 2 [3], as implemented in the clinic's EHR systems). Prescription records of the antibiotic medications commonly used to treat SSTI such as fusidic acid were also examined to identify those SSTI occurrences in which the diagnosis was not coded in EHR. (The identification algorithm, including the list of READ codes and the drug names used in this study are available on request.) To verify the algorithm accuracy, in terms of the positive predictive value, the EHR records (diagnosis, prescription, notes, and laboratory testing results) of a small sample of algorithm-identified SSTI occurrences (n=135) were manually reviewed by a clinician.

The SSTI prevalence rate is calculated based on the algorithm-identified SSTI occurrences within the 12 months and is presented in percentage. Chi-square tests are performed to examine ethnicity differences in SSTI prevalence. The monthly and yearly occurrence rates per 1000 patients are calculated. An example of the monthly rate equation is:

$$\text{Monthly occurrence rate} = \frac{1000 * (\#\text{ of SSTI occurrences in the month})}{\text{Total \# registered patients}}$$

The monthly SSTI occurrence rates by ethnic group are also tracked over the 12 months. Microsoft Excel and SAS package are used in the data analysis (with significance at <0.05 level).

Results

All registered patients aged 24 or younger (N=4644) are included in this analysis. Among these patients, 81% are Pacific people (including 15% Tuvaluan and 66% other Pacific people), 19% are non-Pacific people.

High SSTI Prevalence and Significant Ethnic Differences

As shown in Table 1, the overall SSTI prevalence rate for the 12 months in the sample is 12%, with significant ethnic difference observed (X^2=39.6, p<0.01).

Table 2 shows the total number of SSTI occurrences over the 12-month period and the occurrence rate (per 1000 patients) in this period for each ethnic group. The substantial ethnic differences appear persistent over time, as shown in Figure 1.

Table 1 – SSTI Patient Counts by Ethnic Group

Ethnic group	SSTI patient number	Total patient number	SSTI prevalence
Tuvaluan	125	717	17%
Other Pacific people	349	3053	11%
Non-Pacific people	61	874	7%
Total	**535**	**4644**	**12%**

Table 2 – SSTI Occurrences over 12 Months by Ethnic Group

Ethnic group	SSTI occurrence number	Total patient number	Yearly occurrence rate per 1000 patients
Tuvaluan	201	717	280
Other Pacific people	501	3053	164
Non-Pacific people	79	874	90
Total	**781**	**4644**	**168**

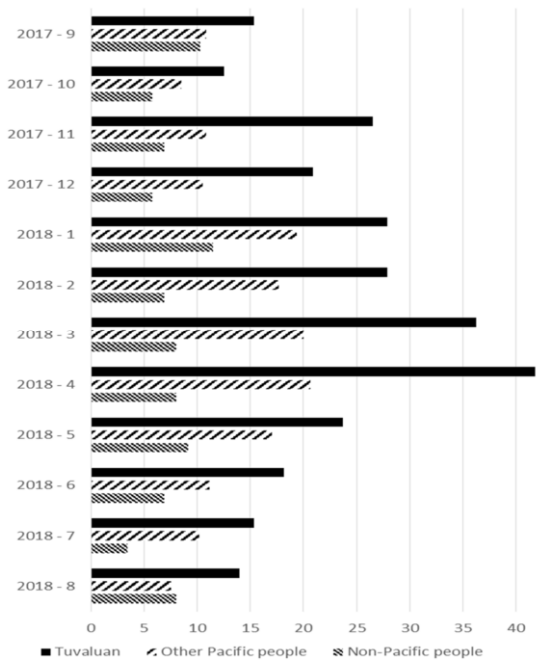

Figure 1 – Monthly SSTI Occurrence Rate per 1000 Patients by Ethnic Group (Sep. 2017 – Aug. 2018)

High Level of Algorithm Accuracy

High level of accuracy is indicated via the manual review of a small sample of the algorithm identified SSTI occurrences (positive predictive value = 100%). Within the ongoing Happy Skin Project, we plan to continue testing for algorithm accuracy and track the intervention impact on SSTI rates.

Discussion

Pacific people living in New Zealand are overrepresented in infectious skin diseases [1]. This study confirms this disparity and finds even higher SSTI rates among a subgroup of the Pacific people, Tuvaluan people. This identifies an urgent need for public health intervention in this population. This study also demonstrates meaningful use of EHR technology in public health initiatives that aims to improve health outcome and reduce health disparity. The seasonal variation of SSTI rates observed in the study (Figure 1) is consistent with previous research that finds higher SSTI rates are associated with higher temperature and humidity [4]. This seasonal variation will be considered when assessing the Happy Skin Project impact on the disease occurrence rate. The outcome analysis may also examine the temporal patterns of the disease and the causes for the variation.

A limitation of this study is that the convenience sampling of one clinic may not represent the clinics or the population in other settings. Another limitation is that we have only tested positive predictive value in the algorithm accuracy evaluation, but further testing with more cases and more measures is planned. Ongoing efforts are also made to support continuous refinement of the SSTI identification algorithm while we monitor the ongoing public health initiative.

Conclusions

High SSTI prevalence and substantial ethnic differences in the disease rates are identified using diagnosis and prescription data recorded in EHR. The current baseline analysis indicates feasibility of EHR data analysis in public health initiatives to identify the population groups with high healthcare needs and to assess the intervention impact on disease rates.

Abstract

A common data model for clinical NGS panel data that is used in a distributed research network to achieve large scale to make evidence for improving patient care should be developed. This study developed OMOP-CDM extension for NGS panel data and confirmed the feasibility of the model by finding the differences between a database generated by research-purpose and clinical practice. We believe this data model can be used in distributed research model and will facilitate the usage of the clinical NGS data in patient care.

Keywords:

High-Throughput Nucleotide Sequencing; Data Analysis; Observational Study

Introduction

An impact on improving the medical care of cancer has increased the role of clinical next-generation sequencing (NGS) in precision medicine. The patient's NGS data are already being generated by large-scale projects that finding the role of clinical NGS in precision medicine [1]. However, the NGS panel data is relatively sensitive in privacy, which raises worries about exporting the data out of the center and collecting it in a silo. Also, the NGS panel data from the study cohort cannot be applied directly to the whole population in the point-of-care due to low diversity.

There has been a global trend to collect genomic data of patients in clinical practice through routine tests [2]. Moreover, since March 2017, the conditional insurance for NGS-based cancer panel has been provided in South Korea. The Distributed Research Network (DRN) uses the Common Data Model (CDM) and allows researchers to share the results of analysis rather than the data of multi-center without exporting sensitive data. The DRN is being adopted by global research consortium, including the Observational Health Data Sciences and Informatics (OHDSI). The Informatics for Integrating Biology and the Bedside (i2b2), a warehouse platform for clinical and genomic data, only covers health centers in the United States, which is resulting in the limitation.

To support diversity, such as ethnicity, and address privacy issues of genomic data, the Observational Medical Outcomes Partnership (OMOP) CDM used in OHDSI was chosen in this study. The OMOP-CDM is developed by OHDSI and their clinical data has been transformed into OMOP-CDM over twenty countries, 1.5 billion patients. However, OMOP-CDM shows low coverage of NGS panel data and is hard to reflect the stream of precision medicine. Although a few standard models have been introduced for genomic data, they had limitations on application.

The aim of this study is to design an OMOP-CDM extension model for NGS panel data that could be used in the DRN. Moreover, we purposed to confirm the feasibility of the data model through conducting multi-center analysis and describing the difference of NGS panel data harvested from the research project and clinical practice.

Methods

Building Genomic CDM

Existing data model and NGS report format, such as COSMIC and ISO20428, were reviewed to design OMOP-CDM extension to cover clinical NGS panel data. Standard nomenclature, such as HGVS (Human Genome Variation Society) and HGNC (HUGO Gene Nomenclature Committee), was adopted for a controlled vocabulary system.

Genomic Data Transformation

Clinical NGS panel data of Ajou University Hospital (AUSOM) were transformed by Ajou University to the genomic CDM. Yonsei University downloaded NGS data from TCGA database and transformed the data to the genomic CDM. R version 3.5.1 was used in the data processing. For storing and querying the sequencing data during data conversion, SQL script on Microsoft SQL Server 2017 was used as the relational database backend.

Data Description

In AUSOM, 92 lung adenocarcinoma (LUAD) and 22 lung squamous cell carcinoma (LUSC) patients had NGS cancer panel test. Public NGS data of the lung cancer cohort studies, Pan-Lung Cancer (TCGA, Nat Genet 2016) [3] were downloaded through the cbioportal of Memorial Sloan-Kettering Cancer Center (MSKCC). The TCGA database (TCGA) contained 603 LUAD patients and 457 LUSC patients.

Study Design

The data in G-CDM, such as gene name, variant type, and actionable variants, was compared between institutions for model validation. Comparison between two different databases is conducted using a Chi-squared test and results with $P<0.05$ were regarded as statistically significant. T-test was computed for the group differentiation. The waterfall plot was generated using an R package "GenVisR" that available via Bioconductor. R Shiny was used in implementing the data explorer as a pilot application of the genomic CDM.

Results

Data Structure of Genomic CDM

For linking clinical data of an OMOP-CDM, the information about a person, specimen, procedure, condition, and care site in NGS panel results was stored in a PERSON, SPECIMEN, PROCEDURE_OCCURRENCE, CONDITION_OCCURRENCE, and CARE_SITE table respectively. The data about NGS panel and pipeline were stored into four tables; GENOMIC_TEST, TARGET_GENE, VAIRNAT_OCCURRENCE, VARINT_ANNOTATION. Relationship between tables can be identified in Figure 1. Specification of a genomic CDM can be identified in the 'CDM Builder' category of the OHDSI forum site (http://forums.ohdsi.org/t/genomic-data-in-the-cdm).

Data Comparison for Model Validation

AUSOM and TCGA databases had differences in variant frequency. The 15 genes as a union of top 10 genes in each database were the targets for profiling. On AUSOM, top 10 genes had a frequency over 75% out of lung cancer patients, while only TP53 gene had a frequency over 25% in TCGA. Especially, EGFR variants had 89.47% frequency in AUSOM, while 6.96% frequency in TCGA. The mean proportion was different between databases (AUSOM: 69.59, TCGA: 12.86, P<0.00, 95%CI: 33.99-79.47). All 15 genes had different proportions between databases (P<0.05). The gene order was also different between databases, but the variant type of most frequent was a 'missense' in both databases (Figure 2).

An Application Based on Genomic CDM

Data exploring application 'GeneProfiler' was developed to generate the results of the descriptive analysis, such as variant types, pathogeny distribution, gene/variant proportion, and it can service patient proportion of input queries such as gene symbol and HGVSp (Figure 3). The 'GeneProfiler' code was uploaded and uploaded to the public in OHDSI Github (https://github.com/ABMI/GeneProfiler).

Conclusions

In this study, we propose a genomic CDM, as an expansion point for a broader discussion. During data comparison, differences in clinical NGS data between institutions were found. This study conducted distributed research using genomic CDM between institutions minimizing privacy issue. This is meaningful in that this study was done in an area of the genomic data that was not previously performed. We believe that the construction and adoption of the standard data model will facilitate the usage of the clinical NGS panel data.

Abstract

Next-generation sequencing has prompted the development of numerous -omics applications. Along with experimental procedures, various computational pipelines became available to address the inherent complexities concerning the volume and quality of data. These pipelines are effective and routinely applied; however, interpreting their outcomes into actionable evidence is still poorly addressed. In this context, this work proposes a method for translating patient genomic profiles to drug response aberrations by integrating pharmacogenomic data into sequencing data analysis pipelines.

Keywords:

Polymorphism, Pharmacogenomic Variants, High-Throughput Nucleotide Sequencing

Introduction

During the last decade, next-generation sequencing (NGS) technologies coupled with bioinformatics advancements have proved their potential to address previously unmet needs, such as improved personalized diagnosis, disease management and stratified treatment. Exome sequencing of patient samples is among the most popular and cost-effective NGS applications that enables the detection of single-nucleotide variants and small insertions/deletions with potential clinical significance. Transforming sequencing data, called reads, to genomic variants is a complex computational problem requiring the execution of several tools that are usually combined into workflows [1-3]. Most of these workflows end up with a set of high-quality variant calls that is annotated with respect to their functional consequence, while the therapeutic importance of the detected variants is rarely evaluated [4].

To cope with this issue, the present work proposes a method that besides the main processing steps it elaborates further on the interpretation of the called variants by identifying those with pharmacogenomic significance and by evaluating the type of interactions and level of evidence that are associated with known drug response aberrations.

Methods

The proposed method comprises of three modules (Figure 1). Module 1 contains a set of chained processes that transforms raw exome sequencing reads to high-quality mappings against reference human genome. Specifically, the reads are first checked for their quality and trimmed to remove low-quality base calls, adapter sequences, etc. Then, BWA [5] is used to align high-quality reads against the indexed human reference genome, followed by Picard [6] and GATK [7], which remove PCR duplicates and detect systematic errors in base quality scores, respectively. Module 1 exports quality reports of the reads and alignments, as well as the alignment files that will be subsequently used to identify variants.

Module 2 performs variant calling for each sample and joint genotyping on multi-sample variant files, using the GATK workflow [7]. Variants are then processed, including quality control, filtering and functional effect analysis. The latter functionality is performed by GEMINI [8], which also annotates variants, with respect to their functional pathways and protein-protein interactions. Finally, Module 3 automates the identification of pharmacogenomically important variants in a two-step procedure that includes: a) parsing of local distributions of curated clinical annotations, and b) identification of interacting drug labels, along with the type of interaction (toxicity, efficacy, metabolism dosage), the level of evidence, the associated phenotype etc., that are available through PharmGKB [9].

Results

The methodology is implemented in an automated workflow that combines freely accessible tools and public data repositories for variants annotation and variant-drug interactions. Currently, the workflow is able to analyse both whole-exome and targeted gene sequencing data for the detection of germline variations. The workflow is built to run on high-performance computing infrastructures, enabling parallelization, that is particularly important for whole-exome data analyses.

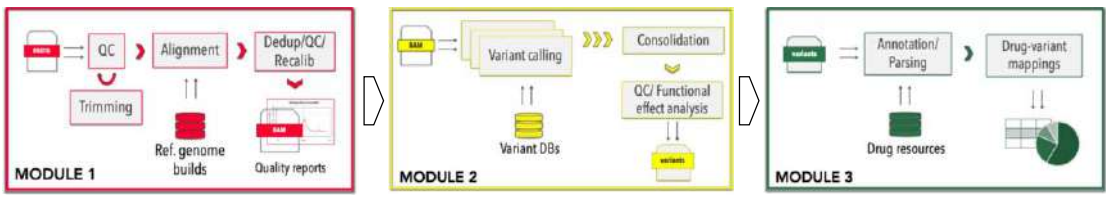

Figure 1 – Modules of the proposed methodology to compute drug-variant interactions from sequencing reads. The modules are chained in a pipeline that exports drug response aberrations together with intermediate data and quality control (QC) reports. FASTQ is the file format of the sequencing reads and BAM is the file format of the alignment files.

Besides the variants and alignment files generated during the execution of Modules 1 and 2, the workflow exports user-friendly reports of the drug-rankings and various visualizations that are built on the variant-drug associations. An example visualization is shown in Figure 2, where variant-drug interactions are depicted with respect to their type of interaction (axis y) and level of evidence (size of concentric circles).

Conclusions

During the last few years pharmacogenomic research has revealed strong associations between genomic profiles of patients and their response to drug treatment. The incorporation of these associations to downstream analysis of high-throughput data sequencing pipelines can be particularly important for ranking the pharmacogenomically actionable variants and for enabling stratified therapeutic decisions. In this context, the proposed method is designed and implemented in order to facilitate targeted treatment decisions and to provide a means to identify biochemical mechanisms underlying variant-drug interactions.

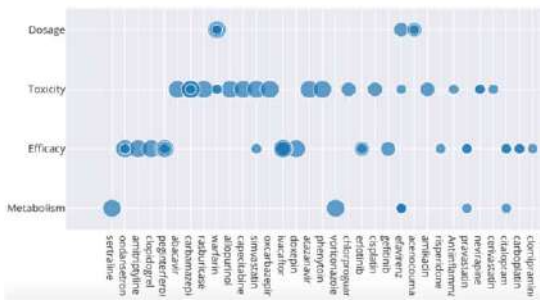

Figure 2 – Example drug-ranking visualization with respect to the type of variant-drug interaction. Concentric circles denote multiple evidence levels. Bigger circles correspond to higher evidence levels (Level 1A/1B), according to PharmGKB [9].

The Preliminary Outcome of Applying a Patient Transportation Management System for Non-Emergency Intra-Hospital Transportation of Patients

Ying-Li Lee[a,b], Tsai-Feng Chien[a], Yu-Wen, Guo[c], Mei-Hui Lin[a]

[a] *Department of Nursing, Chi Mei Medical Center, Tainan, Taiwan (ROC)*
[b] *Department of Nursing, Chung Hwa University of Medical Technology, Tainan, Taiwan (ROC)*
[c] *Department of Information, Chi Mei Medical Center, Tainan, Taiwan (ROC)*

Abstract

In Taiwan, the safety of intra-hospital patient transportation (IHT) is an important issue of patient safety. However, the effects on the quality of patient transportation and the results of patient safety in applying informatics and communication technology were less discussed. The purpose of this study is aimed to understand the current status of IHT events through the patient transportation management system as a reference for further improving the IHT quality.

Keywords:

Transportation of Patients,, Information Technology

Introduction

In hospitals, patients are frequently transported to other professional units in the hospital for further diagnosis or treatment, called intra-hospital transportation (IHT). Over the years, risks and adverse events of IHT have been extensively studied and identified as risky processes, especially for critically ill patients. However, IHT of non-emergency patients is the most frequent event in the hospital, but it is rarely discussed [1].

The goal of IHT is efficiently stated as the 'right patients' to get to the 'right place' at the 'right time'. Yang et al observed 102.5 patient safety events per 100,000 IHTs in Taiwan. 71.8% of the patient safety events were no harm events, and 71.4% were related to the process of transportation. The most common safety events were: delayed departure (13.1%), error in the process (12.1%) and prolonged waiting after arrival (9.2%). 58 (28.2%) events were associated with patient harm, including mild harm in 35 (17.0%) and moderate harm in 23 (11.2%) due to typical acute change in physiological status [2]. Furthermore, poor efficiency of IHT can lead to increased costs for the hospital, longer hospital stays and patient anxiety [1].

The pre-transport communication, the appropriateness of the transport personnel, the timing of the transportation, and the safety and efficiency of the transport processes are key factors that affect the quality of transportation and safety of the non-emergency patient transportation. Non-emergency patient transport processes should be standardized to reduce risks of IHTs and increase the efficiency of patient transportation. The application of information and communication technologies (ICT) may help to improve the quality of transport services for patients [1]. However, related research is rare.

To improve transportation quality of the non-emergency patient, the study hospital has developed a patient transportation management system which was developed by applying ICT and combined with nurses' and patient transport team's participation to transport non-emergency patients. The purpose of this study is to understand the current status of IHT events through the patient transportation management system as a reference for improving the IHT quality.

Methods

The study was conducted at a medical center in southern Taiwan. The hospital has 1,278 beds. Deducting emergency department, intensive care units, and special purpose beds, there are 843 beds in the general ward. There are 5 medical-related buildings in the hospital. All patients have to be graded for transportation safety, according to their condition, by their doctors after hospitalization. According to the hospital's policy, only non-emergency patients can be transported by the patient transport team members in the hospital. The hospital's transport team consists of 2 senior nurses (team leaders) and 43 members.

One or two senior transport team members were in charge of the assignments during each shift before the system implementation. They had to print the transportation schedule from the computer every 4 hours, receive the instant telephone notifications, write down the patient information and assign the task to team members with radio pagers. It was difficult to measure the time interval between each step. Therefore, we fail to obtain data prior to system implementation.

According to the transportation process of the hospital, a patient transportation management system was developed by applying mobile phone and computer network communication technology. The system can receive scheduling appointments for all non-emergency patient transportation every day from the appointment scheduling systems of other departments in the hospital, as well as immediate patient transport requests. Each transport team member must carry a smartphone with him or her during work to receive the assigned task instantly through the mobile application. The detail patient and transportation task information will be presented in the app.

All transport team members followed standard operating specifications. The working status of transport personnel was divided into available, on duty, resting, and at meals. The action flow of each transport event included assigned, took over, transporting, and completed.

We recorded the time of each step performed by each member in each transport event. Variables included time of appointment, time of assignment, transport personnel, the location of take over, time of take over, destination, time of arrival, transport tool, main transport purpose, etc. After 2 months of system implementation, all data was remitted and descriptive statistical analysis was performed through Tableau Desktop public edition 2018.3.0.

Results

Two months after system implementation, the transport team members were familiar with the system operation. We conducted a retrospective analysis on 24,457 patient transport requests from August to September 2018. We excluded 922 (3.77%) requests canceled before transport assignment and 546 (2.23%) uncompleted requests due to patient not ready for transport. A total of 22,913 (93.69%) patients were taken over and completed transportation smoothly, including 76 (0.31%) transportations without recorded completion time. The most frequent patient transportation happened between the general ward and radiology (8,138), followed by general ward and operating room (4,242), and general ward and exam room (4,002) (Figure 1).

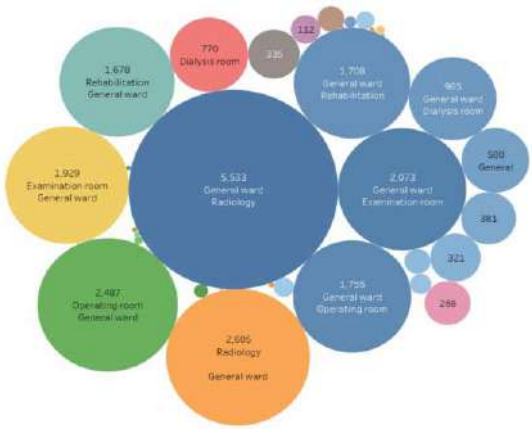

Figure 1- The frequency analysis between the transport units.

The frequency of transportation purpose was the highest for various examinations (12,456, 54.18%), followed by various treatments (6,037, 26.26%), surgery (4,101, 17.84%) and consultation (395, 1.72%). The main purpose and classification of transportations were analyzed and shown in Figure 2.

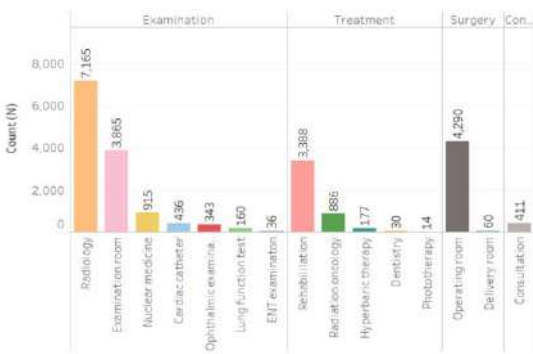

Figure 2- The histogram of the main purpose and classification of transportations.

The duration between the stages of each IHT event was analyzed. After the patient transportation management system implementation, most patients were taken over within 10 minutes of assignment (76.82%). After take over, 62.41% of the patients arrived at the destination within 10 minutes. The rate of transportation completion within 20 minutes was 93.71% (Table 1).

Table 1- The analysis of the execution duration between each stage of each IHT event.

Time interval (minutes)	From assignment to take over patients (n, %)	From taking over patients to mission completed (n, %)
No assign	245 (1.07)	76 (0.33)
> 30	888 (3.86)	385 (1.67)
20~30	714 (3.11)	986 (4.29)
10~20	3,481 (15.14)	7,195 (31.3)
3~10	16,238 (70.63)	10,809 (47.02)
< 3	1,423 (6.19)	3,538 (15.39)

Discussion

Communication, efficiency, and appropriateness are regarded as important issues affecting the quality and safety of non-emergency hospital transport [1]. The implementation of information systems has been widely recognized in improving communication and administrative efficiency of hospitals. One limitation of this study is the inability to obtain data prior to system implementation, but the results of this study can be used as a status analysis before IHT quality improvement. We found that most IHTs were concentrated in transportations between the general wards and the radiology department, operating room or the rehabilitation department. In addition, 6.29% IHTs were not completed within 20 minutes. The results of this study will help us further explore the appropriateness and efficiency of the current examination and treatment process and may prove helpful for designing automatic patient transportation management systems.

Conclusions

In Taiwan, the communication and safety of handing over patients and the risk management of patient transportation are important issues in patient safety. Safe and efficient patient transportation is a common expectation for patients, families, and health providers. Through the implementation of a patient transportation management system, we have gathered baseline data on the timeliness of non-emergency patient transportation. In the future, the impact of this system on the quality and safety of non-emergency patients will be further evaluated.

Requirement Analysis for Developing a Patient Participation Program in Patient Safety

Nam-Ju Lee[a], Shinae Ahn[a], Miseon Lee[a]

[a] *College of Nursing, Seoul National University, Seoul, Republic of Korea*

Abstract

Patients' roles in preventing errors has been emphasized. Patients' and families' participation is one of the important strategies to improve patient safety. Therefore, it is necessary to educate patients and families who visit hospitals. Web-based educational programs can be useful tools to provide patient safety information easily and enhance patients' and families' knowledge. This study analyzed requirements for developing a web-based program for patient participation in patient safety.

Keywords:
patient safety, patient participation, education

Introduction

Patient participation has been recognized as an important factor to improve quality of care, which is associated with positive health outcomes [1]. Ensuring that patients have the information needed to act as advocates for themselves may help to decrease patient safety incidents. The concept of 'patient participation' and 'patient-centeredness' implies that the patient can choose realistic goals independently and engage voluntarily in health care during the care process [2].

Patients and their families who have more knowledge about safety issues and information are more likely to participate in patient safety practices in their health care [3]. To promote patient participation in health care, appropriate interventions with educational materials and health information have been considered a crucial component of the methodology [4]. Therefore, healthcare professionals need to develop techniques and educational tools that increase patients' knowledge in preventing errors. However, there are not sufficient educational programs focusing on patient participation in patient safety activities in South Korea.

The purpose of this study was to assess patients' and families' educational needs for improving participation in safety practices and to identify the most important areas to be addressed in a web-based program for patient participation.

Methods

To construct the educational contents of a web-based program for patient participation, we conducted a survey, focus group interview, and literature review.

Previously, we conducted a online survey of health consumer's willingness to participate, their recognition of the importance of their participation, and their experience of engaging in patient safety practices. Our population was adults aged 19 years or older who had visited hospitals in South Korea within the previous one year [5].

Two-hour focus group interviews were held with two groups of six participants who had completed the survey and volunteered for the focus group interview. Data were collected during March 2018. The key interview question was as follows: "How was your experience with visiting medical institutions as a patient concerning patient safety?" All interviews were recorded and transcribed. After each interview, the research team listened to the recorded data, reviewed the transcribed data, and then coded the data. The qualitative data were analyzed using content analysis.

In addition, we conducted a literature review related to patient participation, patient safety frameworks, and evidence-based strategies for patient involvement in healthcare.

Results

A total of 493 respondents completed the online survey and 65% of the particpants reported that they had experience of patient safety incidents. The survey results demonstrated that their experience of participating in patient safety was relatively low compared to their perceived importance to patient safety and their willingness to participate in patient safety activities. They were reluctant to engage in confrontational situations, such as asking healthcare professionals to wash their hands [5].

Eight interview participants were female and four were male. Respondents' educational needs in patient safety practices varied considerably. Based on the focus group interviews, we analyzed interview data and categorized what patients wanted to know as 'patient rights', 'disease and diagnosis', 'treatment', 'surgery and medical testing', 'medication', 'patient advocacy', 'error disclosure', 'patient question checklists', and 'manuals for empowered patients'.

Through a review of the literature based on the patient safety frameworks and patient participation, we identified four competencies needed to improve patient participation in healthcare; 'speak up', 'ask questions', 'find health information', and 'engage with healthcare'.

According to the survey results, educational needs assessment, and the literature review of previous research on patient participation in healthcare, we identified thirteen priority areas to construct educational contents based on the most effective safety practices in reducing patient safety incidents: 'introduction to patient participation', 'patient rights', 'error prevention', 'patient advocacy', 'medical testing', 'surgical care safety', 'medication safety', 'infection prevention and control', 'fall prevention', 'patient-provider communication', 'patient identification', 'preparation for admission', and 'transitions of care'.

After initial development, the educational contents on patient participation were reviewed by four experts (one doctor, two

nurses, and one pharmacist) for content validity test. On the basis of their comments, some contents were too complex or difficult to understand were modified.

Conclusions

Health consumers are not active in particiting in patient safety activities in South Korea. They need to be informed of more information and resources for patient safety to enhance their engagement in safety practice. We are implementing a web-based program for patient participation in patient safety practice through content development based on the results of this requirement assessment.

Abstract

The results of Human Leukocyte Antigen (HLA) antigen testing in transplant patients are not generally used to predict future adverse events. In this study, free-text HLA screening results of transplant patients were analyzed and stored in a database, and the frequencies of patients with adverse events according to HLA allele were extracted. Approximately 25% of patients had HLA alleles associated with serious drug side effects.

Keywords:

HLA Antigens, Pharmacogenomic Testing, Drug-Related Side Effects and Adverse Reactions

Introduction

Human Leukocyte Antigen (HLA) is a protein that plays an essential role in the immune function of our body with a wide variety of allele types [1]. HLA diversity is particularly important in organ transplantation because transplant recipients and donors with different serological HLA proteins will exhibit organ transplant rejection [2]. Therefore, transplant recipients need HLA screening before transplantation. Recently, HLA diversity has been reported to cause severe drug hypersensitivity as well as organ transplantation rejection [3]. According to the PharmGKB database, there are about 40 drugs known to cause HLA-related adverse reactions, commonly prescribed drugs such as statins and NSAIDs were involved as well [4]. However, the HLA results of transplant patients and donors have not been used to predict future adverse drug reactions. This is because the HLA test is performed in different ways, ranging from a simple serological test to next-generation sequencing (NGS) test. Also, because the nomenclature for the representation of the HLA results is continuously updated, the test results simply stored as free text in the electronic medical record (EMR) [5]. In this study, we designed a data model, GDM-STAR, which expresses HLA test results according to HLA nomenclature and stores the test results in a database. We then used this database to derive predictable drug adverse events using HLA testing.

Methods

We extracted HLA test results performed between February 2002 and June 2018 including basic clinical data of the patients using SUPREME®, a clinical data warehouse at the Seoul National University Hospital. The research design and analysis methods were approved by the Institutional Review Board of Seoul National University Hospital (Seoul, South Korea). We parsed free text in clinical notes to extract HLA test results using the Python 3 regular expression function and loaded them to a database according to the allele type of HLA-A, B, C, DR, and DQ genes. Incomplete test results were filled in by a manual review by a research nurse (JY Lee). We then matched the HLA allele type loaded in the database with the HLA genotype in the PharmGKB clinical variants table. Finally, we derived a patient-drug table associated with a specific allele. All descriptive statistics and graphs were generated using R software [6].

Results

As a result of HLA parsing, a total of 16 HLA-A, 43 HLA-B, 15 HLA-DR, 19 HLA-DR, and 12 HLA-DQ genes were identified respectively. Of the 11,289 total transplant recipients, the HLA allele type of the patient matched the PharmGKB drug adverse event related genotype in 2,813 patients, accounting for 25% of the total patients. A total of 34 PharmGKB drugs or classes were matched to these patients. A total of 258 (9.4%) patients had drug-related HLA alleles in all five gene families (Figure 1). The most common drug associated with the patient was carbamazepine, and a total of 1,975 patients were found to have a side effect-associated gene for this drug. Table 1 shows drugs and frequencies of patients related to that drug with a patient frequency of 1% or more.

Conclusions

In this study, we designed a parser to extract HLA test results contained in free text in EMR and transform them into a tabular form according to the the five HLA gene families. Assuming that the organ transplant recipients are representative of the population, the database of HLA results shows that we could prevent adverse drug reaction in about 25% of the patients by building an HLA database.

It is essential to integrate such a clinical decision support (CDS) system within the EMR to achieve real-time precision medicine. Developing and testing of the CDS system using the HLA database is subject to further study. It is also important to increase physicians' understanding of pharmacogenomics to efficiently utilize the pharmacogenetics information derived from existing NGS tests.

Table 1- Distribution of patients by HLA allele- matching drugs

No	Drugs	#Samples	%
1	Carbamazepine	1975	17.5
2	Nevirapine	1907	16.9
3	Allopurinol	1330	11.8
4	Oxcarbazepine	1119	9.9
5	Lamotrigine	827	7.3
6	Peginterferon alfa-2b,ribavirin	696	6.2
7	Clindamycin	510	4.5
8	Phenobarbital	498	4.4
9	Interferon beta-1a	428	3.8
10	Ticlopidine	400	3.5
11	Statins	308	2.7
12	Antithyroid Preparations	307	2.7
13	Antiepileptics	295	2.6
14	Phenytoin	257	2.3
15	Azathioprine,mercaptopurine	199	1.8
16	Lapatinib	199	1.8
17	Influenza vaccines	173	1.5
18	Sulfasalazine	152	1.3
19	Methazolamide	120	1.1
20	Acetazolamide	120	1.1

Abstract

Clinical Quality Language (CQL), a HL7 authoring language to express clinical quality indicators, provides the capability to express logic that is human readable yet structured enough for processing a query electronically. OpenEHR is a widely used, modeling methodology, but currently CQL cannot support openEHR archetypes which hinders its usage in openEHR environment. This paper presents a method to express and compute clinical quality indicators by extending CQL with openEHR archetypes. To verify the feasibility of this method, 64 indicators from the Centers for Medicare & Medicaid Services (CMS) and 118 indicators from local environment in China were utilized. The results show that those indicators can be well represented and computed in openEHR environment.

Keywords:

Language, Quality Improvement, Quality of Healthcare Care

Introduction

It is a challenge to assess the validity of healthcare services to improve the patients' health. Clinical quality measures are important tools that help achieve the goal. Typically, clinical quality information can be represented in the form of indicators [1]. It can make information about clinical quality comparable across different healthcare service providers.

There exist some problems with the development of indicators. First, they are conducted by different providers for specific purposes, like government and large medical institutions. The absence of a unified and well-defined specification makes it difficult to share indicators among different organizations and cover the need for regional medical organizations. Second, the fuzzy expression of the natural language may lead to inaccurate computation.

Clinical Quality Language (CQL) is a HL7 authoring, language standard and provides the ability to express logic that is human readable yet structured enough for processing a query electronically. It acts as a mature specification and is widely used in the domains of quality measurement and decision support. As a well-known EHR modeling specification, openEHR is designed to ensure universal interoperability among all forms of electronic data. However, currently CQL cannot support openEHR archetypes which hinders its usage in openEHR environment.

The objective of this research is to explore an approach to express and compute clinical quality indicators through extending CQL with openEHR to facilitate the share of clinical quality information in openEHR environment.

Methods

In order to apply CQL directly to archetype-based context, we have proposed three extensions including archetype binding, terminology binding, and metadata.

Archetype Binding

The openEHR specification is used as the information model to express the medical concepts in clinical quality indicators. The archetype binding mechanism in Guideline Definition Language (GDL) [2] has been taken as a reference. It helps design indicators in a unified form. The mechanism established a relationship between medical concepts and data elements in archetypes which can lay the foundation for understanding meaning of indicators and binding terminologies.

Terminology Binding

Terminology can be used to disambiguate the expression of indicators. For the sake of including both public and private terminology sets, terminology binding mechanism was brought in to the extension. Two mechanisms used in Archetype Definition Language (ADL) [3] has been taken as a reference. One is to use the external terminologies directly and the other is defining a set of dictionaries about terms within the archetypes.

Metadata

Metadata was designed to help manage indicators easily and share indicators among different organizations. A series of metadata data elements were defined, including the name, version, purpose and so on.

Results

64 clinical quality indicators defined and revised by CMS in 2016 and 118 indicators from National Health Commission of the People's Republic of China were expressed successfully. A complicated indicator about controlling high blood pressure [4] was chosen to describe the detailed process of expression.

The complete expression is in Figure 1. The overall operational process is shown in Figure 2.

Figure 1. Complete Expression for Controlling High Blood Pressure

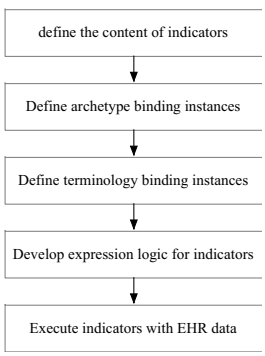

Figure 2. The Overall Operational Process

Discussion

By introducing archetype binding, terminology binding and metadata to formalism of quality indicators, it is helpful to those developers in openEHR community who works on assessment of indicators. Compared to CLIF[5], the method can take advantages of archetypes directly rather than define information models, related terminology and operations. On account of extending from CQL, the method can also support clinical decision support and clinical quality measurement relative to LERM[6]. The limitation of the method is that a relatively small number of indicators were expressed for validation.

Conclusions

We have explored a method to extend CQL with openEHR specification. Metadata, terminology binding and archetype binding have been refined and redesigned to satisfy the need of formalism of clinical quality indicators with the help of unified information models. These extensions can eliminate the inaccuracies of indicators and make them comparable among different organizations.

Near-Real Time Monitoring of Vaccine Uptake of Pregnant Women in a Primary Care Sentinel Network: Ontological Case Definition Across Heterogeneous Data Sources

Harshana Liyanage[a], John Williams[a], Rachel Byford[a], Sameera Pathirannehelage[a], Simon de Lusignan[a]

[a] Department of Clinical & Experimental Medicine, University of Surrey, UK

Abstract

Vaccination against influenza is important in pregnancy for the health of both mother and unborn baby. Influenza introduces risks to pregnancy and to the baby who relies on maternal antibodies for protection. Because the data associated with pregnancy is fragmented across multiple providers of health care, it is challenging to conduct pregnancy-related public health surveillance using a single data source. We report the integration of a novel ontological approach to identifying pregnancies in routine data with a web-based dashboard that feeds back information to general practices in a sentinel network. As a result, practices receive information about how well they are performing influenza vaccination in pregnancy in near-real-time.

Keywords:

Electronic Health Records, Pregnancy, Vaccines;

Introduction

Uptake of influenza vaccine in pregnancy is very important because there are considerable associated risks, both to mother and unborn baby. Influenza in pregnancy can result in preterm delivery and also morbidity and mortality for the mother. This was apparent in the 2009 pandemic. In the UK hospital and maternity data give a complete retrospective overview of data, but this is not available for many months after collection. Public health bodies need near real-time monitoring of vaccine uptake in pregnancy and also to be able to study influenza vaccine effectiveness.

Monitoring influenza vaccination during pregnancy is challenging due to the suboptimal recording of pregnancy data in computerised medical record (CMR) systems [1]. Pregnant women are considered to be a risk group in influenza immunisation programmes and therefore require to be monitored by sentinel networks. The Royal College of General Practitioners (RCGP) Research and Surveillance Centre (RSC) works in collaboration with Public Health England (PHE) to monitor influenza, other infections, and vaccine effectiveness – particularly influenza - in England.

Pregnancy related data is sparse are often scattered across the health care providers. Obstetric care is frequently shared between midwives, the family physician, and specialist obstetric units. Therefore data is stored in different formats and locations.

Dashboards that visualise health data are increasingly being used as decision support tools to make health care delivery more dynamic. This paper describes how a pregnancy case identification method was incorporated into an updated version of the dashboard that is currently being used to monitor the vaccine uptake of pregnant women in the sentinel network.

Methods

Identification of pregnant women from routine data

We developed an algorithm that accurately inferred pregnancies even when the availability of pregnancy-related data was limited. This was achieved by adopting an ontological approach for case finding [2]. Ontological approaches use technology agnostic information structures and can make use of existing technology stacks that assist with semantic reasoning and formal validation of the relationship between concepts used. An ontological approach to identifying pregnancies and associated complications uses a systematic approach to derive this information from routine data. Both direct pregnancy codes and surrogate markers, such as therapeutic data, can be used to identify cases. The ontological concepts were identified from a combination of literature searches and input from experienced General Practitioners. The concepts were annotated using two coding systems used in computerised medical record systems within the sentinel network (i.e. Clinical Terms version 3 (CTV3) and Read V2). The pregnancy ontology was implemented using the OWL (web ontology language) standard using Protégé ontology authoring environment. The pregnancy ontology is currently hosted on the BioPortal ontology repository. We implemented the pregnancy case identification algorithm using Structured Query Language (SQL).

Integration of the pregnancy algorithm outputs with the winter wellness dashboard

The dashboard was developed as part of a "Winter Wellness" dashboard. The purposes of the dashboard were to feedback to the practices about their clinical care. The dashboard interface contained a combination of tabular and graph displays [3].

The RCGP RSC database is refreshed on a weekly basis using increment data extracted from contributing general practices in the sentinel network. The weekly increment update is followed by the execution of the pregnancy case identification algorithm on the weekly data. This allows the identification of additional pregnancy outcomes recorded during the week. This information is processed with the vaccination data received through the same weekly increment data to ascertain the status of vaccination of pregnant women in the sentinel network.

Results

We were able successfully to integrate the vaccination data of pregnancy women in the winter wellness dashboard. The dashboard allowed the user to view the number of pregnant women eligible for influenza vaccination and the number of pregnant women that were administered with the influenza vaccination. RCGP RSC has over 200 practices currently uploading over 2 million patient records each week (www.rcgp.org.uk/rsc) into a freely available national report about influenza and over thirty other monitored conditions. We have now added the ability to report on the uptake of influenza vaccine in pregnancy.

We seem to have a similar cumulative vaccination rate in pregnant women as non-pregnant women in the same age-group The vaccination rates shown in Figures 1 and 2 are the vaccination performance of the sentinel network for the current season from ISO week 35 (2018) to 11 (2019). This information can also be obtained on the dashboard for each practice by entering a practice specific code.

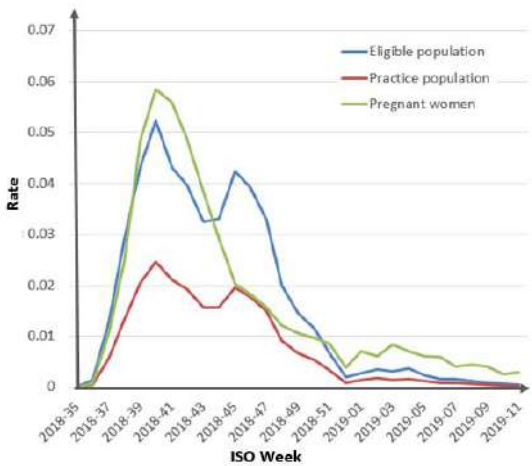

Figure 1 – The graph indicates the rate of practice population, rate of population eligible for vaccination and rate of pregnant women vaccinated at each ISO week (from week 35(2018) to week 11(2019))

Figure 1 indicates two peaks in weekly vaccination (week 40 and 44) when most influenza clinics are held at general practices for the current season. Figure 2 provides a cumulative rate of vaccination for the three groups described above. This information is particularly useful to understand if the vaccination programmes within the general practices are in a trajectory to meet the seasonal vaccination targets set.

Discussion

The use of the ontological approach also allowed us to consistently ascertain pregnancies throughout a network that uses and two different types of clinical coding systems for recording pregnancy events. We anticipate that this method will also make it easy to adapt the case identification in the system to the needs of SNOMED CT once this is fully adopted in English primary care.

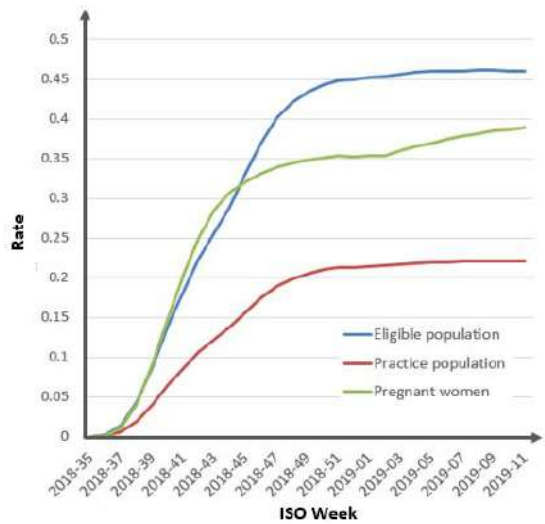

Figure 2- The graph indicates the cumulative rate of practice population, rate of population eligible for vaccination and rate of pregnant women that were vaccinated each ISO week (from week 35(2018) to week 11(2019)) from the beginning of the influenza season

Conclusions

To our knowledge this poster reports the first near-real time monitoring dashboard for influenza vaccine uptake in primary care. Realising this goal was particularly challenging due to suboptimal data quality of pregnancy events in primary care and the heterogeneity of the CMR systems we collect data from and coding systems in use. A web-based dashboard is now operationalised and providing weekly feedback of vaccine uptake to general practices in our sentinel network and will deliver reports about the level of uptake in our nationally representative network of practices to public health colleagues.

Effects of Enterprise Digital Assistants in Medication Dispensing Operations: Case HUS Hospital Pharmacy Meilahti 2014-2018

Teressa Lyly, Santeri Palomäki, Paulus Torkki, Tomi Malmström

Aalto University School of Science, HEMA Institute, Finland
Department of Industrial Engineering and Management

Abstract

Adverse drug effects are a serious problem in hospital patient care [1]. The use of Enterprise Digital Assistants (=EDA) proved succesfull in HUS hospital pharmacy. The quality of order picking was better with EDAs. In 2018 75% of order rows and over 1 milloin packages in are picked with EDAs. There is a growing need for more detailed information of the medicines given to each patient. With EDAs this goal can be achieved cost effectively.

Keywords:

Medication Safety, Barcode Technology, Hospital Pharmacy

Introduction

Medication errors are common errors in hospital treatment and care operations [1]. In order to minimize and prevent the number of adverse drug effect to patients hospitals must find out new solutions to ensure cost effective and reliable medication to their patients. New technologies can help to solve these problems. In HUS the cost of adverse drug event attributed to € 1.8 million in additional costs [2]. Hospital pharmacies supply hospital wards with their daily medication needs. The accuracy of medication picking in hospital pharmacy is an important step in hospital medication safety chain. In this research the hospital pharmacy changed the way the medicines were recognized during medicine picking. The traditional way is to print the medicine order into a paper sheet. The personnel would collect the right medicine with the help of this paper. In the paper there is the name of the medicine, the strength of the medicine and the number of packages ordered, the place of the medicine and the code of the medicine and the details of the ordering ward. It is labourous to read and recognize all this by eye. All these hand picked medicines have to be checked by a pharmacist before they can be delivered to the wards. An enterprice digital assistant (EDA) was introduced to the hospital pharmacy in order to recognize the medicine ordered also with the help of a bar code recognition technique, Picture 1. Also there was no longer need for paper lists as all the information of the medicine order could be found in the screen of the EDA with the help of the new pharmacy software program.

Methods

This study was carried out by analysing the times used in order picking in a hospital pharmacy medicine picking in HUS Pharmacy Meilahti in Finland. First the manual order picking process was analysed by 8843 order lines. Later the order picking of selected hospital wards (n=8) were carried out with the help of EDA equipment in 2014. This sample consisted of 9286 order rows. In 2016 and 2017 a second phase of the pharmacy software program was applied and the EDAs were taken into use to all hospital wards (n = >500 in Meilahti) and all types of orders lines, except the narcotics were the traditional order picking is still in use. In 2018 32000 order rows picked with EDA in Meilahti were analysed.

Results

The number of picking errors before phaumaceutical inspection was smaller with the use of EDAs (0.136%) as compared with the traditional picking, 0.938% in 2014, Table 1 [4].

Table 1 – Comparison of Traditional order picking and EDA picking in 2014

Picking technique, n	Picking speed	Picking errors
Picking with paper, n=8843 order rows	1.4 rows per minute	0.98 %
Picking with EDA, n=9286 order rows	2.29 rows per minute	0.14 %

With the phaurmaceutical inspection the picking error rate reported by the hospital pharmacists was 0.131%. In 2017 an analysis of the order picking errors resulted good as the wrong strengteh and wrong medicine errors dimished with the use of EDAs [3]. Also the speed of order picking was faster with EDAs than with traditional picking in 2014. With traditional order picking the result was 1.4 order rows per minute. With an EDA the order picking rate was faster, 2.29 rows per minute. A secondary check out of the hand picked medicines by a pharmacist was found out unnecessary as the picking result was better with the use of EDAs than with traditional hand picking with pharmaceutical inspection. In 2017 the number of order lines picked with the use of EDAs exceeded 130 000 order rows in HUS Pharmacy Meilahti. In 2018 already 75% of the order rows are now picked with the help of EDAs in HUS Pharmacy Meilahti, Table 2. With the help of the second phase of pharmacy software the amount of medicine packages recognized with the EDAs was raised from 44% to 100%. During 2014 to 2018 the EDAs also developed and the time used for order picking was even faster, 2.1 rows per minute, n=32000. The picking process was also more reliable as in 2014 only one medicine package / order was recognized with the help

of an EDA (57%) but in 2018 all the picked medicine packages were forced to be recognized by the settings of the hospital software program by their bar code (100%) with the help of an EDA. This change in the hospital pharmacy sorfware settings helps in preventing the picking errors very efficiently. Also the EDA equipment developed during 2014-2018 and the third generation of these equipment are faster to work with. With these developments both a faster and a more precise picking process could be achieved.

Table 2 - The development of EDA order picking in Meilahti

Year	Medicine packages recognized with a bar code	% recognized with a bar code	All order rows	Order rows picked with EDA	% of order rows picked with EDA
2014: 4 months	1046	57.75	233725	571	0.24
2015: 12 months	21418	44.17	260698	15394	5.9
2016: 9 months	11469	71.93	262210	5754	2.19
2017: 12 months	5E+05	96.02	251798	1E+05	52.03
2018: 5 months	3E+05	100	113457	86072	75.86

Conclusions

The HUS hospital pharmacy is very satisfied with the new technique of picking medicine packages with the use of EDAs. The number of medicine picking errors is smaller and the rate of order picking is faster with the new EDA models. More pharmaceutical personnel nowadays work at the hospital ward directly with patient medication processes instead of the hospital pharmacy warehouse logistics chain. Therefore HUS hospital phacmacy has now applied this technique of order picking in all their 6 hospital pharmacies during 2016-2018. In year 2018 the number of order lines picked with the help of EDAs in these 6 hospital pharmacies will exceed 1 milloin order rows. HUS Pharmacy will further develop the process by adding more information into the bar coding of each medicine package as there is a growing need for more detailed information of the medicines given to each patient.

Development of a Practical Course to Assist Elementary School Students in Acquiring the Ability to Support for Elderly People with Dementia

Seiko Masuda[a], Kotoka Murashima[a], Yukie Majima[a], Yumiko Nakamura[a]

[a] *Graduate of Humanities and Sustainable System Sciences, Osaka Prefecture University, Sakai, Osaka, Japan*

Abstract

Support for elderly people with dementia is required in the community. Many elementary school students are taking dementia kids supporter training courses, but it is difficult to nurture the ability to correctly understand and respond to dementia.. By using multiple information communication technologies, we developed a practical program with concrete response method to convey knowledge on supporting of elderly people with dementia..

Keywords:

Dementia; primary schools, robotics

Introduction

Supporting with elderly people with dementia is becoming an imminent issue in Japan that is faced with the highest elderly people with dementia prevalence rate of 2.33% among the OECD member countries with its population aging at a rapid pace like none in the world [1]. Neighborhood connections are declining, and more elderly are living alone. Under such circumstances, however, elderly people in need of assistance tend to hesitate to seek help from people around them. Many elderly are also living with dementia [2].The isolation of the elderly leads to abuse, unattended death, suicide of their caregivers from fatigue, and other threats to health and safety[3].

Therefore, existing organizations, such as neighborhood associations, elderly people groups, and parents and teachers associations, are keeping their watchful eye on senior citizens. But young generations know little about how to associate with elderly persons with dementia. Thus, public awareness campaigns about elderly with dementia are necessary among young people.

The elderly with dementia supporters training course, has been developed in Japan, with the aim of nurturing the ability to understand the elderly with elderly without prejudice and treat them with respect. The organizers also established a framework to educate supporters by using learning materials that are commonly applicable in Japan.

The current elderly with dementia supporter training course promotes an understanding of dementia for members of society. Participants apply the knowledge and skills they have learned in the course wtih practical experiences of engagining with elderly. .Elementary school students particpated in the course to increase their enagegement with elderly persons.. Organizers provided sought to create enjoyable learning material that would inspire students' interest in the disease. The developer utilized information communication technologies that are being introduced into school education for its highly expected learning efficacy. The developer combined a set of slides that aimed at raising the awareness of elderly with dementia among primary school students with the communication robot named Pepper and a clicker. The program enabled the robot to play multiple roles, to assist students in gaining knowledge, and learn specific countermeasures related to dementia. The developer is now examining the efficacy of the program.

Methods

We recruited elementary school students through posters placed in three districts of H prefecture from 2016 to 2017. Developed Softbank Robotics, Pepper was used for our study. Pepper is a humanoid robot measuring 121 centimeters high, and was designed to recognize faces and voices and strike a conversation. A special program has been built into Pepper that enables Pepper to play the roles of a tutor and as an elderly person with dementia. The developer has given the humanoid robot multiple roles that target the robotic process of acquiring knowledge and subsequently learning practical skills.. Ethics approval was obtained by the research ethics committee of the affiliated institution of the author.

Materials for Acquiring Knowledge

In the earlier part of the training course, the slides rely on illustrations and stories to encourage participants to draw an affirmative image of elderly people. The content was designed to help participants understand that dementia is a cognitive disease that makes it difficult to remember, think and learn.

To maintain the interest of participants, quizzes about the elderly with dementia were given by Pepper at the beginning, the middle, and near the end of the course. Participants answered the quiz using the clicker. The clicker enabled participants to confirm the knowledge they had learned in real-time and to maintain their motivation. To comparie their degree of understanding of the elderly and the disease, answers from all participants were instantly displayed. Anonymity secured by the clicker encouraged all participants to answer the quiz and compare their answer with other participant's answers.

Materials for Mastering Skills

To effectively achieve a successful learning environment we applied the M. D. Merrill First Principles of Instructional Design (ID) to the design of the teaching material [4]. Figure 1 shows the timing to apply the first principles of Merrill's ID to teaching materials. Specifically, when Pepper showed the symptoms of dementia, participants face ① a problem (① problem) with their knowledge (② activation). After that, when participants did not do the right correspondence, Pepper gentlely provided an example (③ example). Next, participants tried to apply their understanding to different challenging scenarios (④ application), and and and looked back on

Pepper's reaction when answering questions (⑤ integration). Through this process, participants could effectively integrate learning.

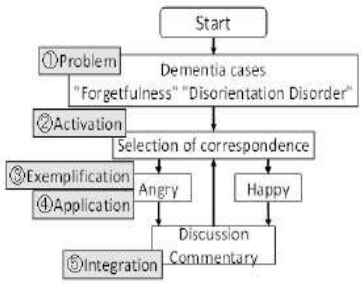

Figure 1-Application Method of Merrill's First Principles of Instructional Design

Results

We recruited 38 elementary school students through the posters. To the question: "Was slide teaching materals easy to understand?", 35/38 people (92%) responded "It was easy to understand". In the free description, there was a statement that "It was easy to understand with colorful pictures and figures, large letters". 36/38 people (95%) answered "It was easy to understand" about "Pepper's talk was easy to understand". Additional statements in the free description, included "the talk stopped suddenly, and it was hard to hear", "it was a one word". Regarding "Was it easy to understand using Clicker", all responded "easy to understand" The following was noted on the questions when comparing the correct responses before and after the course: "Dementia can Affect anyone" ($p < 0.001$), "Dementia patient and trouble family" ($p = 0.002$), "I know about elderly support networks "($p = 0.004$). (see Table 1).

About the learning effect of the modeling of the role of elderly with dementia questionnaires, we conducted a questionnaire by five level evaluations to five experts in community welfare. The average points of the results were 4.2 points for "① problem", 3.6 points for "② activation", 4.6 points for "③ exemplification", 4.4 points for "④ application", and 4.2 points for "⑤ integration". On the whole, we found the course to be effective in showing how elementary school students' behavior affects elderly people with dementia; they can see the influence of their own action and enhance the educational effects.

*Table 1-Comparision of Understanding of Dementia **b**efore and After the Workshop (n=38)*

	Before			After			p
	Yes n(%)	No n(%)	Do not know n(%)	Yes n(%)	No n(%)	Do not know n(%)	
Dementia can Affect anyone	15 (39.5)	12 (31.6)	11 (28.9)	35 (92.1)	2 (5.3)	1 (2.6)	<0.001 *
Dementia patient and troubled family	22 (57.9)	3 (7.9)	13 (34.2)	35 (92.1)	1 (2.6)	2 (5.3)	0.002 *
Everyone is easy to live in the town that will help people in need	34 (89.5)	1 (2.6)	3 (7.9)	37 (97.4)	1 (2.6)	0 (0.0)	0.102
If there is a person who is in trouble, I want to help	33 (86.8)	1 (2.6)	4 (10.5)	35 (92.1)	0 (0.0)	3 (7.9)	0.276
I know about elderly support networks	5 (13.2)	24 (63.2)	9 (23.6)	18 (63.6)	11 (28.9)	8 (21.1)	0.004 *

Signed rank test of Wilcoxon * P <0.05

Discussion

The use of multiple media encouraged participants to be actively involved in the elderly with dementia supporter training course and maintained their motivation. The course helped to build an affirmative appreciation of the elderly, and improve participants' understanding of elderly with dementia. Acting as a tutor, Pepper raised the interest and concern of participants, explaind important parts of the slides and gave a quiz. By making a robot play the role of a tutor, the program created a trilateral relationship that advanced proactive learning, instead of a bilateral confrontational relationship between teacher and learner. In order to strengthen the understanding of dementia among all participants. future development should focus on creating content that will encourage participants to exchange their knowledge with each other and subsequently build such a content into the program. Participants will be able to respond appropriately to elders with dementia through their role-playing interactions with Pepper.

Conclusions

We are incorporating Pepper to serve as tutor and role-play an elderly person with dementia. By making the humanoid robot take multiple roles, will allow for particpants to acquire and practice their new knowledge. Future work will focus on a practical application in the program where the robot will play the role of elderly person with dementia and incorporates the primary school grade viewpoint.

Abstract

Regional disparities in the implementation rates of recombinant tissue-type plasminogen activator and endovascular thrombectomy treatments have been reported in Japan. We simulated the cost-effectiveness of specialist dispatching system in Hokkaido, Japan using Geographic Information System. In the system a qualified specialist is dispatched to another hospital for endovascular thrombectomy. Since the system improved patient accessibility, and the cost-effectiveness was excellent, the system could help enhance the equality and cost-effectiveness of ischemic stroke treatments in Hokkaido.

Keywords:

Cost-Benefit Analysis, Geographic Information System, Ischemic Stroke

Introduction

The proportions of stroke in the medical and nursing care expenditures are not ignorable. Therefore, it is necessary to consider the cost-effective management of stroke treatments. Endovascular thrombectomy (EVT) combined with recombinant tissue-type plasminogen activator (rt-PA) has been known as effective for acute ischemic stroke (AIS) patients [1]. However, due to the time limits, regional disparities in accessibility to the treatments have been reported. Specialist dispatching system (SDS), in which a qualified specialist for EVT is dispatched to another hospital for EVT, has been partly in practice in Hokkaido. SDS can be a solution to the regional disparities that will be achievable without allocating any further resources. However, there is no research that evaluates the effect of SDS on patient accessibility to rt-PA and EVT, and the effect on the cost-effectiveness of SDS. To suggest a solution to enhance the equality and the efficiency of AIS treatments in Hokkaido, this study simulates the effect of SDS on accessibility to rt-PA and EVT, and simulates the cost-effectiveness of SDS from the public perspective.

Methods

Subjects and Outcomes

The subjects in this study are a virtual cohort of patients with AIS in Hokkaido, Japan, at the time setting of 2015. Solitary island areas are excluded. There are 2 scenarios: (1) current scenario in which patients are taken to the closest of the 29 facilities where qualified specialists for EVT work (Hub hospitals); (2) SDS scenario in which a qualified specialist for EVT is dispatched from a hub hospital to another hospital without a specialist that is equipped for rt-PA and EVT, and that is within 60-minute drive distance. The primary outcome is the Incremental Cost-effectiveness Ratio (ICER) from the public perspective, which is calculated by dividing incremental costs by incremental Quality Adjusted Life Years (QALY) (Equation1). In this study, ICER is evaluated using the threshold of 5,000,000JPY per QALY (approximately US$44.154 at the exchange rate on November 7, 2018), which has been suggested for cost-effectiveness evaluation in Japan [2]. Cost gain (reduction) by the system is also analyzed.

$$\mathrm{ICER} = \frac{\text{Cost with SDS} - \text{Cost without SDS}}{\text{QALYs with SDS} - \text{QALYs without SDS}} \quad \text{(Equation1)}$$

Patient Generation

The number of AIS patients in Hokkaido in 2015 is estimated from the patient's behavior survey 2014 by the Ministry of Health Labour and Welfare [3], and are generated on Geographic Information System (GIS) based on the population distribution (Arc GIS Desktop 10-ESRI Inc.), using the "Random Point Generation" function.

Transport Time Analysis

Patient transport time is analyzed with the "Closest Facility Analysis" function of GIS. The sum of ambulance arrival time at the patient's location and the time from the arrival up to the hospital is defined as "transport time". The patients are grouped into four by the transport time windows, 0-1hour, 1-2 hours, 2-3 hours, and 3 > hours.

Patient Outcome Estimation

Patient severity is estimated in the form of modified Rankin Scale (mRS) at 90 days after onset, based on the transport time windows [4] (Table 1). Our analysis attempts to reflect the nature of rt-PA and EVT that the later a treatment start is, the worse outcome will be expected. The data of treatment time and patient outcome from the HERMES research is used for the analysis [4]. It is assumed that 16.9% of patients transported within 3 hours are eligible for rt-PA and EVT, according to the data from the Stroke Databank which is a nationwide database of stroke cases in Japan [5].

Cost and QALY Estimation

Total costs and QALYs are calculated by multiplying the per-patient cost at each time window by the number of patients at the time window, and summing the total costs of all the time window. Medical costs, as well as nursing care costs, are included in the cost analysis since stroke patients are likely to suffer post-stroke disability lifetime. Those costs are estimated

based on the estimated patient mRS stages. Data on the medical cost for patients at each mRS stage is obtained from the Stroke Databank [6] (Table 1). Nursing care costs are estimated from patients' Care Need levels (Table1), which is the official classification of patients with nursing care. (The Care need levels are divided into 7 categories (Support level 1 to 2, and Care Level 1 to 5), with Care Level patients severer than Support Level patients, and larger numbers mean that patients tend to have a severer disability). The estimated mRS stage is changed into the care needs and the nursing costs at each care need level are calculated, according to Yamaga et al. [7]. It is assumed that patients utilize nursing care services at the rates shown in Table2 [8]. QOL utility data at mRS stages are obtained from the study by Hattori [8], which collected data from a cohort of Japanese stroke patients.

Results

The results of patient transport time are shown in Table 4. The rates of patients transported within 3 hours would increase from 98.5% to 99.0% with SDS (45 increase in number). Other 203 patients (2.3% of all the patients) could be benefited from earlier treatment windows. Estimated Per-patient costs at each time window are shown in Table 5. The results showed that shorter transport time led to cheaper cost expectations. The ICER by implementing SDS was dominant since QALY gain, and $214,710 cost reduction would be achieved with SDS.

Table 1 – The expectations of mRS stage distributions at 90 days at the transport time windows and treatment eligibility

Time window	Treat eligiblity	nRS stage (%)						
		0	1	2	3	4	5	6
0-1 hour after onset	Eligible for rt-PA and EVT	0.11	0.216	0.245	0.194	0.116	0.05	0.07
1-2 hour after onset		0.096	0.198	0.24	0.202	0.127	0.057	0.08
2-3 hour after onset		0.084	0.181	0.213	0.209	0.138	0.063	0.092
All time windows	Not eligible for rt-PA and EVT	0.036	0.062	0.125	0.087	0.312	0.15	0.225

Table 2 – Per-patient medical costs, Care need levels, nursing care service utilization rates, QOL utilities for each mRS stage

	mRS stage						
	0	1	2	3	4	5	6
Total medical costs (US$)	7,594	10,244	14,570	16,780	20,130	28,520	23,930
Care need level	/	Support level 1	Support level 2	Care level 1	Care level 2 or 3*	Care level 4 or 5*	/
Nursing care service utilization rate	0.0%	26.1%	91.8%	98.5%	100.0%	100.0%	/
QOL utility	0.89	0.797	0.65	0.588	0.363	0.092	0

Conclusions

This study simulated the effect of SDS on accessibility to rt-PA and EVT, and cost-effectiveness of SDS from the public perspective. Excellent cost-effectiveness, or, cost reduction effect of SDS was revealed. Therefore, even though the potential patients who would be benefited don't account for a large part of all patients in Hokkaido, SDS will enhance the equality and cost-effectiveness of AIS treatments in Japan without allocating any further medical resources. Further analysis is required on each secondary medical area, which is a regional unit to provide in-hospital medicine, for the purpose of evaluating the areas where SDS will be the most effective.

Table 3 – Per-patient nursing costs for each Care need level

	Support level 1	Support level 2	Care level 1	Care level 2	Care level 3	Care level 4	Care level 5
Nursing care costs (US$/year)	3,079	5,263	11,264	15,224	22,296	26,757	30,811

Table 4 – The number of patients in each time windows

Scenario	Transport Time Window					
	Total	0-1 hour	1-2 hour	2-3 hour	Over 3 hours	Within 3 hours
Current	8,528	7,085	8,037	8,397	131	98.5%
SDS	8,528	7,270	8,104	8,442	86	99.0%

Table 5 – Expected per-patient costs at each time window

Transport time	Medical cost	Nursing cost	Total cost
0-1 hours	$14,459	$18,730	$33,189
1-2 hours	$14,877	$20,055	$34,932
2-3 hours	$14,418	$21,242	$35,660
3 hours	$20,177	$35,547	$55,724

Developing a Model for Using Clinical Routine Data to Analyze Nursing Sensitive Patient Outcome Indicators

Renate Nantschev[a], Werner O. Hackl[a], Elske Ammenwerth[a]

[a] *Institute of Medical Informatics, UMIT – University for Health Sciences, Medical Informatics and Technology, Hall in Tirol, Austria*

Abstract

Under the term "big data", the secondary use of available IT-based clinical routine data promises to easily support quality management and research. Available clinical data can, for example, be used to measure care quality, as this is an important aspect in the evaluation of health interventions. Different indicators are available for measuring care quality, e.g. nursing sensitive outcome indicators. However, a specific methodology for using clinical routine data to measure quality of nursing care is not available at the moment. We present first ideas for a model to use clinical routine data to derive nursing outcome indicators measuring quality of care. In particular, we are interested in the question of which care indicators can be extracted to predict care outcome.

Keywords:

health care quality indicators, outcome assessment, patient safety

Introduction

Measuring care quality is an important aspect in the evaluation of health interventions due to increasing economic pressure and legal requirements on health care facilities. For this purpose, meaningful key indicators are necessary.

In many countries, basic indicators for care quality are defined by law. For example, in Austria, the Inpatient Quality Indicators (A-IQI) are already established as a legal instrument for measuring the quality of outcomes [1, 2].

However, this instrument ignores indicators that measure the quality of nursing care. Nursing sensitive outcome indicators can be used to measure the quality in nursing. Nursing-sensitive outcomes are measurable patient conditions based on interventions for which nurses are responsible [1]. These indicators can be subdivided into subjective and objectively measurable outcomes. The subjective outcomes are e.g. patient satisfaction, well-being and quality of life. The objective outcomes are e.g. patient safety, symptom management, functional status and self-management.

Nursing-sensitive outcomes may also focus on patient safety. Six types of nurses-reported adverse events are often described. These are: medication - administration errors, pressure ulcers, patient falls with injury and three types of healthcare-associated infections (urinary tract, catheter related bloodstream infections and pneumonia). All are considered sensitive to nursing care [3].

Currently a standardised collection of data with scientifically supported instruments for assessing the quality of nursing care outcomes does not exist in Austria [1].

In the USA, for example, data on nursing outcome indicators are collected in a standardised way in national databases such as the collaborative alliance for nursing outcomes (CALNOC) or the national database of nursing quality indicators (NDNQI).

This data is used as a basis for analysing Nursing Outcome. In Europe the currently largest study on nursing outcomes was conducted in 12 countries and with a total of 30 hospitals. Data was collected on structure, process and outcome quality. With this data the research group was able to perform nursing specific outcome analyses [4].

In practice, models of this kind require a considerable amount of additional documentation, and the collection of data is always carried out on a selective basis, e.g. once a quarter. However, routine clinical documentation is a key task in nursing practice and produces a great amount of electronically available data. Standardised methods for using clinical routine data to measure nursing outcomes are currently not available. A further challenge is to structure the clinical routine data in order to make it usable for analysing quality of care.

Objective

To develop a model for using clinical routine data to analyze quality of care for selected patient safety nursing sensitive outcome indicators.

Methods

The development of the model is based on the SPIRIT (Systematic Planning of Intelligent Reuse of Integrated Clinical Data) methodology. SPIRIT provides a general framework to plan and design solutions for the reuse of clinical routine data [5].

The development of the conceptual data model follows three steps (cf. Fig. 1):

1. Expert interviews

Experts from nursing quality control divisions from different hospitals are sampled for interviews. A semi-structured interview guide is used. The interviews cover four areas: (1) Relevance of nursing outcome indicators; (2) Currently used measurement methods; (3) Process of creating and structuring care data (4) Needs for care outcome analysis. The interviews are analysed using the qualitative content analysis according to Mayring [6]. Based on the results, questions for the data model are developed.

2. Identification of influencing factors for outcome.

In a second step, evidence for factors influencing nursing outcome indicators (e.g. patient falls) are collected from scientific literature. A systematic literature research is conducted in scientific databases such as Pub Med and CINAHL. All influencing factors from studies and guidelines considered to be relevant are included as objects in the conceptual data model.

3. Identification of clinical processes

Scenarios are created in order to obtain information about where routine clinical data is created in the process of care. Based on this, the relationships between the objects in the data model are detailed. The scenarios are evolved using five phases as described in Kosow (2008). First is the identification of the scenario field, second is the identification of the key factors, third key factors are analysed, then the scenario is generated and finally transferred [7].

After the development of the conceptual data model, a case study is conducted to match the objects of the data model with the available clinical routine data in a health care facility. Statistical analyses are carried out with the available data and a procedure for the analysis is described. Based on the results, a framework for using clinical routine data to analyse nursing sensitive patient outcomes is created.

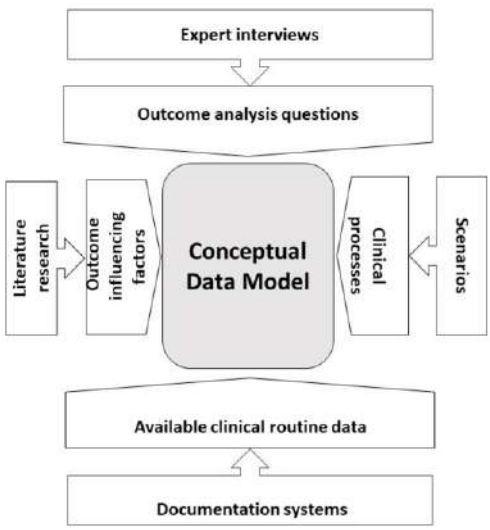

Figure 1: Overview of the conceptual nursing sensitive outcome data model with the different steps of development.

First Results

Expert interviews and literature research are currently under way. Nursing outcome indicators and quality measurement approaches have been identified based on a broad literature research.

Discussion

This study will offer a way to detect quality of care by using routinely collected patient data. The conceptual nursing sensitive outcome data model is developed as a best-practice framework, which permits the use of clinical data to measure nursing outcomes. This study will reveal if routinely collected patient data is suitable for measuring quality of care and patient outcome. If it fails to do so, it can produce input into how clinical documentation must be modified in order to achieve this goal.

The Survey for Determining Knowledge-Related Problems in the Dissemination of ICD-11

Akemi Nishio[a], Eizen Kimura[b], Ryoma Seto[a], Yoko Sato[c], Hiroshi Mizushima[b]

[a] *Tokyo Healthcare University Setagaya, Tokyo, Japan*
[b] *National Institute of Public Health, Wako, Saitama, Japan*
[c] *National Defense Medical College, Tokorozawa, Saitama, Japan*

Abstract

Changes in the 11th revision of the International Classification of Diseases (ICD-11) from ICD-10 may significantly impact coding quality. We conducted a field trial in 2017 to evaluate the line coding quality of 19 cases coded using the coding method of the World Health Organization. The cases with low agreement between the accuracy rates of ICD-10 and ICD-11 were cases that required the extension code. We should prepare effective educational content about how to use the extension code for proper coding in ICD-11.

Keywords:

International Classification of Diseases, World Health Organization, Clinical Coding

Introduction

The World Health Organization (WHO) requires that investigations of the effects of the revisions through field trials assess applicability, reliability, and usefulness so that the WHO may fix issues before the rollout of the final version of ICD-11[1]. Field trials are conducted by experts who perform ICD coding in actual medical settings so that they not only provide useful information on the effects of revision on statistical data but also measure the effectiveness of the revision itself[2; 3]. The WHO provided the ICD-11 Reference Guide and the ICD-FiT (a web-based data entry tool to support the protocols of implementation of ICD-11 field trial core study), case scenarios, and diagnostic terms for the field trial[4]. We conducted a field trial in 2017 and evaluated line coding and case coding. In this study, we investigated the relationship between the gold standard code provided by WHO and the codes entered by the participants to determine what education and training are necessary for ICD-11 dissemination.

Methods

We conducted a field trial from August 2017 to September 2017, in collaboration with the Japan Society of Health Information Management and the Japan Hospital Association. Participants were recruited online. During the trial period, they logged into the field trial system (ICD-FiT) and entered the answers at their convenience time. We translated the ICD-11 reference guidelines and some of the instructions in ICD-FiT into Japanese. However, the overall interfaces and messages in ICD-FiT were left in English. We examined whether the ICD-10 and ICD-11 codes coded by participants were consistent with 19 gold standard diagnostic terms provided by WHO.

Agreement analysis using Gwet's AC1[5] was carried out to confirm whether the answers of ICD-10 and ICD-11 were consistent with one another. If divergence observed in the accuracy rates of ICD-10 and ICD-11, we assume that there is some gap of knowledge for coding. We used the R Statistical Software v.3.5.1 (R Foundation for Statistical Computing, Vienna, Austria) and 'sirt' package (supplementary item response theory models).

We classified comments of respondents who found difficulty during coding into eight categories and tabulated the proportions of each category for ICD-10 and ICD-11 (Table 2): (1) the classification code was ambiguous; (2) the inclusion term was insufficient or missing; (3) the classification code was indistinguishable from the others; (4) the coding guide was incomplete or unclear; (5) the description of a diagnostic term was ambiguous; (6) lack of knowledge about the code; (7) the concept of the code was too broad; and (8) other. After the field trial, we administered a questionnaire on English proficiency to the participants.

Of note, the ICD-11 provided by WHO in this trial was the development version as of August 2017 and is not identical to the ICD-11 that is currently published.

Results

Three hundred seventy-eight health information managers participated as evaluators of ICD-Fit. The total number of responses for line coding was 3,959 for 19 diagnostic cases. The accuracy rates of ICD-10/11 on Central line associated Escherichia coli (E. coli) sepsis and Kaposi's sarcoma of the soft palate with AIDS were 0%. The results of the other 17 cases are shown in Table 1. Cytomegalovirus Colitis, Right breast angiolipoma, Pleomorphic adenoma of right parotid gland showed extremely low Gwet's AC1 value; however, Cytomegalovirus Colitis had higher accuracy rate for ICD-11 than that for ICD-10. There were 8 cases where the accuracy rate of ICD-11 exceeded the ones of ICD-10, and 9 cases were lower than the ones of ICD-10. In the case where an extension code was required, the accuracy rate of the ICD-11 was meager.

The numbers of participants who experienced difficulty in coding were 91 and 115 for ICD-10 and ICD-11, respectively (Table 2; *n* represents the number of responses and *%* the proportion). Lack of knowledg of ICD-10 and that the concept of code was too broad for ICD-11 were the top reasons for causing difficulty in coding. In the cases with 0% accuracy rate in ICD-11, too broad concept of the code was the most common reason. There were 93 respondents to the questionnaire on English proficiency; 25 people chose "understand to a certain extent," 67 people chose "do not understand well," and 1 person chose "other.".

Table 1. The agreements and accuracy rate of the coding results of ICD-10 and ICD-11

ID	Disease Name	n	Gwets'AC1	ICD10 Accuracry Rate(%)	ICD11 Accuracy Rate(%)	w Extention
1192	Puerperal sepsis	291	0.8968	93.47	95.88

7	18	19.78	43	37.39
8	17	18.68	6	5.22
Total	91		115	

Discussion

In most of the cases that require an extension code, the accuracy rate of ICD-11 was low. The current study was conducted only on infectious diseases; therefore, we could not determine the critical factors influencing whether the ICD-11 codes by participants matched the gold standard. We should investigate the cases requiring extensions with other types of diseases and the details in errors. Since this study was generally conducted in English with only a few materials translated into japanesse, its influence on the low accuracy rate in the complex code was considered to have been great. For a short diagnostic term, ICD codes can be easily retrieved by copy and paste in the coding tool. However, for the longer ones, it's hard for evaluators to choose the appropriate word to search. Linguistic problems might have inhibited non-English native participants from acquiring the appropriate search terms. We plan to confirm how the accuracy rate will change after all materials in ICD-FiT translated into Japanese.

For future work, we will investigate sections other than infectious disease, identify common causes of gaps between ICD-10 and ICD-11 in accuracy rates, and develop an effective curriculum in which participants can learn new features of ICD-11 efficiently.

ConclusionIn the cases that the extension code was included, the coincidence rate between ICD-11 respondents and the gold standard was very low. The low accuracy in the cases with extension code might be also due to the language barrier. We think it is necessary to translate the materials into Japanese and to have more field trials after teaching the notions of extension code to take ICD-11 to the practical stage.

Detection Algorithm for Inadequate Blood Specimens Due to Contamination with an Infusion Solution in the Clinical Chemistry Tests: Prevention of Incidents by Blood Draw Error

H Nozaka[a], H Sazawa[b], E Ozaki[a], M Nakano[a], H Takami[a]

[a] *Hirosaki University Graduate School of Health Sciences, Hirosaki City, Aomori, Japan*
[b] *Department of Clinical Labolatory, Hokkaido Cancer Center, Sapporo City, Hokkaido, Japan*

Abstract

The aim of this work is to study the influence of contamination with infusion in clinical chemistry tests and to design an algorithm for detection of inadequate blood specimen. We show that panic value of postassium (K+)/ glucose (GLU) or decrease of total protein (TP), albumin (ALB), urea nitrogen (BUN), uric acid (UA), high-density lipoprotein cholesterol (HDL-C), total cholesterol (T-CHO), and calcium (Ca) is an index of contamination of drip infusion solution. Through a clinical study, we show that our algorithm is useful for preventing adverse medical errors.

Keywords:
Patient Safety, Medical Errors, Clinical Chemistry Tests

Introduction

Panic value due to inadequate blood specimen is often reported in hospitals as one of the causes of contamination with drip infusion solution into the blood [1 – 2]. It is shown that contamination with drip infusion solution is caused by incorrect blood drawing techniques or positions. Therefore, drawing blood guidelines are determined by Japan Committee for Clinical Laboratory Standards (JCCLS) or National Committee for Clinical Laboratory Standards (NCCLS). Panic values due to incorrect blood drawing may be detected and confirmed using conventional quality control methods. However, it is difficult to detect contamination with drip infusion solution, where tests may not reach the panic value and may go unnoticed, leading to adverse incidents in hospital. The aim of this work is to study the influence of contamination with drip infusion in clinical chemistry tests, and to design an algorithm for detection of inadequate blood specimen that is contaminated with drip infusion solution.

Materials and Methods

Materials

The subject of research is a healthy adult person. We used five types of drips with different contents of electrolytes and glucose isotonic electrolyte infusion solution (Lactec) or hypotonic electrolyte infusion solution (T1 /T2 /T3 /T4)) for this study.

Methods

The infusion needle was injected into median antebrachial vein and the drip solution was then infused. The flow speed of infusion was controlled from 0 ml/h to 150 ml/h with infusion pump. Blood was drawn from up/down stream position of same side vein as well as from the opposite side vein (see Figures 1 and 2). After blood centrifugation, serum was collected and analyzed using a dry-chemistry auto-analyzer (FUJI DRI-CHEM 4000). We then extracted the biochemical test items that changed due to the contamination and determined the cutoff value of infusion contamination. We designed a detection algorithm for inadequate blood specimens due to contamination with infusion solution in the clinical chemistry tests. The sensitivity and specificity of the algorithm was evaluated using contaminated or non-contaminated (blineded) blood specimen from 20 patients.

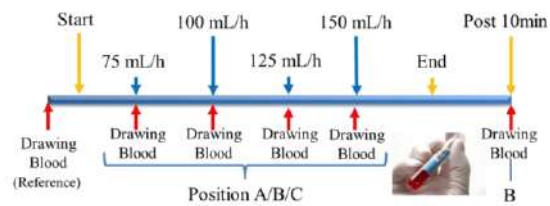

Figure 1 - Flow Chart

Figure 2 - Blood drawing position

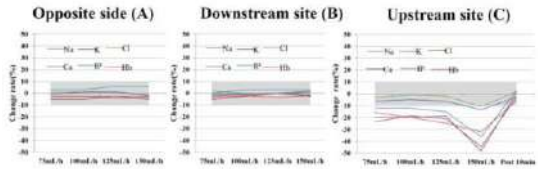

Figure 3 - Influence at each blood drawing site by T3 solution

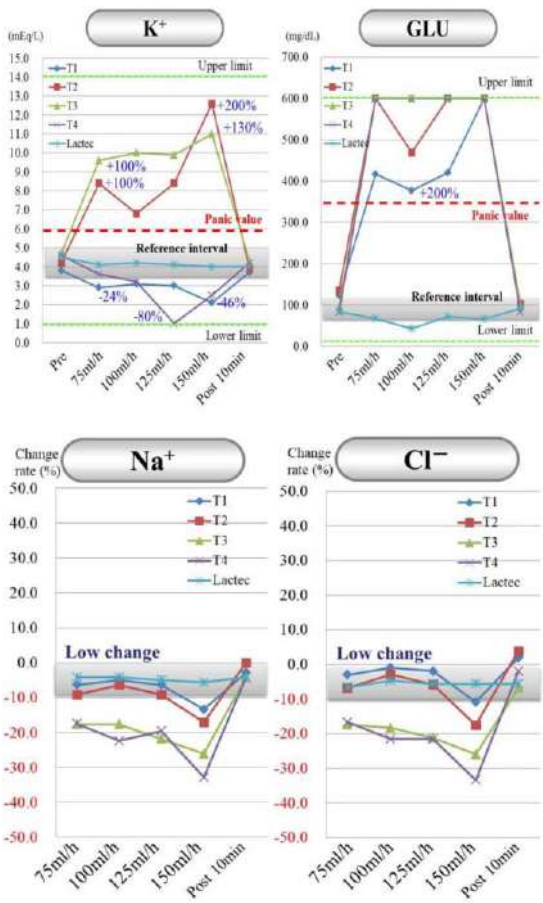
Results

The influence at each blood drawing site is shown in Figure 3. The change of value was not observed at the downstream site and the opposite side. Conversely, significant change was observed at the upstream site. The influence of infusion speed by infusion type at the upstream site is shown in Figure 4. Potassium (K+) and glucose (GLU) values changed significantly (over +200%:75ml/h), reaching panic values.



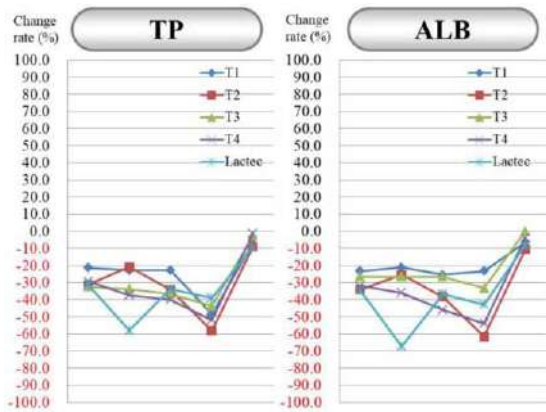


Figure 4 - Influence of infusion speed by infusion type

Total protein (TP), albumin (ALB), urea nitrogen (BUN), uric acid (UA), high-density lipoprotein cholesterol (HDL-C), total cholesterol (T-CHO), and calcium (Ca) decreased in proportion to flow speed (-20%:75m/h, -60%:150m/h). Other biochemical tests showed slight changes (within -20%), trending towards the lower limit level of analysis.The detection algorithm for inadequate blood specimens is shown in Figure 5. We designed two kinds of algorithm based on the result. Type A showed 66.7% sensitivity and 100% specificity. Type B showed 83.3% sensitivity and 75.0% specificity.

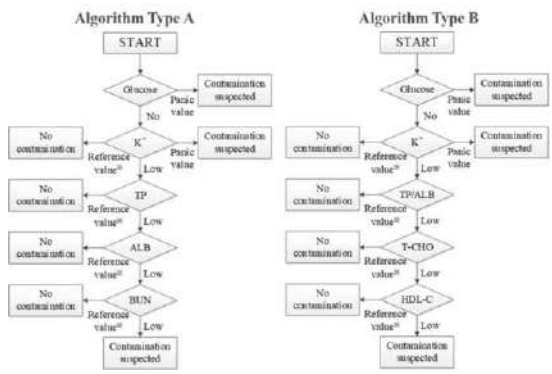

Figure 5 - Detection algorithm for inadequate blood specimens

Conclusions

We showed that increase in K+/ GLU to panic values or decrease in of TP, ALB, BUN, UA, HDL-C, T-CHO, Ca is an index of contamination of infusion solution. For the latter case, even if each of these biochemical values do not to reach the panic value, we should suspect contamination with infusion solution, when the tests show a downward tread. Our detection algorithm seems to imply that confirming the reduction of red blood cell related values may prevent medical errors. This algorithm is also effective for detection of contamination of infusion at low speed. The sensitivity of the algorithm, however, needs improvement. Our future study will be focused on quality control methods for auto analyzer in contamination of infusion.

Development and Use of a Cancer Research Funding Database: Promoting Strategic Global Cancer Research Using the International Cancer Research Partnership Database

Toshio Ogawa[a], Lynne Davis[b], Teruhiko Yoshida[c], Yuri Kitamura[d], Tomotaka Sobue[d]

[a] International University of Health and Welfare Graduate School, Tokyo, Japan,

Abstract

The International Cancer Research Partnership (ICRP) has developed a cancer research funding database since its establishment, with data gathered from the participating funnding organizations. We estimated and compared the total amount of cancer research funding from governmental organizations in the USA, the UK and Japan using ICRP and publicly available databases. We also discussed use of the ICRP database as a tool to consider the cancer research funding allocation at a national level.

Keywords:

Cancer research, Database, Government organizations

Introduction

Strategic cancer research funding is needed to maximize the impact of the funds at both national and global levels. The International Cancer Research Partnership (ICRP) was established in 2001 [1], and is an alliance of governmental and charitable organizations funding regional, national, and international cancer research grants and awards. There are 24 Partners, representing 129 cancer research funding organizations in 2018 from Australia, Belgium, Canada, Denmark, France, Hong Kong, Japan, the Netherlands, the United Kingdom, and the United States.

ICRP partners code their annual funding portfolios to a common format and submit the coded portfolios to a publicly-available database on the ICRP website (hereinafter, ICRP database). The ICRP database currently contains over 78,000 awards from 1990, and estimated roughly 60% of cancer research funding at global level.

The ICRP database contains a classification system, "Common Scientific Outline" (hereinafter, CSO) [2]. CSO was originally developed by the National Cancer Institute and the US Department of Defense to analyse cancer research funding comprehensively. The CSO has been used by ICRP and various funding agencies and countries to analyze and achieve appropriate allocation of cancer research funding.

The current version of the CSO (CSO v2) was adopted by the ICRP in April 2015 and all awards in the ICRP database are coded to this version. CSO v2 is organized into six broad areas of scientific interest in cancer research (Table 1) [1] .

Table 1– CSO codes [1]

CSO 1	Biology
CSO 2	Etiology
CSO 3	Prevention
CSO 4	Early Detection, Diagnosis, and Prognosis
CSO 5	Treatment
CSO 6	Cancer Control, Survivorship, and Outcomes Research

The ICRP database also contains a standard cancer type coding scheme. CSO and site coding lay a framework to improve coordination among research organizations, making it possible to compare and contrast the research portfolios of public, non-profit, and governmental research agencies.

ICRP publishes regular data reports using ICRP database, e.g., 2005-2008 benchmark analysis of cancer research funding, Disparities in cancer research, and Childhood cancer [1].

The governments fund a considerable amount of medical research to cancer care including biology, aetiology, prevention, treatment and public health [3]. Given that the total amount of money devoted to cancer research is limited, it is important to maximize allocation of cancer research funding as a part of national caner control programmes (NCCPs). As the ICRP database contains most of the cancer research funding from governmental organizations in some countries, such as the US and UK, it could be a useful tool to consider the cancer research funding allocation at national level.

The purpose of this study is to estimate and compare the total amount of cancer research funding from governmental organizations (hereinafter public cancer research funding) in the USA, the UK and Japan using ICRP database and publicly available databases, and to discuss effective use of the ICRP database as a part of national cancer control programmes.

Methods

We extracted data of public cancer research funding between 2011 and 2015 from the USA and the UK from the ICRP database.

As most of Japan's public cancer research grants data has not yet been included in the ICRP database, we extracted public cancer research grants data in Japan between 2011 and 2015 from publicly available databases of three ministries of Japan; namely the Ministry of Health, Labour and Welfare (MHLW), the Ministry of Education, Culture, Sports, Science and Technology (MEXT) and the Ministry of Economy, Trade and Industry (METI). We allocated at least one CSO and one site

code per grant. Grants with more than one CSO or site codes were divided equally by the number of CSO or site codes for the analyses. All Japanese grants were converted from Japanese Yen to US$ using the exchange rates of 1 JPY = US$ 0.0114.

We estimated the total amount of public research funding in the USA, the UK and Japan. We conducted a comparative analysis of public cancer research funding among the three countries, CSO and cancer site. All data was analyzed using SPSS ver. 25 (IBM, NYC).

Results

Annual public cancer research funding between 2001 and 2015 was estimated at US$ 4,407 – 5,814 million in the USA, US$ 289 – 324 million in the UK, and US$ 244 – 333 million in Japan.

Public cancer research funding was distributed primarily to "CSO5 Treatment" in all three countries, followed by "CSO1 Biology". The smallest proportion was estimated as "CSO3 Prevention" in the USA and Japan, and "CSO2 Etiology" in the UK (Table 2).

Table 2– Total Amount of Public Cancer Research Funding in the USA, UK and Japan in 2011-2015

		Total Amount (Million US$, [%])				
		2011	2012	2013	2014	2015
US	CSO1	1,274.3 (24.5%)	1,155.3 (24.6%)	977.5 (22.2%)	1,089.4 (23.3%)	1,477.1 (25.4%)
	CSO2	738.7 (14.2%)	630.5 (13.4%)	617.0 (14%)	623.7 (13.4%)	840.4 (14.5%)
	CSO3	424.8 (8.2%)	438.7 (9.3%)	440.5 (10%)	416.1 (8.9%)	469.3 (8.1%)
	CSO4	690.4 (13.3%)	640.9 (13.6%)	651.3 (14.8%)	659.2 (14.1%)	775.3 (13.3%)
	CSO5	1,426.6 (27.4%)	1,269.1 (27%)	1,222.2 (27.7%)	1,376.4 (29.5%)	1,661.7 (28.6%)
	CSO6	646.1 (12.4%)	569.0 (12.1%)	498.8 (11.3%)	502.6 (10.8%)	590.4 (10.2%)
	Total	5,200.9 (100%)	4,703.5 (100%)	4,407.3 (100%)	4,667.3 (100%)	5,814.1 (100%)
UK	CSO1	73.8 (25.6%)	62.9 (20.8%)	60.2 (20.8%)	64.4 (21.5%)	60.0 (18.5%)
	CSO2	21.5 (7.4%)	14.7 (4.9%)	11.5 (4.0%)	13.7 (4.6%)	17.6 (5.4%)
	CSO3	22.8 (7.9%)	28.8 (9.5%)	26.8 (9.3%)	27.1 (9.0%)	29.1 (9.0%)
	CSO4	45.9 (15.9%)	51.9 (17.2%)	51.4 (17.8%)	51.9 (17.3%)	56.4 (17.4%)
	CSO5	91.9 (31.8%)	106.6 (35.3%)	101.9 (35.3%)	104.1 (34.7%)	122.1 (37.7%)
	CSO6	32.7 (11.3%)	37.6 (12.4%)	37.2 (12.9%)	38.8 (12.9%)	39.0 (12%)
	Total	288.6 (100%)	302.4 (100%)	289.1 (100%)	300.1 (100%)	324.2 (100%)
JP	CSO1	56.7 (21.9%)	63.6 (23.5%)	59.8 (24.5%)	50.6 (13.1%)	70.6 (21.2%)
	CSO2	23.7 (9.1%)	24.2 (8.9%)	24.9 (10.2%)	36.3 (9.4%)	31.1 (9.4%)
	CSO3	9.7 (3.8%)	12.3 (4.5%)	9.2 (3.8%)	7.8 (2.0%)	4.8 (1.4%)
	CSO4	40.1 (15.5%)	31.8 (11.7%)	31.9 (13.1%)	54.6 (14.1%)	61.8 (18.6%)
	CSO5	100.1 (38.7%)	112.2 (41.4%)	97.1 (39.8%)	213.1 (55.2%)	144.6 (43.5%)
	CSO6	28.7 (11.1%)	26.9 (9.9%)	21.1 (8.7%)	24.0 (6.2%)	19.6 (5.9%)
	Total	258.9 (100%)	271.0 (100%)	243.9 (100%)	386.3 (100%)	332.5 (100%)

Among the cancer sites evaluated, "Not Site-Specific Cancer" received the highest amount of funding in the three countries. There were differences in the allocation of public cancer research funding per cancer site among the three countries. In the past 5 years, breast cancer, prostate cancer and lung cancer were funded as the top three cancer sites in the USA, while leukemia, breast cancer, colon and rectal cancer, and prostate cancer in the UK, and lung cancer, colon and rectal cancer, leukaemia and liver cancer in Japan. The differences may be partly explained by the cancer mortality and incidence of each country.

Table 3– Top Three Publicly Funded Cancer Research by Cancer Site in the USA, UK and Japan in 2011-2015

		2011	2012	2013	2014	2015
US	1	Not Site-Specific Cancer	Not Site-Specific Cancer	Not Site-Specific Cancer	Not Site-Specific Cancer	Not Site-Specific Cancer
	2	Breast Cancer	Breast Cancer	Breast Cancer	Breast Cancer	Breast Cancer
	3	Prostate Cancer	Prostate Cancer	Lung Cancer	Lung Cancer	Lung Cancer
UK	1	Not Site-Specific Cancer	Not Site-Specific Cancer	Not Site-Specific Cancer	Not Site-Specific Cancer	Not Site-Specific Cancer
	2	Leukemia	Breast Cancer	Breast Cancer	Breast Cancer	Prostate Cancer
	3	Breast Cancer	Leukemia	Colon and Rectal Cancer	Prostate Cancer	Breast Cancer
JP	1	Not Site-Specific Cancer	Not Site-Specific Cancer	Not Site-Specific Cancer	Not Site-Specific Cancer	Not Site-Specific Cancer
	2	Lung Cancer	Lung Cancer	Lung Cancer	Liver Cancer	Lung Cancer
	3	Colon and Rectal Cancer	Leukemia	Liver Cancer	Lung Cancer	Leukemia

Conclusions

This study indicated that public cancer research funding can be analysed using the ICRP database. The USA, the UK and Japan have common features of public cancer research funding in general, i.e., relatively higher investments in treatment and biology (CSO), and breast cancer (cancer sites). However, some differences have been revealed from our analysis particularly in the allocation of cancer research funding by cancer sites.

Use of Alternative Currencies, Blockchain Technology, and Predictive Analytics for Chronic Disease Prevention: A Conceptual Model

Alessia Paglialonga[a], Karim Keshavjee[b]

Abstract

This contribution outlines a conceptual model of a novel approach to chronic disease prevention and management: Preventative Health Account Supported by Electronic Medical Records (PHASE). The PHASE model combines predictive computation of risk scores for chronic disease and use of alternative currencies on blockchain technology to build a preventative health account to help individuals invest in a healthier lifestyle, reduce their risk scores and, in turn, reduce the related potential cost to the healthcare system.

Keywords:
Electronic Health Records, Preventive Medicine, Social Determinants of Health.

Introduction

The financial and societal burden of chronic diseases (CD) is very high worldwide. Globally, more than 70% of deaths are due to CD. CD directly affects health care budgets, employee productivity, and economies [1-2]. CD are highly preventable as health promotion and prevention policies can limit the impact of modifiable risk factors. One way to limit risk factors is to focus on behavior and lifestyle as typically what an individual does (or fails to do) along with general well-being, play a key role in CD development [3-4]. In general, the concept of individual health extends beyond the absence of disease as it encompasses the state of complete physical, mental, and social well-being [5]. In the past decades there has been a growing interest in health promotion and prevention strategies but they typically follow a generalized approach of CD prevention which does not consider the individual profile and context nor the fact there are differences in CD risk patterns and incidence related to socioeconomic status (SES). For example, the fact that people from lower SES are disproportionately affected by CD and have difficulty affording the cost of preventative care [6]. A variety of financial incentives have been proposed to promote healthy lifestyle and CD prevention, for example cash rewards, shopping vouchers, discounts for goods, or in-kind benefits, as well as non-guaranteed rewards (e.g. the chance of winning a lottery or raffle) [7]. Similarly, the concept of health spending accounts (HSAs) has been introduced as an alternate method to decrease healthcare costs for CD. HSAs work by providing the insured individual a specific amount of funds to be used exclusively for healthcare, typically for standard medical services [8]. However, financial incentives and HSAs have not been explored systematically for prevention in any country yet.

In general, the current systems largely focus on treating diseases rather than providing sufficient funding for services or products to improve mental and social well-being, and they do not compensate or reward disease prevention [9]. There is a need for health promotion and disease prevention programs that take into account SES as well as risk profiles for CD and that are able to focus on the individual behavior, lifestyle, and well-being. In this contribution, we outline the conceptual model of a novel approach to CD prevention that combines alternative currencies (ACs) on blockchain technology and predictive analytics supported by Electronic Medical Records (EMRs) data for individualized intervention.

Conceptual Model

Figure 1 outlines the conceptual model of the proposed approach, the Preventative Health Account Supported by EMRs (PHASE).

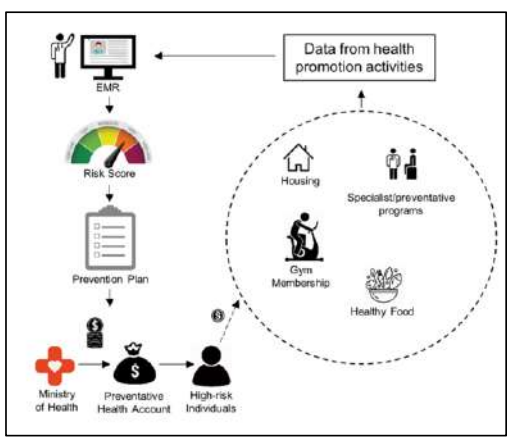

Figure 1 – Conceptual Model of PHASE

In the PHASE model the government or, in general, the organization overseeing healthcare expenditures, determines an allotted amount of money to provide to pre-identified individuals. Each individual has an associated risk score that identifies the potential high-cost users of the healthcare system. The risk score is computed by using predictive analytics on data collected from physician EMRs including, e.g., specific risks for CD, SES, and other variables. The risk score determines the individual prevention plan and the related amount of funds

deposited in the individual's preventative health account. The risk score is evaluated regularly by a family physician to determine any changes and update the individual's prevention plan and account accordingly. Data are collected within the physicians' EMR which is sent to the organization overseeing healthcare expenditures.

In the proposed PHASE model two different ACs can be deposited into the individual's account, namely the Healthcare AC (hAC) and the Reward AC (rAC). ACs are supported on a blockchain to automate transactions following user-defined criteria and logic through the use of its smart contract functionality.

The hAC can be used to purchase services or products that would help individuals to lower their risk scores. For example, the hAC can be spent at pre-approved businesses/organizations, such as healthcare providers or participating stores, e.g. to purchase fresh food, to sign up for a gym membership, to pay for housing, and so on. As the aim of hAC is to decrease the risk scores, allotment will be revised based on changes to risk scores and healthcare costs avoided. Since hAC can only be used at pre-approved organizations it will help to prevent any misuse of funds. The PHASE model also includes incentives to businesses/organizations to participate in such a program, for example a tax break or an annual credit related to the amount of hAC spent. The rAC is introduced in the PHASE model, in parallel to the hAC, to reward individuals who successfully lower their risk scores. The rAC acts as a rewards-based incentive for individuals to actively improve their health. It is deposited in the individuals' account based on their progress and how much they have saved the healthcare system. The rAC may be a combination of loyalty points and monetary incentives to be used on a wider variety of products or services compared to hAC. The goal of the rAC is to encourage individuals to continue maintaining or lowering their risk scores.

The proposed PHASE model is supported on a private, permissioned Ethereum blockchain to capture hAC and rAC transactions between government, physicians, individuals, and businesses/organizations. The solution will require two types of smart contracts built within the blockchain, owned and updated by the government or agency responsible for ACs:

1. The Complete Data Contract, holding a data structure containing the logic requiring all necessary patient information to be entered before the information can be stored in the data structure and used to assess their eligibility for hAC and rAC.
2. The AC Distribution Contract, containing the logic outlining how much hAC and rAC can be distributed based on data provided by the physician's EMR.

For the proposed model to be successful, key components such as the correct balance of hAC and rAC (amount and timing), which CD to focus on, as well as how to compute the risk scores, need to be optimized. The amount of the incentive acts as a motivator or demotivator, shaping the individual's perspective of the behaviour whereas the timing of the incentive influences reinforcement of the desired behaviour.

In general, the program would be considered effective and sustainable to the extent that allocation of AC to individuals with selected conditions can induce behavior change, lower risk scores, and help individuals maintain a healthy lifestyle. For these reasons, the program must have stringent eligibility criteria that take into account factors such as genomic predisposition and social determinants of health in order to serve its intended population and help reduce the related healthcare costs.

Conclusions

We have presented the conceptual model of PHASE, a disease prevention solution drawing on components of HSAs and incorporating two types of ACs as a way to provide necessary financial assistance to people from lower SES to prevent and/or better manage their CD. The use of blockchain technology can help reduce transactional costs between stakeholders and ensure accountability, as well as record a history of transactions. Further investigations are needed to determine how to correctly implement the model (identification of selected CD, computation of risk scores, allottment of AC, monitoring of healthcare costs, and role of the various stakeholders) in a way that it can contribute to sustained health behaviour change, decreased CD risk scores, and reduced financial burden on the healthcare system.

Understanding U.S. Adults' Zika Virus Risk Perceptions and Mitigation Behaviors to Improve Technology-Supported Risk Communication

Tera L. Reynolds[a], Xinning Gui[a], Yunan Chen[a], Kai Zheng[a]

[a] Department of Informatics, University of California Irvine, Irvine, CA, USA

Abstract

Understanding public risk perceptions, and how these affect behavior, is critical to public health's ability to leverage technology for risk communications. However, little is known about Zika virus risk perceptions. We addressed this gap by analyzing nationally representative (U.S.) survey data. Our results suggest that a minority of U.S. adults perceive Zika to be a major threat (13%), and only about 15% have taken protective actions. Our findings have implications for improving technology-supported risk communication.

Keywords:

Zika Virus Infection, Risk, Social Media

Introduction

One of the most important public health (PH) responses to the threat of Zika virus (ZKV) is communicating the risk to the public and empowering people with the knowledge they need to protect themselves. PH authorities continue to disseminate such information through traditional media; however, increasingly, they also leverage information and communication technologies (ICTs), such as social media. This shift is a response to the rapid growth in the public's use of the internet to get news[1] and to seek health information [2].

Recent qualitative studies have found that people do indeed seek information about ZKV from PH authority websites and, when faced with scientific uncertainty, some turn to social media to collect additional information to inform their personal decision-making, and to collaboratively assess the risk of ZKV at multiple levels [3], [4]. Unfortunately, this research also suggests that PH authorities' ZKV communication through ICTs, especially social media, has been insufficient [3], [5].

These studies have provided important insights into social media users' risk perceptions – their judgements about the risk associated with ZKV – as well as into their information needs and the extent to which PH authorities have met those needs. To improve their technology-supported risk communication, though, PH authorities need to understand the pervasiveness of different ZKV risk perceptions and the factors that predict these perceptions and taking protective actions. We aimed to address this gap by quantitatively analyzing publicly available data on different ZKV risk perceptions and their effects on self-reported mitigation behaviors.

Methods

The results of this cross-sectional study are based on data from the Pew Research Center (PRC) Wave 17 American Trends Panel Survey, which was conducted between May 10 and June 6, 2016. The dataset, as well as the detailed survey methodology, are available on PRC's website [6]. Briefly, 4,563 adult members of the national, probability-based American Trends Panel completed the self-administered online (90%) or mailed (10%) survey in English or Spanish. PRC provided survey weights to account for differential probabilities of selection into the panel and nonresponse. We utilized the data from Form 1 (of three survey forms), which was completed by 1,549 individuals. Although PRC has released a report based on this survey, [7] it did not include results related to ZKV.

We examined factors associated with two main outcomes:

1. Risk Perception: ZKV risk perceptions were measured by the survey question, "How much of a threat, if any, is the Zika virus for…" (a) "The health of the U.S. population as whole" (N=1,510); (b) "Your personal health" (N=1,525); and (c) "For women who are pregnant or trying to get pregnant today" (N=1,514). For (a)-(c) the following options were provided, "A major threat," "A minor threat," and "Not a threat." While we compared perceptions for different target groups, we focused our bivariate and multivariate analyses on (b), using weighted chi-squared tests of independence for the former and a multinomial logistic regression model for the latter.

Based on the literature, [8] we hypothesized that the following would be associated with perceiving ZKV to be a threat to personal health: higher Zika knowledge; discomfort with scientific uncertainty; social **factors (e.g., recently discussed health**); personal risk factors, including demographic variables associated with higher risk of getting ZKV (i.e., U.S. region, age). We included internet use, sex, race/ethnicity, income, and education as control variables [8], [9].

2. Risk Mitigation: We were also interested in the factors associated with U.S. adults taking protective actions. This was measured with the survey question: "Have you, personally, taken any actions to reduce your risk of getting the Zika virus, or haven't you done this?" (N=1,523). While "action" was left to respondents' interpretation, based on PH recommendations, one action may be avoiding travel to high-risk areas – areas with cases of locally transmitted ZKV. In addition, if one decides to travel to or lives in a high-risk area, it may include actions such as preventing mosquito bites.

We developed risk mitigation hypotheses and selected factors based on the widely used Health Belief Model [10]. Weighted chi-squared tests were used for bivariate analyses, and a binomial logistic regression model for multivariate analysis. Specifically, we hypothesized that taking action would be more likely among those: perceiving ZKV to be a risk to their personal health, and a more severe threat (i.e., major vs. minor); with indicators of being "activated" – higher general health self-efficacy and higher knowledge of ZKV; and with personal risk factors *(see above)*. We also hypothesized that the following may be barriers to action: comfort with scientific uncertainty, limited access and interest, lower education, and lower income. Finally, based on previous studies, we included sex and race/ethnicity as control variables [9].

Results

Risk Perceptions: A majority of U.S. adults judged ZKV to be a major threat to pregnant women (60%) and a minor threat to the U.S. population (60%). In both cases, fewer than 10% believe that ZKV poses no threat. On the other hand, only 13% of adults believe that ZKV is a major threat to their personal health, and 38% no threat at all.

***Personal Health*:** The descriptive analysis revealed that all hypothesized factors were significantly associated with ZKV risk perception (α=0.05 level), with the exception of age (p=0.10). All statistically signficant factors were included in the multinomial logistic regression model. In addition, we controlled for differences in technology use by age, and an interaction between income and education. Table 1 summarizes the significant results from the multivariate analysis.

Table 1– Results of Multinomial Logistic Regression Predicting Perceiving ZKV to be a Threat (Major and Minor) to Personal Health Compared to No Threat.

Risk Mitigation: About 15% of U.S. adults have taken action to reduce their risk of ZKV infection. The descriptive analysis showed that all hypothesized predictors were significantly associated with the outcome variable. Thus, all factors were included in the binomial logistic regression model, with the exception of potential barriers with descriptive evidence of not actually being barriers – internet use, education, and income – which were excluded on a conceptual basis. Table 2 summarizes the significant results from this analysis.

Conclusions

The results of this study suggest that a relatively small portion of the U.S. population perceives ZKV to be a major risk to their personal health. This perception may be a result of intuitive judgments, research, or some combination. Since perceiving ZKV to be a major threat to personal health is a key predictor of taking action to mitigate risk of infection, our results may indicate a need for PH authorities to adjust their ZKV risk strategies and communications to reach and engage new audiences and address misperceptions. Towards this end, social media presents key opportunities, including to better engage the public in mitigating the risk of ZKV in their community.

[b] Huzhou University, Hu Zhou, Zhejiang province, China

Abstract

Patients with nervous system disorders with an accurate nursing assessment can experience an improved prognosis and promotion of health.The lack of uniform terminology limits the accuracy of nursing in China. ICF constitutes a unified and standard language can help standardize nursing assessment terms. This study show that ICF is suitable for Chinese nursing practice by using ICF Clinical Checklist and ICF-linking-rules to map the nursing assessment terminology of neurological conditions with ICF.

Keywords:

nursing informatics; International Classification of Functioning; Disability and Health; neurological;

Introduction

According to Chinese epidemiological investigation, stroke is the leading cause of death and confers a huge burden and effort on patients and health professionals. The American Heart Association points out that about 90% of patients who survive a stroke have varying degrees of dysfunction, which seriously affects the patient's psychological status, social function, and quality of life. Neurological conditions have become a global concern. Nursing assessment reflects the functional status and changes of patients accurately and provides an objective basis for diagnosis and treatment. Patients with nervous system disorders with an accurate nursing assessment can experience an improved prognosis and promotion of health. Standardized nursing terminology is the basis for improving work communication and promoting sharing of patient information. The electronic nursing information system(e-NIS) is the product of standardized terminology. The e-NIS is widely used in clinical practice, which is helpful to improve work efficiency. The lack of uniform terminology, different hospital has different e-NIS in China, which limits the accuracy of nursing and the sharing of information. For nurses, sharing knowledge with other health care workers can contribute to a broader understanding of patients' situation. Comparability of information is essential to ensure that the widest range of information is available for any decision-maker at all levels of the health system. The ICF constitutes a unified and standard language suitable as a reference for comparability of health information. ICF has a complete set of terminology systems related to function, disability, and health. The characteristics of the terminology system are accurate definitions, neutral words, the separation of structure and function, alternatives of disability and participation disabled (humanities), category definition is consistent in meaning and logic, the concept of all kinds of categories are specific and identifiable, can accurately expression the basic properties of the concept [1]. The application of the ICF in clinical nursing practice is mainly in the field of Rehabilitation Nursing about nursing diagnoses and interventions in Europe. However, there is no study of ICF cross-mapping with nursing terms in China. It is not known whether ICF is suitable for Chinese nursing assessment terminology. **The purpose** of this study is to analyze the application status of neurological nursing assessment terms and determine whether the ICF covers nursing assessment.

Methods

Three hospitals from the different cities of Zhejiang province in China were invited to participate in this study, all of them agreed. All participants were recruited, and case documents were collected between January 2016 and December 2016. Three research staff travelled to each hospital to evaluate the patients who met the standards and collected their care documents. A total of 377 patients participated in this study.

Research Tool: ICF Clinical Checklist(ICC) [2].

At first, we set up a research team consisted of a chief nurse, a postgraduate nurse, and two nurses who have been clinically active in neurological for more than ten years. The research team leader conducted a one-week theoretical and practical training for team members. The training content includes the concept of standardized nursing terminology, concept, and intention of ICF, how to use ICC, etc. Then the three members used the ICC to conduct a one-year on-site assessment of patients in neurology and neurosurgeon department at three tertiary general hospitals, and collected electronic nursing evaluation records, medical records, self-reports, family member's reports, medical examinations, clinical records, etc., from which, extracted nursing assessment terms related to neurological conditions. Forming a term pool. Next, we mapped the nursing assessment terminology with ICF based on well-established ICF-Linking-Rules [3]. Two researchers familiar with the ICF and ICF Linking Rules were appointed who link the identified source of information independently to the ICF and then compare and contrast their linking. In the case of ambiguity, a third researcher would be consulted for final decision on the most appropriate linking. If nursing assessment terms comprised more than one concept, every single concept was linked to the ICF, meaning that one nursing assessment terms could be linked to more than one ICF category. Finally, content analysis was used to analyze the current status of electronic nursing assessment terminology of neurological disorders.

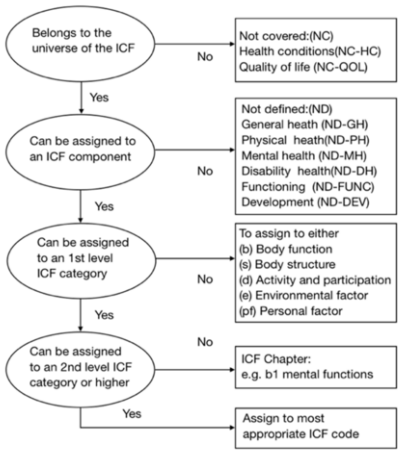

Figure 1 Linking Decision Tree

Results

One hospital has an independent daily nursing assessment form which is convenient for nurses to assess the patient's physical function and health every day. The electronic nursing assessment records of hospitals vary from one language to another. Evaluation rate of 4 (75%) neurological nursing assessment concepts were 100% (377), evaluation rate of "Dizziness" was 95.5% (360), evaluation rate of 10 (17.9%) concepts were range from 50% to 90%. There were 37.5%(21) nursing assessment concepts are closely related to neurological conditions, but did not appear in the existing electronic nursing assessment records, unrecorded rate of 9 (16.1%) categories were range from 40% to 50%, unrecorded rate of 8 (14.3%) concepts were more than 80%, of these concepts, the unrecorded rate of "orientation", "muscle tension", "fine motor skill" and "blepharoptosis" are all more than 90%. The evaluation rate of "quality of sleep" was 100%, but the evaluation rate of the sub-concepts including "on set of sleep", "maintenance of sleep" and "functions involving the sleep of cycle" were only 53.3%. Nobody evaluated and recorded the "memory"

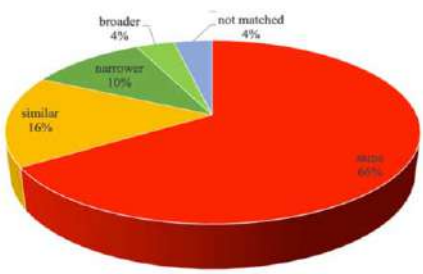

Figure 2 Mapping result of neurological diseases nursing assessment languages with ICF

Conclusions

The nursing assessment related to functional status is incomplete and electronic nursing assessment terms still lack of unified standards in China, resulting in failure to fully reflect the content of nursing work and thus fail to reflect the value of nursing.

ICF is a multidimensional "biological-psychological-social" ecological model, which can comprehensively assess the function and health status of patients. ICF can help standardize nursing assessment terms.

A total of 54 (96.4%) concepts matched with a corresponding ICF category, in terms of 37 "same" concepts (66.1%) and 9 (16.1%) concepts of "similar" granularity, which means ICF is applicable to describe the nursing assessment terms of neurological conditions. There were 6 (10.7%) of the nursing assessment terms more specific ("narrower"), such as "b134 Sleep function" in ICF, including amount of sleep, onset of sleep, maintenance of sleep, quality of sleep and functions involving the sleep of cycle, which means the original ICF categories cover the electronic nursing assessment language. ICF is applicable to describe the nursing assessment terms of neurological conditions.

Limitations

Research may be limited by the region. Zhejiang Province is one of the fastest growing provinces in e-NIS in China. It is probably that the status of nursing assessment terminology in other provinces is worse than in Zhejiang. So it is an essential issue to carry out standardized terminology as soon as possible.

Research prospects

In the next phase, the research team intends to construct a terminology system for neurological conditions nursing assessment that meets China's national conditions based on ICF and collaborates with software engineering developers to embed it into the e-NIS and apply it to clinical practice to verify its scientificity and practicality.

Organizing Health Data Standards Based on Knowledge Map

Liu Shen, Panpan Deng, Haixia Sun

Institute of Medical Information/Medical Library, Chinese Academy of Medical Sciences & Peking Union Medical College

Abstract

To facilitate easy use of health data standards, we collected health data standards and parsed them into more fine-grained knowledge units. Reference and inclusion relations among these standards were constructed into knowledge map. Until now there are 156 standards collected and 4796 reference relations linked within those standards. Besides, an interface was built to enable users to easily get one standard's main information without referring to numerous PDF documents.

Keywords:
ICD Codes; Data Linkage; Knowledge Bases

Introduction

The increasing volume of data in healthcare makes it a challenge to use these health data correctly and effectively. The standardization of the health data is the precondition to perform analysis methods [1]. National Health Commission of the People's Republic of China released many health data standards covering many fields in medical management activities [2]. Besides, some commercial literature databases also include some health data standards. But data in health data standards are difficult to capture and are not systematically collected and linked in those databases, usually as they are "trapped" in PDF documents that can be difficult to parse into structured fields computationally. For example, to know what data item and their allowable values in a laboratory test report would be a time-consuming task, for several databases and documents should be searched and checked. Health data standards will be collected, parsed and organized in a formalized, editable and searchable way. Also based on the reference relations among standards, linkage among those health information standards will be built into a knowledge map thus researchers, as well as clinicians, can easily get well-organized knowledge from the national health data standards.

Methods

Data Overview and Preprocessing

The health data standards can be divided into 3 main collections[2]. One part is health data elements which consist of 6 properties and focused on one subject. Take the standard 'Health data element dictionary-Part 12: Medical plan and intervention' as an example, abdominal pain degree code is one of the data elements in it. As listed in table 1, the six properties are: data element identifier; data element name; definition; data type of data element value; presentation format; and the allowable values. In that data element, the data type is S3, meaning they referred to other code systems and the presentation format is N..3, which means the code is a number with at most 3 characters, which were all defined in the primary health data standards. Sometimes the allowable values may be an enumerated type, or sometimes they may be referring to other resources like other code systems or other code value domain standards.

Table 1–Data Element for Administration Route Code

Items	Values
Identifier	DE06.00.134.00
Name	Administration route code
Definition	Indicate the route of medication in a particular coding system
Data Type	S3
Presentation Format	N..3
Allowable Values	Refer to the standard "WS 364.12-2011 Classification and coding for value domain of health data element-part 12: Medical plan and intervention", one of the common value sets CV06.00.102 Administration route code

Other important parts are standards for medical activity records, like electronic medical records and residents' health records. These standards have specifications for the document of different medical activity scenarios, like outpatient and emergency medical record and consultation record. They defined what items should be included in those standards, how these data should be organized and what standards should be referred to or adopted. Besides, standards for coding value domains are collected which consist of allowable values for some of the data element. Most of the health data collected standards documents are in a non-editable format. To parse the knowledge units in them and digitize and create linkage among health data standards, we conducted Optical Character Recognition (OCR) process to all the collected health data standards and put them in a structured database.

Knowledge Linkage Design

To construct the knowledge map, we digitized each standards' data elements, code values and document content compositions and specifications. We defined three main relations in the knowledge map: has part; refers data model and refers data value. Has part means the inclusion relationship. Refers data value indicates the value range will be based on the other standards'. Refers data model means one standard may adopt the other standards' data elements which provide not only data values but also data types and formats. Thus linkage can be constructed based on the inclusion relationships and reference information. The health data standards knowledge map linked among standards are listed below in figure 1. Besides referred

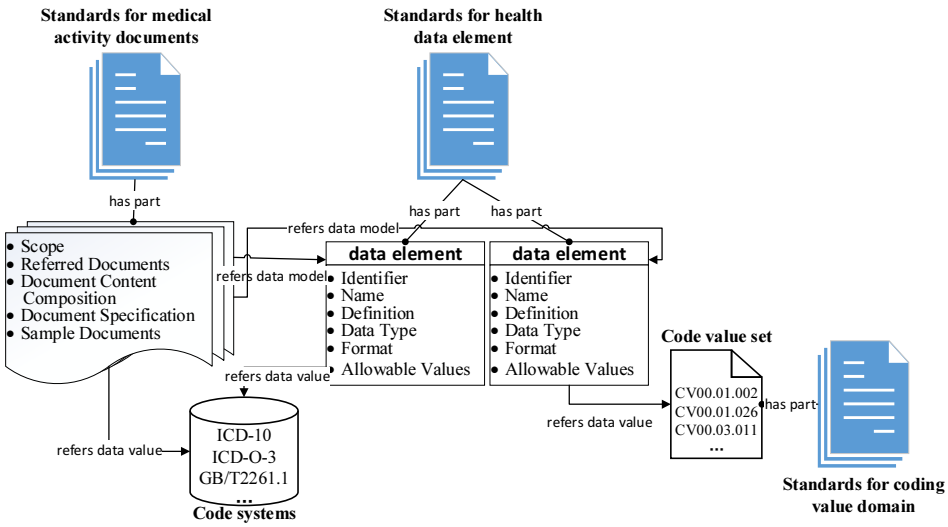

Figure 1–Health Data Standards Knowledge Map

to other standards' code values, some data elements' allowable value range may also adopt some common international code system's standard, like International Classification of Diseases (ICD) and national recommended standards. In this way, we linked all those three collections of health data standards and they can be easily reached and explored.

Results

This work provided a more fine-grained and searchable health data standards database, which currently consists of 156 health data standards, of which 37 are mainly standards for medical activity documents and 119 are mainly standards for health data elements and code values. There are 622 code value sets and 1748 data elements who will provide references for other standards. Up to the submission, there are 4796 reference relations. Besides, we also provide users an interface to search and check standards, more finely grained data elements and the reference map. The health data standards were linked by the data elements, code value sets and other code systems, and both the standards and data elements can be browsed or searched in a user-friendly interface. All of the data have been curated and standardized. Here is an example of data linkage based on the knowledge map.

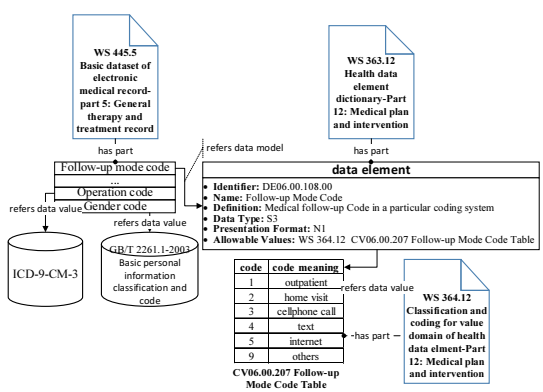

Figure 2– Data Linkage examples

Conclusions

By digitizing and connecting health data standards in a knowledge map, the detailed items and referrention relations can be more directly obtained thus in the future could improve the efficiency for researchers and medical staffs. Compared in searching abilities with WANFANG DATA and CNKI, two of the most commonly used commercial literature databases in China, and Chinese Health Information Standard Portal, our system can provide data element retrieval function within hundreds of health data standards. Properties of data elements will be easily accessed, especially the allowable value which may be the most commonly used ones. Besides, reference relations like which standards have referred to one same data element are showed clearly. However, there are still some places needed to be further explored since we haven't opened this interface to researchers and medical staffs to facilitate their work and get their feedbacks and evaluations.

Quality Improvement of Blood Drawing Through Targeted Training Using an Operation Support System

Ryoko Shimono[a], Rie Akinaga[b], Norikazu Inaba[c]

[a] *Presidential Endowed Chair for "Platinum Society," The University of Tokyo, Tokyo, Japan,*
[b] *Department of Clinical Laboratory, Iizuka Hospital, Fukuoka, Japan*
[c] *Kobayashi Create Co., Ltd., Nagoya, Japan*

Abstract

In order to reduce the rate of needle re-insertion (hereafter, retaking) during a blood drawing operation, we proposed a method for training blood drawing staff, based on data analysis. The method is composed of three steps: (1) analysis of collected data for selecting staff to be trained intensively, (2) training, and (3) assessment of training results. We obtained the result that the retaking rate was reduced for the trained staff.

Keywords:
Phlebotomy, Data Analysis, Training Programs

Introduction

In order to assure quality in a blood test, phlebotomy, the act of drawing blood, is important as an upstream process step. Reducing the rate of needle re-insertion (hereafter, *retaking*) reduces adverse events and ensures smooth operation.

Akinaga et al [1] have developed a system to match the level of difficulty of a blood draw from a particular patient, and the level of skill required for the staff drawing blood. The matching system has been effective in reducing the rate of retaking and the time required to draw blood. This matching system on its own, however, does not contribute to raising the skill level of phlebotomy staff.

In order to increase the level of blood drawing skill, suitable training for staff is required. General contents of training have been developed by the World Health Organization [2] and by the Japanese Committee for Clinical Laboratory in Japan [3]. These standards are however not sufficiently precise for targeted training.

In this study, we aimed to assess the effectiveness of a targeted training, which makes use of an operation support system, in reducing the rate of blood retaking.

Methods

This study was implemented as follows:

Analysis of collected data about retaking

The authors collected data for all outpatients at Iizuka Hospital who had blood drawn in daily work. The data included detailed information on both patients who had blood drawn and phlebotomy staff.

When blood retaking occurred, the condition of the patient's blood vessel was also collected. The condition of the patient's blood vessel was described using thirteen elements that describe characteristics of the blood vessel, such as "thin," "difficult to anchor," and so on.

Then, we analyzed the collected data to select staff who required intensive training. These staff were selected based on the number and the situation of blood retaking.

Training of selected staff

The selected staff received training that included:

- lecture following the prepared procedures,
- practical phlebotomy exercise, and
- on-site training by an educational committee for one or two days.

During the on-site training, selected staff were observed peforming the phlebotomy procedure, and the correct procedure was explained in accordance with each staff member.

Assessment of training based on data analysis

In order to verify the effectiveness of the training, we conducted data analysis of the rate of retaking defined as below:

$$\text{rate of retaking (p)} = \frac{\text{number of patients with retaking (r)}}{\text{number of patients (n)}}$$

Then, we analyzed the rate of retaking by comparing the rates before and after training. We used chi-squared tests to compare the pre-training rate of retaking and the post-training rate of retaking for the eight trained staff members.

This study was approved by the institutional review boards of Iizuka Hospital.

Results

The results showed the following:

Analysis of collected data of retaking

Based on analysis of the collected data for all staff members, eight staff members who had the greatest number of retaking due to blood vessel being "thin," were selected for intensive training.

Training of selected staff

The selected eight staff members were trained through the designed training program. In the on-site training by the education committee member, the explanation for each staff was different. For example, one of the eight staff members was instructed about the position for phlebotomy, and another staff member was instructed about how to anchor a blood vessel to perform the procedure.

Assessment of training based on data analysis

We observed the rate of retaking by the selected eight staff members. *Figure 1* shows the monthly rate for six months, including the training period.

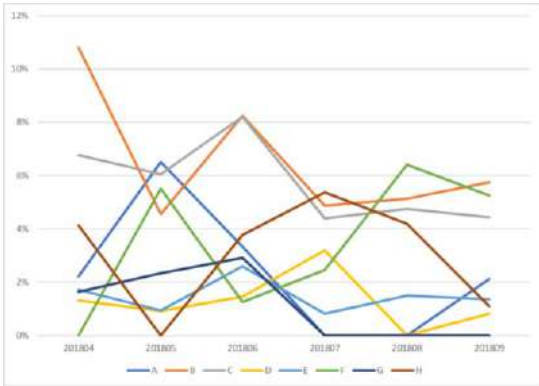

Figure 1–Monthly rate of retaking for eight trained staffs

Then, we analyzed the rate of retaking by comparing the rates before and after training. *Table 1* shows a significant reduction of the rate of retaking.

Table 1– Comparison of the retaken patients before and after training

	Before Training (n=2130)	After Training (n=4365)	P
Retaken Patients, n (%)	98 (4.6%)	133 (3.0%)	0.001

Conclusions

First, we analyzed the data collected for all outpatients who had blood drawn in daily work in order to select the staff members who received intensive phlebotomy training. Then, the assigned members trained the selected staff members. Our analysis found that the rate of retaking of trained staffs was reduced significantly when comparing post-training to pre-training retaking rates. These findings could provide a method to train assigned staff members based on data analysis in healthcare operation.

Development of a Graphical Interface to Visualize and Analyze the Pathways of Patients During Their Hospital Stay for Thoracic Surgery

Lucile Trutt[a], Nicolas Mauduit[b], Brice Leclère[a]

[a] *Department of Medical Evaluation and Epidemiology, Nantes University Hospital, Nantes, France*
[b] *Department of Health Information Management, Nantes University Hospital, Nantes, France*

Abstract

The multidisciplinary aspect of patient care is not yet sufficiently taken into account in hospital ward management. By gathering data from the administrative database of hospital stays and the operating theaters management software, we developed a graphical user interface to visualize and analyze the pathways of patients who underwent thoracic surgery in the Nantes University Hospital of France in 2016 and 2017.

Keywords:

Data Display, Critical Pathways, Hospital Records

Introduction

In the last decades, medicine has evolved from organ-by-organ treatments to multidisciplinary patient care. But the hospital organisation and the administrative management of hospital stays are still compartmentalised, and the complexity of patient pathways is little-known. We are not currently able to determine the typical pathways taken by patients during their stay, their relative frequencies, variations, time trends, etc.

Some attempts have been conducted to visualize medical data in a dynamic way, but they focused on the evolution of care and pathology, rather than hopitalization pathways [1,2]. Medicine can benefit from the achievements of other fields, such as social science [3], energy management [4], or multi-parametric visualisation design [5].

Our objective was to develop a management support tool by means of a graphical user interface (GUI) enabling the visualization and the analysis of the patient pathways. We focused on patients who underwent thoracic surgery at Nantes University Hospital of France in 2016 and 2017.

Methods

Data

We based our work on two software databases used in the hospital: the administrative patients management software and the management software for the operating theaters. The first provided us with admission, transfer and discharge data, and the second allowed us to select patients who underwent thoracic surgery in 2016 and 2017.

These two datasets were merged into a single dataset of hopitalization sequences representing the patient pathway among medical units and operating suites. These sequences were the series of what we called "positions": combinations of the code of the medical unit where the patient went through and an index number in relation to the first surgical intervention. The data management was carried out using Python 3.6.

Interface

Our GUI was composed of two parts. The first was used for displaying a flowchart of all patient pathways within a year by a Sankey diagram. The user was able to adjust the chart through parameters like its length or precision level.

The second part was dedicated to a closer analysis of the datasets. We used a sequential pattern mining (SPM) algorithm to retrieve the most frequent patterns among the patient pathways. SPM allowed us to keep repetitions visible within the patterns and were more adapted to our linear data than algorithms relying on cycles or networks, like in process mining [6]. Then, every pattern was associated with indicators like its support (frequency) or the confidence of sequential rules between its items. The user was able to adjust parameters like the length of the pattern, requirement of specific medical unit codes, or posting of selected indicators.

The GUI was built as an interactive webpage in order to make it portable and easy to use. The SPM was carried out using the SPMF Java library [7] and the Hirate-Yamana algorithm to forbid leaps over consecutive medical units [8].

Evaluation

We evaluated the user experience of the GUI. We devised an experimental protocol with a sample group of managers and a control group of external users (with knowledge only in either medicine, statistics or computer science), and conducted user observations followed by a debriefing. We also designed five exercises to do on either part of the interface, and observed how the users used the GUI to solve them. We focused on usability and recorded all difficulties encountered by users.

Results

We retrieved 3331 total hospital stays in 2016 and 2017.

Examples of the GUI can be seen in the Figures 1 and 2. Figure 1 depicts the flow chart part for 2016, and Figure 2 shows the results of a SPM.

We observed three manager users and three control users. Overall, the user experience evaluation was satisfactory. The GUI was appealing, but some exercises showed that it can be hard to use, especially when users have a low statistical background. Participation in the construction of the tool and knowledge in the operation of hospital records seem to be the most important facilitating factors for its use and

understanding. Some areas for improvement were highlighted, especially in ergonomics. Users were overall satisfied and reported being "interested" or even "very enthusiastic" about this project.

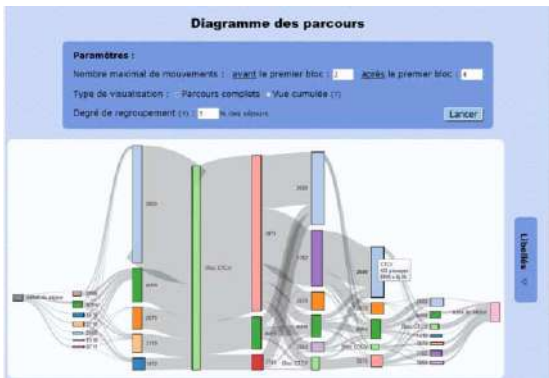

Fig.1 – Screenshot of the first part of the GUI: flow chart of patient pathways in 2017.

Fig.2 – Screenshot of the second part of the GUI: SPM beginning and ending with specific medical units in 2017.

Discussion

Overall, the user experience of the application was satisfactory; the professionals enjoyed it, and it helped them understand the patient pathways, correct the way they pictured them, and reorganize the patient coordination management properly. Some professionals from other medical specialities (e.g. surgical intensive care) who took part in meetings about this GUI even asked for a version with their own patient pathways.

However, despite its novelty and its perceived usefulness, this tool remains difficult to use, as it requires a minimum of knowledge in both statistics and hospital record operating. As requested after the evaluation, a guide has been written to help users understand how the GUI works, aside from ergonomic improvements and a context-sensitive help. Integrating users in the development of this tool was a great chance to make it more convient. Although a small amount of people were targeted, a larger evaluation of the new version should be conducted.

Another limitation of this work is that it was based on data extraction; therefore, we cannot apply it directly elsewhere with other parameters and a new database, such as in years to come or other reasons for hospitalization. A committee shall be formed to integrate this tool into the hospital information system (IS). But one of the main difficulties of this will be merging two databases from two unconnected software applications. Thus, this work points out the necessity of interoperability within IS.

Conclusions

We developed a GUI to improve the understanding of patient pathways during hospital stays. Based on two management software databases, our tool displays a Sankey diagram of all patient pathways in a year and the results of a SPM procedure. The user-experience evaluation highlighted great interest but also low user-friendliness due to a high level of specialization. This tool allowed managers to better depict the patients flows and to discuss their reorganization in a more informed way.

Despite the need for ergonomic improvement, we managed to create a helpful tool to better understand the patient pathways. Efforts should be made both to pursue this project to adapt it to suit other reasons for hospitalization and to widen its use, and to assess its usefulness on a larger scale.

An Evaluation of the Belgian Community Pharmacist's Satisfaction with the Implementation of the Electronic Prescription Within a Pharmacist's Software

Sven Van Laere[a], Pieter Cornu[b], Ronald Buyl[a]

[a] Department of Public Health (GEWE), Vrije Universiteit Brussel, Brussels, Belgium,
[b] Centre for Pharmaceutical Research (CePhar), Vrije Universiteit Brussel, Brussels, Belgium

Abstract

In a cross-sectional study, we evaluated the perception of the community pharmacist in Belgium about his satisfaction with the implementation of the electronic prescription in his software. 246 community pharmacists scored the implementation in their software with an average of 6.46±2.16(SD) on a score of 10. This satisfaction is associated with the software used ($p<0.001$), the frequency of slow responses ($p<0.001$), the perception of unavailability of systems ($p=0.003$) and the knowledge of the pharmacist ($p=0.036$).

Keywords:

Electronic Prescribing; Pharmacies; Belgium

Introduction

Electronic prescribing, or "e-prescribing" is the computer-based electronic generation, transmission, and filling of a prescription, taking the place of paper and faxed prescriptions [1]. Often the terms electronic prescribing, e-prescribing, ePrescribing and eRx are used interchangeably.

ePrescribing was introduced in healthcare primarily for increasing patient safety and reducing prescription errors. Another reason for introducing ePrescribing was the potential administrative simplification for healthcare practitioners, healthcare insurance institutions and other governmental institutions [2].

In Belgium, the government started the e-MED project in April 2007 with the intention of developing a coherent action plan for making the ePrescription of medicines in ambulatory care possible [2]. During a pilot phase in 2009-2012, infrastructure was tested. In 2013, software vendors of both physicians and pharmacists were invited for mini-labs to test all use cases related to ePrescribing and in 2014, the project was introduced to the Belgian public. As of 2017, a unique barcode (i.e., the Recip-e ID (RID)) was added on the paper proof of ePrescription. Independently, the organization Recip-e is responsible for the temporary storage of encoded ePrescriptions on a national server.

In the flow of ambulatory ePrescribing, there are three main actors: the prescriber, the patient and the pharmacist; they are sometimes referred to as the 3 Ps within ePrescribing [3, 4]. Since pharmacists are at the end of the chain and thus are most likely the party that observes the most problems and hindrance in processing ePrescriptions, we are interested in the perception of the implementation of the ePrescription within his software package and what other factors that influence this.

Methods

A cross-sectional study was conducted among pharmacists working in community pharmacies in Belgium, between March and May 2018. The survey included self-administered questions about demographic characteristics, pharmacy software characteristics, satisfaction with the implementation of the ePrescription in the software, knowledge about the ePrescription workflow (tested with 7 questions about the ePrescribing workflow and the handling with ePrescriptions inside the pharmacy), and frequency and hindrance of problems encountered in practice. The questions of problems in practice were based on an evaluation of pharmacist fora [5], where pharmacists reported the problems they encountered in practice during a one-year period, ranging from January 2017 to December 2017. In total six problems were identified: (1) unavailability of the eHealth system; (2) slow response of the software; (3) differences between paper proof and digitally stored prescription; (4) unclear error messages; (5) incorrect use of codes linked to medication; and (6) not allowed manual additions of the prescriber on the paper proof of prescription.

The survey was sent to all pharmacists that were members of the national pharmacy organization, i.e. Algemene Pharmaceutische Bond (APB), via a newsletter in their language of preference.

Multivariable linear regression was conducted to investigate what variables are associated with the pharmacist's satisfaction with the implementation of the ePrescription in their software, verifying the underlying assumptions of linearity and homoscedasticity. All p-values were 2-sided and $p < 0.05$ were considered statistically significant. For model building, both forward and backward model selection using AIC was used. Afterward, a significance check was performed for each covariate that was included in the model; covariates with a P-value of less than 0.10 were included in the final model.

Ethical clearance and approval were obtained from the Ethical Review Committee of the university hospital UZ Brussel, Brussels Health Campus (reference number B.U.N. 143201835300).

Results

The survey was distributed to 7,487 pharmacists [6] of respectively 4,943 community pharmacies. In total 4,200 newsletters were sent in Dutch (56.1%) and 3,287 newsletters sent in French (43.9%) (Table 1). A total number of 246 respondents completed the survey (response rate of 3.3%).

Respondents were asked to score how satisfied they are with the implementation of the ePrescription in their software on a scale of 1 to 10, where a score of 1 indicates very poor satisfaction and 10 indicates excellent satisfaction.

Belgian pharmacists rated the implementation of the ePrescription in their software with an average score of 6.46±2.16 (SD) out of 10 (Table 2). The minimum score obtained was 1 and the maximum score obtained was 10.

This satisfaction score was significantly associated with the software used in the pharmacy ($p < 0.001$, Table 3). For privacy reasons, no information about software vendors (n=6) was given. The perceived frequency of occurrence of a slow responsive system was associated with satisfaction, adjusted for other covariates ($p < 0.001$). A better knowledge of the workflow was associated with higher satisfaction with the implementation in their software package, adjusted for all other covariates ($p = 0.036$). A trend was observed for the perceived frequency of unavailability ($p = 0.086$). When both of these problems were perceived to occur less frequently, the community pharmacist's satisfaction was higher. If a pharmacist indicated to have problems with the unavailability of the system, the community pharmacist was asked to estimate the percentage of time that the services were down. This covariate was also significantly negatively associated with satisfaction ($p = 0.003$).

Table 1– Characteristics of mailing and respondents

	Belgium	Respondents
Pharmacists		
- Mail messages sent	7,487	-
- Language used		
Dutch	4,200 (56.1%)	143 (58.1%)
French	3,287 (43.9%)	103 (41.9%)
- Community pharmacies	4,943	246 (3.3%)

Table 2– Satisfaction of the implementation

	Score (n = 246)
Satisfaction	
Mean (± SD)	6.46 (±2.16)
Median	7
Min – Max	1 – 10
Q1 – Q3 (IQR)	5 – 8 (3)

Conclusions

In this study, the satisfaction of the Belgian community pharmacists about the implementation of the ePrescription in their software along with their knowledge and problems with it was questioned. The relation between these factors and the community pharmacist's satisfaction was observed. In general, Belgian community pharmacists are moderately satisfied with the implementation of the ePrescription in their software package. Satisfaction with the implementation of ePrescribing is mostly associated with the software package itself, the frequency of a slow responsive system, the knowledge a pharmacist has about the ePrescribing process, and perception about the percentage of unavailability of the system. A limitation of the study is that 3.3% response rate might limit the generalizability of the study. Moreover, causal associations cannot be inferred due to the cross-sectional study design.

Table 3– Multivariable analysis of satisfaction (squared transformation was applied)

	Beta ± SD	p-value
Intercept	30.950 (±3.850)	< 0.001
Software [a]	-	**< 0.001**
Frequency of slow responses		**< 0.001**
Daily (reference)	**-**	-
Weekly	13.644 (±3.392)	< 0.001
Monthly	16.710 (±4.005)	< 0.001
Less than monthly	13.823 (±4.868)	0.005
Never	14.155 (±6.091)	0.021
Knowledge	**2.563 (± 1.222)**	**0.036**
Frequency of unavailability		**0.086**
Daily (reference)	-	-
Weekly	8.787 (±3.610)	0.016
Monthly	6.053 (±4.100)	0.141
Less than monthly	9.742 (±5.422)	0.074
Never [b]	NA	NA
Perception of the percentage of unavailability	**-0.225 (±0.076)**	**0.003**

[a]: For privacy reasons no detail about the software is given;

[b]: One observation was dropped out of the analysis, because when a pharmacist indicated he never faced problems with unavailability of the system, he never obtained the question about the perception of the percentage of unavailability. (n = 245)

Acknowledgements

We are thankful to the senders of the survey to the community pharmacists on a national basis.

Implementation and Support of an Electronic Health Record in Youth Olympic Games in Buenos Aires 2018

Romina Frangella, Nicolás Vilnitzky, Manuel Farias Palma, Lautaro Olivera, Analía Baum, Santiago Esteban, María Victoria Giussi Bordoni, Leandro Alassia

Health Information Systems Office, Ministry of Health, Buenos Aires City, Argentina

Abstract

On October 2018, Buenos Aires hosted the Youth Olympic Games. The organization asked the Health Information System Office to provide the health stations and clinics with an Electronic Health Record (EHR) and bring support during the duration of the games. Four hundred and fifty healthcare professionals from different disciplines were trained in the use of the EHR.

Keywords:

Electronic Health Records, Health Plan Implementation, Massive Event

Introduction

The 2018 Youth Olympic Games (YOGs) was the most important multisport event in the history of Buenos Aires city. The event took place on October, and 4012 athletes from all over the world were housed in the Olympic Village. [1] As with other large-scale events, YOGs presented many challenges to the teams involved in their organization. The Ministry of Health had two central goals, on one hand to organize the healthcare delivery around the needs of the event and, on the other hand to implement an Electronic Health Record (EHR) in all healthcare delivery points.

Previous editions of the YOGs focused on the clinical record during the event in order to get statistical data on the most common lesions and illnesses of the athletes. This information could be valuable for decision making in the participants prevention and care. [2]

While the previous Games registered around 1000 medical encounters per Olympic game [3] [4], Buenos Aires presented a record of 2161 consultations between those registered in the clinic of the Olympic Village, the medical offices of the venues and referrals to Hospitals.

This mass event was held in four theme parks located in different parts of the city and in four independent venues around the suburbs of the Buenos Aires City.[1] The venues were scattered across all around the city district (203 km2). An Olympic Village was built to house the athletes and delegations over 100 hectares of Goverment real estate. The Olympic Village had a clinic built specifically for athletes' medical care and had an own pharmacy. 34 medical posts were built within the venues that provided healthcare for both the athletes as well general audiences. In addition, medical care delivery operated in coordination with the public emergency medical system and with 14 acute care hospitals and 2 pediatric hospitals.

Methods

Descriptive analysis of the processes carried out for the implementation of the EHR during the YOGs Buenos Aires 2018. For this description, we took the eight sociotechnical dimensions of Sittig et al. [5] as a guiding point

Results

Hardware and Software.

Each of the 34 Health posts of the venues and clinic was equipped with a desktop PC. The software used is an in-house Electronic Health Record (SIGEHOS) developed by the Ministry of Health, which allows the recording of clinical notes and the entry of structured data, such as anthropometric values and clinical problems. Connectivity was provided by the Government's Information Systems Agency.

Clinical Content

Following the International Olympic Committee (IOC) recommendations, a digital form was developed and included in the EHR, which allowed to fill specific information called "athlete injuries and diseases form" (Figure 1). In previous editions, this form was was filled out on paper. It recorded the athlete's discipline, the venue and the time of the episode to attend and days of absence from training or competition. The Injuries section included anatomical fields, type and cause of the same. The section Diseases, registered diagnosis, symptoms and causes. In addition, it was decided, in conjunction with the medical area of BAYOGOC (Buenos Aires Youth Olympic Games Committee), to add fields to record additional information such as: Patient's state of consciousness (conscious or unconscious), the treatment administered and if it needed a referral to a hospital, thus achieving a more complete record. Therefore, it was possible to comply with the requirements of the IOC information register.

Human Computer Interaction

SIGEHOS presents several modules, each of them represents a functionality. There are user profiles that organize access to each module according to the role that the user has. It was decided that both health professionals, administrative employees and site coordinators had to have access to the EHR. Within the Olympic Village also, professionals

Daily Report on
Injuries and Illnesses

Figure 1. Electronic health form

belonging to the pharmaceutical area could access another specific module called "drug administration". To speed up the process of registration and registration of the "Olympic family" (athletes, delegations, workforce, etc.) [6] it was decided to carry out a massive information transfer from the IOC, in order to have EHR available for every member and also avoiding mistakes in the records' identification.

Peopleware

The medical staff consisted of more than 450 professionals that included: doctors, pharmacists, dentists, kinesiologists, psychologists, nurses and administrative staff. The areas that took part in the coordination and development of the work protocols and the computer tools that were used were "BAYOGOC"; formed by the Argentine Olympic Committee and the Government of Buenos Aires City, the Special Olympic Games Project Unit (BAYOGOC-MED), the Health Information Systems Office, the informatic helpdesk (MDA) and the Information System Office (ASI) that It was in charge of the governmental policies that regulate the use and management of electronic media, also guaranteeing interoperability and accessibility of the electronic services of the Government of the City [7].

Communication and Workflow

The Health Information Systems Office was in charge of training and support for all the professionals who participated in the field, within the clinical devices installed in the different Olympic parks. The initial task was to train in the use of applications to professionals and administrators who were going to use the system both in the clinics and in the field of play. Training was carried out in two instances: a virtual one where the professional had a first approach with the application. The second instance was carried out in person at the offices of the Health Information Systems Office. It consisted of an explanatory class about the contents of the virtual course.

To complete the registration to the trainings, an email was sent to each professional with a link to a questionnaire. This had to be completed with the personal information that would allow him later, to generate the permissions to access the application from his work stations.

The user's request for registration would be received by the informatic helpdesk, which would then communicate to each successful discharge professional and the procedure to establish a personal password.

The health professionals transmitted the different problems of use of the system to the medical coordinator of the headquarters where they were working, and this was in charge of communicating it to the supporters of the Health Information Systems Office. In this way, they would evaluate the necessary measures for their prompt resolution in the field. This would be communicated through the same channels. The means of communication used were telephone call, instant messaging and email.

As a contingency plan, paper forms on were distributed to all offices and of hospitals' Emergency Rooms which gave assistance in order to ensure no data loss in case of unavailability of service.

Regarding the referral of patients to hospitals, it was performed by the Emergency Medical Attention System (SAME).

Conclusions

The advent of an event of the magnitude of a Youth Olympic Game involves a great planning. Regarding a Health Information System, this planning is of utmost importance for ensuring infrastructure and connectivity, an adequate software, and implementation efforts. A fourth item to have in mind regards troubleshooting and assistance for endpoint users.

The use of the Socio-Technical model described by Sittig et al [5] served as a checklist for these means. Regarding troubleshooting, it became a fortitude to have available a dedicated team in all the venues to assist the clinical caregivers.

Design and Pilot Testing of an English and Spanish Behavioral Health Patient Survey on Data Privacy

Marcela P. Aliste[a], Adela Grando[a], Anita Murcko[a], Hiral Soni[a], Michael Todd[b], Madhumita Mukundan[a], Michael Saks[c], Caroline Horrow[d], Richard Sharp[d], Christy Dye[e], Darwyn Chern[e], Mary Jo Whitfield[f], Mark Callesen[f]

Abstract

We piloted a Spanish and English survey on data privacy. Thirty-one Latino behavioral health patients completed the survey in person with a preference for paper (78%) over electronic questionnaire. Dialect variations across Latino countries and the lack of tools to assess reading level in Spanish affected comprehension. Our experience will help others address similar tasks more effectively and encourage inclusion of Latino populations in future research.

Keywords:

Health Surveys, Privacy, Behavior, Latinos

Introduction

In the US, behavioral health conditions affect 44 million adults, a quarter of whom suffer from a serious mental illness (SMI).[1] About 17.8% of the US population is Latino or Hispanic, and of those, 15.6% had a diagnosable mental illness in the past year compared to an overall past year prevalence of 18.3%.[2] The rate of illicit drug use for Hispanic individuals ages 12 and up was 8.9%, while the national average was 10.2%.[3]

Latino patients often do not seek mental health treatment due to stigma. [4] We are moving towards more integrated care models where electronic data exchange is being facilitated by the electronic health records and health information exchanges. This means non-behavioral care providers might gain access to sensitive health information. Understanding the perceptions of Latino patients with behavioral health conditions relating to privacy and data sharing is vital to better inform and guide successful transitions to integrated care models.

The purpose of this study was to design, pilot test and refine Spanish and English surveys to elicit behavioral health patients' perspectives on data privacy.

Methods

Sample

Inclusion criteria were: 1) speak either English or Spanish; 2) no legal guardian; 3) receive care at the partnering outpatient facilities; 4) have a diagnosis of a behavioral health condition; and 5) be 21 years or older. This study was approved by the Arizona State University Institutional Review Board (IRB).

Procedures

Initial questionnaire design and organization

A 17-item English-language survey was designed to collect patient demographics (Q1-5) and behavioral health diagnoses (Q6), experience and willingness to share medical information for care (Q7-10, Q12-15), sensitivity perceptions of the information in those records (Q11) and willingness and motivation to share data for research (Q16-17).

Translation of questionnaire from English to Spanish

Two researchers, both native Spanish speakers with graduate degrees and academic knowledge of the subject, translated the survey. Back-translations were performed by a third native Spanish speaker to ensure that literacy levels commensurate with the patient's educational background and reading ability. An accuracy certificate was presented to the IRB.

Questionnaire administration

After consenting, participants completed the University of California, San Diego Brief Assessment of Capacity to Consent (UBACC) test.[5] Patients scoring lower than 15 were excluded. Eligible participants completed the survey in English or Spanish, using a paper survey or electronic tablet. The participants completed the survey twice (test-retest), 14-21 days apart. The time taken to complete the survey was recorded.

Survey revision

Questionnaire items were revised in response to reliability testing and recruiter feedback. Review of the Spanish versions of the revised items was performed by two native Spanish speakers born in Mexico. During the revision, we had access to behavioral health-specific vocabulary used by a Spanish-speaking behavioral health academy in Arizona.

Data analyses

Test-retest reliability was assessed using Cohen's Kappa and intra-class correlations (ICCs). Frequencies and percentages of item responses were tabulated.

Results

Sample characteristics

Threre were 31 (16 Spanish and 15 English) participants; 11 SMI; most were women (74%), aged 21-50 years (65%), completed high school (74%) with an annual income of ≤$20,000 (74%). Most participants presented with depression (75%) and/or anxiety or panic disorder (71%). The average UBACC score was 17.3. The paper format was preferred (78%) over electronic.

Reliability testing and revision of questionnaire

Questions yielding low ICCs < .50 and/or kappas < 0.40 were revised. Highlights below.

Q9 "*Which providers do you see outside this Clinic?"* yielded a poor kappa (-0.07 to 0.51). Response "*Yes, primary care providers. Such as a family doctor, nurse practitioner (NP), physician assistant (PA) or PCP*" was revised to: "*Primary care providers. Such as a family doctor.*"

In Q10 with kappa (-0.03 to 0.52), we replaced *"Has anyone at the facility explained to you the benefits and risks of sharing your data outside of the facility?*" with the less complex question: "*Have you been asked if you want to share your data with providers outside this Clinic?"*

Q12, ICC satisfactory, (0.53–0.86), "*Extremely willing to share*" was replaced with "*Always share.*" A new response ("*It does not apply to me*") was added for when participants did not receive care from certain types of providers. In Q13 (ICC: 0.41–0.75) and Q14 (ICC: 0.56–0.79; kappa: 0.19–0.54), difficulties in answering questions related to sharing drugs or alcohol use data, sexual transmitted diseases, etc., were noted. Recruiters reported that participants had difficulties when they did not feel a diagnosis or problem applied to them. To avoid hypothetical questions, a new option *"It does not apply to me"* was included.

Q15 and Q16 yielded poor kappa (0.13 and 0.12, respectively) and were simplified to more direct questions, e.g. Q15, *"Suppose that you don't share data with your provider. You have an emergency. Your provider wants to see all your data. Do you want your provider to see the missing data?"* to *"You have an emergency. What do you want your emergency provider to see when he looks at your data?".*

Q17 (ICC: 0.24–0.93) and Q18 (ICC: 0.37–0.95) were simplified. In Q19 when participants were asked with whom they would share data for research, the option *"State, county, or federal agencies. Such as the Arizona Department of Health Services"* was not well understood. We changed it to *"government agencies."*

Discussion

Valuable lessons learned in designing and pilot testing a bilingual data privacy survey included the following:

Tools to assess the reading level for Spanish documents are not easily accessible: Though limited methods are available to measure readability in Spanish, there is insufficient evidence of reliability or correlation to English reading levels.

Differences between Mexican and South American Spanish affected survey comprehension: Translations did not target the ancestry of the Latino population of Arizona. In response, the survey was reiwritten in Mexican Spanish and reviewed by three Mexican Spanish speakers.

Information to better characterize Latino subjects was not captured by the survey: The survey did not ask for country of origin or descent, years in the US, birth and immigration status, etc. which could healp acount for differences in culture between immigrants and the children of minorities born in the US.

Technology adoption barriers encountered when offered the electronic survey: Most of the participants preferred paper surveys and were more familiar with the term "tablet" compared to "iPad".

On-demand educational material could enhance explanation of data types: Participants often asked for clarifications on topics such as genetic data. On-demand education material could have improved comprehension.

Conclusions

The design and revision of the Spanish and English survey was complex and resource-intensive, involving a multidisciplinary team as well as native Spanish and English speakers. The result was a Spanish survey at a 6th grade reading level, high understandability, culutrally-correct behavioral health-specific vocabulary, accurate translations, and adaptation to a more Mexican-friendly Spanish. We have shared the lessons learned to help others address similar tasks more effectively and facilitate the inclusion of Latino behavioral health patients in future research.

Online Support Groups as a Source of Empowerment for People with Type 2 Diabetes

Abdulaziz Almanea[a], Peter A. Bath[a], Laura Sbaffi[a]

[a] *Information School, University of Sheffield, Sheffield, United Kingdom*

Abstract

People with Type 2 Diabetes (T2D) control much of their illness by making daily decisions regarding their health behaviours. They require certain skills, information, and support, which might not be obtainable from healthcare providers, and they may seek support through other media, such as online support groups (OSGs). This study seeks to understand the role of OSGs in empowering people with T2D by thematically analysing threads and posts from two UK OSGs.

Keywords:

Patient Empowerment; Self-Help Groups; Diabetes Mellitus, Type 2.

Introduction

Diabetes is a serious chronic condition that has serious comorbidities, such as increased risk of stroke, vision loss, and kidney failure. It is a growing global threat with approximately 425 million adults diagnosed worldwide in 2017, a figure that is estimated to reach 629 million by 2045 [1]. In 2017, approximately 850 billion United States Dollars (USD) were spent on the treatment of diabetes and its complications worldwide, which is around 10% of global healthcare expenditures [1]. In the UK, approximately 4.5 million people have diabetes according to estimates, including 1 million undiagnosed cases [2].

Type 2 diabetes (T2D) accounts for 90% of all diabetes cases, and people are usually diagnosed with T2D in late adulthood [1], which makes them struggle with managing the illness. Because of its ongoing nature, people with T2D manage 95% of their condition and healthcare professionals (HCPs) only have limited control [3]. Therefore, it is especially important to empower people with T2D, since the proposed behavioural changes relate strongly to their lifestyle [4]. However, with the limited information provided during and after diagnosis, they often seek other sources of information, e.g., the Web and online support groups (OSGs), which have been shown to be effective media to provide information and emotional support for patients [5].This is particularly important when these types of support are not readily available from HCPs.

Empowered patients are knowledgeable, skilled, and responsive to set and attain their own health goals [6]. Patient empowerment (PE) can lead to more effective communications between patients and HCPs [7], increased quality of decision making [8], improved control and management of the illness [8], and lower costs for healthcare providers [9]. Healthcare organisations around the world, including the UK [10], the EU [11] and the US [12], have set PE as a main component and have developed many initiatives to achieve this.

The Health Care Empowerment model (HCEM) identifies empowered patients as those who are engaged in the treatment of their illness, committed to it, collaborative with HCPs, informed about treatment options as well as their rights, and are able to cope with uncertainty, which can occur during any phase of the treatment [13]. The model proposes that a dynamic interplay of contextual factors, personal resources, and intrapersonal processes can influence PE for a patient who undertakes ongoing treatment. The aim of this study was to investigate how these elements, as well as empowerment elements identified by the model (i.e., patient engagement, being informed, collaborative, committed, and able to cope with uncertainty), are influenced by the use of OSGs for people with T2D. In particular, it seeks to answer the following research questions: 1) what are the information needs and behaviours of people with T2D using OSGs? 2) how do various contextual and intrapersonal factors and personal resources influence PE for people with T2D? 3) how do patients with T2D utilise the information they receive on OSGs, and how does this influence their health behaviours?

Methods

To answer the research questions, an inductive approach, utilising qualitative methods was adopted for this study. Two UK OSGs, *Diabetes.co.uk* (DCU) and *Diabetes-support.org.uk (DSOU)*, were selected, and threads from June 1st to July 31st 2017 in the general discussion sections in the groups were purposively sampled and analysed. In order to investigate the importance of OSGs in the context of empowering patients in the UK's National Health Service (NHS), members who indicated a non-UK location in their profiles were excluded from the analyses. A total sample containing 57 threads, which included 555 posts, were purposively selected (with an inclusion rate of 25% for Diabetes.co.uk and 17% for Diabetes-support.org.uk of the total sample). These threads clearly showed how the use of the OSGs helped people with T2D to manage their illness and overcome social, environmental, and intrapersonal barriers. In a number of threads, members reported how using the OSGs helped them to overcome the barriers. Members with T2D themselves posted the sampled threads and posts, not family members or friends. The first author analysed the collected threads thematically [14]. Tracy's eight criteria were followed to enhance the quality of the study [15]. Further research (i.e., interviews with OSG users) will be used to check the validity of the findings.

Prior to the data collection, the managers of the OSGs within the above organisations provided consent for undertaking the study. The study received ethics approval in accordance with the University of Sheffield Research Ethics Policy.

Results

The sample included posts from a total of 189 unique members with a mean number of 2.9 posts each. Preliminarily analyses uncovered several themes, as shown in Figure 1 below.

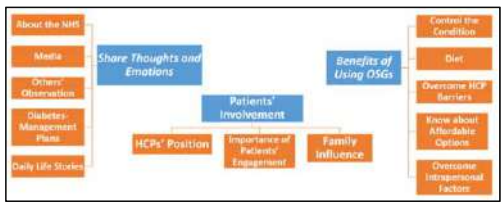

Figure 1– Map of the Themes and Sub-Themes

Members mainly benefited from the use of the OSGs to control and manage the illness, learn about dietary options, overcome barriers with healthcare professionals (HCPs), seek information about affordable options for tools to manage diabetes, and cope with intrapersonal factors (e.g., fear, anxiety, etc.). Information obtained from other members in the OSGs helped them to understand test results and set realistic plans to achieve better outcomes. Diet plans, recipes, and eating tips were widely discussed, and this clearly informed many members about eating options and how to make healthier choices. As a result, a number of members reported that the information and support they received from OSGs contributed to different elements of empowerment elements mentioned by the HCEM.

Emotions and thoughts about how members felt about the UK National Health Service (NHS), how the media was criticising the amount of spending on diabetes, and how they have been observed by others (especially employers and insurance companies) were expressed. They also discussed thoughts and plans about the management of the illness. Members also used the OSGs to share daily stories that were not necessarily related to diabetes. This was observed more in the Diabetes-support.org.uk OSG, since it is smaller in size and the members appeared to be closer to and confide more in each other.

Members had debates about whether HCPs expect them to be involved in the management of the illness, and if they are knowledgeable and capable enough to get involved in health decisions. On different occasions, they assured the importance of patients' engagement in diabetes management, especially when not receiving an effective healthcare service.

Conclusions

This study has provided a preliminary overview of ongoing research that seeks to understand the role of OSGs in empowering people with T2D in the UK. The results indicate that OSG members use the platforms to control various aspects of diabetes management. While the results answered some of the research questions, others remain unanswered; therefore, in the future, threads from the same period will be collected and analysed from a further OSG, to investigate whether these findings are present across other communities. Additionally, semi-structured interviews with current or former OSG users will be undertaken to understand in greater depth how the use of OSGs has changed their level of empowerment and to check the validity of these findings. The results of this study might help OSG moderators, HCPs, healthcare organisations, such as the NHS, friends and family members of people with T2D to understand their needs and challenges in managing the illness.

Acknowledgements

We thank the managers of the OSGs for giving permission to include these groups in the study.

Digital Literacy Program for the Use of Social Media, Aimed at Health Professionals

P Alonso Galbán[a], N Vialart Vidal[b]

[a] *Department of Special Information Services, Cuban National Center of Medical Sciences Information. Havana, Cuba.*
[b] *National School of Public Health. Havana, Cuba.*

Abstract

The WHO Strategy and Plan of Action on eHealth 2012-2017 highlights knowledge management and digital literacy as key elements for quality of care, health promotion and disease prevention, insofar as they guarantee training and better access to information in an equitable manner.

This work proposes a digital literacy program for the development of skills in social media use for information management, communication and eLearning, aimed at Cuban health professionals.

Keywords:

Health Informatics, eHealth, Information Management.

Introduction

More than 3.196 billion people use social media in the world (42%), which represents a 13% growth compared to 2017 [1]. In Cuba, the figure reaches 38% of the population [2].

The training of human resources in the use of social media in the field of health is a key element for the use of technology on the road to universal health coverage and to achieve the Sustainable Development Goals of the 2030 Agenda [3].

In the context of public health, social media favors information sharing, autonomous and networked learning, teamwork, communication, feedback, access to other related networks and contact with different experts, everything which contributes to management and collective construction of knowledge. In addition, it allows us to detect patterns and behaviors associated with the search and supply of health information.

The potential of these applications for surveillance, planning of services, development of intervention programs and health promotion are evident.

In the information society, a health professional capable of using this valuable resource in the management of information and knowledge, communication and eLearning will undoubtedly be better prepared to develop health promotion, disease prevention and medical care, based on the intensive and timely use of information and communication technology. At the same time, it will facilitate the exchange of information among professionals, academics, researchers, students and managers.

In the Cuban context, characterized by the particular importance of health issues in government public policies and, at the same time, one of the lowest rates of Internet penetration in the region (40 users per 100 inhabitants in 2017), the use of social media for health information management is a topic of particular relevance.

The WHO Strategy and Plan of Action on eHealth 2012-2017 highlights knowledge management and digital literacy as key elements for quality of care, health promotion and disease prevention, insofar as they guarantee training and better access to information in an equitable manner.

The strategy points out social media potential for the management and acquisition of new knowledge and the development of digital competencies as one of the topics to be considered in educational programs aimed at health professionals.

This work proposes a digital literacy program for the development of skills in social media use for information management, communication and eLearning, aimed at Cuban health care professionals.

Methods

A digital literacy program was designed considering the digital competencies established as necessary for the efficient use of social media in the field of health. We also considered the goals proposed in the WHO Strategy and Plan of Action on Knowledge Management and Communications [4], the WHO Strategy and Plan of Action on eHealth 2012-2017 and the PAHO IS4H project and Framework [5].

The program was designed following a human-centered design process and it was developed by four digital literacy experts from different Cuban health and academic institutions.

Results

The program consists of three postgraduate courses, one Massive Online Open Course, one blended learning course and a third in face-to-face mode, so that it can be developed according to the needs and conditions of health professionals in different contexts.

The program targets all kinds of health care professionals interested in the use of social media for health information management, communication in healthcare and eLearning, and other professionals from related sectors.

Its main objective is to develop digital skills for the efficient use of social media for information management, communication and eLearning in health, through recognition and experimentation in different social networking platforms.

Each course is organized into four thematic units covering the following content (Table 1)

The program was accredited by the University of Medical Sciences of Havana and is integrated to three master's degree programs and one diploma program. By October 2018 three blended, five face-to-face and two virtual editions had been developed, reaching 232 Cuban health professionals. Its incorporation into the self-learning resources of the Virtual Campus of Public Health of PAHO is foreseen.

Table 1

Thematic units	Contents
Internet, information and communication. From web 1.0 to web 3.0. Social media. Web 2.0 tools	History and background of networks. Internet, information and communication. Transition from web 1.0 to web 3.0. Social media. Web 2.0 tools: email lists, wikis, blogs, shared favorites, forums, websites, virtual communities of practice
Social media. Horizontal networks.	Social media: conceptual elements, emergence, characteristics and classification. Social networks in information management, communication and eLearning. Horizontal social networks: Facebook and Twitter.
Academic social networks.	Role of social media in science, scientific research and health communication. Science 2.0. Academic social networks: ResearchGate. Academia.edu, Mendeley, LinkedIn.
Infomed´s Social Networks	Infomed 2.0. Tools: discussion email lists, collaboration groups, blogs, Info links, wiki, image gallery, comments, instant messaging. Specialty and health topic websites.

Conclusions

The WHO Strategy and Plan of Action on eHealth 2012-2017 states that one of the components of eHealth is continuous education in information and communication technologies, which will facilitate its application in health. The digital literacy program that we designed can be reused for other countries that want to deploy the same kind of program. Further research about the impact of the program is needed.

Abstract

Social media has a growing presence in the eHealth research agenda. This research aims to characterize the use of social media in the Cuban National Health System for health information management and communication in healthcare.We specifically examine the strategy developed by Infomed and its main results.

Keywords:

Social Media, Health, Information Management

Introduction

According to the 2018 Global Digital report, published by We Are Social and Hootsuite, more than 3196 billion people use social media in the world (42%), representing a 13% growth compared to 2017 [1]. In Cuba, the number reaches 38% of the population [2].

One of the main expected trends regarding the use of Internet is the increased use of social media in the field of information search, Google search engine direct competition.

Social media has a growing presence in the eHealth research agenda. To date, their use in healthcare have been identified as a resource efficient approach to information and knowledge management and specialized communication, that could be used in many settings, and particularly where care providers and patients do not have the opportunity to have personal contact.

As part of the analysis of this new digital environment, some studies have examined social media impact on health knowledge management. In this sense, it has been pointed out the need to adapt the communication between health professionals and patients to the new scenario of the so-called electronic health, in a process that leads to the expansion of the possibilities of social interaction and the consequent empowerment of citizens for healthcare, as well as the best use of the potential of ICT [3].

In the context of public health, social media favor information sharing, autonomous and networked learning, teamwork, communication, feedback, access to other related networks and contact with different experts, everything which contributes to management and collective construction of knowledge. In addition, they allow to detect patterns and behaviors associated with the search and supply of health information. The potential of these applications for surveillance, planning of services, development of intervention programs and health promotion are evident.

In the Cuban context, characterized by the particular importance of the health issue in government public policies and, at the same time, one of the lowest rates of Internet penetration in the region -40 users per 100 inhabitants in 2017- the use of the social media for health information management is a topic of particular relevance.

Infomed is the Cuban National Health System network that coordinates all the health institutions of the country in terms of communication and information management [4]. One of its goal is that social media became channels for health information management and communication in healthcare for the entire country. Each health institution in the country is expected to develop a social media strategy that relates to its particular purpose, as well as to the goals of the Cuban national health system.

This research aims to characterize the use of social media in the Cuban National Health System for health information management and communication in healthcare.We specifically examine the strategy developed by Infomed and its main results.

Methods

A descriptive study was conducted, including all the social media profiles of Cuban health institutions, from January 2017 to October 2018. The variables used were: presence on Facebook and/or Twitter, update frequency, type of resources, topics, Facebook ranking according to LikeAlyzer [5], Twitter impact according to Twitonomy [6].

Infomed's strategy for social media was described and its main results were examined with specialized analytics tools.

Results

Ninety-seven institutional profiles were studied (including Facebook fan pages and Twitter accounts). There has been an annual increment of more than 1000 Facebook followers and about 600 in Twitter since January 2017. However, most of Cuban healthcare institutions have presence only on Facebook (64%), only 38% have also a Twitter account and 64% of them maintain a systematic update (at least once daily).

The most used types of resources were articles and pictures, mainly about news, information resources (scientific articles and books), courses and events promotion, all of this related to health. The main topics covered include hypertension, cancer, obesity, diabetes, Zika, dementia, aging, pregnancy and HIV/AIDS. 53% of Facebook profiles obtained a ranking lower than the average value for any type of page (53/100) according to LikeAlyzer. On average, 28 out of 100 tweets are redistributed, according to Twitonomy.

Infomed profiles shows a growing trend, with more than 11000 Facebook followers and 2291 in Twitter, until November 11, 2018. To date, the National Center for Medical Sciences

Information has five fan pages on Facebook and five users in Twitter**.**

The average daily range on Facebook is 86528 people. Infomed fan page rank in Facebook is 75/100, higher than the average value for any type of page (53/100), for pages of the same type -health / medicine / pharmaceutical products- (51/100) and even with respect to similar brands. (70/100).

Also, 48 out of 100 tweets are redistributed, indicating a high level of impact, committed audience and favorable impact on web statistics. According to Alexa [7], Infomed users spend about five minutes per day navigating and review four pages on average. In 2017, Infomed main website (http://www.sld.cu/) was located as the Cuban web portal with the best positioning in Alexa´s ranking. Throughout the year, it remained among the 6000 most visited portals among all Internet sites and among the top 10 most visited websites in Cuba.

The main components of Infomed social media strategy included: goals; strengths, weaknesses, threats and opportunities; audience; actions for each channel; guidelines for the design of the visual identity, formal elements and content management; interaction framework with the community; material and human resources; technological means and evaluation method.

Discussion

Social media is changing the nature of interactions in the field of health. Simple qualitative methods were used that showed increased social media use, but suboptimal use of Facebook profiles and insufficient use of Twitter within the Cuban National Health Service Network.

The analysis of the social media profiles of Cuban health institutions showed that the main difficulties were the low frequency of content updating, the scarce use of hypermedia resources, the inadequate selection of images, low interaction with users and the absence of a web content linked to the publications.

Among the studied profiles highlight the Infomed ones. Our results show that the strategy implemented by the Cuban National Center of Medical Sciences Information, which integrates the social participation spaces of Infomed with Facebook and Twitter, is a good practice. It strengthens cooperation through the structuring of information services and resources around knowledge networks and develops spaces for interaction, training, advice and discussion that favor permanent exchange among the people involved in the processes, motivating new knowledge generation and facilitating access to it.

Interaction between peers in social media is shaping a new model of knowledge management and learning, a different way of obtaining training and information, updating and developing necessary skills for professionals in healthcare sector.

Additional research is needed to further characterize the social media strategies of our health institutions and evaluate their results. Such information can be used to design interventions that improve use within a health system.

Conclusions

In the context of the Cuban National Health System, the consolidation of social media use for information management and communication in helathcare would increase access to information as a pillar of knowledge production. It would also contributed to the development of digital skills in human resources, which support the integral approach to health.

Digital social networks are considered today as the main standard of the new digital communication environment. However, this study suggests that their use in the Cuban National Health System is still incipient. The definition of institutional policies and strategies constitute the greatest challenge. The results of the implementation of Infomed´s strategy is a good example.

Acceptance of Tele-Dental Health Education Among Head and Neck Cancer Patients in Saudi Arabia

Sarah Alradhi[a], Ahmed Albarrak[a], Meshael Alghamdi[b]

[a] Medical informatics and E-learning Unit, Medical Education Department, College of Medicine, King Saud University, Riyadh, Saudi Arabia
[b] King Fahad Medical City, Dentistry Administration, Riyadh, Saudi Arabia

Abstract

Based on the latest published cancer report by the Saudi Health Council, Saudi Cancer Registry (SCR) in 2014, the percentage of cancer incidence got higher than the previous report in 2012 by 10.2% [1]. Increasing the incidences of head and neck cancer (HNC) remains a local public health burden that provoke us to consider technology innovations to manage its serious health consequences. We aimed to evaluate patients' preception toward technology usage in reciving health care.

Keywords:

Technology Acceptance Model, Head and Neck Cancer, Saudi Arabia

Introduction

Researchers indicate that at the time of diagnosis, cancer patients retain less than 20% of the information they collect [2]. For that, dental health education needs to be warranted in the patient care routine. Effective dental health education is encouraging patients to minimize their risk factors in order to reduce and prevent severe oral complication following cancer therapy. Prevention will aid to better nutrition, enhance comfort, increase adherence to cancer therapeutic process. Moreover, prevention care will lead to better health outcomes as well as improve the quality of life [3]. The purpose of this study was to evaluate patients' preceptions of using mobile dental health education among head and neck cancer patients in Saudi Arabia.

Methods

We adopted the technology acceptance model (TAM). Since the original questionnaire was in English, we used the recommended translation process by World Health Orginzation(WHO) to translate it into Arabic. The quistionare consisted of four main sections: demogeaphic, clincial data, mobile technology using data, and TAM containing 28 items scored of 5-point likert scale measuring both PU and PEOU (14 questions for each variable). This cross-sectional study was conducted in the dental department of King Fahad Medical City tertiary care hospital in Riyadh of Saudi Arabia from March till April 2019. Targeted population were 253 head and neck cancer patients who was treated there. Data were collected by phone based intrviews.

Results

Table 1 – Demographic and Clinical Data of Patients Participating in the Study (n=253)

Varibles	No. (%)
Sex	
• Male	151(59.7)
• Female	102(40.3)
Age	
• Range	19-73
• Mean±SD	49.9±11.5
Nationality	
• Saudi	230(90.9)
• Non-Saudi	23(9.1)
Education	
• Primary	4(1.6)
• Middle	39(15.4)
• Secondary	87(34.4)
• Bachelor	115(45.5)
• Master	7(2.8)
• Doctorate	1(0.4)
Duration of disease in years	
• Range	1-18
• Mean±SD	6.4±3
Tumor type	
• Benign	1(0.4)
• Malignant	252(99.6)
Treatment type	
• Surgery	108(42.7)
• Radiotherapy	245(96.8)
• Chemotherapy	166(65.6)
Duration of radiotherapy in months	
• Min-max	0-9
• Mean±SD	4.27±1.5
Duration of chemotherapy in months	
• Min-max	0-9
• Mean±SD	4.08±2.8
Time taken in minutes between home and medical service	
• Min-max	1-900
• Mean±SD	208.9±247.4
Type of electronic device you use	
• Tablet	66(26.1)
• PC	53(20.9)
• Laptop	131(51.8)
• Mobile phone	3(1.2)
• Smartphone	248(98)
Have you ever communicated with a health care provider using telemedicine?	
• Yes	45(17.9)
• No	206(82.1)
Do you want to communicate with your healthcare provider using telemedicine tools?	
• Yes	249(99.2)
• No	2(0.8)

Results (Table 1) showed an excellent usage of technology devices among participants, 98% were using smartphones and 51.8% were laptop users. 82.1% were reported that they never communicated with healthcare providers by mobile technologies. Almost 18% were contacted with healthcare providers to reschedule their appointments or to have referrals to other departments such as speech therapy. Results also showed that 99.2% of the participants were willing to communicate with healthcare proviers using mobile dental health from home to get dental health education. The correlation between those who accepted using telemedicine and different variables such as sex, nationality and tumor type (Table 2) had no significant association with the acceptance of using telemedicine. Whereas tumor type was the only factor significantly associated with receiving health education (P-value=0.03).

Table 2 – The Correlation Between Receiving Health Education and Different Variables

Variables	Receiving dental health education n (%)/ mean±SD		P-value
	No	Yes	
Sex			
• Female	86(86)	14(14)	0.51
• Male	120(79.5)	31(20.5)	
Education			
• Secondary and less	107(83.6)	21(16.4)	0.52
• Bachelor and above	99(80.5)	24(19.5)	
Nationality			
• Saudi	188(82.1)	41(17.9)	0.92
• Non-Saudi	18(81.8)	4(18.2)	
Tumor type			
• Benign	0(1)	1(100)	0.03*
• Malignant	206(82.4)	44(17.6)	

By investigating the attitude of participants toward the importance and using dental health education program (Table 3), the range of attitude score was 52-70 with a mean ±SD= 62.3±2.96. There was a significant negative correlation between duration of disease and attitude (r=-0.148, P=0.02). Nationality and receiving education program had no significant impact on the attitude score, whereas education was significantly associated with attitude score, the higher education was significantly associated with a higher score of attitude (P-value=0.01).

Discussion

The strength of this study is that this is the first study to assess the acceptance of head and neck cancer patients toward using mobile health education in Saudi Arabia, whereas the limitations include the lack of similar studies so we couldn't compare our findings with others.

Table 3 – Correlation Between Attitude and Different Variables

Variables		Mean attitute score	Std. Deviation	P-value
Nationality	Saudi	123.48	3.08013	0.989
	Non-Saudi	123.5	2.83816	
Education	Lower Education	**122.6**	**6.38967**	**0.017**
	Higher Education	**124.4**	**5.21762**	
Receiving Education	Yes	123.6	5.86741	0.490
	No	122.9	6.07678	

Conclusions

There was acceptance among patients to communicate with health care providers by using smartphones, and they had a positive attitude toward mobile dental health education.

Exploring the User Engagement Scale Short Form as a Determinant of Adherence in Digital Health Interventions

Andre Q Andrade[a], Alline MR Beleigoli[b,c,d], Tiago MS Silva[e], Maria de Fátima H Diniz[c,d], Antonio LP Ribeiro[c,d]

Abstract

Adherence determines the impact of digital health interventions. Standard tools provide a measure for user experience and predict adherence. We evaluated the User Engagement Scale Short Form (UES-SF) during the POEmaS project, a randomized clinical trial of an online weight loss platform. We received answers from 178 participants (13.7% of the cohort) and correlated the UES-SF scores with the number of sessions attended. Our findings suggest the UES-SF is an accurate evaluation of user experience, but only one domain (reward) was associated with long-term use.

Keywords:
Patient participation, telemedicine, clinical trial

Introduction

Lack of user engagement and adherence with digital health tools is a common issue in large-scale online interventions. The User Engagement Scale (UES) is a tool that helps evaluate the main determinants of adherence. Initially developed for e-commerce, social media, and search situations, the UES is based on general psychological constructs and can be used in other domains [1]. The UES has a short form (UES-SF) [2] which is composed of 12 questions divided between 4 domains: perceived usability (PU), aesthetic appeal (AE), focused attention (FA), and reward (RW). The RW domain is a summary of three domains from the original UES: endurability, a measure of how successful the interaction was and the likelihood of recommending the application to others; novelty, a measure of curiosity and interest; and felt involvement, a measure of the feeling of being "drawn in" and having fun [2].

We evaluated the applicability of the UES-SF to the digital health domain. We explored the use of the UES-SF to evaluate how users perceive a digital health intervention for weight loss and to understand which facets of the UES are most predictive of long-term adherence.

Methods

The Online Platform for Healthy Weight Loss (POEmaS) project has been extensively described elsewhere [3]. It was a randomized controlled trial that investigated the effectiveness of an online platform which delivered a 24-week behavior change program on weight loss and lifestyle habits. The yearlong trial (September 2017 to October 2018) enrolled 1298 eligible participants (≥18 years of age, BMI ≥ 25kg/m^2, not pregnant or undergoing other treatments for weight loss) who were students or staff of the Universidade Federal de Minas Gerais (UFMG) in Brazil. The project was approved by the UFMG Ethics Committee (CAAE: 73545717.5.0000.5149) and is registered as NCT03435445.

Participants were randomly allocated at a 1:1:1 ratio into three parallel arms: 1) those given access to the web-based platform; 2) those given access to the platform plus online coaching with a registered dietitian; and 3) the waiting list group, which received access to the platform after six months. The behavior change intervention was similar for all groups [4].

Prompts for answering the UES-SF were submitted to all participants by email. Users in groups 1 and 2 (platform access) were prompted at the end of the program (six months). Users assigned to the waiting list were prompted one week after gaining access to the full platform in order to evaluate whether the scale's predictive capacity changes over time. All questionnaires were answered electronically at a webpage built specifically for the purpose and were not part of the normal usage session.

Answers were analyzed after the end of the trial. We determined Pearson's correlation coefficients between long-term engagement and the score for each domain separately, as well as the overall score. We also used Student's t-tests to compare the mean UES-SF score in each domain between users who only used the platform for one day and users who returned at least once; we did the same to compare users who attended more than seven sessions with those who did fewer than seven sessions. Statistical analysis was performed using the SciPy package v1.1.0.

Results

The questionnaire was offered to all 1298 participants of the POEmaS project. We received 178 (13.7%) responses. Responders were older than non-responders but had similar baseline body mass indices (BMI). The responder group had significantly more female users. The clinical trial arm was not determinant for whether the user answered the UES-SF questionnaire. The comparisons between the responder group and the non-responder group can be seen in Table 1.

Table 1 – Baseline Characteristics of UES-SF Responders and Non-Responders

	Non-responders	Responders	p-value
Female (%)	847 (75.6%)	149 (83.7%)	0.023
Mean age	33.35	35.27	0.020
Mean baseline BMI	29.96	29.46	0.15
Waiting list (%)	349 (31.1%)	59 (33.1%)	0.79
Total	1120	178	

The platform was highly rated by the users in the four domains of the UES-SF. The response averages can be seen in Figure 1. Platform evaluation was not significantly different between participants in different trial arms.

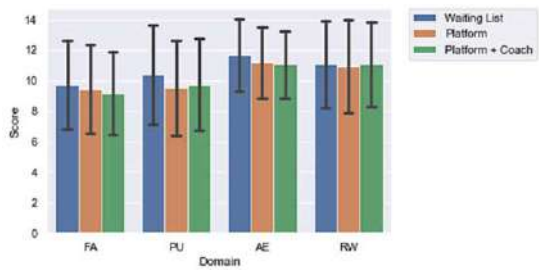

Figure 1 – Average UES-SF scores, stratified by domain and trial arm (mean and standard deviation shown). FA=focused attention, PU=perceived usability, AE=aesthetic appeal, RW=reward

The overall UES-SF score was positively associated with engagement measures. When considering the different domains, only the RW domain retained statistical significance (Table 2).

Table 2 – Association Between UES-SF Scores and the Total Number of Sessions, Stratified by Domain

	Pearson correlation coefficient	p-value
UES (all domains)	0.1864	0.013
Focused attention	0.1202	0.110
Perceived usability	0.0493	0.514
Aesthetic appeal	-0.0111	0.883
Reward	0.3011	<0.001

UES-SF scores stratified by domain between users who used the platform for only one day and users who returned at least once were significantly different for the FA, AE and RW domains (Table 3). When comparing between users who attended more than seven sessions and those who did fewer than seven sessions, only the differences in the RW domain retained statistical significance.

Table 3 – Association Between UES-SF Scores and Short-Term Engagement, Stratified by Domain

	1 session	> 1 session	p-value
Number of users	41	137	
FA (mean)	8.24	9.8	0.002
PU (mean)	9.81	10.17	0.524
AE (mean)	10.61	11.51	0.029
RW (mean)	9.76	11.39	0.001

Conclusions

The UES-SF was useful as an engagement evaluation for digital health interventions. Among the four dimensions explored in the questionnaire (reward, perceived usability, aesthetic appeal and focused attention), all but perceived usability are associated with short term engagement. However, only the reward dimension is associated with long term engagement.

Postgraduate Studies in Digital Health (eHealth): Developing a Blended-Learning Model and Real-Life Spaces

Raul Antônio Morais Melo[a], Patrícia Smith Cavalcante[b]

[a] *Medical Sciences, University of Pernambuco, Recife, PE, Brazil*
[b] *Center of Education, Federal University of Pernambuco, Recife, PE, Brazil*

Abstract

Digital Health (e-Health) is the use of the technologies of information and communication in the health area. We report the design and implementation of a course in e-Health for multi-professional postgraduate students. It was based on two key ideas: a blended-learning model and real-life spaces. The methodological triangulation approach included the educational planning of a course. In this work, we present and demonstrate the feasibility to use a blended-learning model to teach e-Health to postgraduate students based on interactive distributed learning spaces.

Keywords: *health education, learning, informatics.*

Introduction

Digital Health (e-Health) is the cost-effective and secure use of information and communications technologies in support of health and health-related fields, including health-care services, health surveillance, health literature, and health education, knowledge and research [1].

Most health professionals use information technology daily in their work, but few know how to adapt their roles and work processes to incorporate it for the most significant benefit [2]. In this respect, blended learning (b-learning) might be more suitable for health care training because of the need to combine hands-on, skills-based training at a practical level, as well as self–directed learning [3,4]. We report the development of a course in digital health, which combined both a blended-learning model and real-life spaces.

Methods

The course is an elective, open discipline, offered to post-graduate students attending the master's or doctorate on Mathematics and Technological Education (Edumatec) at the Center of Education of the Federal University of Pernambuco (UFPE) in Recife, Brazil. We, the teachers, used a design-thinking approach for the educational course planning with brainstorming and canvas map techniques, and analyses of future learning spaces and scenarios. The basic structure of the course considered the content (academic and real-life), the learning spaces (physical and virtual), and strategies (scenarios and activities).

The educational contents were digital health history and resources; and concepts, characteristics, and landmarks in education. The real-life themes included e-Health applied to the electronic health record, accreditation in the health area, innovation in health, telehealth, and development of personal competencies for health workers. All real-life contents were studied physically through visits plus chats with health or educational workers.

The physical learning spaces were the UFPE physical post-graduate classroom, a primary public health unit, a tertiary private health unit, a school of innovation, a telehealth unit, and a symposium attendance. The online learning spaces were an online classroom and a social media network. We used a freeware Learning Management System - LMS (MoodleCloud) on the Internet, office productivity programs (Microsoft Office, H5P) and interactions in social media software (Telegram), because of their availability and usability [5-8].

Three interdependent and simultaneous tracks of learning scenarios were envisaged: physical and real life (regular classroom and guided visits), online and interactive (virtual classroom and social media network) and innovative production (hackathon). As evaluation criteria for the course, we used pre- and post-tests, weekly task accomplishment, the Hackathon solution, and the degree of interaction of the participants.

Results

Thirteen students and two teachers were enrolled in the discipline for eight weeks. As a result, a thirty-hour course was developed in a b-learning model using an LMS platform, software, and social media. A myriad of activities were planned to better consolidate learning, both in real and virtual scenarios (**Table 1**). A hackathon with a real health problem was also created so that the students could follow the various phases of problem presentation, ideation, construction, validation, implementation, and solution presentation.

Table 1 - Structure and Timeline of the Course on Digital Health.

Structure / Week	0	1	2	3	4	5	6	7

Workforce Development Strategy for Health Information System Implementation at the Public Health System of Buenos Aires

Jacquelina Celis[a], Analía Baum[a], María Victoria Giussi Bordoni[a], Leandro Alassia[a], Adriana Stieben[a], Mariano Franco[a], Fernán Gónzalez Bernaldo de Quirós[b]

[a] *Health Information Systems Office, Ministry of Health, Buenos Aires City, Argentina,*
[b] *Government Health Advisor, Buenos Aires City, Argentina*

Abstract

One of the challenges of implementing health information and communication technology is the need for a skilled workforce that understands health care and ITC. There are also people and organizational challenges involved. This work describes the strategies to create such a workforce for the public network of healthcare facilities in the City of Buenos Aires, which include promoting the adoption of technologies and providing lines of contention for continuous training.

Keywords:

Organizational Innovation, Capacity Building, Health Information System

Introduction

Developing and managing workforces to carry out Health Information System (HIS) implementations is key and challenging. Having trained professionals in the discipline that do not meet the required task force demands when it comes to regional implementations [5] increases the challenge.

The Ministry of Health of the Autonomous City of Buenos Aires started the implementation of the Health Information System two years ago that involved 114 effectors [2]. This led to the creation of different working teams to carry out the implementation, provide support in the transformation processes, and ensure the adoption of new technologies during the management period 2015-2019 [4].

This paper describes the strategies designed and used for the conformation, growth, and consolidation of the working teams implementing HIS in the public health system of the Autonomous City of Buenos Aires.

Methods

Setting

The Buenos Aires city healthcare network is conformed by a Ministry of Health, 114 centers, structured into 12 geographical areas to organize health care delivery. The healthcare system has a total of 41,000 employees. Since June 2016, an Electronic Health Record (EHR) has been gradually implemented in the outpatient setting [2; 4]. When the Ministry of Health decided to implement the EHR, a Special Project Unit (SPU) was created and the necessary manpower was assigned to carry it out.

Study Design

This is a descriptive study about the designed strategies that were used for the conformation, growth, and consolidation of the working teams that are in charge of implementing EHR within the City of Buenos Aires. The description has been approached from four axes:

1. Talent Management: The challenge of digital transformation becomes the challenge of selecting professionals with adequate digital competences and digital culture [6]. In this sense, and considering that health systems are understood as complex systems that consist of dynamic and complicated networks of interconnected actors [1], it becomes relevant to form multidisciplinary working teams.
2. Communication and Internal Training: The working team in charge of carrying out the implementation becomes the prolocutor for organization that works on agile methodologies. The team must be trained in change planning processes, have the ability to establish a sense of urgency, form the coalition of a local team, empower people, provide short-term results and collaborate to consolidate the introduced changes [3; 7].
3. Contention lines: Training and communication programs are contention mechanisms for the working teams that can also foresee the demands that may be received by end users. Digital knowledge, information management, communication, networking, continuous learning, the strategic vision, network leadership and the user's orientation, are the thematic axes on which the training of the work team should focus.
4. Geographical distribution: The demographic distribution of the effectors has been laid out within an area of 204 Km². This distribution is a variable to be taken into account when it comes to organizing and distributing HIS implementation teams, especially if the implementation happens to be simultaneous or exponential.

Results

Talent Management

The SPU EHR is a team that combines disciplines, organized in 5 different roles and functions (Table 1).

Table 1– SPU EHR Team Profile

Role	Function	Discipline (N)
Director	Establish Strategic guidelines; coordinate with Project Leaders	Healthcare Informatics (5)
Project Leader (PL)	Establish tactical guidelines; develop the gantt and track the project	Physicians (2), Sociologist (1), Political Scientist (1), Communicator (1), Education (1), Inter-disciplinary Residency Program in Health Information Systems (*IRHIS*) (15)
Coordinator	Operate the strategic lines; manage field work	Healthcare professionals (16)
Implementer	Perform survey and implmentation tasks	Advanced Health Science students (65)
Auditor	Ensure the pattern's quality	Professionals of Administrative Careers (8)

Due to the shortage of this professional profile, the IRHIS was developed to create a training program based on in-service training. Currently, the IRHIS has 15 active professionals (physicians, psychologists, sociologists dentist, anthropologists,) who have been assigned the PL role.

The approach of all actors requires the involvement of other disciplines, ensuring the convergence of different perspectives and proving suitable solutions for end users, understanding their interests, needs and idiosyncrasies.

Communication and Internal Training

The SPU EHR designed a three-stage training process for the implementers. This training allows collaborators to pass down HIS implementation values, as well as teaching the use of their applications and finally provide certain soft tools to manage change.

Project Coordinators and Project Leaders receive their training through similar post-graduate courses such as project management programs, AMIA's 10x10 program and a master's degree in health informatics.

On the other hand, Coordinators and PL meet every two weeks to share both advances and unexpected consequences in order to generate consensus and find alternatives to continue with the implementation plan.

Contention Lines

In order to support the training of collaborators, a series of instruments as face-to-face and virtual trainings, an internal campus and meetings, were established to facilitate access to knowledge.

Likewise, prior to the launch of a new functionality in the EHR, every member of the working team must undergo virtual training designed for end users and attend every required specific training meeting.

Finally, given the complexity implied in introducing changes in health organizations and considering that implementers are those who usually receive the most unmet demands, the Project Management promoted dialogue and contention meetings with a team of experts in coaching. In these spaces, we sought to capitalize on the collaborators' experiences and provide useful soft tools to manage change within the field.

Geographical distribution

Geographical distribution of health effectors as well as the committed goals influence the way grouping and collaboration work among coordinators when simultaneously implementing several effectors. There are two main implementation scopes (primary healthcare facilities and hospitals) which are crossed by several transversal projects (contingency, printing Health records, Digital Signature, etc.)

The PL team works with the coordinator to integrate the implementation of transversal projects to the deployment of EHR positions assumed as government commitment.

Conclusions

Digital transformation does not have to be thought as the transformation of the organization. Instead, it has to be thought as the transformation of the people that are part of it. Thus, the talent management of the working team that carries out the implementation of HIS is key when adopting change. Even though the SPU EHR has put a lot of emphasis on different strategies for the development of high-performance teams, there are still evaluation instances of internal processes to be developed.

The EFMI Working Group "Healthcare Informatics for Interregional Cooperation": An Evolving Strategy for Building Cooperation Bridges

Arriel Benis [a, c], Mihaela Crisan-Vida [b, c], Lăcrămioara Stoicu-Tivadar [b, c]

[a] *Faculty of Technology Management, Holon Institute of Technology, Israel*
[b] *Department of Automation and Applied Informatics, Politehnica University Timisoara, Timisoara, Romania*
[c] *European Federation for Medical Informatics, Working Group "Healthcare Informatics for Interregional Cooperation*

Abstract

The Working Group "Health Informatics for Interregional Cooperation" (WG HIIC) of the European Federation for Medical Informatics (EFMI) is dedicated to develop, to implement and to disseminate a strategy for promoting exchange of information, knowledge and experiences all around the world and more particularly, between Health Informatics arena players in the different European continent regions.

Keywords:

Europe, Social Participation, International Cooperation

Introduction

The European Federation for Medical Informatics Association (EFMI) is in Europe, since 1976 [1], is the leading organization in the field with more than 30 partner-countries affiliated societies. Among the main objectives of EFMI, a central one is promoting co-operation inside and outside Europe by supporting dissemination of academic and professional education, knowledge, standards and experience.

For matching with these goals, in a continuously changing scientifically, technologically and regulatory contexts, EFMI has workgroups (WGs) focusing on how to investigate, to disseminate and to promote a large range of sub-specialties of Medical Informatics by taking into account cultural differences. EFMI WG "Health Informatics for Interregional Cooperation" (HIIC) has been created continuing the activity of the EFMI WG Medical Informatics for Countries in Transition (MICIT) chaired until 2003 by Prof. George Mihals and from 2003 by Prof. Lacramioara Stoicu-Tivadar who proposed to EFMI Council the new WG in 2007. Since 2018 a new chair – Dr. Arriel Benis - and co-chair – Dr. Mihaela Crisan-Vida took the lead of the WG and will continue the activities in a dynamic manner for the next 4 years.

Objectives

- The EFMI WG HIIC activities consist of promoting exchange of information, knowledge and experiences all around the world and more particularly, between Health Informatics arena players in the different European continent regions. For addressing these, the EFMI WG HIIC is over the years developing and improving a dedicated continually evolving strategy [2].
- The main objectives of the EFMI WG HIIC are [3]:
  - to promote exchange of information and experiences between actors in different regions in Europe;
  - to investigate the needs, opportunities and obstacles for e-health and to review and select from different education options for developing regions;
  - to disseminate European and world-wide results and experiences across regions and between professionals;
  - to facilitate access to European groups and their facilities and outcomes by students and health professionals from developing regions;
  - to disseminate European and world-wide results and experiences across developing regions and professionals.

Implementation

During the last decade, the EFMI WG HIIC has been involved in different projects and missions, for example,

- to support the development and the implementation of the Electronic Health Record in Europe;
- to motivate national societies to join EFMI as members and also its WGs;
- to support the organization and the community involvement in the Medical Informatics Europe (MIE) conferences;
- to organize EFMI Special Topic Conferences (STCs) and workshops allowing researchers and practitioners sharing their work in a specific sub-domain [4].

Several of these EFMI WG HIIC actions during 2008 - 2017 were:

- 2008: in April the WG chair conducted a mission of evaluation and support the EHR Serbia, with participation in The Conference «Electronic Health Record, options for the Future», Sava Center, Belgrade, April 17 (from EFMI Prof. Rolf Engelbrecht, EAR, MoH Serbia); participation in MIE 2008 Goteborg and in July Organizing the Workshop "Integration of Electronic Health Records" National / International and Technical Aspects, 24-25 July; in September participation in STC 2008, London.
- 2009: during MIE 2009 in Sarajevo HIIC organized the the Workshop "Is There a Common Background to Support Better Healthcare in Central and South East Europe?" - to assess healthcare informatics stage for 6

countries in Central and East European area, and the real need for cooperation and its driving forces [5];

- 2011: HIIC chaired EFMI-STC in Laško, Slovenia, e-Health Across Borders Without Boundaries with prof. Lacramioara Stoicu-Tivadar as SPC chair and prof. Bernd Blobel and Tomaz Marcun co-chairs and editors [6].
- 2014: EFMI WG HIIC organized together with EFMI Primary Care WG the STC 2014 in Budapest, Hungary, dealing with cross-border challenges in informatics with a focus on disease surveillance and utilization of big-data, editing the volume Cross-Border Challenges in Informatics with a Focus on Disease Surveillance and Utilising Big Data [7]
- 2015: the WG supported the program and participation in EFMI MIE2015, Madrid, Spain; mediating EFMI-IMIA WGs meeting during MIE 2015; in April participation in EU-USA project Trillium bridge workshop; preparing projects for consolidating cross border cooperation with neighbours, Hungary (Szeged) and Serbia (Vrsac) in e-health projects under INTERREG frame.
- 2016: participation at STC 2016, Paris, France with scientific contributions; participation in EFMI MIE 2016, Munich, Germany and organizing the workshop on regional projects and low cost solutions for financially challenged regions: Sustainability of Telemedicine Projects for Resource Challenged Regions having as invited speaker the regional projects expert Michael Weinhara.
- to develop active cooperation at the national level between EFMI country (e.g. Romania / Hungary / Serbia since 2009), academic institutions in different regions of Europe (e.g. "Politehnica" University of Timisoara in Romania and the Holon Institute of Technology in Israel since 2017) in medical informatics education and e-health projects [8].

The results of the previous years show that interregional cooperation in the European health informatics arena is active and gradually moving from focused interested to broad one which combine academic and industrial researches and higher eduction training. The EFMI WG HIIC focused, focus and will focus on common problems that extend beyond national borders such as health, legal, political, economic and cultural factors.

Lessons and future outcomings

In the nowadays, connected world the EFMI WG HIIC is proud of the previously accomplishments.

From these experiences, the group has pointed-out new needs and challenges for taking to the next level, the interregional cooperations based on medical and health informatics projects.

An important part of the EFMI WG HIIC strategy consists for the next years to increase the numbers of its members, their academic and professional background and country of origin. Accordingly, it will allow the WG to be involved in more projects, such as taskforces, and so will be able to support them by sharing experience and expertise in running multinational and interregional projects.

The virtualization of the workspace is a huge opportunity for establishing scientific, technical, educational and mostly human active and productive partnerships in the European landscape and further.

As some examples of future outcomings, we can mention: collateral involvements in health informatics courses between academic institutions in EFMI partner-countries and the development and implementation of a collaborative and multilingual dictionary focusing on Health and Medical Informatics.

Development of a Research-Based Teaching Course as Blended-Learning Format in a Medical Informatics Program

Nils-Hendrik Benning, Petra Knaup

Institute of Medical Biometry and Informatics, Heidelberg University, Germany

Abstract

We consider Medical Informatics programs at universities as one of the main education resources for young scientists in our field and thus present a new design for a course teaching scientific skill at the University of Heidelberg as blended-learning format. We utilize common E-learning methods and created the whole course with respect to the concept of research-based teaching. Finally, we present our lessons learned from the current activities of the course.

Keywords:

Education, Distance, teaching, medical informatics.

Introduction

Medical informatics is a scientific discipline with variety and evolving research topics [1]. Therefore, an important aim of academic medical informatics programs is to allow students to participate in scientific work. In the medical informatics bachelor program at Heidelberg/Heilbronn (Germany), the students have a compulsory practical course where all participating students work as a research team together on an up-to-date scientific question of medical informatics.

Academic teaching in Germany is mostly organized by conducting weekly classroom instruction. This format is not so adequate for a large group of students who are working together on a project. There are times in the course of the project where intensive instruction and feedback in short intervals is necessary and there are phases in which the learners can work independently for longer periods of time. Therefore, we developed a blended-learning concept for practical training that implements research-based learning.

Blended-learning formats are used rarely (18 % of German university teachers used such formats regularly in 2017 [2]). Therefore, a process model on how to establish such a course was not available.

Methods

We used existing work from Salmon [3,4] to implement an active and social Virtual **L**earning Environment (VLE). The overall design of the VLE was created following the concepts of research-based learning by Healey and Jenkins [5] and the guidelines for research-based courses from Sonntag et al. [6]. For the implementation of the VLE, an existing instance of the open-source learning management system *Ilias* (version 5.3.7) was used. To measure the students learning success and the general satisfaction with the course, an evaluation was conducted at the end of the winter term 2018 / 2019. For this evaluation a German questionnaire was created, which utilizes the F-Komp-model from Böttcher and Thiel [7], a questionnaire that specifically addresses the evaluation of research-oriented courses. The items from the F-Komp-model were combined with the standard evaluation form of the university's quality management department.

Results

The blended-learning concept covers a 15-week term and is suited for a course which grants 6 ECTS credit points. The course is organised in weeks which include classroom teaching and exclusive E-learning weeks. The sequence of these types of weeks has to be flexible to a certain extent to allow adjustments throughout the term (see Table 1).

Structure of the VLE

During all weeks of the course the VLE is used to offer different resources, like literature, tutorials or formative tests, to the course members. The course is structured at two levels: on the first level the phases of research-based learning from Huber (see *Figure 1*) are represented as blocks in the VLE, which clearly distinguish different phases of the course from each other.

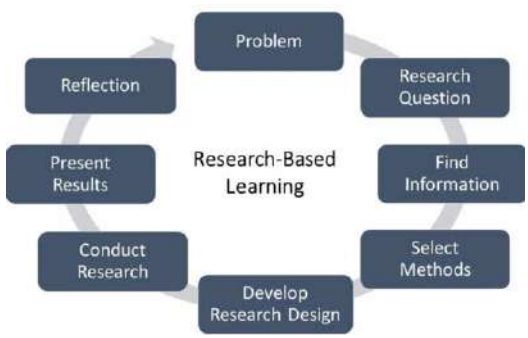

Figure 1— Research Cycle (cf. [7])

On the second level, each block uses expandable container objects for each course week. Each week consists of an overview and the actual content. The overview summarizes if classroom teaching takes place, which tasks should be completed, and which resources are needed to complete them. The content consists on the one hand of the aforementioned resources and on the other hand of interactive online-forums. The forums are used for multiple purposes: for each classroom teaching there is a forum, which shall be used to discuss organizational and content-related matters like the absence of participants or summaries of classroom discussions. Other forums represent the so-called E-tivities. These forums are an activating way of assigning tasks to learners, which not just motivates them to work on the task, but also fosters collaboration in a VLE [4]. This collaboration is supported by a teacher all the time. According to Salmon's principles of moderating, the teacher takes the role of an E-moderator, which is an important and different from the known role of university teachers [3].

The described structuring results in a course layout that is shown in Table 1.

Table 1 – General course layout

Week	Teaching Type	Content
1	E-learning	Problem: overall subject
2	Classroom	Problem: specific problems
3	Classroom	Research Question
4	Classroom	Find Information; Select Methods
5	Classroom	Develop Research Design
6-12	*Flexible*	Conduct Research
13	*Flexible*	Present Results: preparation
14	Classroom	Present Results: trial presentation
15	Classroom	Present Results; Reflection

Course Layout

The first week is used to assign the learners with reading fundamental literature to get to know to the subject matter. To make sure everyone arrived at the VLE and worked on the assignment, each learner has to write a short message introducing himself and take a short formative test about the literature that has to be passed. This introduction to the VLE results in an online brainstorming for problems in the defined research field. In week two, the preparations from the first week are used in the classroom to define the problems the learners want to work on. Week three is dedicated to the definition of the research question. To enable the learners to select the aims of their research, methodical skills are conveyed in the classroom, before the learners are divided into groups of 4 to 6 people. These groups are supported individually afterwards. The next two weeks (4 and 5) cover a deeper look in the field and the selection of research methods, which are used to create the research design for the coming weeks. These last preparing parts of the research cycle take place in the classroom. Now the learners should be ready to conduct their own research project. In this extensive part of the research cycle most teaching can be done in the E-learning setting, as the learners are expected to work independently. Classroom teaching is recommended in cases where the E-moderator finds a need for face to face motivation or discussion. The last three weeks take care of the preparation and presentation of the results. First, the preparation consists of defining requirements for the presentation, which can be done either in classroom or in the VLE. The trial presentation and the final presentation should be done in the classroom to create a setting, which is comparable to presentations at scientific events like conferences. Finally, the learners should be supported by talking about their collaboration within the course.

Implementation

We implemented the course according to the introduced concept and 18 advanced students who participate currently in our medical informatics bachelor program. The students work in the field of patient participation and consider especially applying components supporting this paradigm. Selected research questions are: “which requirements exist for application components that support patient participation?” and “which software solutions and frameworks are currently available, to support patient participation?”.

Conclusions

Generally, we found a higher workload for teachers of a blended-learning course, because the contact time with learners is not limited to fixed appointments in a work week but open for contact whenever it is needed. Furthermore, the configuration and preparation of the E-learning environment is more demanding than the preparation of materials for classroom teaching. In return, it is possible to achieve a much closer mentoring of the learners while they go through the research cycle. As this is the first time the course takes place, we expect a reduced workload for future terms, because it was implemented as a general concept, which can be instantiated by each year’s individual medical informatics research question.

With a focus on optimized results of the research projects, the time constraint of a university term limited to 15 weeks is challenging especially for the first phases of defining a research question and creating a research design that has a varying demand of time. The VLE helped us to closely accompany the students in this crucial phase of the project.

When term’s lecture period ended in January we evaluated the course with the tools mentioned. The evaluation results will be presented on the poster and we will use the results to revise the concept for the next group of students.

Acknowledgements

The course was developed in the context of the HiGHmed working package teaching and training, which is funded by the German Federal Ministry of Education and Research (grant id: 01ZZ1802A) as part of the Medical Informatics Initiative. [9]

A Taxonomy for Survey Measures Used to Evaluate Complex Digital Health Innovations

Tim Benson

R-Outcomes Ltd; UCL Institute of Health Informatics

Abstract

Evaluators need to measure whether innovations help patients and staff, but have lacked the tools needed to do this as part of routine care. We provide a taxonomy for the classification of survey measures, which can be used together on a pick and mix basis. These are described in the context of the evaluation of digital health innovations.

Keywords:

Healthcare evaluation mechanisms; Outcome and process assessment (health care); Healthcare quality, access and evaluation; Complexity; Patient-centred care.

Introduction

Many digital health innovations have been abandoned, failed to be adopted, scale-up, spread or be sustained [1]. We need the tools to understand not just what happens but also why.

Most patient-reported outcome and experience measures (PROMs and PREMs) address a single dimension and were developed in isolation.

This paper presents a taxonomy covering twenty-one short generic measures, which form a coherent family covering the patient needs, treatment outcomes, patient experience, other factors and key aspects of digital innovation.

These measures are designed for digital data collection and results reporting using mobile devices. This taxonomy can help people understand the role of each measure and any gaps or overlaps.

Methods

These measures were all developed in a similar way.[2]

- Recognition of the need for a new measure
- Review of existing literature and brainstorming
- Initial proposals for discussion with potential stakeholders (patients, clinicians, commissioners)
- Iteration, fine-tuning and revision
- Testing and revision
- Validation studies

Results

We created a taxonomy of measures, which may be completed by patients, staff and carers, covering a range of perceptions about their health needs, treatments, experience, social factors and innovation (see Figure 1).

Needs

The **howRu** health status measure is a short generic patient-reported outcome measure (PROM) to track and compare patients' perceptions of how they feel physically and mentally and what they can and cannot do (disability and dependence) [2].

Figure 1 Taxonomy of measures

The **Personal Wellbeing Score** (PWS) covers life satisfaction, worthwhileness (eudomonia) and positive (happiness) and negative (anxiety) affect. It is based on the Office of National Statistics ONS4 [3].

The **Health Confidence Score** (HCS) captures people's confidence in their knowledge of their health and treatment, ability ot self-manage their health, access the right help if they mneed it and shared decision-making [4].

Social isolation and **loneliness** are important determinants of health and wellbeing. People need companionship, someone to confide in, people to help them and do things with.

Sleep hygiene is another important determinant of health and wellbeing.

Treatments

Self-care, including diet, physical activity, weight and medication management.

Acceptance of loss, how people have learnt to live with events, including recognition of capabilities and change, how to do things differently and to move on with life.

Medication adherence including remembering to take medications, following instructions given side-effects or recovery and satisfaction.

Assessment of need (**howRthey**) by staff of people with cognitive loss about how much support people need

Experience

HowRwe is a short generic patient-reported experience measure (PREM), which measures their perception of the the care and service provided by one service [5].

The **Service integration** measure captures patients perception of how well different services collaborate. Perceived quality across services is often lower than that within each service.

The **Shared Decision-Making** (SDM) measure covers several aspects of how involved patients have been in making health care choices together.

Social Factors

Social determinants of health, such as education, self-esteem, housing and poverty play an large role in determining peoples' health [6]. The Social Factors measure covers these.

Neighbours, community cohesion and social capital are impacted by how well people know, trust and help each other.

Innovations

The following measures were designed for use in digital health innovation evaluation [6].

The **Digital Confidence Score** assesses people's confidence in using digital apps and similar devices. Many patients are old and frail and are on the wrong side of the digital divide.

The **Innovation Readiness** measure where people and their organisations fall on the innovativeness spectrum (innovator, early adopter through to laggard), covering whether they think new ideas are needed, their up-to-dateness, organisational support and capability.

The **Innovation Process** measure is based on Normailisation Process Theory (NPT) in terms of how innovations are implemented.

The **User Satisfaction** measure focuses on peoples perception of whether an innovation is useful, is easy to use, they can get help and their overall satisfaction.

Behaviour change, based on the COM-B model covering capability, opportunity and motivation to change behaviour [7].

Discussion

We have developed a taxonomy with five main branches, covering patient needs, treatment outcomes, experience of care, other factors and innovation-specific aspects. This taxonomy covers 21 separate measures, many of which have variants for patients, staff and carers. This structure is more complex and sophisticated than the traditional division between patient-rported outcome measures (PROMs) and patient-reported experience measures (PREMs).

This family of measures shares a common look and feel with four items and four responses. They are research-based and validated, quick and easy to use with simple unambiguous wording and low reading age, readily understood by thoise whose first language is not English. They are generic, suitable for almost all situations, irrespective of case mix across health and social care. They are channel-neutral and can be used on paper, smart-phone, tablet, PC or via text message or voice.

Any practical implementation needs to give detailed consideration to (a) selection of measures, (b) the data collection process, (c) data visualisation of results, and (d) how the results are used to improve services.

The results show trends, changes and comparisons. These are quick and easy to interpret, giving immediate feedback to all stakeholders tracking changes and differences between units.

For reporting and visualising results, a common approach is used. High is always good. Different items may be aggregated. Mean scores for groups are always reported on a 0-100 scale, with 100 indicating that all respondent chose the best option and 0 that all chose the least desirable option.

These measures were developed to meet the need for a coherent family of short generic surveys for use in evaluation and as key performance indicators of services. They are characterised by brevity and low reading age. Most other measures have been developed as academic research projects resulting in relatively longer measures, whith higher reading age and little compatibility between measures.

These measures have been used with success in evaluations of new care models, social prescribing, care homes, digital health applications, such as for diabetes self-care and AF detection.

Conclusions

This paper provides a taxonomy with five branches covering patient needs, treatment outcomes, experience of care, other factors and innovation-specific aspects. This taxonomy covers 21 separate measures, which have been used together in a pick and mix way in a wide variety of evaluation studies.

Developing an Intuitive Intelligent Inpatient Medical Record System

Chia-Jung Chen[a], Hsien-Yi Wang[b], June-Dong Lin[a], Chung-Feng Liu[*cd]

[a] Department of Information Systems, Chi Mei Medical Center, Tainan, Taiwan
[b] Department of Medical Information Management, Chi Mei Medical Center, Tainan, Taiwan

[d] Medical Research Department, Chi Mei Medical Center, Tainan, Taiwan

Abstract

Chimei Medical Center developed an intuitive intelligent inpatient medical record system which integrates structured, unstructured, and textual medical records and provides health insurance payment suggestions from the collaborative medical record writer's point of view. Combined with the use of intelligent technology (Python language with the smart Content Difference Recognition software component), the system can ensure medical record quality by focusing on the differencse in recorded progress notes.

Keywords:
Medical records, intelligence, insurance

Introduction

The medical record is an important basis for the diagnosis and treatment of patients and also reflects the quality of medical care in a hospital. Medical records document the patient's condition and the medical behaviors of the medical team members. For example, progress notes in a medical record are where healthcare professionals record details to document a patient's clinical status or achievements during the course of a hospitalization [1]. However, physicians may just copy and paste past records (known as *DITTO*) with no change or very few changes while writing notes. Therefore, using the hospital's existing data, including structured, unstructured, and textual data, combined with the use of intelligent technology such as Natural Language Processing (NLP), could free physicians from cumbersome medical records by considering a collaborative medical record writer's point of view and focusing on the differences in medical recordings to achieve the ultimate performance of collaboration within teams.

NLP is one kind of artificial intelligence (AI) technology that concerns text and speech recognition and differentiation [2]. NLP techniques are suitable for processing health record identification (e.g.[3]). In this study we introduced a system using NLP concepts to improve medical record writing in Chimei Medical Center, Taiwan. The top programming language today for data scientific exploration and development is Python [4], and Python and associated smart data analysis components are suited for processing large numbers of medical records. In this paper, we describe how an inpatient intelligent medical system was developed with Python and the AI functions of text recognition and differentiation.

Methods

JCAHO points out that human factors analysis is an essential step to designing equipment, procedures, tasks, and work environment in order to support human strengths and mitigate human weaknesses while studying patient safety and medical quality (5). Thus, the concept of human factors analysis should be kept in mind while developing the intuitive intelligent inpatient medical record system.

Chimei used the Python language and AI-based content difference recognition technology to develop a prototype of an intelligent medical record system that integrates physician orders, medical records, disease coding (ICD-10), and cost estimation (Figure 1). It provides a more convenient and smart way for physicians to write medical records. In addition, the system also displays medical record coding recommendations and medical expenses to the physician for immediate reference. This system uses the Web Flask architecture so that the user can clearly obtain the required information without installing any software components.

For smooth development, we will complete a three-stage test before going online: the first stage tested the availability of information systems with representative users (seven physician members of the Medical Record Management Committee); the second stage tested the system with seed personnel from each unit to eliminate imperfections (ten physicians from five departments); the third stage will be a full user-side introduction and system on-line installation for optimizing and adjustment to ensure the availability, integrity, and ease-of-use of the system (still under voluntary use).

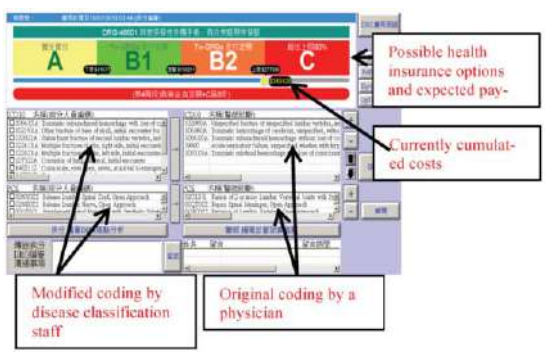

Figure 1- Integrated medical record writing with physician's orders, medical records, and disease coding as well as cost pre-calculation.

Results

For ease of operation, the system provides an intuitive visual graphical interface displaying instant interpretations of Taiwan Diagnosis Related Groups (TW-DRG) to achieve diagnostic accuracy. The design feature of the Problem-Oriented Medical Record (POMR) [6] in the system allows physicians to instantly integrate disease diagnosis with medical records to ensure consistency in disease diagnosis and medical record writing. When a physician completes a progress note and presses the "SAVE" button, the system triggers a difference comparison between the past and present records and then shows differences in colored text (Figure 2). If the difference from the past is less than 30% the record will not be saved, forcing physicians to modify the content. In addition, the system also provides cost pre-calculation for possible health insurance alternatives for physicians while considering a final decision.

Based on this rule, we computed that within nearly 40,000 progress notes recorded from May to July of 2007, the system reminded the medical record makers to correct or optimize medical records in about 1 in 10 records.

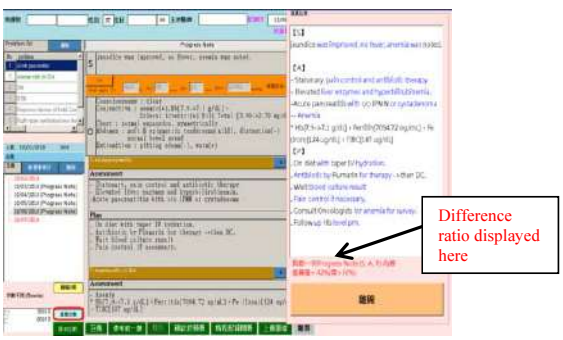

Figure 2- Medical record difference ratio displayed in red.

Evaluation

The system was derived from the viewpoint of the medical record management department with the aim of improving the quality of medical recording, and then improving medical care quality. Seven physician members of the Medical Record Management Committee and ten seed personnel of each unit were invited to pilot test this system. In general, they were satisfied with the system regarding its usefulness and ease-of-use (means=4.25, 3.88 of two five-scale questions). The core opinions are listed below:

1. The difference-rate of 30% is high for some specific departments such as pediatrics because there is little difference in patients' daily conditions.
2. The system did not work properly on old computers with Win XP OS. This problem was solved by the IS Department with Web Service technology.
3. In the initial stage, the system uses a "warning" message to remind the physicians rather than forcing the physicians to obey. More experience should be collected and discussed to decide the official launch time.

Discussion and Conclusions

Combining intelligent technology in medical record writing can improve the quality of medical records and writing efficiency. After a one-month pilot trail, this intelligent medical record system has been fully launched except for a few departments (e.g. the psychiatry department). At present, Chimei Medical Center is developing the expansion for Chinese medical records, and will try to introduce machine learning technology in the future to develop the function of optimizing the coding of medical records.

Undoubtedly, AI applications are revolutionizing how the health sector works to reduce spending and improve care quality [7]. The intuitive intelligent inpatient medical record system can be regarded as the touchstone of Chimei Hospital's AI developmemt. At present, Chimei Hospital is actively developing other AI applications. We believe that Taiwan's development of AI will be very much in line with Taiwan's excellent medical service and information communication technology.

"D/C the CC (Carbon Copy)" - Improving the EHR Signal-to-Noise Ratio for Clinicians by Selective Feature De-Implementation

Ling Chu[a,b], Seth M Toomay[c], Cameron S Ginnings[b], Kyle G Gabriel[b], Ethan A Halm[a], Duwayne L Willett[a,b]

[a] *Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, Texas, USA*
[b] *Health System Information Resources Department, University of Texas Southwestern Medical Center, Dallas, Texas, USA*
[c] *Department of Radiology, University of Texas Southwestern Medical Center, Dallas, Texas, USA,*

Abstract

De-implementation of a 10-year EHR configuration resulted in over 50% decrease in the volume of the most-common InBasket message type received by PCPs. Pro-actively seeking out ways to not only (a) implement helpful new EHR features but (b) de-implement detrimental ones offers an opportunity to accelerate improvement in the S/N ratio and reduce clinician frustration and dissatisfaction with the EHR. Balancing governance decision agendas with de-implementation opportunities can enhance the clinician experience.

Keywords:

Electronic Health Records; Burnout, Professional; Cognitive Science

Introduction

Anticipated clinician benefits of migrating from paper medical records to an electronic health record (EHR) stubbornly continue to lag behind expectations. Initial high hopes for EHRs making clinical work more efficient, clinical decision-making more streamlined, and seamless access to information across systems gave way to unintended consequences of decreased productivity, increased documentation burden, and information overload. While physician burnout is certainly multifactorial, the concept of "cognitive load" is now seen to play an important role [1].

The term "signal-to-noise" (S/N) ratio originated in the field of electrical engineering and can be defined as the ratio of the power of a desired electrical signal to the level of background interference or noise. While this phrase's origins in the deterministic world of electrical engineering may seem far afield from the highly variable environment of modern clinical care and the psychology of physician cognition and burnout, important similarities emerge. Both electrical signal-to-noise and the psychological cognitive load concept consider two information types: relevant to the situation at hand ("signal") vs. irrelevant ("noise"). Accordingly, improvement strategies can involve increasing relevant information (boosting signal), decreasing irrelevant information (dampening noise), or both. In our local EHR, we sought an opportunity to measurably reduce the S/N ratio's denominator and improve clinician experience.

Methods

Software:

The authors' institution has used Epic (Verona, WI, USA) for its electronic health record (EHR) continuously since 2001 in its clinics and since 2009 across its hospitals. Clinician patterns of use of the EHR are available for review via an online portal (signal.epic.com), with appropriate security rights. EHR data is extracted via Epic's Clarity reporting database into a Data Warehouse (SQL Server, Microsoft, Redmond, WA, USA) for analysis. For this report, data analysis and visualization of EHR data were performed using PowerBI (Office 365 suite, Microsoft).

Procedures:

Project initiation:

One author (LC) noted that available data on patterns of EHR use by clinicians at our organization revealed that General Internal Medicine (GIM) physicians were receiving three times as many "CC Chart" (Carbon Copy of Chart to other than the primary recipient) messages in their InBasket as specialists in the same organization. By inspection, it appeared that GIM was receiving CC Charts from all specialist visits, not just ones with information meant for the GIM physician. In discussions with fellow GIM clinicians, consensus emerged that many CC Chart InBasket messages were extraneous and irrelevant, and wading through them had proven burdensome.

Generating support:

The opportunity for reduction in InBasket overload was brought to the GIM Division Chief, who strongly supported addressing the root cause of the problem, then to the Ambulatory Chief Medical Officer, who further encouraged looking at the issue Health System wide.

Investigation:

The lead physician (LC) worked with the EHR team (CG and colleagues) to assess the sources of the high volume of CC Chart messages.

Results

Results of Investigation:

In a review of 3 years of InBasket messages received by PCPs (in GIM and Family Medicine), CC Chart messages were found

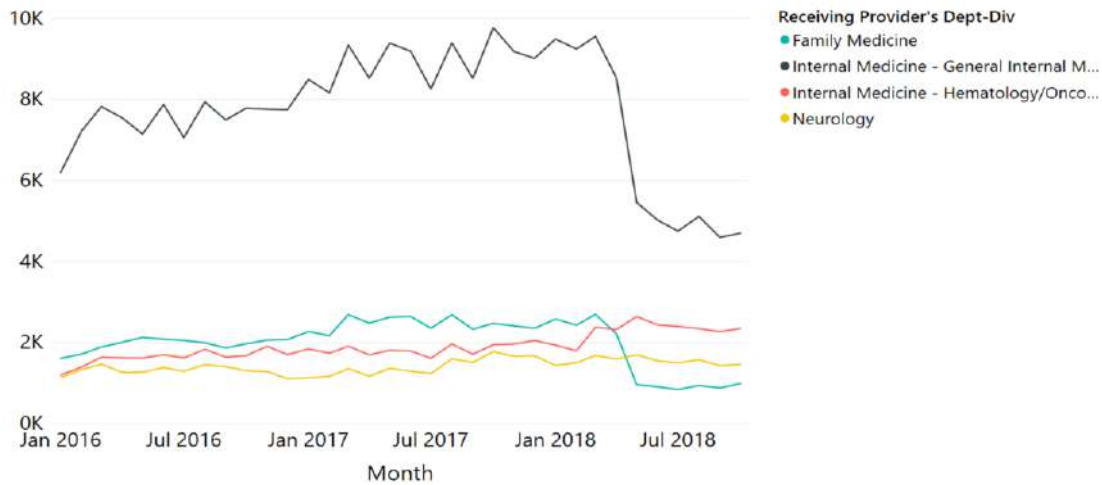

Figure 1: CC Chart InBasket message volume by Department-Division, thru Sept 2018

to be the largest volume message by a considerable margin: 332K total CC Chart messages received by these primary care physicians, followed by 256K for Results messages, and 234K for Patient Call messages, with other message types lower still.

Approximately 50% of CC Chart messages were found to be due to a programming point that automatically sends a copy of each specialist's clinic note to the Primary Care Physician on file when the encounter is closed. Further investigation revealed this practice had started early in the ambulatory roll-out of the EHR at our institution (>10 years prior), then propagated to over 50 clinic-specific settings over the years, covering the vast majority of specialist clinic physicians. Consensus was reached among physician leadership and the practicing clinicians—GIM and specialists alike—to abandon this practice and use only intentional CC Chart routing. The EHR team located where each automated programming point was set, and on a designated date removed them all. To mitigate concern for any unintended consequences from PCPs being unaware of key specialist visits, specialists remained able to "CC" the PCP on any individual note deemed important for PCP awareness.

Results of Intervention:

Prior to the EHR intervention, the frequency of CC Chart messages received by GIM physicians was growing steadily, exceeding 9,500 CC Chart messages per month (Figure 1). After the intervention, this frequency was cut in half, to under 5,000 messages per month. Though a smaller practice, Family Medicine physicians saw an even larger relative decrease (60%) in CC Chart messages, from approximately 2,500 per month to less than 1,000 per month. Non-primary care Departments-Divisions served as controls and saw no contemporaneous decrease in their CC Chart messages.

Discussion

De-implementation of a 10-year EHR configuration resulted in over 50% decrease in the volume of the most-common InBasket message type received by PCPs. Pro-actively seeking out ways to not only (a) implement helpful new EHR features but (b) de-implement detrimental ones offers an opportunity to accelerate improvement in the S/N ratio and reduce clinician frustration and dissatisfaction with the EHR [2]. This perspective may hold implications for local EHR governance committees, where agendas often overwhelmingly contain only proposed new features. Balancing governance decision agendas with de-implementation opportunities can enhance the clinician experience.

Conclusions

An initiative to reduce the denominator of the EHR "signal-to-noise ratio" for primary care clinicians succeeded in reducing unwanted instances of their most common type of InBasket message by 50-60%. De-implementing unhelpful old EHR features can measurably lessen clinicians' cognitive load, and complements adding helpful new EHR features. Studies of varied additional de-implementation initiatives are underway.

Improving Education of Medical Students Through Telehealth

Magdala de Araújo Novaes[a,b], Amadeu Sá de Campos Filho[a,b], Paula Rejane Beserra Diniz[a,b]

[a] *Telehealth Center, Clinics Hospital, Federal University of Pernambuco, Recife, Pernambuco, Brazil*
[b] *Department of Internal Medicine, Federal University of Pernambuco, Recife, Pernambuco, Brazil*

Abstract

Telehealth can be used in medical education to promote teaching-service integration as a low-cost solution to broaden the field of medical practice, especially in rural areas of low and middle-income countries. This article presents our experience in the use of telehealth to broaden the practice field of medical students. In 2017, two itinerants' actions were carried out in municipalities in the state of Pernambuco. In both actions, 396 patients were assisted by a team of professionals, teachers and students in various specialties, with emphasis on mental health and dermatology. 9 students experimented with the use of an electronic patient record system, telehealth platform and a mobile application for tracking of disorders and diseases. The students reported high satisfaction with digital distance practices, and the enrichment of their learning. This digital approach to medical education has fostered greater collaboration among students, faculty and staff, teaching students the skills necessary for their future digital practices.

Keywords:

Medical education; Telehealth; Digital Health

Introduction

Health has changed faster than other areas of knowledge and in this scenario, preparing health professionals to succeed in their careers is the greatest challenge for universities. One strategy to improve students' learning is to broaden their field of practice by learning from other health realities, but for this to happen it is necessary to ensure supervision of these students by university teachers. We present our experience with collaborative interprofessional practice at a distance, in which students participate in an itinerant health service provided by the Telehealth Centers Network of Pernambuco [1] connected to the university through the telehealth service.

Methods

Students of the Medicine Course were invited to participate in field actions carried out by the university Telehealth Center. These actions aim to assist patients who were waiting for medical attention in vulnerable municipalities. In 2017, 9 students participated in two itinerant actions in small towns in the rural area of the state of Pernambuco. The students and staff were previously trained and had access to notebooks, tablets, diagnostic equipment, an electronic health record system (EHR) and a telehealth platform.

Results

In the first itinerant action, 3 medical students participated, where 335 patients were attended in the areas of medical clinic, ophthalmology, cardiology (consultation and ECG test) and mental health. The students used the EHR systems and performed mobile device screening in 26 elderly patients (Figure 1).

Figure 1 - Medical student screening mental disorders in elderly patients during the itinerant health service event.

Figure 2 - Mobile data collection interface for telehealth platform tracking.

In the second one, 6 medical students participated in an itinerant action in Dermatology, where 61 consultations were carried out and educational activities in skin cancer prevention were performed for patients who were waiting. Skin exams were performed and those altered were launched on the telehealth platform for evaluation and discussion by experts and students.

In both action students and staffs analyzed the data. Exams results for ECG and Dermatoscopy were returned to patients through the primary care units delivered by the internet using the telehealth platform (Figure 3).

Figure 3 - Telehealth Platform interface used by students to connect with teams and access test results.

Conclusion

The use of telehealth as a strategy to strengthen the teaching-learning process is being implemented at our university. The students who participated in the telepathic-supported activities were reported to have high satisfaction, had access to a greater number of patients in different health situations, including the digital practices that they would not have if they were only in the hospital unit, and this enriched their training. Since 2003, the Telehealth Center, in partnership with the Health Informatics Discipline of the Medicine Course, has made efforts to insert telehealth in the pedagogical project of the Medicine Course. So far, these insertions have been carried out in a non-systematic way, but from 2017, with the good results by itinerant actions, the high level of satisfaction of the students who participated, followed by evidence in the literature of the benefits of distance health practices [2; 3], we believe we are on the right path for the future.

Abstract

The ApiAppS ongoing project aims to provide physicians with a decision support system for the prescription / recommendation of mHealth technologies. We describe the context and the components of the project which includes: 1) a technical part on modelling and implementing the decision support system, and 2) a psychosocial investigation part designed to have a better knowledge of general practitioners (GPs) and patients' expectations, beliefs and practices.

Keywords:

Mobile health, Computer Systems, Health comunication.

Introduction

Mobile Health (mHealth) can play an effective role in various domains affecting individual's health conditions (well-being, prevention, management, monitoring or follow-up of known or suspected pathologies). The use of mHealth (apps or devices) can reduce the number of medical visits, increase convenience for the patient while minimizing healthcare system cost [1]. However, several factors hinder this potential: diversity and plethora of frequently confusing products; relative variability and/or relevance of a solution depending on the context of its use; difficulties in assessing its qualities and added values; multitude of covered areas (health and / or wellbeing); and diversity of users/patients characteristics (clinical and paraclinic data, lifestyle, individual preferences). Furthermore, there is a lack of implementing knowledge of the psycho-social aspects/effects related to the arrival of this new technological third-party in the patient-doctor relationship [2].

As well as medical prescriptions, general practitioners (GPs) have a crucial role to play in ensuring that the use of mHealth can really be at the service of the patient and be properly integrated into his/her follow-up and health management [3]. We believe that it is necessary to move towards a mechanism of technical integration (in practice and patient management software) and human integration (in the physician-patient relationship) of mHealth comparable to the mechanism of a usual medical prescription. In order to achieve this, as it is the case with drugs prescription tools, GPs must have the adequate tools to appreciate (as best as possible): the quality, the indications and contraindications, the possible effects of mHealth apps/devices and their evolution/revision (new market entrant, removal, modification of features). In addition, GPs need to know the possibilities of integrating and analysing the data produced by these mHealth apps/devices and how they can be efficiently used to enrich the relationship with the patient.

Cataloguing mHealth apps and devices is already underway. There are indeed specialized health platforms, which offer such catalogues (for examples: myhealthapps.net, appscript.net, mhealth-quality.eu, medappcare.com). Some technical or conceptual problems still have to be resolved: advanced categorization of apps, rich and standardised medical terms indexing, indications concerning tools complementarity.

Beyond the intrinsic improvements that can be made to these platforms, the key step to guide the choice of an mHealth app/device that meets the patient's needs, is to couple these platforms with one or more information sources which give a detailed level of the medical context. The electronic medical record (EMR) is a valuable source because it contains information rigorously collected, numerous, diversified, semantically rich and medically validated with an individual detail level (concerning the patient). Medical knowledge repositories/databases (clinical practice guidelines, medical drugs characteristics) are other sources to take into account for at least two reasons. First, consulting such repositories reflects the user's particular concern (a medical context) for the accessed information (for example: consulting web pages about asthma or a beta2-mimetic drug expresses a very specific concern). Second, these repositories contain validated knowledge (evidence-based practice recommendations, drugs indications or effects to monitor) that must be taken into account when suggestion of an mHealth app/device consistent with this knowledge is desired (for example: suggest an app for daily steps tracking is consistent with guidelines indicating that regular physical activity is recommended for diabetic persons).

To this date, EMR, medical knowledge databases and platforms cataloguing mHealth apps/devices (mHealth app web store), function in silos without interoperating. mHealth app web

stores operate as standalone applications and are based on rudimentary data to guide the choice of an mHealth app/device, limited to what a user can (and agrees to) fill through a search form. Using EMR and/or medical knowledge databases, GPs do not have access to mHealth apps/devices selected for their relevance in the management of a given patient.

The objective of the ApiAppS project is to identify, explore and, when possible, remove technical and psycho-social obstacles so that GPs can use a system to be of help in the prescription of mHealth apps / devices adapted to their patients.

Methods

The ApiApps project has two fundamental components:

1. **ApiAppS SHS investigations (Social and Human Sciences)**: psycho-social, anthropological, usability studies.
2. **ApiAppS Techno**: implementation of a decision support system and interoperability of the 3 sources of information.

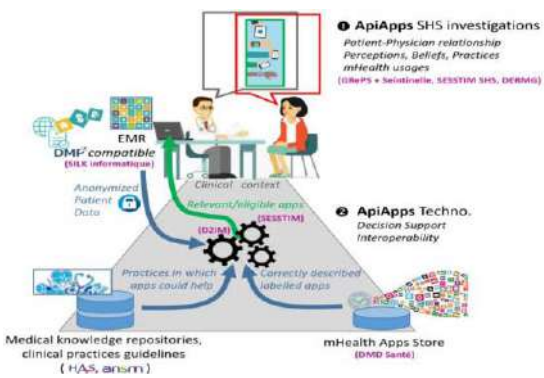

Figure 1 – ApiAppS big picture

ApiAppS implementation will integrate the psychosocial aspects related to the mHealth usage and to their prescription. These aspects are identified and analysed in a dual approach (anthropological and psychosocial), with qualitative and quantitative studies, in order to better document:

- Representations, expectations, beliefs and practices of GPs and patients, related to mHealth apps and devices. Are mHealth apps/devices perceived as tools to enhance personal responsibility (patient empowerment) or is mHealth perceived more as control and standardization tools by health stakeholders and authorities?
- The place of mHealth apps in the doctor-patient relationship [4]: Are they perceived as intrusive, disruptive to the relationship, or conversely, as an element that can reinforce it (or even on a symbolic dimension, the extension of the relationship as for medical drugs)? It will also be questioned whether the prescription itself induces new ethical problems and fears in terms of data security.

ApiAppS project aims to provide a web-service for decision support so that the selection/prescription of a mHealth app/device is adapted to the patient's profile and is relevant to the doctor-patient relationship and the care process. We try to resolve the following technology and information challenges:

1. What kind of information should be available in the electronic medical record, in the knowledge databases, and in mHealth app web stores to allow a basic coupling between these systems? Which data will allow an optimal coupling?
2. What are the coding format(s) and the terminology(ies) adapted to such data?
3. Are the existing interoperability frameworks adaptable to the problem of communication with a store dedicated to mHealth apps/devices?

Results

ApiAppS is a work in progress (from 2018 to 2021). A first qualitative study [5] (semi-directive interviews carried out with 20 GPs) shows there is a gap between mHealth innovation and GPs' everyday practice. GPs perceive mHealth as a potential tool in the relationship with patients but are not familiar with mHealth tools and have doubts and questioning about: How to integrate mHealth into a medical consultation? What place should be given to mHealth in medical follow-up? What to do with the produced data? Is there a risk of isolating patients and/or giving them illusions of safety? Others qualitative and quantitative studies focused on patients' groups are ongoing.

ApiAppS Technological components will lead to the definition and implementation of an interoperability framework in compliance with EMR programs, knowledge databases and mHealth app web stores. First results of the project will be communicated during the poster session.

Conclusions

mHealth is a means to have supplementary options for the patient follow-up or for other aspects in the patient-doctor relationship. This project is in line with: the current evolution of the healthcare mobility; the integration of mHealth apps and devices in care prescription; and the need to better inform practitioners and patients of their relevant/irrelevant use in certain situations. ApiAppS project is a contribution to remove the bottlenecks that constrain rational use of mHealth.

Abstract

We report a qualitative analysis of higher education biomedical informatics (BMI) teachers' opinions on the needs for BMI workforce and employment opportunities in the Croatian health care system. Needs were perceived as considerable; however this was not coupled with adequate employment opportunities. Barriers were identified to correcting this imbalance, including the failure of the health care system planners to recognise BMI experts as an important part of the workforce and lack of adequate educational opportunities.

Keywords:

Medical Informatics/education; Medical Informatics/organization and administration; Qualitative Research

Introduction

Although medicine has been slow to adopt the rapidly developing information and communication technologies, digital medicine has become a thing of the present as well as future [1,2]. How to prepare the health care workforce and how to organize services in the digital age has been a topic of much debate. It seems clear that what is needed is educating and employing biomedical informatics (BMI) specialists, but also acquiring important new competencies related to the field by all health professionals [3].

A course in BMI at the University of Zagreb School of Medicine was first introduced in 1967 [4]. Postgraduate BMI studies as well as preparations for starting BMI subspecialisation programs for medical doctors of all specialties, which were under way in the late 1980s, were interrupted in the last decade of the 20th century, not to be renewed.

Describing the current educational landscape of BMI in Croatia, we previously reported teachers' characteristics and their attitudes about educational opportunities [5]. Here, we report the teachers' opinions on the needs and employment opportunities for BMI workforce in the health care system.

Methods

We conducted an online questionnaire survey of BMI teachers in Croatia. We acquired the initial list of participants from the Croatian Society of Medical Informatics (CroSMI). This list was extended by online searches for higher education courses and programs in BMI in Croatia and affiliated teachers.

The final sample consisted of all teachers of BMI in Croatia, 44 women and men who were invited by e-mail to participate and received up to three reminders during the eight days while the survey was active in the spring of 2018. For data collection we used LimeSurvey. Participation was anonymous and voluntary.

The questionnaire comprised 24 items, spanning participants' demographic characteristics, educational and academic status, as well as experience in teaching BMI and details of courses they teach. Attitudes about BMI education in Croatia were assessed by 13 items with Likert scale answers, which has been reported previously [5]. In addition, participants were asked to express their opinions in free text about the need for and work opportunities for medical informaticians in the Croatian health care system, which we are reporting here. Opinions were assessed through three open ended items:

1. Please describe the needs for BMI cadre in the Croatian health care system.
2. Please describe employment opportunities for BMI cadre in the Croatian health care system.
3. Final thoughts, comments, and suggestions.

Before the analysis was undertaken, all participants were assigned pseudonyms. Two researchers (KF and DR) independently analysed the answers using descriptive thematic approach [6], which included coding and refinement of themes and subthemes. Disagreements were settled consensually. We used QSR International's NVivo 12 software for qualitative data analysis.

Results

Twenty-two teachers responded to the survey (response rate 50%) with equal numbers of women and men. Median age was 47.5 years (range 30-69), median time spent working in BMI education 11 years (0-40), and median length of overall working experience 23.5 years (4-42). Fourteen participants volunteered their answers to the three open ended items, seven women and seven men.

The word frequency query showed that the most common word mentioned by the participating teachers was '*the system*', in several declension forms of Croatian language, with a total number of 35 occurrences. The next most common words were

'*medical*' with 18 occurrences as well as '*informatics*' and '*needs*' with 13 occurrences each.

The health care system was depicted as rigid, sluggish, poorly organised, unable to govern data and processes, and lacking awareness of the importance of evidence-based decision making, with quotes such as:

- "The system is crying for quality [BMI] cadre, but due to its rigidity in opening new positions as well as lack of recognition of the importance of good organisation of informatics services in health care, employment opportunities are limited. … BMI is often learnt informally when needed in the workplace. This leads to … inability to govern data and processes." (Marta, female, 47)

Teachers unequivocally recognised a great need for BMI experts at all levels of the health care system, but they also pointed out a lack of recognition of these needs by the health care planners as well as lack of adequate employment opportunities.

- "The needs for BMI cadre in the Croatian health care system are increasing, yet what it currently missing, in my opinion, is exactly a systematic, multidisciplinary approach. … Although the lack of health care cadre is becoming increasingly conspicuous in Croatia, I'm unconvinced planners are aware of the need for the BMI cadre." (Đuro, male, 30)

Other participants used words such as *'huge'*, *'urgent'*, and *'inestimable'* to describe the needs for BMI cadre in the health care system. To describe employment opportunities, words such as *'limited'* and *'mediocre'* were used. Further subthemes identified regarding the health care system were the inability to ensure adequate pay for BMI experts, as well as lack of regulation of employment opportunities but only in the public health care sector.

Not only does the lack of recognition of needs for BMI experts exist in the health care system; similar is apparent in the academic community. No dedicated BMI studies exist, and individual courses that are taught to future medical doctors, nurses, and other health professionals are often positioned too early in the curriculum or are considered less important courses for which assigning a numerical grade is not needed. Consequently, competencies are often inadequate, and this reflects poorly on the current workforce.

- "Besides, the scientific circles do not recognise medical (biomedical, health) informatics, considering that medical informatics is like any other informatics, i.e. it is neither science nor profession so it should not be viewed as such." (Koraljka, female, 69)

Offering thoughts on solutions to these problems, several of the participants identified the need for congruence between employment and educational opportunities as key.

- "Solutions should be sought through cooperation of health care and educational institutions in clearly articulating the needs for BMI cadres and defining educational programmes for all health care workers at all levels of education. Rapid development of infomation technology also imposes the need for life-long learning, which is conceivable in cooperation of educational and health care institutions." (Gašpar, male, 56)
- "Education in BMI should be expanded/viewed from the aspect of the application of information/digital technologies in the daily work of staff employed in different institutions in health care - which primarily relates to the use of various health care - clinical - business information systems." (Maja, female, 52)

Participating teachers expressed hope that two bodies in the making, a central national e-health body being set up at the Ministry of Health Care and a CroSMI education working group, would help with recognition of the BMI as a discipline, improvement of educational opportunities, as well as correcting the imbalance between the needs for BMI experts and employment opportunities in the health care system.

Conclusions

Congruence between educational and health care systems is needed to correct the imbalance that currently exists between the needs and employment opportunities for BMI experts in the health care system. The many challenges we face in setting up the BMI workforce can be best tackled by concerted multi-sectoral, multi-institutional efforts, led at the national level by a dedicated e-health body supported by all stakeholders including CroSMI.

Analysis of Financial Factors Which Driving the Operating Margins of 880 Public Hospitals in Japan Using a Business Intelligence System

Yuta Fushimi[a], Takahito Takagi[a], Yutarou Kishizuchi[a], Takanori Uchiyama[a], Tokiharu Miyahara[b]

[a] Department of Medical science, Faculty of Medicine, Kawasaki Medical School, Kawasaki Medical school, Kurashiki, Okayama, Japan,
[b] Department of Healthcare Information Resource Management, Faculty of Medicine, Kawasaki Medical School, Kawasaki Medical School, Kurashiki, Okayama, Japan

Abstract

Management improvement was strongly required at public hospital and Local Incorporated Administrative Agency hospitals in Japan. We analysed financial statements of 880 public hospitals using Business Intelligence System.

In order to raise the efficiency of management, it is important to have patients with a high profitability (seriously ill patients) at municipal hospitals; whereas, in Local Incorporated Administrative Agency hospitals, avoiding producing ordinary losses and not incurring excessive expenses will be important for management improvement.

Keywords:

Financial statements, Business Intelligence System, public hospital

Introduction

With the aging of patients, medical costs in Japan have steadily increased year by year, and now account for 10.9% (2016) of GDP [1]. Even under ordinary circumstances, management improvement was strongly required even at municipal hospitals and Local Incorporated Administrative Agency hospitals, which undertook the management of unprofitable sectors of the national public insurance. The purpose of this research is to analyze the financial situation of public enterprise hospitals nationwide and to extract factors for efficient management of public hospitals.

Methods

We used the financial statements of public hospitals publicly announced by Japanese Ministry of Internal Affairs and Communications.

We collected financial data from the balance sheets and profit-and-loss statements of about 880 municipal hospitals and 88 Local Incorporated Administrative Agency hospitals. In addition, non-financial hospital data such as the number of hospital beds, the number of inpatients, the number of outpatients, etc. were collected [2]. Approximately 30 financial indicators were calculated from the balance sheets and profit-and-loss statements. Among them, we analyzed which factors affect the representative indicators that represent revenue and expenses. For the analysis, a business intelligence system (IBM, Cognos Analytics 11.1) was used, and correlation analysis by scatter diagram and driver analysis by spiral visualization were performed.

Results

Forecasting a single driver affecting the profit margin of medical service, the most influential factor on the profit margin of 880 municipal hospitals was “outpatients unit profit per person per day (56%) and inpatients unit profit per person per day (52%)”.

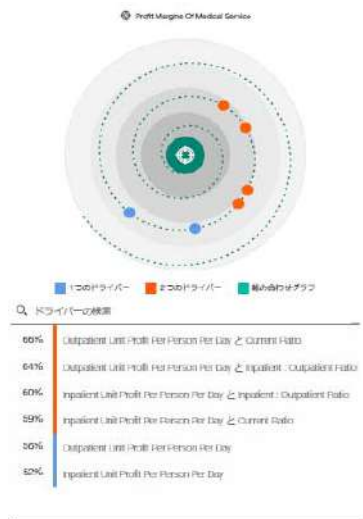

Figure 1– target analysis for profit margin of municipal hospitals

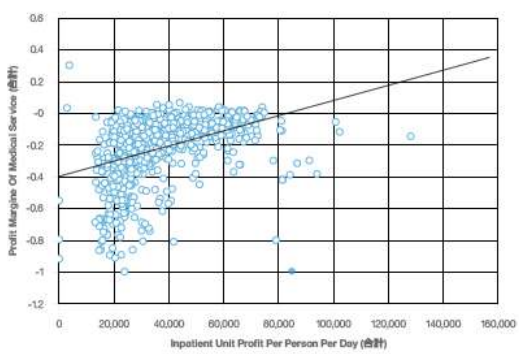

Figure 2– correlation between profit margin and inpatient unit profit per person per day of municipal hospitals

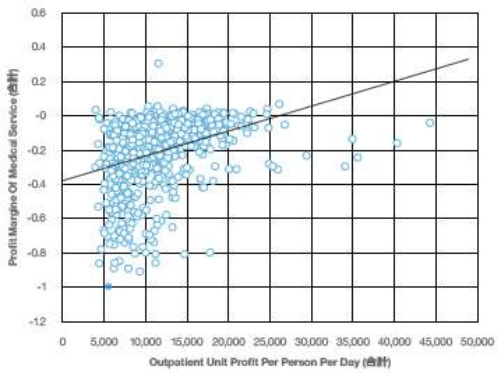

Figure 3– correlation between profit margin and outpatient unit profit per person per day of municipal hospitals

Meanwhile, the driver which influenced the profit margin of medical service of 88 Local Incorporated Administrative Agency hospitals was "ordinary loss per one bed (54%)".

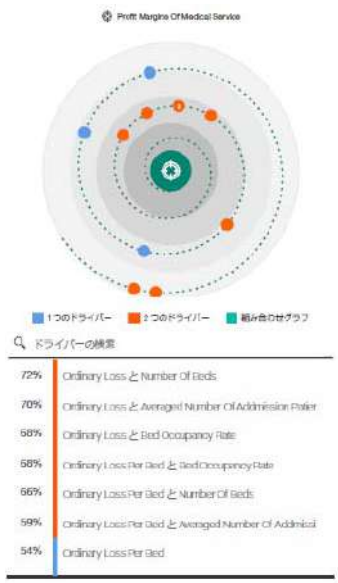

Figure 4– target analysis for profit margin of Local Incorporated Administrative Agency hospitals hospitals

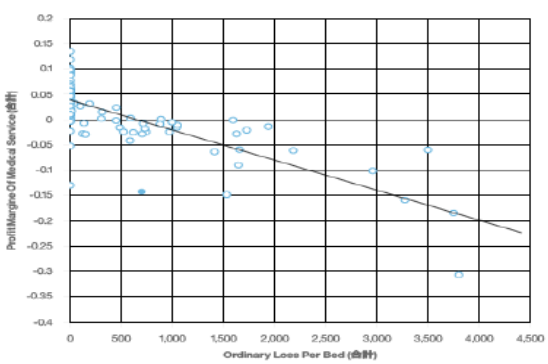

Figure 5– correlation between profit margin and ordinary loss of Local Incorporated Administrative Agency hospitals

Conclusions

In order to raise the efficiency of management, it is important to have patients with a high profitability (that is, seriously ill patients) in both the outpatient and inpatient units of municipal hospitals; whereas, in Local Incorporated Administrative Agency hospitals, avoiding producing ordinary losses and not incurring excessive expenses will be important for management improvement.

Improving Patient Participation in Cancer Clinical Trials: A Qualitative Analysis of HSRProj & RePORTER

Lynette Hammond Gerido[a] and Zhe He[a]

[a] *School of Information, Florida State University, Tallahassee, Florida, 32306 USA*

Abstract

Enrollment and representativeness, in cancer trials, have been a problem resulting in studies with poor generalizability to the real-world population. This study uses qualitative analysis of two publicly available datasets (HSRProj and RePORTER) to explore funded research projects, which employ strategies at the macro, meso, and micro levels. Our research shows that although the number of projects designed to increase participation in cancer clinical trials peaked in the 2000s, most employ a single level strategy.

Keywords:

Clinical Trial, Patient Selection, Qualitative Research

Introduction

Cancer is the second leading cause of death in the United States, exceeded only by heart disease [1]. According to the statistics of the Centers for Disease Control and Prevention, over half a million people in the U.S. died due to cancer in 2015 [1]. Since early in the 20th century, cancer research has grown rapidly [2]. Appropriately designed clinical studies, especially Randomized Controlled Trials (RCTs), provide gold standard evidence for determining the efficacy and safety of medical interventions [3]. Evidence in RCTs is used by healthcare providers to guide their clinical decisions, and by the regulatory agency to support their approval and adoption of new therapies into clinical practice. However, the enrollment and subsequent population representativeness in cancer trials have been a problem in clinical research [4], resulting in studies with poor generalizability to the real-world population

The passing of the National Institutes of Health (NIH) Revitalization Act in 1993 sparked increased efforts to raise awareness about cancer clinical trials and to reduce barriers to participation. In 2014, Heller et al. conducted a systematic review of the literature to assess the use of complex and interwoven strategies to increase participation in clinical trials at multiple levels; research system level, community level, and individual level [5]. This study qualitatively analyzes the abstracts and metadata of funded projects in two publicly available databases to classify goals, identify target populations being served, and to identify frequency patterns and trends in multilevel strategies to improve participation in cancer clinical trials over the past three decades.

Methods

The National Institutes of Health (NIH) funds the clear majority of medical research to advance cancer research and improve cancer care. One tool offered by the National Library of Medicine (NLM) is the Health Services Research in Progress (HSRProj) database, which contains descriptions of health services research in progress that has been funded by federal and private grants and contracts before results are available in a published form. The researchers queried the HSRProj database to identify projects related to increasing participation in Cancer Clinical Trials (CCTs). After iterative discussions between the researchers, the following search string was formulated and used: "*cancer" AND "clinical trial" AND "participation" NOT "conference".* The query included all available content regardless of fiscal year or active status.

The NIH Research Portfolio Online Reporting Tool's Expenditures and Results module (RePORTER) is a repository of NIH-funded research projects and resulting publications and patents. The same query used in HSRProj was executed using the advanced text search query. The search was limited within the project title and abstracts. Then researchers exported the titles, abstracts, project start dates, and the funding amounts for all available projects initiated prior to 2018. The HSRProj database resulted in 196 abstracts for review, whereas the initial RePORTER results were 1062 studies but when restricted to unique project numbers, there were 218 projects.

We imported the data into Nvivo 11 for coding and analysis. Each abstract was reviewed to determine if it was in fact intended to increase cancer clinical trials participation. Then we identified abstracts as primary when it directly indicated increasing participation as a major goal or outcome of the project. The final number of projects with a primary goal was 94 (52 HSRProj and 42 RePORTER).

Abstract Coding

Descriptive information about each abstract was recorded, including: (1) project title, (2) start and end dates of research, (3) funded entity, and (4) unique project database ID. A directed content analysis was conducted to identify funded entities, under-represented populations, and strategies to increase participation in cancer clinical trials. To develop a coding schema, the researchers independently reviewed a sample of cases to make observations about themes among the cases. Together they reconciled the observations and then devised a scheme based on the reconciled observations. One researcher carried out the coding and another reviewed to confirm agreement.

Strategies

Health-related decision-making and health care delivery is generally distinguished using three levels; micro, meso, and macro [6]. The micro level targets the individual patient. It involves interactions between patients and providers at the

bedside, clinic, or health center. The meso level represents families, groups, or communities. It involves interactions between institutions, regional networks, and local agencies. The macro level represents research intended to benefit large populations. Each strategy was categorized as belonging to one or more of the four categories associated with the three levels: Micro (1a) *consumer*: outreach and education projects to improve consumer awareness and knowledge about clinical trials. Some projects include translation of educational materials; (1b) *provider*: workforce development and recruitment initiatives to increase accessibility to clinical trials; Meso (2) *system*: enterprise improvements, technological innovations, and strategic alliances to improve regional cancer care delivery, and Macro (3) *research*: studies to better understand barriers, develop interventions, and generate best practices for increasing participation.

Results

Charateristics of Included Projects

The studies in the sample have start dates between 1983 and 2015. The number of studies initiated in each decade, appears to increase linearly each decade. In both databases, a majority of the research was conducted by a university. The HSRProj sample shows a slightly greater proportion of research conducted by universities (N =26, 50%) than the RePORTER sample (N=19, 44%). National Cancer Institute's funded entities, NCORP and CCOP, represent a little over one third. In each sample, nearly half of the studies targeted a specific race or ethnic group as the underrepresented population (HSRProj: 49% (N = 22) vs. RePORTER: 51% (N=18)). In HSRProj, each of the other underrepresented populations (women, elderly, or rural) combined were identified in less than 23% (N=12) of the studies. A similar trend was observed in the RePORTER sample with less than 40% (N=17) of the studies identifying women, elderly, or rural underrepresented populations.

Strategies for Improving Participation

The researchers aligned the three levels and with respective strategies that projects employed to improve participation in cancer clinical trials. There appears to be consistent frequencies between the level at which the projects acted.

Single-Level Approaches

Table 1 shows both HSRProj and RePORTER, have projects acting at the macro level by using research as the sole strategy to increase participation in cancer clinical trials (HSRProj N = 12; 23% vs. RePORTER N=10; 24%).

Table 1 – Comparison of Strategy-Level Combinations.

Level(s)	HSRProj n, %	Level(s) n, %
Macro Only	12, 23.1%	10, 23.8%
Meso Only	7, 13.5%	5, 11.9%
Micro Only	3, 5.8%	7, 16.7%
Macro/Meso	5, 9.6%	4, 9.5%
Macro/Micro	5, 9.6%	4, 9.5%
Meso/Micro	13, 25.0%	8, 19.0%
Macro/Meso/Micro	7, 13.5%	4, 9.5%

Multilevel Strategy Combinations

Some projects employed more than one strategy in the attempt to improve participation in cancer clinical trials. It should be noted, when a program employed more than one strategy of the same type (e.g., two consumer outreach projects within a single project), the researchers counted the project only once in association to its relevant strategy classification. Table 1 provides a breakdown of frequencies of studies based on approaches targeting multiple levels and using two or more strategies. The most used multilevel strategy combination in both HSRProj or RePORTER was the meso-level paired with the micro level (HSRProj N = 13; 25.0% vs. RePORTER N=8; 19.0%).

Discussion

Clinical trials are the gold standard for cancer research. The cancer patient population is diverse [7]. Therefore, it would be expected that the development and testing of new cancer therapies would include a representative sample of individuals from diverse racial and ethnic groups, of different genders, including the elderly, and rural populations. This has not been the case, despite several decades of efforts to address these disparities. Barriers to clinical research participation are complex and interwoven between multiple levels and stakeholders [8-9]. Successful projects need more than one strategy to address multiple barriers in study design, at provider enrollment sites, for the individual, and within the community [5]. Our research shows that there have been increases in projects designed to increase participation in cancer clinical trials. Despite these efforts, the accrual strategies employed tend to be employed alone and not combined with others.

Abstract

Descriptive statistics, Classical Test Theory (CTT), and Item Response Theory (IRT) are used to analyze learning. These results are a powerful synthesis for students to evaluate their progression into their personal pathway of learning, for teachers to improve the quality of different multiple-choice questions (MCQ) series, and for administration to assist in making pedagogical decisions. Our study explores tools to evaluate MCQ tests, and MCQs. Answers to tutorials and final examination of students of the first year of health contest were collected and analyzed.

Keywords:

Psychometrics, Educational measurement, Learning

Introduction

Ongoing improvements in the quality and efficiency of education is a key effort. This is a huge opportunity for researchers because learning management systems can track various details of the interaction between the student and the learning platform. Pertinent interaction details include: time spent on a lecture, responses to tests, questions submitted online. These details represent an enormous amount of data, and are thus substantial work for researchers to analyse. In an effort to improve it and to optimize education, dashboards for students or teachers have been developed. Additionally, the fields of learning, teaching, and academic analytics let us analyse closed question series, such as multiple-choice questions (MCQ), with different tools. Such tools include: descriptive statistics, Classical Test Theory (CTT) and Item Response Theory (IRT) [2].

Since 2006 at the Grenoble faculty of medicine, lecture courses have been substituted with blended learning, where lectures have been deleted in favour of multimedia resources and skills interactions [1]. The learning process is divided in 4 sequences: self-learning using multimedia resources, questions submitted online, meetings for interactive question-answer sessions with teachers, and tutorials in preparation for the rank exams using MCQs [3]. Analysis of the answers provide a student dashboard, which serves as a tool for monitoring and motivation. The objectives of the dashboard is to assess the student's level more accurately than with a single mean, and to provide ranking information among other students. The objectives of the teacher's dashboard are to provide an evaluation of students' overall level and evolution, and to highlight students having difficulties. The teacher's dashboard also improves testing by assisting instructors to select MCQs based on quality. Thus, we propose how to perform a qualitative and quantitative statistical analysis that will provide second step recommendations in order to build a dashboard that serves the learner, teacher, and institution.

Methods

Classical descriptive statistics are used to characterize each test: the number of students who passed it, thenumber of MCQs, success rates, mean score of 20, median score and Cronbach's alpha. Classical Test Theory (CTT), or True Score model, is based on the assumption that for a particular test with a sample, the observed score on a test is the sum of the "true score" and of the random "error". CTT is a collection of many statistics, including the average score, item difficulty defined as the proportion of examinees who did not respond in the keyed direction, discrimination index that indicates how well different levels of knowledge can be differentiated and the test's reliability. Finally, CTT is used to analyse tests, rather than to check MCQs.

More recently, the development of the Item Response Theory (IRT) permitted the detection of problematic MCQs, such as questions that are too difficult or those that are misunderstood. In addition, the IRT allows the calculation of the 'true score' of a learner at a test, which can be useful for students to assess their real knowledge independently of the difficulty of the test. The main assumption of the IRT is that a test is built to measure an ability, called "latent trait". There are two types of IRT model depending on the assumption made on the latent trait; use a unidimensional model if the trait is unique, or use a multidimensional model if it can be assumed that multiple abilities are involved in the test.

For unidimensional latent and dichotomous correction, logistic functions are mainly used. Unidimensional models are characterized by the number of parameters they include. In a three-parameter logistic model (3PL) the parameters are difficulty, discrimination and pseudo-guessing. The most well-known model is the Rasch's model, which is considered as a one-parameter model, and calculates difficulty and discrimination too, but assumes that the discrimination level is equal for all items.

In this study, we built each type of model, and then chose the best one for a given test using the Akaike information criterion (AIC). Graphical approaches, such as the Item Characteristic Curve (ICC), indicate the difficulty parameter. This parameter is defined as the level of ability for a probability of a keyed response of 0.5. The pseudo-guessing parameter is readable as the intercept. The Test Information Curve (TIC) as the sum of

the Item Information Curve (IIC) of each item in the test, and determine ability levels that can be differentiated by the test.

Results

During the 8-year study period, 12,478 students were enrolled. 472 MCQ tests took place in which 16,731 MCQs asked for 15,915,916 answers.

Global overview with CTT per item

We reviewed MCQs on one test in order to characterize questions. On this test, no MCQs appear difficult, the max was found to be 0.75. However, this index is linked to students' results, so in our case of a rank examination, where students work a lot, the difficulty is probably underestimated.

Non-sigmoid curve detection for students abilities adequation with IRT by Item

In Figure 1, ICCs are shown as sigmoid spread along ability levels with a significant slope so that the test may distinguish differences in students' ability. The ICCs for MCQ 4 (in blue), 7 (the turquoise one on the left of the group), 21 (turquoise), 23 (the red one on the right), are abrupt across space sigmoid from each other. A flat ICC indicates that the item measured something else other than the test's objective. An MCQ adapted to all student levels and should not be constant or decreasing.

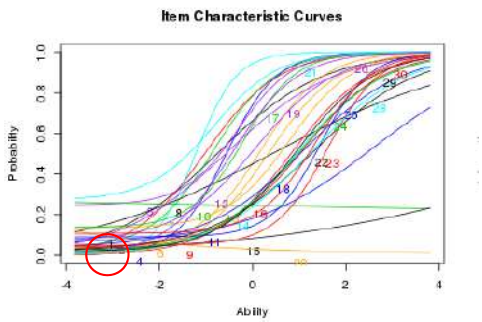

Figure 1- ICC graphs based on BioPhysics 3 2015-16

Selection of questionable MCQs

Figure 2 highlights only questionable MCQs: those with an ICC's intercept higher than 0.2, too high pseudo-guessing parameters (box a), a probability of keyed answer for an ability at 4 lower than 0.8, too difficult (box b), a maximum level of information lower than 3 times the maximum level of information in the test, and not informative.

Discussion

Our study explored several tools to evaluate MCQ tests, and MCQs themselves. The diversity in available tools gives flexibility in analyzing an MCQ, but there is also a complexity factor. None of the tools can be considered as better than the others. Thus we choose to show CTT index to the student and

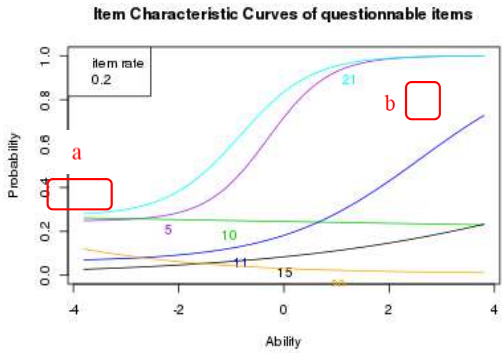

Figure 2- ICC graphs of questionable items

IRT parameters to the teacher, because IRT needs explanation to be understood, while students might want instant results. Our use of IRT presents an issue based on the type of model chosen. Logistic models are the best ones for IRT, but they need a dichotomous explanatory variable. While it is not the type of correction used during tests, and polytomous correction gives fine grain understanding of the score. To remedy this situation polytomous IRT has been developed but it is not possible to provide quickly understandable conclusions. The use of these Rasch-type methods, in addition to the traditional approach, is now essential in the face of the emergence of educational big data, particularly in health. These methods require a pedagogical step of explanation with teachers who are not specialists in these fields, in order to guide them, but the gain in using the IRT can no longer be called into question. The era of "learning and teaching analytics" has already begun, it should not be missed.

Abstract

Over 3 million hospitalizations and 17 million ER visits occur in Canada each year. A substantial proportion of these encounters are preventable and attributable to medication non-adherence. Non-adherence to medication changes during discharge increases the risk of adverse events post-discharge. A mobile application was developed to improve medication management of post-discharge patients. A pilot randomized controlled trial was conducted to assess the application's usability and efficacy in decreasing non-adherence to medication changes made at discharge.

Keywords:

Medication therapy management, Medication adherence, Mobile applications

Introduction

Over 3 million hospitalizations and 17 million emergency department visits occur in Canada each year [1]. Seventy percent of hospitalized patients experience an adverse event involving medication(s) within 30 days of discharge [6]., At least 58% of medication-related adverse events are preventable and are the result of prescribing or dispensing errors, incomplete drug information, and the underuse or overuse of medications [3; 8]..Patients are often discharged on a substantially different medication regimen than the medication regimen prior to their admission[2]. . A previous study of 2,655 patients discharged from one academic health centre determined 55% were non-adherent to at least one medication change made at discharge. Patients non-adherent to all changes had a 35% increased risk of adverse events compared to those who were adherent to all changes [11].

Patient interview data suggest that unclear communication with patients about medication changes may be driving non-adherence, as might difficulties in managing complex drug regimen information and dosing schedules. We must consider innovative approaches to implementing and evaluating patient support mechanisms to reduce medication non-adherence post-discharge. Mobile technologies are a potentially powerful tool to provide individual-level health support. Studies suggest that mobile health(mHealth) technologies are effective in improving health behaviours [7]. With 77% of adults in the United States reporting smartphone ownership in 2017, an opportunity has been created to assess the efficacy of mHealth technologies in improving health behaviours and outcomes [9]. Smart About Meds (SAM) is a mobile application designed to improve medication management for patients following discharge. The study protocol aims to evaluate SAM's usability and efficacy in reducing non-adherence to medication changes made at hospital discharge.

Methods

A pilot randomized controlled trial of 100 discharged patients will be conducted at an academic health Patients in the intervention arm will receive access to the app, while patients in the control arm will receive usual care. A usability assessment will compare, between the two arms the rates of non-adherence to medication changes in the 30 days post-discharge. The pilot begins in mid-2019 and will be completed by March 2020.

Study Population

The study population will comprise 100 patients discharged from the internal medicine unit of one academic health centre. Patients must be covered by the Quebec public insurance drug plan, be ≥18 years old, own a tablet or smartphone with internet, and must speak and read English or French.

Randomization and Blinding

Permuted block randomization with varying block sizes of two and four will be used to randomize 100 patients 1:1 to the control or intervention group. Data analysts are blinded to group allocation while study participants and personnel are unblinded.

Intervention

Control arm (Usual care)

At discharge, patients will be given a prescription, and may or may not receive written or verbal instructions about changes made during medication therapy management.

Intervention arm (Mobile application)

At discharge, patients will receive access to the SAM application. SAM was developed using a user-centred design and agile development processes that incorporated user feedback in iterative cycles of design, testing, and evaluation. The application retrieves medications prescribed to a patient from the discharge prescription and dispensed medications via real-time linkage with the provincial pharmacy claims database.

The app creates a patient-friendly list of prescribed/ dispensed medications, grouped by therapeutic class, and offers tools targeting barriers to adherence:*Integrated adherence monitoring and feedback:* Alerts patients, caregivers, and hospital pharmacists to adherence problems. Discharge prescriptions are linked to dispensed medications and decision algorithms that generate alerts: 1) prescribed medications not filled, 2) medications filled as the wrong dose, and 3) discontinued medications that are refilled.*Pharmacy connect:* Patients connect with hospital pharmacists about discharge prescription(s), therapy changes, and alerts through a secured messaging service.

Symptom checker: Patients determine which of their medications has side-effects similar to experienced symptoms.

Social connect: Patients share experiences of their medications (e.g. effectiveness and side-effects). Patients can view comments from other patients using the same medications.

Caregiver connect: Caregivers access to the app

Health professional dashboard: Pharmacists manage a group of patients, receive and respond to questions, manage alerts or potential medication-related problems, transmit and manage requests for consultation from treating physicians and pharmacists, and document services.

Other features: User access to directives, pill images, drug information, dosing schedules, and daily pill reminders.

Beta-testing the app

A beta-test was conducted using the think aloud protocol [5] during the final stages of design and development. Eight users completed six standardized tasks in the application. The users were audio-recorded as they performed the tasks, and completed the System Usability Scale (SUS) survey [4]. The mean SUS score of 79.1 suggested that the app is usable and likely to be recommended by users to a friend. Audio recordings were analyzed and were integrated into the final version of the application.

Outcome Measures

Usability assessment

One week post-discharge, the intervention group completes a questionnaire that assesses satisfaction with the app and collects feedback on its usability. The questionnaire has been designed using extended versions of the technology acceptance model [10]. The think aloud protocol [5] will be used to assess the app's (1) ease of use, (2) user-friendliness, (3) efficiency, and (4) features that may cause confusion, frustration, or user errors.

Non-adherence to medication changes

Pharmacy claims data from the provincial health insurer will be used to identify medications dispensed within 30 days post - discharge. These data will be compared with the discharge prescription to identify non-adherence to medication changes, defined as (1) failure to fill newly prescribed medications, (2) refilling a prescription discontinued at discharge, or (3) filling a previous prescription where the dosage was modified at discharge, but was dispensed at the incorrect daily dose.

Data sources

Pharmacy claims data from the Régie de l'assurance maladie du Québec will be used to identify prescriptions filled post-discharge. Medications prescribed and changed at discharge will be determined using patients' discharge prescriptions.

Data Analysis

Descriptive statistics will be used to summarize patient demographic and clinical characteristics, technology assessment questionnaire results, and non-adherence rates for each group and overall. The two arms will be compared to measure, the average number of medication changes not adhered to in the 30-day follow-up period using the Student's t-test. Quantitative analyses will be conducted using SAS version 9.4 and the think aloud protocol.

Conclusion

The medication management app can be an effective tool to increase adherence to medication changes made at discharge. The use of the app can potentially reduce adverse events post-discharge. Results of the pilot will be used to support a larger clinical trial to assess impact on adverse events. This data will provide supporting evidence for the use of health informatics tools to promote patient outcomes.

Assessment by Patients of a Connected System for Telerehabilitation: Lessons Learned from a Randomized Qualitative Study

Maurice Hayot[a], Roxana Ologeanu-Taddei[b], Wafa Bouaynaya[c], Bronia Ayoub[a], François Bughin[a]

[a] *Department of Clinical Physiology and PhyMedExp, University of Montpellier, CNRS, INSERM, CHU Montpellier, Montpellier, France*
[b] *University of Montpellier, Montpellier, France*
[c] *LEMNA, University of Nantes, France*

Abstract

This poster presents the design of a connected system for telerehabilitation for patients with obesity and the assessment of the system through a randomized qualitative study on a sample of 15 patients. The patients expressed positive motivation but negatively assessed (as a deficiency) the system operation. All patients found that the system was neither intuitive nor easy to use.

Keywords:

Telerehabilitation, telemedicine, rehabilitation.

Introduction

Rehabilitation is a multidisciplinary intervention process combining retraining with effort, therapeutic education, nutritional programs, and psychosocial and behavioral interventions. This process can improve physical and psychological conditions and decrease multimorbidity mortality. Rehabilitation takes place in specialized centers, but accessibility is limited to a small number of patients. Nevertheless, the benefits of rehabilitation decrease over time due to loss of patients' motivation.

The number of mobile health applications (mHealth), especially those dedicated to the management of chronic diseases, has increased to improve access and efficiency and reduce costs in some areas of health. In the context of obesity, applications provide an additional tool that can help in behavioral management programs by promoting the modification of regular lifestyle habits. Therefore, the recent development of telerehabilitation [1] is a promising approach that has been addressed mainly in pilot studies.

Given technology advances, French healthcare professionals have designed a telerehabilitation system (Telerehab) to empower a population of obese patients to modify their behaviors regarding physical activity and nutrition. Telerehab was designed in 2017 by a French hospital team composed of two physicians specialized in rehabilitation, a nutritionist, and a physiotherapist in collaboration with a health app publisher and a rehabilitation center. The goal is to help patients with obesity self-monitor their nutritional and physical activities to maintain their motivation and behaviors related to physical activity and nutritional programs. The informational and educational content of the system is based on the French guidelines for rehabilitation for patients with obesity. The final objective of the designers of Telerehab was to evaluate in a prospective randomized controlled study on whether a 3-month treatment with Telerehab makes it possible to reduce the amount of fat in obese patients with respect to a control group.

In the meantime, a qualitative study aimed to assess the usability of Telerehab in order to improve it and to evaluate the final objective. This paper provides the methods and results of this assessment. Telerehab is composed of an application and a website that provide a program of adapted physical activity (video capsules) and nutritional information, complemented by medical teleconsultations by videoconference and by connected devices (pedometer, heart rate monitor, cycle ergometer, bike). Patients can track their nutrition and physical activity using the declarative data entered in a form. Technical support was provided by email and phone to help patients use the system.

Methods

A mock-up of the system was tested in February 2018. A randomized controlled study was conducted for 50 patients to assess the clinical objectives. Patients were recruited from the Departments of Clinical Physiology and Internal Medicine in Montpellier University Hospital (France) and from the rehabilitation centers of Groupe 5 Santé (France). The inclusion criteria were patients aged from 25 to 65 who were considered obese with a body mass index (BMI) greater than 30 kg / m². The study was conducted on two groups, an experimental group and a control group, each composed of 25 patients. The experimental group used Telerehab for 3 months. The ethics committee approved of the study (CPP 17/39 - F. Vasseur, clinical trial agreement UF 9799).

The patients from the experimental group received a short training session (6 h) by a research assistant who was recruited for the study. A technical support person would come to the patient's home after 48 h and 4 and 8 weeks to help the patient use the application. Patients had access to teleconsultation with a physician. This physician would schedule a teleconsultation for a patient according to the medical parameters recorded. The qualitative study, consisting of 15 semistructured interviews, was conducted among voluntary patients of the experimental group, 3 months after Telerehab implementation. The interview guide focused on the ease of use and usefulness of the application as well as any positive aspects and aspects that should be improved. The demographic characteristics of the patients interviewed are summarized in Table 1.

Table 1– Demographic characteristics of the patients

Sex	**Number**
Men	8
Women	9
Age	**Number**
25-29 years	2
30-39 years	1
40-49 years	3
50-59 years	9
60-65 years	2

The analysis was performed using open coding, which is an "*analytical process through which concepts are identified and their properties and dimensions are discovered in the data*" ([2] 101). Data were coded independently by two authors of this paper. Then, they compared the coded data and, in case of disagreement, they discussed their results in order to reach a consensus. Moreover, these authors also looked at the negative or positive assessment of the themes that we identified.

Results

Patients in the experimental group expressed that information recording was time consuming and lacked benefits, e.g., personalization of advice for meals. They also emphasized that the application suffered from functionality overload and a cumbersome system. However, a majority of patients emphasized the potential usefulness of the system for motivation.

The issue of personalization often came up in the various reflections by the patients. Personalization is one of the things that has been of most interest to patients. They consider that their use of the application should result in more personalization:

"*With the video capsules you should be able to propose personalized tricks adapted to the person, because as we enter many data I would like to receive, for example, a personalized menu with respect to my weight and my size*." (Patient 26)

Personalization of the system is also associated with other aspects of perceived utility, such as the desired added value of the information offered. Nevertheless, patients were satisfied by the teleconsultation aspect of the application.

Another issue is related to the usefulness of connected objects, especially the pedometer, mainly for technical reasons. Indeed, the majority of patients were concerned about the synchronization between the cycle ergometer and the application and believed that the data collected from the cycle ergometer was biased. The main themes that were coded are summarized in Table 2. We have to mention that these themes were assessed negatively, that is, the table shows instances where those themes were found lacking (with the exceptions of software slowness, human support, usefulness of teleconsultation and overall motivation). Most patients considered that information input was very time consuming, while at the same time they did not receive any information output, such as relevant alerts and notifications.

Table 2–Themes coded

Themes	Number of patents	Number of quotes across all patients
Intuitiveness	15	39
Utility of the information recorded	13	36
Technical issues, i.e., failures	12	24
Ease of use	11	22
Overall motivation	11	24
Slowness	10	20
Data preservation	9	13
Motivation for physical activity	8	19
Human support	8	14
Customization	6	9
Usefulness of teleconsultation	6	8
Behavior change	5	8
Added value	5	7
Perceived clinical effects	4	10

Discussion

These results show that Telerehab was not considered easy to use or useful by patients. While patients emphasized that Telerehab should increase their motivation for healthy activities, e.g., physical activity and adapted meal plans, they considered that the system could not yet achieve this objective because of an unsatisfactory design.Previous studies have shown that functionality comprising ease of use and quality of information is an important criterion for health apps [3]. Clinical outcomes, clinical processes, healthcare utilization and costs have all been evaluated in assessing telerehabilitation [4]. Our study adds the importance of technical issues and usefulness, i.e., customization, usefulness of teleconsultation, behavioral changes, added value and perceived clinical effects, to the list of issues that should be considered when studying methods of telerehabilitation. Moreover, our results highlight the importance of technical problems related to connected objects in the context of the lack of interoperability of these objects [5].

Conclusions

This paper presents the design of a medical connected system for telerehabilitation and a randomized qualitative study to assess this system. The results highlight several issues: technical problems, lack of ease of use and little usefulness of the information recorded.

Cost-Effectiveness of Digital Wound Care Education in a Healthcare Organization

Anna-Maria Hiltunen[a], Riikka Laurila[a,b], Katariina Silander[a], Timo Kuosmanen[b]

[a] HEMA Institute, Department of Industrial Engineering and Management, Aalto University
[b] School of Business, Department of Information and Service Management, Aalto University

Abstract

Advantages of digitalization are understood, but implementation to healthcare is slow. Cost savings and quality improvements are needed in healthcare. Continuous education of healthcare professionals is essential for quality, and digital education (DE) enables that cost-efficiently.

The aim was to evaluate the cost-effectiveness of a DE for wound care by comparing it to lecture education (LE).

DE enabled a slightly better learning outcome than LE. However, combination resulted in superior outcome. DE provided best cost-effectiveness.

Keywords:

Education, Continuing, Cost-Benefit Analysis, Information Science

Introduction

Continuous development of professional skills is essential to ensure good-quality care. Wound care is the key competence of nurses as it is estimated that approximately one percent of the population in developed countries suffer from a hard-to-heal wound during lifetime [1]. Wound care skills will be emphasized in the future as the population gets older.

Even though it is important that professionals are knowledgeable, lecture education (LE) is expensive and takes time. With digital tools costs can be reduced and education offering scaled up [2], especially as digital tools are as effective as traditional learning method in professionals' behavior [3]. Cost-effectiveness (CE) analysis is considered to be a good tool to help the decision making, and can be used to evaluate digital education (DE). The aim is to study the CE of a DE compared to traditional LE.

The three main research questions are:

1. What is the relationship between the wound care education method and health care professionals' knowledge level?
2. Do the costs of the DE differ from LE?
3. What is the CE of the DE in wound care compared to LE?

The study was done in a health and social care organization, which had two ways for educating professionals for wounds: 1) traditional classroom LE, and 2) a DE, which included three modules (ABC of wounds, Local treatment of open wounds and Prevention of pressure ulcers). The DE had written material and visuals to support the learning. The DE included final exam. Neither visits to the DE platform nor exam sits were limited, but the employee was allowed to visit the DE platform and sit the final exam as many times as they wished. The DE platform could be accessed from the organization as well as the employees' homes. The DE was provided by Duodecim Medical Publications Ltd (later Duodecim), a Finnish Company publishing information content for medical and healthcare professionals. Since 2017, the organization had shortened the LE from a day to half a day and decided the DE to be a prerequisite for the half day LE. Before 2017, the one-day LE alone covered the education in wound care.

Methods

Data on knowledge level and professionals' background factors were collected with a web-questionnaire, which was distributed to all healthcare professionals in departments possibly facing wounds regularly or randomly (approx. 2k professionals).

The knowledge was tested with a knowledge test, which was identical to the original final exam of the DE. The background questions related to demographics, experience in the industry, and the participants education. All the participants were categorized into groups based on completed wound education. First, the participant data was divided into three: 1) completed one-day LE, 2) completed half-day LE, 3) no LE. Second, the groups were split in two: 1) completed DE, 2) no DE completed.

The knowledge tests were graded and the data analysis was carried out by IBM SPSS Statistics. The average scores between different groups were tested by Kruskal-Wallis H-Test and Mann-Whitney U-test. Finally, a multiple linear regression model to control the background variables was conducted.

Information regarding education costs was estimated by the organization and Duodecim. The data included the costs of DE, one-day and half-day LE, and organizational cost of one nurse per hour. The estimated cost consists of the (1) direct costs from acquiring LE or DE (fees and teaching), and (2) indirect costs (working time). The estimated direct cost of one DE per participant was allocated from the total acquirement cost of the DE license. CE of the DE was evaluated with a CE ratio: cost of additional (incremental) intervention and the additional outcome (effect caused by the outcome, i.e., knowledge level).

Results

Description of the participants

In total, 94 professionals (=N) responded to the questionnaire, corresponding approximately 5% response rate.

The age range was from 23 to 64 years with a mean of 42. There were no great age differences between groups. The overall average of experience was 17 years, but the group with half-a-day LE and DE had lower average experience in healthcare industry than other groups. The participants had worked in the organization for 12 years on average, shortest in the group of DE and half day LE, longest in the group with only one day LE. On average, the respondents had worked in their current department for 10 years. Most of the participants were females (98%) and registered nurses (66%). The frequency of practical wound care work was divided more evenly between participants, and 52% announced to work with wounds at least once a week, 23% at least once a month and the rest less frequently. Total 20 respondents (21%) were wound care nurses. In DE, 60% had completed at least one of the module, and 33% had accomplished the organization's one-day LE about basics of wounds. Total 14% of the respondents had accomplished the half-day LE, which was available from 2017. The rest of the respondents (53%) had not taken part in the wound care LE in their organization.

Knowledge test outcomes

The distribution of the knowledge test scores is close to normal. The variation was -2 to 20 (out of 27). The average score was 10.05 points. The most frequently earned score was eight points. The more education the participant had, the higher the knowledge test score was. All the score averages in DE groups were higher than in the groups without any DE. Also, the longer the LE had been (one-day > half-day > no LE), the higher the scores were. The one-day LE together with the DE resulted in more points than the half-day LE and the DE combined (11.90 vs. 11.10). If the participant had only carried out the DE alone, the average (9.4) was still better than if the participant had carried out only the one-day LE alone (average 9.2). However, this difference was not statistically significant.

Statistical significance of the effect on knowledge was tested for six variables (research group, LE, work experience, wound care frequency, DE, and wound care nurse). The group with an accomplished DE had higher score average than without DE (10.7 vs. 8.9, p=0.035), and wound care nurses' average was higher than other respondents (12.1 vs. 9.5, p=0.024).

Cost estimation

The direct cost for the DE calculation was 0.55€ per person per one module. The referential time to execute the DE is three hours in total. Because mostly nurses are participating the DE and LEs, the cost of nurses is used to identify the indirect cost: it is counted from the average cost of a nurse per hour. The average cost (incl. side costs, excl. holiday compensations) is 17.85€ per hour.

The direct cost of LE per nurse consists mostly of the compensation for lecturer. The direct cost estimation per person for the one-day LE is 50€ and for the half-day 30€. The length of one working day is approximately seven, five hours and for half-day course it is four hours.

Cost-effectiveness analysis

DE is inexpensive and has good learning results, thus the DE cost (55.19€) per outcome (9.4) ratio was 5.87€ per knowledge unit, and the relative CE ratio was 0.29. The one-day LE together with the DE achieved the best absolute outcome (11.9). However, this combination was the most expensive (239.02€). Thus the cost per outcome ratio was 20.09€ and and relative CE ratio was 1.

The half-day education is not typically executed alone without the DE, so it is irrelevant to be analyzed individually. The cost (156.57€) per outcome (11.10) ratio of a combination of the DE and a half-day LE was 14.10€ per one knowledge unit, and the relative CE ratio was 0.71. The cost for one-day education alone was 183.84€ and the outcome was 9.2. Thus the cost per outcome ratio was 19.98€ and relative CE ratio was 1.

The incremental cost-effectiveness (ICE) ratio was defined as the ratio between the additional cost and additional outcome. The additional outcome refers to the knowledge level of participants with education minus with participants with no wound education (8.9). The score from the DE is 9.4, so the additional effect on learning is 0.5 units. The additional learning was highest in DE and one day LE (3). For one day LE additional learning was 0.3, and in combination of DE and half-a-day LE 2.2. ICE ratio for DE was 110.37€, for DE combined with half-a-day LE 71.17€, for one day LE 612.79€ and for combination of DE combined with one day LE 79.67€.

Conclusions

The relationship of wound education and wound knowledge is proved to be positive based on the results of this study. The more education, the higher knowledge test scores. DE can enable cost savings, increase the amount of professionals trained or enable better learning outcomes. Even though DE performed well in terms of CE, the additional LE improved the outcomes. With the comparison of ICE ratios, the optimal choices for organizations would be the combinations of DE and either half-day or one-day LE.

However, the decision between the learning methods does not need to be fixed. A relevant response to the results is segmentation. Professionals could be segmented based on the different levels of requirements concerning wound care. The priorities of an organization and value judgments between cost and learning must be taken into consideration along with CE analysis.

Virtual Student Collaboration: Connecting Student Health Professionals

Michelle Honey[a], Kim Young[b], Hazel Cowls[b]

[a] *School of Nursing, University of Auckland, Auckland, New Zealand*
[b] *School of Nursing & Midwifery, University of Plymouth, Plymouth, United Kingdom*

Abstract

This pilot study aimed to provide students with a learning activity to develop a global perspective of health care. Senior nursing students from New Zealand and the United Kingdom (n=15) were allocated to eNetwork small-groups. Students met weekly for one month via audio/video-conferencing for discussions. Students reported that this collaborative activity enabled them to engage purposefully with other students. While cultural differences were noted, similarities were also found and multiplestudents expressed interest in working overseas.

Keywords:

Students, Nursing; Pilot Projects; Videoconferencing

Introduction

Information and communication technologies (ICT), such as Skype, can provide opportunities for engagement across the globe [1]. The ways in which individuals communicate within their personal and professional lives is rapidly changing [2]. Health professional students, including nurses, are considered 'digital natives' as they commonly utilise a range of internet-sourced communication media to support their knowledge development and interaction with others [3]. Extending the use of ICT provides an opportunity for health professional students to colaborate demonstrating international eNetworks in action. This poster describes a pilot which aimed to provide students with a learning activity to give a more global perspective of nursing and health care.

Advances in social media can facilitate opportunities to develop understanding of different countries and cultures. Nursing has a global presence, yet students can have little knowledge of the health and social care needs and provision outside their local environment and country [4]. Exchange activities are well-established in higher education and facilitate excellent opportunities for intercultural learning. Such scholarly collaborations are usually abroad. The outcomes for student exchange are often related to global appreciation, cross-cultural knowledge and the skills required in a diverse nursing workplace. These attributes are important for all health professionals given the cultural dexterity required in the delivery of health and social care [5].

The faculties at both schools of nursing who participated in this pilot study already had experience in using social media activities with students [6,7]. This project sought to increase student participation and collaboration using technological media to facilitate opportunities to collaborate and learn from each other. It was designed to help prepare nurses for their professional career in a global environment where eNetworking will be valuable to address diverse population health issues.

Methods

The aim of this pilot study was to determine student nurses' perceptions of an international collaborative learning activity mediated by ICT. Participants were volunteers drawn from students enrolled in the third year of their undergraduate nursing programmes at the University of Plymouth in the United Kingdom (UK) and the University of Auckland in New Zealand (NZ). The nursing students were placed in one of three groups, with each group having three UK and two NZ students. Ethical approval was obtained from each university.

Students were asked to contribute during four, 30-minute audio/video meetings (using Zoom) with their small group during February 2018. Discussion guidelines were provided for each week's meeting.

As this was the first time this learning opportunity was offered, the researchers were interested in the students' experience of the small group meetings and what they may have learnt from virtually meeting students from a different country. An anonymous evaluation survey comprised of open- and closed-ended questions was emailed to each student as a link to Microsoft Forms at the conclusion of the month-long learning activity. The evaluation form included ten Likert-scale statements. In addition, there were three open-ended questions: *What aspect of the collaborative learning activity was most helpful for your learning? What improvements would you like to see?* and *What, if anything, do you intend to do as a result of participating in this collaborative learning activity?* Data analysis comprised collating the Likert items and thematic analysis for the open ended responses.

Results

Nine students volunteered from the University of Plymouth, and six volunteered from the University of Auckland. Of the 15 participants, 13 responded to the survey (87% response rate). All students agreed (31%) or strongly agreed (69%) that this collaborative learning activity enabled them to engage purposefully with other nursing students. Similarily, all students agreed or strongly agreed with the statement: 'I would recommend other student nurses participate in future collaborative learning activities with international nursing students.

Thematic analysis of open-ended responses identified four themes:

1. Cultural differences

2. International connections & future employment
3. Benefits of e-engagement
4. Limitations of e-engagement

Overall students decsribed this pilot as “an interesting experience” and that it was “positive to engage with students from another country”. However, eNetworking did not negate the idea that a “lovely travel grant to enable us to meet face to face” would be ideal.

Discussion

This study describes an international collaborative virtual engagement activity, reports, the students’ experiences, and identifies practical issues. The findings from this study confirm that ICT provides students with opportunities to gain a global perspective of nursing and healthcare, concuring with earlier studies which also identified that students can gain experience and intercultural skills without having to leave their homes [8-10]. Internationalisation is high on the agenda for tertiary education institutions as they produce graduates that are global citizens [11]. The dialogue between students brought about an interest in future employment and working overseas which supports some intriguing results from web-based interaction with international peers who were ready for international work [8].

Students appeared to enjoy the virtual engagement activity making international connections and seeing friendships beginning to form. This was despite the inconvenience of time differences between the two countries, although time differences are a known issue when two hemispheres, or multiple countries are involved [6,12]. It was evident that the students developed an awareness of similarities, as well as differences, within healthcare provision, thus enhancing their understanding of health with a global perspective, which has been noted in other uses of virtual student engagement [4,6].

The limitations of this study were the small number of participants involved. Areas for further research include maintaining contact with the participants to see whether their eNetworks developed over time. Also, as it has been recognised that newly qualified nurses may experience mixed emotions upon qualifying from a sense of achievement to apprehension [13], it would be interesting to establish whether the challenges facing newly qualified nurses are the same globally. Furthermore, students who participated in this study may be able to support each other as newly qualified nurses.

Conclusions

Health professionals are part of global community, so encouraging and supporting virtual student interaction can help to connect professionals develop a broad perspective on health care. eNetworking amongst the students enabled identification of cultural differences and similarities in their programmes of study, health care systems, and issues being faced. Barriers included using synchronous audio/video-conferencing and the ensuing problems of managing time differences.

Factors Affecting Smartphone Usage Self-Report Levels

In Hye Yook[a,b], So Jin Park[c], Mun Joo Choi[a,b], Dai-Jin Kim[c], In Young Choi[a,b]

[a] Department of Biomedicine & Health Sciences, The Catholic University of Korea, Seoul, Republic of Korea
[b] Department of Medical Informatics, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea
[c] Department of Psychiatry, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

Abstract

For the treatment of smartphone addiction, it is important to understand users' smartphone usage patterns. Most of the studies are based on self-report surveys. However, there are differences between self-reported usage and real usage. For a better understanding of usage patterns, this study identified demographic and social factors that affect smartphone usage self-report levels. Also, it was confirmed that the influencing factors differ depending on the smartphone usage content by application category.

Keywords:
Smartphone, Self Report, Data Accuracy

Introduction

As smartphone addiction becomes a social problem, it is necessary to understand how people use smartphones. Most of the previous studies were based on self-report surveys, and the diagnosis and treatment of smartphone addiction also relied on self-reports [1,2].

Some studies using both self-report surveys and real log data showed there was a difference between them [3,4,5]. However, there was a lack of confirmation as to which factors made that difference. Since self-report usage is a major indicator of the diagnosis of smartphone addiction, it is necessary to identify the cause of the difference between actual and self-reported usage.

In this study, we used self-reported usage, real usage, demographic, and sociological information to find factors influencing the under or over estimation of smartphone usage. We also identified whether the factors are different for the under or over estimation of smartphone usage depending on the application (app) category.

Methods

We developed a mobile application system to collect the mobile use log. The system was implemented for four weeks to 382 participants who lived in a metropolitan area. At the same time, we obtained all participants' self-reported usage, demographic, and social information through online surveys.

Then we categorized participants to the under or over estimation group using self-reported and real smartphone usage. We used a Chi-square test to find factors influencing the under or over estimation of smartphone usage. In addition, to figure out whether a factor was different depending on the content, the top five categories of smartphone usage were analyzed.

Results

There was no perfect match between self-reported usage and real usage. For this reason, people were divided into two groups: under or over estimation of smartphone usage. Table 1

Table 1 – Self-report levels by factor (N=382)

Factor		Self-Report (%)		χ^2
		Under	Over	
Gender	Male	62 (29.2)	150 (70.8)	8.55***
	Female	28 (16.5)	142 (83.5)	
Age	20's	20 (18.0)	91 (82.0)	2.73
	30's	34 (25.2)	101 (74.8)	
	40's	36 (26.5)	100 (73.5)	
Marriage	Single	35 (21.1)	131 (78.9)	1.26
	Married	54 (25.7)	156 (74.3)	
	Divorce/ Separation	1 (16.7)	5 (83.3)	
Education	High school	22 (27.5)	58 (72.5)	0.87
	Graduate school	68 (22.5)	234 (77.5)	
Family emotional support	Never	3 (10.7)	25 (89.3)	5.01*
	Sometimes	47 (21.9)	168 (78.1)	
	Usually	40 (28.8)	99 (71.2)	
Bullied	Have	11 (14.5)	65 (85.5)	4.35**
	None	79 (25.8)	227 (74.2)	
Suicidal impulse within a year	Have	20 (17.2)	96 (82.8)	3.69*
	None	70 (26.3)	196 (73.7)	
Family history of mental disorders	Have	4 (12.5)	28 (87.5)	2.37
	None	86 (24.6)	264 (75.4)	

***: <.1, **: <.05, ***: <.01**

shows the number of people who are in the under or over estimation group by factor. We found four factors, Gender, Bullied, Family Emotional Support, and Suicidal impulse within a year, were related to an over estimation of smartphone usage. Females, people without Family emotional support, people who had experiences of being Bullied, and people who had a Suicidal impulse within a year had a greater over estimation of their smartphone usage.

Table 2 – Influencing factor by app category (N=382)

Factor		SNS (%)		χ^2
		Under	Over	
Age	20's	9 (8.1)	102 (91.9)	610**
	30's	19 (14.1)	116 (85.9)	
	40's	26 (19.1)	110 (80.9)	
Bullied	Have	4 (5.3)	72 (94.7)	5.28**
	None	50 (16.3)	256 (83.7)	
Factor		**Game (%)**		χ^2
		Under	**Over**	
Suicidal impulse within a year	Have	24 (20.7)	92 (79.3)	9.77**
	None	100 (37.6)	166 (62.4)	
Family history of mental disorders	Have	24 (20.7)	92 (79.3)	9.77**
	None	100 (37.6)	166 (62.4)	
Factor		**Entertainment (%)**		χ^2
		Under	**Over**	
Family emotional support	Never	6 (21.4)	22 (78.6)	5.39*
	Sometimes	51 (23.7)	164 (76.3)	
	Usually	19 (13.7)	120 (86.3)	
Factor		**Web (%)**		χ^2
		Under	**Over**	
Gender	Male	34 (16.0)	178 (84.0)	4.54**
	Female	14 (8.2)	156 (91.8)	
Marriage	Single	23 (13.9)	143 (86.1)	8.74**
	Married	22 (10.5)	188 (89.5)	
	Divorce/ Separation	3 (50.0)	3 (50.0)	
Factor		**Finance (%)**		χ^2
		Under	**Over**	
Age	20's	43 (38.7)	68 (61.3)	4.69*
	30's	40 (29.6)	95 (70.4)	
	40's	57 (41.9)	79 (58.1)	
Bullied	Have	17 (22.4)	59 (77.6)	7.58**
	None	123 (40.2)	183 (59.8)	
Family history of mental disorders	Have	6 (18.8)	26 (81.2)	4.01**
	None	134 (38.3)	216 (61.7)	

***: <.1, **: <.05, ***: <.01**

Table 2 shows the factors affecting the self-report level in the top five app categories of Social Network Service (SNS), Game and Entertainment, Web, and Finance, of smartphone usage. The self-reported level of SNS was influenced by Age and experience of being Bullied. Game and Entertainment was influenced by the social factors of Suicidal impulse within a year and Family history of mental disorders. The Web was influenced by Gender and Marriage while Finance was influenced by Age, experience of being Bullied, and Family history of mental disorders.

Conclusions

As a result of the research, we found there are different influencing factors between self-reported levels of total smartphone usage and self-reported levels of the content. For future work, it will be helpful to consider this difference. In addition, it is presumed social factors are closely related to the self-reported levels of smartphone usage. In future research, it will be necessary to study this correlation.

An Efficient Simulation-Based Optimization Approach for Improving Emergency Department Performance

Ibtissem Chouba[a,b], Farouk Yalaoui[a], Lionel Amodeo[a], Taha Arbaoui[a], Philippe Blua[b], David Laplanche[b], Stéphane Sanchez[b]

[a] *Institut Charles Delaunay, LOSI, Université de Technologie de Troyes, FRE2019, CNRS, 12 Rue Marie Curie, CS42060, Cedex, 10004, Troyes, France*

Abstract

In recent years, health care organizations, in particular emergency department (ED), have come under increasing pressure to provide quality care. In this context, human resources are a central aspect: a good utilization of health worker could improve quality of care. In this paper, a simulation model is proposed. The model represents an ED coupled with an optimization method to optimize the allocation of medical and para-medical human resources in the hospital center of Troyes. We aim to improve the quality of services offered to patients through the minimization of Average Waiting Time (AWT) and Average Inpatient Stay (AS). The proposed approach has proved to be effective to reduce AWT and AS by 12 minutes and 21 minutes respectively.

Keywords:

computer simulation, resource allocation, emergency departments

Introduction

In recent years, health care organizations, in particular emergency departments, have come under increasing pressure to provide quality care while overcoming increasing volume pressure. In the other side, simulation has become an effective decision-making tool to optimally allocate the often-limited resources in health care to improve patient flow while minimizing the costs of providing care and increasing patient satisfaction. In addition, combined optimization and simulation tools allow decision makers to efficiently find optimal emergency department configurations, even for complex integrated installations.

Over the last decade, there have been several studies in the literature dealing with the optimization of human and material resources in a health care through the technique of coupling simulation with optimization [1, 2, 3, 4].

In this paper, in order to improve the quality of services offered to patients in the ED of the hospital center of Troyes (CHT) (France), a simulation-based optimization approach is developed. This method uses a discrete-event simulation model, combined with a genetic approach. This tool allows the users to evaluate the Average Waiting Time (AWT; the time that the patient spends from their arrival to their first medical exam) and the Average Inpatient Stay (AS; the time the patient spends from the first exam to their exit) of patients for different organizations of the service. The expected value of patient arrivals is obtained through forecast models developed in a previous work, and that reached a very good performance (up to 91.24 % for the annual total flow forecast) and robustness to epidemic periods [5].

Methods

Simulation model

The developed simulation model requires three kinds of inputs: 1) patient arrival rates, 2) the frequency of each pathway, and 3) the processing times of services. These were obtained from data collected from the emergency database for the whole 2017 year. We modeled the considered probability distribution using the "fitdistrplus" package of R® software [6]. These data were used to determine the best probability distribution to represent each stage of the patient flow. The time of inter-arrival process (T_i) follows an exponential distribution with average of $Y_j * T_h$, i.e $T_i \sim e^{Yj * Th}$, where T_h is the average arrival rate observed for the hour h of the day, and Y_j the number of daily arrivals for the day j.

Optimization

The optimization problem considered in this work aims to minimize the AWT and the AS of patients. In order to reach the optimization goal, the problem was solved with a genetic algorithm coupled with the simulation model (as an objective function evaluator) in order to optimize emergency staff planning. Thus, the optimization problem can be represented as follow:

Minimize $F(x)$

Subject to

$$\sum_{j=1} X_{ij} = Ci \qquad \forall i = 1 \dots 4 \quad (1)$$

$$X_{ij} \in N \qquad \forall i = 1 \dots 4 \;\; \forall j = 1 \dots 4 \; (2)$$

Where X_{ij} is the decision variable that represents the number of available staff per slot time of 6h. $i(= 1 \dots 4)$ is the index of staff type: 1 for emergency physicians, 2 for resident physicians, 3 for nurses and 4 for caregivers, and $j = 1 \dots 4$ is the index of the slot time of 6h per day. The constraint (1) ensures that the same number of hours worked by each type of staff is fixed because the ED of CHT, as a first step, does not seek to increase or decrease its workforce.

Table 1 shows the availability of interchangeable staff per 6 hour time slot.

To define the best parameters of the genetic approach, the experimental design methodology proposed by [7] is used. Then, the parameters used for our GA are: population size = 100, probability of mutation = 0.9, number of maximal iterations = 500 and probability of crossover = 0.9. The time limit was set to 1h30

Table 1: Availability of staff per slots of 6 hours

	00h -6h	**6h - 12h**	**12h - 18h**	**18h - 00h**
Emergency physician	2	2	2	2
Resident physician	3	3	3	3
Nurse	3	3	3	3
Caregiver	3	3	3	3

Results

To assess the efficiency of the proposed simulation model, the performance indicators obtained from our simulation model were given to CHT's decision makers who compared them to daily indicators of the hospital. The assessed gap between real and simulated indicators is less than 9%. Based on this assessment, the model was considered reliable and able to support experiments.

The best solution of the emergency staff planning returned by the genetic approach is presented in table 2. In terms of performances, the solution reduces the AWT by 12 minutes and the AS by 21 minutes.

Table 2:Optimized solution of the annual planning

	00h - 6h	**6h - 12h**	**12h - 18h**	**18h - 00h**
Emergency physician	1	1	3	3
Resident physician	2	2	4	4
Nurse	2	2	5	3
Caregiver	1	2	4	3

Discussion and Conclusion

After improving the current staff planning by keeping the same number of staff, the effect of increasing the number of staff by 1 for each type is studied.

Results show that the nurse resource has the greatest impact on the system. Adding a nurse allows the hospital to reduce the AWT by 25 minutes and the AS by 32 minutes.

To conclude, a simulation-based optimization approach that aims to minimize the AWT and the AS for patients in the hospital center of Troyes, France is presented. The proposed solution provides a gain of 12 minutes in AWT of patient and a gain of 21 minutes in AS which represents a noticeable reduction in waiting times for patients.

This work can be extended to include the planning of human resources, in which the assignment of resources can further reduce waiting time by effectively assigning resources on overloaded shifts.

The SNIK Graph: Visualization of a Medical Informatics Ontology

Franziska Jahn[a], Konrad Höffner[a], Birgit Schneider[a], Anna Lörke[a], Thomas Pause[a], Elske Ammenwerth[b], Alfred Winter[a]

[a] Institute of Medical Informatics, Statistics and Epidemiology, Leipzig University, Germany
[b] Institute of Medical Informatics, UMIT – University for Health Sciences, Medical Informatics and Technology, Hall in Tirol, Austria

Abstract

SNIK, a medical informatics ontology, combines knowledge from different literature sources dealing with the management of hospital information systems (HIS). Concepts and relations were extracted from literature, modeled as an ontology and visualized as a graph on a website. We demonstrate the potential of the graph visualization for tuitional scenarios. SNIK complements teaching and learning with conventional literature by concentrating knowledge that is scattered over different pieces of text around one node of a graph.

Keywords:
Semantic Web, Information Management, Hospital Information Systems

Introduction

Although computer scientists have provided theory and applications for ontologies, they rarely apply ontologies to their own fields of research. There are well-known biomedical ontologies [1], but there are almost no ontologies structuring medical informatics knowledge. With SNIK, the semantic network of information management in hospitals (German: Krankenhäuser) we developed an ontology that describes HIS management from a functional point of view: Who performs which function and which information is needed or updated by this function? The role "CIO", for example, is responsible for the function "strategic information management" which updates the information artifact "strategic information management plan". Statements like these are coded as RDF (Resource Description Framework) triples in SNIK.

A typical use case of SNIK is teaching HIS management at universities [2]. Due to its use in teaching, we needed a way to visualize the ontology, so that students and lecturers can browse through the knowledge and can easily discover how different concepts are linked to each other. In previous work [3], we tested the visualization of SNIK with the help of graph visualization tools. Although offering useful functionalities, these desktop tools are not easy to handle by occasional users. Moreover, the ontology could only be used after having downloaded the latest SNIK file and having installed the tool. Now, with SNIK being available as Linked Open Data together with a web-based graph visualization based on cytoscape.js [4], users can easily analyze the linked concepts of HIS management. It is the aim of this work to demonstrate;

- the visualization capabilities of web-based SNIK ("SNIK graph") and
- their use for specific teaching and learning scenarios.

Methods

SNIK is based on knowledge from text books, frameworks, and expert interviews dealing with HIS and their management. As a first step to develop SNIK, literature was selected in accordance with the learning objectives of lectures on HIS management at Leipzig University. In these lectures, students shall learn a clear terminology for roles, functions, and information artifacts of HIS management. For its use in teaching, SNIK had to provide answers to the questions "Who performs which HIS management function and which information is needed or updated by these functions?" Thus, the SNIK metamodel was specified, which, determines the rules for extracting knowledge from texts. Relevant concepts found in texts have to be assigned to one of the metamodel classes "role", "function" or "entity type", the latter representing types of information artifacts. For linking concepts to each other, 16 different relationships were defined. Extraction from the texts was then done pairwise by reading through a chapter and extracting knowledge to spreadsheets with predefined columns. Each pair of extractors prepaired a consolidated spreadsheet for a chapter. All spreadsheets were checked again by another group in order to have one consolidated .csv-file containing the textbook's subontology. In addition, interlinks between different subontologies were specified within a further spreadsheet. The .csv-files were then converted to RDF, published on the SNIK website, [5] and the extracted knowledge became a part of the SNIK graph.

Results

The SNIK graph, which represents the current status of the SNIK SPARQL endpoint, consists of 2,845 entity types, 1,090 functions, and 234 roles (16.11.2018). It comprises knowledge from five different sources which are linked to each other by 704 interlinks (Figure 1).

The following teaching and learning scenarios can be visualized within the SNIK graph (http://www.snik.eu/graph):

(1) A teacher prepares a lecture on strategic HIS directing. He or she uses the "circle star" visualization for the function "Strategic HIS Directing" and gets a mind map to structure the lecture (Figure 2).

(2) A student has decided to be a project manager in a students' hospital project and wants to know his or her responsibilites. The "circle star" around the role "project manager" shows 24 functions and 8 entity types from three different sources a project manager is responsible for.

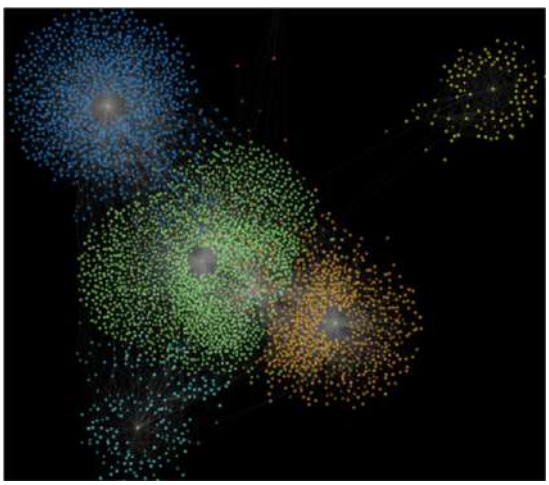

Figure 1 – Five colored clouds representing subontologies of SNIK. The clouds contain knowledge from three books (dark blue, green and orange), a CIO interview (light blue) and a framework (yellow).

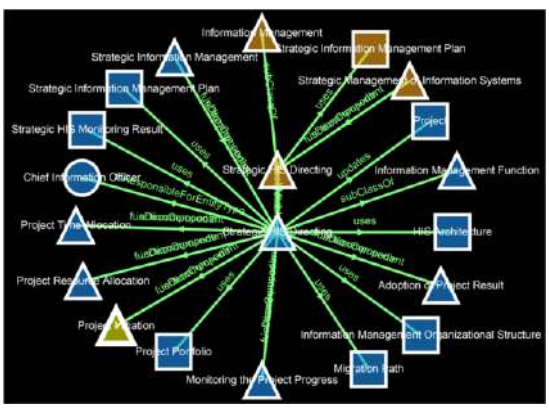

Figure 2 - Circle star for the function "Strategic HIS Directing" (rectangles represent entity types, triangles represent functions and circles represent roles).

(3) Students learn new concepts about HIS quality by linking them to concepts already learned. A teacher asks a student to find out how the new concept "Quality of Data" is linked to the "Patient Identification Number". The student connects the two concepts by using the spiderworm visualization and learns that a patient identification number is associated with object identity. Object identity is a subclass of integrity of data. Besides integrity of data, there are also 13 other criteria for quality of data (Figure 3).

Conclusions

The SNIK graph enables students and teachers to browse through the knowledge of HIS management on a website. With the help of the visualization capabilities like "circle star" and "spiderworm" specific questions arising during learning, the preparation and the execution of lectures can be answered. The SNIK graph complements texts on HIS management by a highly interconnected map. Knowledge about a concept, which is often scattered over different chapters or even books, can be found around one node of the graph visualization. Other possibilities of teaching support by SNIK, like the automatic generation of multiple choice tests (e.g [6]), are subject of further research. Nevertheless, due to its size, SNIK is not free of errors. Hence, every user can participate in the continuing quality assurance process and report bugs directly within the graph visualization.

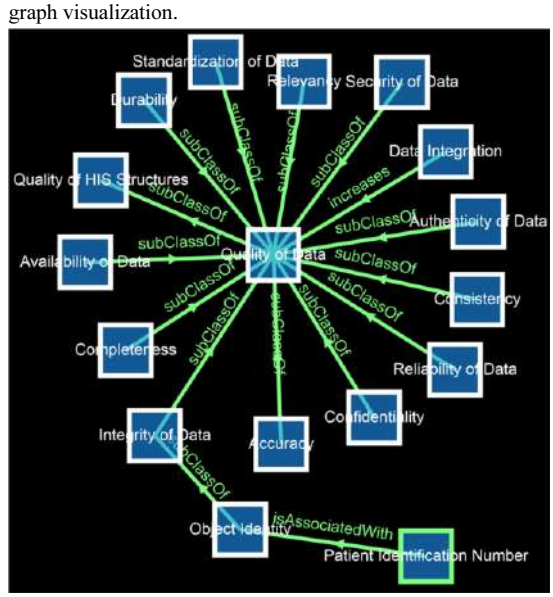

Figure 3 - A spiderworm connecting "Patient Identification Number" and "Quality of Data"(surrounded by its neighbors).

[b]*Department of Internal Medicine, Hospital Italiano de Buenos Aires, Ciudad de Buenos Aires, Argentina*

Abstract

Technology has led to the communication of the hospitalized patient and their family with clinical knowledge. The objective of this study is to describe the rate of use of the Inpatient Personal Health Record of Hospital Italiano de Buenos Aires. A cross-sectional study was conducted between May and September of 2018. The rate of use was 2.10% (95% CI 1.89-2.32). The most used functionalities were analyzed. New strategies are needed to improve the rate of use.

Keywords:

Personal Health Records, Inpatients, Electronic Health Records

Introduction

Health organizations are moving towards greater health information technology, allowing more comprehensive patient care, and improving communication within the health team. Often the implementation of these technologies in hospitals has been directed mainly to health personnel, more specifically, to the health care professional instead of the patients and their families [1,2].

The scope of 21st century medical care has generated strategies for Effective Health Care, and one of the established requirements is the "Empowerment of patients and their families in the effective management of health care decisions, and their implementation, including personal health records (PHRs), education about the individuals conditions and options, and support of timely and focussed communication with professional health care professionals" [3]. This scope is not only necessary in the home and ambulatory care environments, when the patient is hospitalized, it should also be considered.

A PHR is one of those tools, which provides convenient access to personal health information from any location with Internet access [4]. The development of online PHRs involved the patient in the process of medical care, generally in the outpatient environment [5]. The initiatives of inclusion of health information technologies in the hospitalization field, encourage the institutions to offer patients electronic access to some clinical data [6,7]. Interventions that provide patients with clinical information have been effective in promoting patient participation in health-related decision-making, increasing the patient's adherence to their own care plans [8,9].

The Department of Health Informatics developed and implemented an Inpatient Portal (IP), which is being used since May 2018. This work aims to describe the rate of use of the IP and the characteristics of the users in our Institution from the implementation to the present.

Methods

Design

A cross-sectional study was carried out that included all admissions of adult patients, hospitalized during the period between May 20 and September 30, 2018, at Hospital Italiano de Buenos Aires.

Statistic Analysis

We defined to report the patient's rate of use with the amount of patient that login to the IP during the hospitalization. It is constructed with a denominator, defined as the totality of patients admitted to the hospital within the study period; and numerator, defined as users who log in to the IP during their hospital stay. It will be reported as a percentage with its respective 95% confidence interval (95% CI), calculated through normal approximation.

Quantitative variables will be described as mean and standard deviation or median and interquartile range, as appropriate for distribution. The categorical ones will be described as relative frequency and percentages, with their respective 95% CI.

Results

The characteristics of the patients who were admitted are detailed in Table 1.

Table 1: Patient Characteristics

Variable	Porcentage	Users
Age 18-20	4.0%	15
21-30	12.1%	45
31-40	18.9%	70
41-50	10.5%	39
51-60	11.0%	41
61-70	15.1%	56
71-80	13.2%	49
81-90	11.8%	44
91-99	2.9%	11
Female	58.9%	218
Healthcare Insurance Plan	53.2%	384
Total	100%	370

The rate of inpatients who made login to the IP during the study period was: 2.10% (95% CI 1.89-2.32). Out of a total of 17,612 patients only 370 login. Figure 1 shows the income by month.

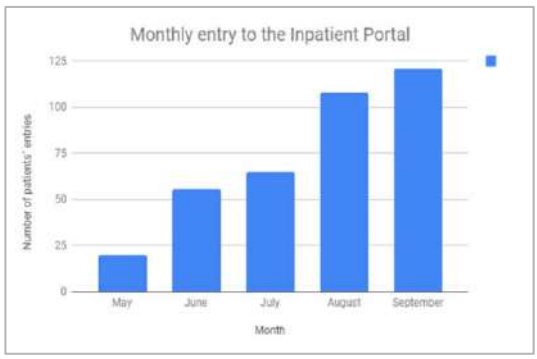

Figure 1: Monthly Entries to the Inpatient Portal

The 370 users who login the IP, made 9249 clicks. The most frequently used sections Vital Signs, Hospitalization data and location transfers. (Table 2)

Table 2: Used Sections

Sections	Use %	Total use
Vital Signs	24.6%	2278
Hospitalization data	15.6%	1444
Location transfers	14.5%	1350
Health care team	14.4%	1341
Food service	13.1%	1217
News	7.0%	656
HIBA TV	6.2 %	579
Phone numbers	4.1%	384

Conclusions

The rate of use between May and September 2018 was 2.10% (95% CI 1.89-2.32). Of the 370 users who logged the IP, the majority were female, affiliated with Healthcare Insurance Plan and youth. The most used functionalities were: vital signs, hospitalization data, and location transfers. New planning and implementation strategies are needed to improve the rate of use.

Abstract

Chronic kidney disease (CKD) is a Public Health problem worldwide. Treatment in complex and depends on patient education to achieve adequate adherence. We describe in this paper novel strategies for patients' education based on internet (youtube and instagram), through videos, images and texts information directed for patients in a project developed in Brazil.

Keywords:

Chronic kidney disease; Internet; Social media; Health education.

Introduction

It is estimated that 10% of world population has chronic kidney disease (CKD) [1]. This trend is related to the increase in life expectancy and the prevalence of chronic non-communicable diseases such as hypertension [2] and Diabetes Mellitus [3], the main causes of CKD. Studies have been developed to investigate the knowledge of population about CKD and the results show that groups of all parts of the world have low awareness about the disease which can reflect in adherence to prevention [4,5]. However, there is an even greater aggravation in situations of low knowledge about CKD: studies show that many individuals that make up the groups at risk of developing the disease, as hypertensive and diabetic, are not aware of this [6].

The repercussions of low knowledge on CKD can be seen in the high percentage of patients with late diagnosis, that is, in the more advanced stages of the disease, which unfortunately is related to the reduction of life expectancy in all age groups [7], and higher mortality during treatment [8]. The study of Ricardo et al. [9] has shown that low health literacy was associated to low estimated glomerular filtration rate (GFR). The aim of this study was to describe the use of social media as strategy for health education in the context of CKD.

Methods

This study is part of the Renal Health Project which develops several strategies for prevention and treatment of CKD. The project was funded by the International Society of Nephrology (ISN) through the Clinical Research Program, and is supported by the Brazilian Society of Nephrology. We created two tools of communication with the internet users, a channel on YouTube and a profile on social media Instagram in order to share digital content about the CKD. Although the goal of both is to disseminate information about prevention and treatment of the disease, it is believed that these two channels can achieve different population groups that have low knowledge about CKD, as general population [9, 10], non-dialysis patients [11, 12] even between health team [13, 14].

Channel on YouTube

YouTube is indisputably the biggest online video platform worldwide and the second most famous social network website worldwide as of July 2018, ranked by number of active users (1 900 millions) [15]. The YouTube channel Renal Health proposal Created in December 2017, (https://www.youtube.com/channel/UC3-GHeHAndcrRmbE4I_qE_w). It was designed to describe, in a logical sequence of videos, from kidneys definition and functions through the CKD diagnosis to the guidelines about treatment of this disease. A doctor called "Kidney" was chosen to answer the questions made by a woman voice.

Profile on Instagram

The Instagram App is one the most popular social networks worldwide. While the number of monthly active Instagram users from January 2013 was 90 million in June 2018 was a 1 billion. In that period Brazil was in third position on number of Instagram users (63 millions) [15]. Initially, we choose this social media to test the acceptability of general populations and CKD patients. The profile on Instagram (https://www.instagram.com/renal_health) was developed in June 2018, and arose from the need to broaden the spectrum of health education actions. The published content is based on the most current guidelines in Nephrology and contents are often shared by great and reliable institutions such as the Health Ministry of Brazil, World Kidney Day, World Health Organization and Brazilian Society of Nephrology.

Results

Currently, the channel has four videos and a total of 157 views. The first and the longer has (3:01 minutes), it is about

notions of Nephrology and concepts of CKD, the second on diagnosis "How the doctor discovers that a person has CKD", the third is a tutorial for the use of the application Renal Health, developed by our research group, and the last is about of CKD stages. Until the end of this work the Instagram profile counted on 223 publications and 832 followers. It is noteworthy that on August 28th the profile had 300 followers, reaching 600 on October 16th, 2018, showing significant growth. Only from October 8th throw 14th, 2018, according to Instagram's management data, publications had been viewed 8,904 times, from 1,366 accounts. A post on the CKD stages was viewed 1,074 times, indicating the range of reach of the publications. As for followers, 33% live in Fortaleza, Ceará, Brazil, followed by São Paulo (6%), São Luís (3%), Rio de Janeiro (3%) and Recife (2%); 41% are in the age range of 25 and 34 years old, 30% are 35 to 44 and 73% are women.

Discussion

For CKD patients the aim of this channels is to familiarize them with the aspects related to their health status because from the acknowledge of an expanded understanding. The patients have the autonomy to discuss with the health team about the best behaviors to be implemented in their treatment, which is, what makes them the co-managers of their health care. On the profile on Instagram it is noticed that many CKD patients feel free to post comments on their personal experiences demonstrating identification with the topics covered. For Moorhead [16], social platforms enable chronic patients to share their health issues, anguish, and experiences with other patients, generating empathy for those who once accommodated regarding the disease or felt alone.

Conclusions

Based on the increasing number of followers in both channels developed there is interest by general population and CKD patients of to improve the knowledge about CKD. Although it is known that knowledge does not determine behavior, it is evident that the absence of knowledge hinders the adherence to measures aimed to prevent health problems. Therefore, the population, especially the groups at risk for the disease development, after having access to more information on strategies for the protection of renal function and early diagnosis, might be able to make conscious decisions about lifestyles and their effects on their health status.

Evidence-Based Usability Principles for Safe Computerized Provider Order Entry (CPOE) Interface Design

Gurprit K. Randhawa[a,b], Ashley Garnett[b], Sihong Huang[c], Parvin Dhot[b], and Mary-Lyn Fyfe[a]

[a] *Island Health, Victoria, BC, Canada*
[b] *University of Victoria, Victoria, BC, Canada*
[c] *Fraser Health, Surrey, BC, Canada*

Abstract

There is a dearth of evidence-based tools to design the safest Computerized Provider Order Entry (CPOE) system possible. An evidence-based list of usability principles for the design of the CPOE interface was developed following a literature review, and validated with the Chief Medical Information Officer and CPOE team at Island Health. The list includes 11 usability principles that can be used to inform ongoing CPOE interface design and evaluation efforts to improve patient safety.

Keywords:

Medical Order Entry Systems, User-Computer Interface.

Introduction

The design of a Computerized Provider Order Entry (CPOE) system is a significant decision factor in reducing medication errors and maximizing safe use. Although the first CPOE system was implemented in 1971, there are several outstanding challenges concerning the usability of CPOE [1] even 47 years later. The underlying issue "appears to be that there is no consolidated source of evidence that provides organizations with tools to design the safest CPOE system possible" [1]. Davis and Stoots' 2012 article on EHR adoption emphasizes that organizations ought to incorporate checklists and tools to minimize any unintended consequences [2]. They suggest simple tools such as checklists act as a highly-effective quality-control instrument that "can prevent potential costly mistakes and even fatal medical errors" [2]. The literature highlights that though there is no "best" method in designing a CPOE system, it requires trial and error work at an organizational level [1]. Sengstack (2010) underlines that there is a need for tools that:

1. Are based on lessons learned and documented in the literature;
2. Can be used to evaluate CPOE systems; and
3. Can be used as a guide for informatics specialists at all levels as the iterative process of improvement continues to cycle [1].

A study from Sunnybrook Health Sciences Centre in Toronto also highlights the importance of organizational commitment to CPOE design to improve efficiency, usability and safety prior to system implementation [3]. Similarly, Yuan et al. (2011) underscores the importance of using a design framework to identify requirements and functional specifications for the User Interface (UI) design of clinical decision support (CDS) [4]. To address the aforementioned recommendations from the CPOE design literature, Island Health developed evidence-based guidelines for the design and evaluation of its CPOE system, as there is currently no comprehensive usability tool to inform CPOE interface design. Three CPOE design tools were developed for CDS Alerts, the CPOE User Interface, and references within CPOE Order Sets. This paper summarizes the usability guidelines developed and adopted by Island Health for the safe and usable design of the CPOE interface. Island Health is a health care organization in British Columbia, Canada with over 23,000 staff and physicians.

Methods

A literature review of CPOE interface design was conducted from November 2017 to January 2018 using Google Scholar. Various search terms were used, including "CPOE design" AND "colour" OR "color"; "CPOE design" AND "font"; "CPOE design" AND "alerts"; "CPOE design" AND "screen"; "CPOE design" AND "icons"; "CPOE design" AND "lists." The inclusion criteria for the literature review included primary or secondary articles that (1) were in English, (2) published between January 2000 and January 2018, and (3) that discussed CPOE design principles. The references of included articles were also mined for relevant articles. Recommendations for CPOE interface design were extracted from the included articles. A thematic analysis of the recommendations was conducted to identify themes from the articles, as well as to develop general usability principles for CPOE interface design. To confirm the congruence of the CPOE interface design principles with general user interface design principles (e.g., Nielsen's ten general principles for interface design), usability heuristics were also reviewed. The resulting CPOE interface design usability principles and sub-principles were iteratively reviewed and refined to produce a final list usability design principles. Face validity was evaluated with the Chief Medical Information Officer (CMIO) and CPOE order set team at Island Health. In addition to a list of usability principles, a designer-centred checklist for CPOE interface design was developed for use by the CPOE team and clinical informatics specialists at Island Health. The checklist presented the usability principles in the form of a question.

Results

In total, thirty articles were included in the literature review, and a list of 11 CPOE interface design usability principles was developed. The list of usability principles for CPOE interface design fall into 11 categories: (1) layout, (2) terminology, (3) use of headings and sub-headings, (4), placement and proximity, (5) general use of colour, (6) use of colour combinations, (7) text style, (8) use of punctuation, (9) use of icons, (10) use of lists, and (11) alert visibility. These principles align with 5/10 of Nielsen's ten general principles for interface design. Due to space limitations, only the sub-principles for Principle 1 (Layout) are presented below. The full (detailed) CPOE interface design checklist with principles, sub-principles, and corresponding literature/evidence will be presented in the poster.

Principle 1: Layout

1. Minimize the layers of screens (to a maximum of 3 layers) to facilitate user's navigation in the system [5].
2. Use visual cues (i.e., colour, font or conspicuous spatial arrangement) consistently. For example, use visual cues within the ordering screen to indicate the difference between the latest results vs. previous results) [5,6,7]
3. Organize the screen elements into logical groups, visually separated by space, alignment and borders; their meaning should be easily recognized by users [5].

Discussion

Island Health's comprehensive and validated list of usability design principles for safe CPOE interface design addresses the current gap in the literature surrounding the need for a consolidated source of evidence for designing safe CPOE systems. The list and check-list of design principles have been adopted by Island Health for its CPOE interface design practices. However, it is interesting to note that the authors did not come across any literature published on the use of special characters in CPOE design, such as asterisks. This was an area of particular interest for Island Health, as asterisks had been previously used in CPOE interface design in the organization. As such, it is unclear if the use of special characters may have any effect(s) on the quality and safety of CPOE interfaces.

Given the iterative process of continuously improving CPOE design, it is important to note that the consolidated list of usability design principles presented in this paper is a "living and breathing" guideline that should be continually updated based on usability-related lessons learned by health care organizations. Based on ongoing CPOE usability evaluations, health care organizations across the globe should regularly document and make recommendations for CPOE interface design to ensure that the design principles are based on emerging best practices in the field. Specifically, pre- and post- evaluation design may be used to evaluate changes in the usability of CPOE before and after adopting the design principles.

A major limitation of this research is that a scoping or systematic review of the CPOE interface design literature was not conducted due to time constraints, and only one database (Google Scholar) was searched. It is recommended that a scoping or systematic review be conducted. Additionally, the list of CPOE usability design principles was only validated with the CMIO and CPOE team at Island Health. The list should be further validated with stakeholders in other health care organizations at the provincial, national, and international levels.

Conclusions

This paper contributes a list of 11 evidence-based usability design principles for CPOE interface design, including principles related to: (1) layout, (2) terminology, (3) use of headings and sub-headings, (4), placement and proximity, (5) general use of colour, (6) use of colour combinations, (7) text style, (8) use of punctuation, (9) use of icons, (10) use of lists, and (11) alert visibility. Specifically, this paper addresses the suggestions made by Sengstack [1] by developing a usability principles tool for CPOE interface design that (a) is based on the literature, (b) can be used to evaluate CPOE usability, and (c) can be used to guide health informatics specialists at all levels in CPOE design and quality improvement. As such, the list of principles has implications for usability evaluation of CPOE; the usability design principles may be applied by health care organizations as a check-list to support the evidence-based design, adoption, ongoing evaluation, and improvement of CPOE interfaces. Given that the authors did not find published literature on the use of special characters (e.g., asterisk) in CPOE interface design, it is recommended that further research be conducted to evaluate the usability and use of special characters to ensure safe CPOE interface design.

Abstract

My Little Smart Personal Assistant is a co-designed remote connected device with an interactive vocal assistant that provides a panel of social/medical services for the rural European elderly population. The aim is to create a new patient-centered solution to improve quality of life, self-autonomy, and integration within local community. This should improve aging-well at home in rural settings.

Keywords:
aging, patient-centered care, remote consultation.

Introduction

Background

The aging society is one of the major challenges for the healthcare system. About 17% of the overall population is aged 65 years or older in members of the OECD (Organisation for Economic Co-operation and Development), and particularly higher in France and Portugal (18 and 20%, respectively)[1,2]. These statistics will rise in the next years. A main concern associated with aging is the forthcoming frailty, which affects around 10% of people 65-74 years and increases within older population[3].

Besides frailty, the prevalence of chronic conditions and co-morbidities also increase with age. In Europe, 8 in each 10 people older than 65 suffer from at least one chronic disease. Frailty/chronic diseases are particularly threatening for isolated aged patients, as they do have little or none informal caregivers helping them to manage properly on their basic needs. This situation is even worse for those living in rural areas where access to health ressources is usually challenging.

Proposed solution

Our consortium brings together actors from the academic, technological, research network, associative, and industrial sectors in Portugal and France.

My Little Smart Personal Assitant (MLSPA) proposes to develop a remote connected device which integrates an interactive vocal personal assistant aiming to support health and social care services delivered in rural areas. This package is co-designed starting from an existent technology - the Virtual Social Companion (ViSoCo) developed by the Instituto Pedro Nunes (IPN) in Portugal[4]. IPN leads the technological development of the solution and works closely with GLINTT (Global Intelligent Technologies), a Portuguese company managing the market and business tasks to implement this solution in the European healthcare systems. Our endeavour takes advantage of their consolidated experience in Portugal and Spain.

The consortium also benefits from the participation of EURIPA (European Rural and Isolated Practitioners Association), which is charged with the implementation in rural areas of the solution in Portugal and France. In addition, MaDoPa (Centre Expert en Technologies et Services pour le Maintien den Autonmie à Domicile des Personnes Agées) assists the co-developpement and evaluation of healthcare and autonomy innovative solutions.

Université Grenoble Alpes (UGA) enriches MLSPA ensuring the overall management of the project and takes advantage of the competences of INSERM (Institut national de la santé et de la recherche médicale) for field investigation, experimental methodology, data analysis, usability, and social evaluation.

Together, these multidisciplinary competences will cover the needs required for the first evaluation of MLSPA solution. The goal is to validate a panel of multilevel indicators obtained from a patient-centered approach consolidating a market deployment strategy.

Methods

Approach and experimental plan

MLSPA proposes an innovative approach which allows the overall maturation of the project through a first co-construction phase (i.e. sinergy with end-users and stakeholders) and a following field-test in real settings (i.e. rural communities).

The maturity process of our solution follows the methodology proposed by INSERM via the CIC-IT department of Grenoble (Centre Investigation Clinique – Innovation Technologique) for innovations in the healthcare domain. It allows to validate the prototype faster when compared to the time reported in other projects (3-4 years instead of 8-10 years). The innovation maturity cycle will decrease the costs for innovation

(technology implementation) and increase potential collaborations in healthcare domains[5]. This methodology improves the relationship amongst the consortium partners. In respect to an efficient behavior, a dynamic work emerges to ensure a beneficial agreement that provides sufficient incentives to market actors in order to constantly improve products and services in the healthcare system[6]. In addition, a technological maturity of the device is expected to escalate to TRL 6 (technology readiness level).

In particular, MLSPA solution will be tested by the design of an experimental plan deployed for free in 2 rural places in Portugal and 2 in France, with a total of 100 volunteers (25 patients in each place). The patients will be selected by their general practionners (GPs), and the cohort has been calculated in order to ensure an appropriated pilot study. The population selected for this phase are people over 65 years old living in rural settings, demonstrating frailty (assessed by the FRAIL scale – Fatigue Resistance Ambulation Illnesses and Loss of Weight)[7], with chronic condition, absence of cognitive decline (MMSE "Mini Mental State Examination" over 23), and an "Index of Independence in Activities of Daily Living" (ADL) over 3.

During a visit, GPs will collect the following clinical data using a standardized questionnaire and evaluation protocol: age, FRAIL scale, MMSE, ADL, weight, height, BMI (body mass index), IADL (Instrumental activities of daily living), Up and Go test, self-reported exhaustion by patient, number of treatments (molecules), consultations (number in 2018), hospitalisations (number in 2018), self-perceived frailty by patient (numerical scale), and perceived frailty by GP (numerical scale). Additionally, non-clinical data will be collected at the inclusion including: demographic data, existing internet connection at home (or possibility to obtain access), social environment (i.e. local community activities). Data collected will be recorded electronically with the support of a personal health data hosting provider.

MLSPA will be compliant to the ethical standard, the clinical study regulations and the patient data treatment (e.g. European General Data Protection Regulation 2016/679). All data acquired by this project will be in encrypted databases (e.g. personal healthcare authorized data host). Furthermore, we will ensure that the data flow and their communication will be handled only under secure connections (e.g. HTTPS protocols, Secure Sockets Layer, and Virtual Private Network).

Impacts and Conclusions

The short-term objective is to demonstrate our solution in terms of benefits on the follow-up of the global activities of this population.

In addition, this study will provide social-medical-economic indicators that will be used by the stakeholders for a further large-scale deployment plan (i.e. market access strategy, reimbursement policy, healthcare companies involvement…). Finally, data on the participation of GPs and social worker will be collected to optimize and correctly address the project in terms of usability (user's feedback), participation, and personalized services.

We aim to enable older adults to live with dignity in their homes and to improve their social engagement in rural communities. MLSPA will improve the follow-up of physical activity, healthy eating, monitoring of medical treatment for chronic diseases and social life involvement and connection of the participants. This paves the way to a future empowerement of the self-health management by citizens, providing them an active and participative role.

The final goal is to provide support and guidance features related to self-management and health literacy associated with frailty prevention. This may promote social prescribing and reduce the impact of frailty and chronic morbidity on the targeted population.

All together, this will facilitate positive, active, and healthy aging at home, reduce the risk of dependency, and avoid unexpected hospitalisations in decreasing the cost for the healthcare system.

Figure 1 below displays MLSPA project vision.

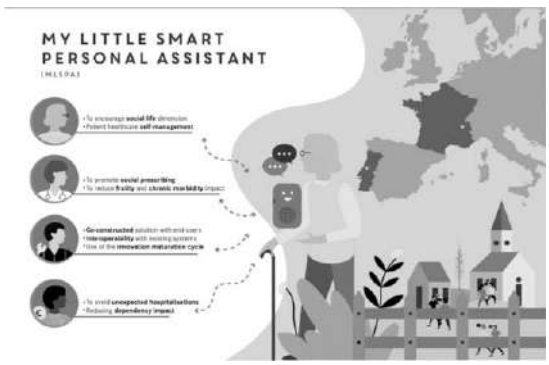

Figure 1: MLSPA vision

Abstract

In higher education, programs in specialization in Health Informatics, Medical Informatics, Health Engineering are continuously growing. In this research, almost 1800 universities and colleges were checked in order to find related educational programs at all academic levels. Approximately 1000 academic leading degree programs in those domains have already been identified. The detailed records of the related educational programs will help to understand the current educational needs and priorities. Although, the growth of the related educational programs is not the same in each country.

Keywords:
Medical Informatics, Education, Europe

Introduction

Information technologies and telecommunications improve prevention, public health, quality of health care and biomedical research. The majority of new technological tools focus on access, processing and management of medical data and information, enhancing the decision-making process. Thus, it is important for the health scientists and professionals to be well trained by instructive programs in order to develop and operate these systems successfully [1; 2].

The past few years, in higher education, programs such as biomedical informatics, health informatics and biomedical engineering are continuously growing. Recent domestic and international articles emphasize curricula with specialization in Health Informatics, Biomedical Informatics, Medical Informatics, Medical Engineering and Biomedical Engineering of the European Universities which are offered at undergraduate and postgraduate level. However, there is a remarkable absence of detailed recordings of the European educational programs in these specializations. Thus, the scope of this research is to fill in this gap. The established EFMI Accreditation and Certification Committee (AC2) tries to fill in this gap among other tasks as well. This initiative was launched at that time by the EFMI President and endorsed by the EFMI Board in consultation with the EFMI WG EDU Chair. The main task of the AC2 Committee is to search for ways to develop and implement the Accreditation and Certification initiative in Europe. Since, the Committee in order to achieve its aim, has detailed records of the educational programs in specialization in Health Informatics, Medical Informatics, Biomedical Informatics, Bioinformatics, Nursing and Dental Informatics, Health and Medical Technology, Health Engineering, Medical and Biomedical Engineering at all academic levels [1-3].

Methods

This project follows a series of steps in order to achieve the aim. First of all, online searching was conducted on Coursera, EdX, FutureLearn and Udemy databases. Secondly, a full list of the universities, colleges, institutions etc. of each European country was compiled via Google searching. Thirdly, the official website of every university was carefully checked so as to locate educational programs related to our subject. It is a fact that the duration of the search process has been conducted a couple of years before and the research is still in progress [2]!

It is worth mentioning that the research is limited only to European countries that are members of the European Federation for Medical Informatics – EFMI (Table 1) [4].

Table 1- The list of EFMI Countries-Members

Countries-Members of EFMI			
Armenia	Austria	Belgium	Bosnia-Herzegovina
Croatia	Cyprus	Czech Republic	Denmark
Finland	France	Germany	Greece
Hungary	Iceland	Ireland	Israel
Italy	Republic of Moldova	Netherland	Norway
Poland	Portugal	Romania	Russian Federation
Serbia	Slovenia	Spain	Sweden
Switzerland	Turkey	Ukraine	United Kingdom

Specifically, this study has covered almost 27 EFMI countries-members out of 32 [2]. In more detail, Figure 1 shows the countries have completed this process and the countries will have been completed in a few weeks.

Almost 1800 universities and colleges were checked in order to find related educational programs at all academic levels. About 180000 courses in total were checked.

Results

More than 1000 educational programs in these domains have been found in a wide variety of undergraduate and postgraduate degrees so far.

Figure 1-Twenty seven EFMI Countries-Members

Specific information was collected for each educational program. All these elements are included in Access Database (Figure 2). The information is being collected for each study program: university/ies, department/faculty, study program name, academic level (e.g. undergraduate / postgraduate / doctoral / postdoctoral Studies), type of education (full time – part time – combined), mode (on campus – e-learning / distance learning), specializations, director of the education program, details about contact person of the program, curriculum, time table, learning outcomes, competencies and program's language (English – local – bilingual). Additionally, Program's ECTS and academic staff's details are contained. Needless to say, the authors' interest focuses only on academic degree programs [1; 2].

Figure 2- Catalogue of Educational Programs

Furthermore, this database includes educational programs in specific areas such as Nanomedicine, Medical Electronics, Clinical Informatics, Clinical Technology, Clinical Engineering, Computational Biology, Life Science Informatics, Clinical Data Management, Big Data in Healthcare, Data Mining in Healthcare and Medicine, Digital Health Systems, E-Health, Telemedicine, Healthcare Analytics, Wireless Networks in Healthcare, Internet of Thing in Healthcare etc. Until now, the authors' have no view on specific countries such as the Russian Federation, Turkey and Ukraine due to local issues.

Finally, the data on this database is published in the appropriate established website (http://www.bmhi-edu.org). This website is under development and is available on the network. As verification of the included information is still in progress the information is not still available to the public. Only the registered users have access to the content.

Discussion

Earlier efforts in developing databases of educational programmes at an international level have been made. It is worth mentioning the effort by WG1 on health and medical informatics education of the International Medical Informatics Association (IMIA). The initiative of IMIA had aimed at the creation of an online database that would provide information about programs and courses in Health and Medical Informatics worldwide [5]. In our case, the data of the research comes from European Countries and provide information about programs in Health and Medical Informatics, Biomedical Informatics, Bioinformatics, Medical and Biomedical Engineering etc. In addition, this study has included only the academic degrees of bachelor, master or doctoral and postdoctoral level in related educational programs. While the certificates, short courses, modules, summer schools, exchanges studies, lectures and seminars were excluded. Due to the limitations of this research, there is an unclear viewpoint for specific countries such as Belarus, Estonia, Georgia, and Latvia.

AC2 Committee strongly supports the promotion and provision awareness of the educational initiative to the wider biomedical and health informatics community in Europe. Consequently, this information to explore in order to understand the current educational needs and priorities of each European country. Presently, the educational priorities in Biomedical and Health Informatics for Europe are closely interlinked with the European Union's educational framework [3]. Thus, the Educational Policy should be focused on local, state, national and international activities and addresses short- and long-term needs [6]. The Committee will work diligently to seek collaborations and invite other international organizations to cooperate [3].

Conclusions

The present educational programs are offered at undergraduate and postgraduate level including a variety of specializations such as health informatics, bioinformatics etc. However, the growth of educational programs is not the same in each country. It would be useful to see if in each country a satisfying number of educational programs is provided with well-detailed curriculum at each level depending on their specialization [1; 2].

Relating Factors for Acceptance of Health Care Technology: Focus on Mental Workload

Lisanne Kremer[a], Sumona Sen[b], Bernhard Breil[a]

[a] *Faculty of Health Care, Niederrhein University of Applied Sciences, Krefeld, Germany*
[b] *Faculty of Industrial Engineering, Niederrhein University of Applied Sciences, Krefeld, Germany*

Abstract

Medical information systems and care robots are two typical examples of human computer interaction in health care. Although used in a stressful environment, effects on mental workload and acceptance are hardly evaluated. We conducted an experimental design including collaborative robotics and eye tracking in a nursing situation to test the practicability and plausibility of eye tracking as a measuring method for workload. Results showed that eye tracking is feasible if context factors are adjusted. Data reduction and classification of tasks are necessary.

Keywords:

Workload, Eye Movements, Health Information Systems

Introduction

Health information system (HIS) has already become an important part of daily health care. Investigations of usability of HIS often focus on technical issues and not on the whole system (technical, human). Interacting with a computer while operating daily working tasks means to switch attention between patients, computer and other competing tasks. This can lead to a high workload. Comparable to the use of HIS in medical settings are Human Robot Interactions (HRI) in health care: care assistance robots have the potential to compensate gaps in patient-centered care caused by demographic change [1]. The topic of HRI poses the challenge of safety issues as well as usability and acceptance by users. Meanwhile, physical limits in interaction with robots are well defined, there remain open questions – as well as in the topic of HIS - regarding mental issues like stress and strain and acceptance by users [2]. Working and interacting with a robot or a HIS for a whole working shift needs a high amount of attention. As a result, the workload can be too high to manage all competing tasks.

"Workload is defined as the physical and/or mental requirements associated with a task or combination of tasks" and "refers to that portion of the operators limited capacity actually required to perform a particular task" [3]. Accordingly, mental workload (MWL) may be an imbalance of resources of the operator and requirements of the task influencing the operator's performance. O'Donnell & Eggemeier addressed the lack of valid, objective measurement methods regarding psychophysiological correlates that can be applied in real work situations [4]. Advantages of psychophysiological methods are that they are uncontrollable and unmodifiable by the proband as well as spontaneously in response to stimuli. They can be an effective approach for workload analysis in a highly demanding work situation like a health care situation [5].

One aspect of analysing HIS is the integration of physiological (MWL) and intentional measures (for example, acceptance) [6]. For analysing "acceptance", there exist several models, e.g. the *unified theory of acceptance and the use of technology* (UTAUT) identifying four key factors (performance expectancy, effort expectancy, social influence and facilitating conditions) and four moderators (age, gender, experience and voluntariness) [7]. Several studies investigated mostly one or two of the factors, but only a few studies showed extensions as including individual characteristics to the UTAUT model. Leaving out individual characteristics is one of the main criticism of the UTAUT model as well as in health care research [8]. We propose MWL as an additional factor to the UTAUT model that influences behavioral intention.

As MWL is determined by task complexity and difficulty, it is probably a good predictor to explain the high amount of stress of health care staff [9]. Work psychology states that mental stress emerges of strain resulting from task requirements [10]. Knowing about a lack of acceptance of new technologies in health care – especially HIS – leads us to further hypotheses. Our main objectives are to validate eye movements as well as pupil width as physiological correlates for MWL measurements in health care settings to be able to test possible extensions of the UTAUT model.

Methods

Embedded in a students project, we developed an experimental simulation design. We used a simulated hospital room that holds environmental conditions stable (noise, lights). It contains a nursing bed, an over-bed table, a collaborative robot, a flatscreen TV as well as decoration equipment to make the hospital situation more realistic to the probands. Sirens and other hospital sounds are played for a more realistic scenario. The patient sits in bed with the over-bed table beside his right side, the collaborative robot is placed behind the table. The executing task of the robot is to handle the patient medication, something to drink as well as something to eat. The robot puts the three different objects on the over-bed table one after another and puts it back afterwards. The patient needs to lift up the objects in the time between and before the robot takes the object back 30 seconds later. There's a planned pause in HRI when the patient tries to solve a Sudoku. The described procedure is repeated twice; at the end of the setting, the proband is asked to fill out an adapted UTAUT questionnaire. The setting (without the UTAUT questionnaire) takes about 10 minutes. As the experimental setting – as well as real nursing settings – is complex and cannot be interrupted for standard subjective measurement methods, we use the eye tracking method for measuring cognitive parameters. We propose the use of mobile *pupil labs* binocular glasses that include two infrared (IR) spectrum eye cameras for dark pupil detection and a scene camera. The mobile using solution makes the pupil labs glasses very flexible as well as the very low weight of 37gr which supports the flexible research setting.

Additionally to physiological measures of workload, we use an adapted form of the UTAUT questionnaire including some questions addressing MWL and leaving out questions not matching to our research question. We already conducted pre-tests, each execution with another proband. The planned sample size is a minimum number of 90 probands, divided into two groups considering differences between "digital natives" and people over the age of 40.

Results

The first pre-tests – conducted by a group of students – showed the practicability of the study design and the potential of the method of eye tracking to measure MWL during a high demanding task situation. The pupil labs glasses only weigh around 37 grams and as reported by probands are well suited and pleasant to wear for a long time (around 15min). Wearing the eye tracker reportedly does not disturb the visual field of the proband, nor do the wires that are connecting it to the mobile phone. Those parameters ensure that the probands in this stationary – but as well as probands in more flexible – study designs are not extra loaded by the eye tracker. We asked our pre-test probands if the simulated area the experiment is performed in, felt like a realistic scenario for them. As one main goal of our study is to test eye tracking on its plausibility and practicability in a real nursing setting, it was important to create a realistic scenario. We optimized some objects concerning critic points the probands pointed out, like adding more hospital associated decoration to the walls.

Measuring stress via eye tracking in the first step means extracting data concerning pupil width. As we wanted do define MWL in interaction with technology (in this case: human robot interaction), we focus on extracting pupil width data at timestamps that refer to the collaboration of the proband and the collaborative robot. First data analyses within the pupil labs software resulted in a great amount of data as the world camera produces additional data. The results in the test setting are promising as parameters of pupil width and fixation were recognized correctly and could be correlated to specific situations in a qualitative manner. As Pupil Capture ejects a gaze map directly after recording, we could already point out that fixations on the robot took much longer than needed actually. While the robot already paused, the probands still fixated his arm.

While it does not seem reasonable to assess results to our UTAUT questionnaire with only n = 3 probands, we asked our probands about comprehensibility and content-related relevance.; we changed the wording of some questions to improve critical aspects

Discussion

We discussed possible extensions of the UTAUT model and identified first hints for MWL as a possible predictor to influence acceptance of new supporting technologies used in health care settings (MIS and Robots). This study demonstrated that it is feasible to use eye tracking in a real setting as glasses are small and lightweight. The investigation of an experimental setting including a collaborative robot seems to be a good starting point for testing our hypotheses in a protected realistic – but laboratory setting. Our goal was to validate whether the eye tracking method can be transferred to similar settings, we see some first results.

Nevertheless, there are some limitations which are relevant to consider. In the current setting we worked with inexperienced students, there was less equipment (i.e. medical records, information systems) and fewer sources which attracted attention (i.e. no interaction with other colleagues). Although the simulation is as close as possible to a real scenario, we expect more distraction in a real clinical setting. Therefore, our results may be less transferable.

Conclusions

We conducted a first pre-test for the eye tracking method as a valid measurement method for measuring MWL. While first pre-tests showed some promising hints for further studies, we identified the need for reducing relevant data as well as the need for another method measuring MWL to correlate the matching parameters.

Nursing Informatics as a Specialization in India: Present and Future

S. K. Meher, Sanjay Gupta, Shailendra Sharma, Mohamed Ibrahim M, Kamal Ajmera

Department of Computer Facility, All India Institute of Medical sciences, Ansari Nagar, New Delhi, India

Abstract

Nurse informatics specialist is the new concept in India moreover it's a kind of challenge in the highly populated All India Institute of medical sciences, a quaternary care premium medical institute in India to digitalise all the medical / administrative paper work.

The paper emphasizes on nature of duties for nursing Informatics practicner, desirable skills, challenges and finally implementing nursing Informatics concept in India, in All india Institute of Medical sciences. For the first time the nursing informatics concept is used and implemented in India, and I am the part of this concept. I will be further sharing my experiences of Nursing informatics practice in India.

Keywords:
Nursing Informatics, NIS, NI future.

Introduction

Nursing informatics is a career that focuses on finding ways to improve information management and communications in nursing to improve efficiency, reduce costs and enhance the quality of patient care.

The Institute has comprehensive facilities for teaching, research and patient-care. As provided in the Act, AIIMS conducts teaching programs in medical and para-medical courses both at undergraduate and postgraduate levels and awards its own degrees. Teaching and research are conducted in 52 disciplines. In the field of medical research AIIMS is the lead, having more than 1500 research publications by its faculty and researchers in a year. AIIMS also runs a College of Nursing and trains students for B.Sc. (Hons.), Nursing (Post-certificate) degrees.

Primary emphasis of nursing care is Documentation so the main emphasis of nursing informatics too is documentation and patient education. It's well known fact that quality care depends on effective communication among healthcare providers, since healthcare providers communicate primarily through the notes they write in a patient's health record/ in-patient chart, nurse informaticists seek to continually improve the speed, timeliness and accuracy of patient charting. The doctor can access all the patient records from anywhere and anytime at his own ease, which increases the efficiency of doctor and decreases his anxiety about patient's condition. When health workers have access to more up-to-date, complete patient notes, they can make better decisions about patient's care.

Some of the nurse informatics specialists perform patient care duties but most focus on developing, improving, testing or training nurses to use EMR and different modules of Hospital information system. Recognizing the potential of nurse informatics to improve quality care and reduce costs, some hospitals and health systems are creating staff roles for nurse informaticists.

Their titles include clinical analyst, informatics nurse specialist, and director of clinical informatics or clinical informatics coordinator.

Methods

The fully in house developed Hospital Information system is implemented first time in AIIMS, New Delhi. the system includes all the modules of HIS including ADT, laboratory management, Inventory management system, Stores management system, radiology module, OT management system etc. once the HIS developed and implemented in the hospital there was the requirement of trained man power to manage and further train others. Then the volunteers were asked from the Nursing practitioners to be part of it, and new concept of nursing informatics was born in India. The highly motivated and dedicated 60 nurses were selected and they were trained. They were successful managing the system with the help of IT staff. I was the team leader of the Nursing Informatics practitioners

Nurses are the major users of the EHR in the hospital because they use most of the modules of HIS and are responsible for a large portion of the documentation that addresses quality measures, safety measures and the overall clinical picture of the patient.

Need of nursing informatics in hospital information system:

- Analyse clinical and financial data.
- Promote and facilitate access to resources and references.
- Provide nursing content in standardized languages.
- Enable cost saving and productivity goal.
- Nurses focused to get a device that are integrated, voice activated, handheld, use biometrics, provide translation are portable are wireless, auto settle, and are mainly smart.
- Greater nurse satisfaction leads to greater patient satisfaction.

- Nurse Informaticists promote and facilitate access to resources and references'.
- Support for their mission to deliver high quality, evidence based care.
- Support for better services by facilitating true interdisciplinary care.
- Improvement in key relationships with provider and care recipients.
- Enable cost saving, time saving and productivity goal.
- Facilitate change management
- Enhance continuity of care
- Support and improve health information system
- . In All India Institute of medical sciences we have started our manual lab system to completely computerised lab results, tracking is also a most useful and productive part in health care system.
- In All India Institute of medical sciences Nurse informatics specialist helped hospital information system to full digitalise stores and all inventory system in hospital.
- We have successfully made all paper note and documents electronic.

Researchers are also been done and available through hospital information system

Results

Information management is integrated into nursing process and to digitize Assessment, Planning, Implementations, evaluation of nursing practice and complete healthcare system.

Discussion

The role of Nursing Informatics is to Standardized Documentation by collection of information

And its Management by reconciling the patient data.

They are the key to successful implementation of any electronic health related activities.

It plays a major role in Research and Evidence Collection

Conclusions

Nursing Informatics is developing field of study that is highly interdisciplinary. It is strongly connected to education, business and computer sciences.

Result and Effectiveness of Malicious E-mail Response Training in a Hospital

Hye Sook Lee, Da Na Jeong, Su In Lee, Shin Hae Lee, Kyung Hwan Kim, Hae Young Lee, Hyun Jai Cho, Sae Won Choi, Taehoon Ko

Office of Hospital Information, Seoul National University Hospital

Abstract

Malicious e-mails sent intentionally to institutions have caused an increase in data breaches. Measures against these methods must be taken by healthcare institutions to prevent leakage of sensitive personal medical information. As a form of training, we conducted a phishing simulation to gauge the response of the hospital staff to similar email attacks, and to raise awareness about information security protocols.

Keywords:
Education, Electronic mail, Hospital.

Introduction

In recent years, risk of personal information leakage has increased due to malicious e-mails sent intentionally by hackers. [1] These malicious e-mails are usually sent to staff accounts [2] and can infect the employee's computer to compromise and damage important data when opened. The infected computer can then be used to spread to other computers through the intranet and cause secondary damages. Because personal health information is extremely sensitive information, data leak involving hospital records may result in serious harm to the patients involved and damage the reputation of the hospital. For these reasons, Seoul National University Hospital (SNUH) has preemptively conducted malicious e-mail simulation training. This training is designed not only to understand the level of security awareness of the hospital employees, but also to prevent information leakage by raising the awareness of the employees.

Methods

Malicious e-mail response training was organized by the Office of Hospital Information of Seoul National University Hospital and was conducted with support from an external security consulting company. Employees who have intranet accounts with access to hospital information system, general staff of the information office and human resources department, system administrators of other departments, and clinical fellows were selected as the target group.

Response training was organized in three stages: preparation, training, and analysis. In the preparation stage, the target group was selected after setting up a response training plan. Information protection and personal information protection campaigns were conducted through banners and notices on the hospital intranet to raise employee's awareness. In the training stage, a fake phishing mail was randomly sent to the subjects in three different scenarios: modification guide of personal information from a shopping mall, penalty payment from Seoul Gangnam police station, and notice about certificate leakage by malicious code. The reaction information was collected and divided into cases of just reading, clicking on a link, or downloading an attachment. All cases were considered to be infected by malicious code and subjects were notified via a pop-up to contact information security officer of the information/system security team. In the analysis stage, the results of the response training were analyzed to derive future security strategy.

Results

Among 405 employees targeted, 222 people (55%) viewed the malicious mail, 63 people (16%) of the viewers clicked on the link, and 66 (16%) people downloaded the attachment. Of the 222 people required to report malicious mail, 70 (32%) reported the incident to the information/system security team.

The details of the training, risk of malicious code infection, and compliance were shared through intranet with the entire hospital staff.

Conclusions

The number of reports of suspected malicious mail to the information security team increased after the malicious email response training. It is expected that the awareness of personal information protection will be improved by expanding the number of trainees in the future and periodically conducting malicious e-mail response training with scenarios modified to better suit the hospital's characteristics.

Comparison of Medical/Health Informatics Education at the Best Global Universities for Clinical Medicine in Mainland China, Japan and South Korea

Jialin Liu [a b], Siru Liu [c], Yong Li[a]

[a] *Department of Medical Informatics, West China Medical School, Sichuan University, Chengdu, China;*
[b] *Department of Otolaryngology, West China Hospital, Sichuan University, Chengdu, China*
[c] *Department of Biomedical Informatics, University of Utah, Salt Lake City, USA*

Abstract

The aim of this study is to better understand the differences between medical/health informatics education in mainland China, Japan and South Korea. We compared medical/health informatics education at the top 10 universities in these three countries. Japan and South Korea have developed modernized education systems in medical/health informatics showing core features in the education of medical/health informatics. The universities in mainland China offer very few curriculum systems for medical/health informatics.

Keywords:

Education, Health informatics, Medical informatics

Introduction

Education in medical/health informatics has been discussed from various points of view around the world. The need for education in medical/health informatics has also been well recognized [1]. Curriculum development is a core issue, and there is a medical/health informatics program designed particularly for undergraduate and graduate students in medical school [2]. Asian countries such as Japan, mainland China, and South Korea have developed medical/health informatics programs. Compared with Japan and South Korea, the development of medical/health informatics as a discipline in mainland China is relatively lagging behind [3]. This study is to provide an overview of the medical/health informatics education in these countries and compare them. The aim of this study is to better understand the differences between medical/health informatics education in mainland China, Japan, and South Korea in order to further advance the development of medical/health informatics in mainland China and other developing countries.

Methods

We chose the top 10 universities for clinical medicine in mainland China, Japan and South Korea according to the U.S. News Rankings from 2018 [4]. We gathered information directly from the websites of the selected universities. Some information was found through Google and Baidu by constructing a query composed of one or more keywords. The search terms used were combinations of "education," "medical informatics," "health informatics", "undergraduate medical education," "graduate medical education," "curriculum", "course" and "university name". All the data were collected through the websites of government agencies, universities, academic societies, associations of practitioners, and relevant organizations. These data were categorized into undergraduate medical/health education, and graduate medical/health education, and the educational system in each category was compared across the countries.

Results

According to the U.S. News Rankings 2018, the top 10 universities for clinical medicine in mainland China, Japan and South Korea rank: 1. Japan from 85 to 299 (mean rank 204.5, mean score 57.86±4.57); 2. mainland China from 125 to 336 (mean rank 227.5, mean score 56.22±5.59); 3. South Korea from 72 to 418 (mean rank 248.5, mean score 55.18±8.30) (Table 1). According to the top 10 universities for clinical medicine in Japan, medical/health informatics courses are taken by both undergraduate and graduate students. Among the top 10 universities in South Korea, nine of them provide medical/health informatics course for both undergraduate and graduate students. However, among the top 10 universities in mainland China, they have not offered medical/health informatics courses.

Table 1. The Top 10 Universities in Mainland China, Japan and South Korea (clinical medicine)

No.	Mainland China	Japan	South Korea
1	Peking Univ.	Univ. of Tokyo	Seoul Nat'l Univ.

Discussion

This study selected higher education institutions in three major Asian countries to analyze, compare, and contrast their medical/health informatics education. The top 10 universities have shown strength in producing research and developing disciplines. Therefore, we examined the medical/health informatics curriculum system in the top 10 universities for clinical medicine in mainland China, Japan, and South Korea. The curriculum development is a core component in the educational process[5]. The curriculum development in medical/health informatics has an exceptionally broad scope. It is not only about the students, the teachers, and the school, but also about the development of society and the discipline. Through studying the design of medical/health informatics curriculums in these universities, we may better understand the development of medical/health informatics in the countries. There are no medical/health informatics curriculum systems in the top 10 universities in mainland China. The result may be associated with the scarcity of teaching staff and professionals with comprehensive backgrounds in medical informatics, and the unclear teaching direction of the discipline in mainland China [3]. This comparison study provided information about the further development of medical/health informatics education in mainland China and developing countries. The educational needs of health and medical informatics should be well recognized and provide various forms of educational opportunities [6,7]. The findings of this study may facilitate medical/health informatics curriculum development in mainland China and developing countries.

The data collection in this study was based on official websites. Due to funding, time, and regional limitations, there is a lack of survey data, which may have some impact on the accuracy of this research output on medical/health informatics education.

Conclusions

Medical/health informatics has been recognized as a standard curriculum in the top 10 universities in Japan and South Korea. However, there is not a standard curriculum of medical/health informatics in the top 10 universities in mainland China. The design of the medical/health educational systems in Japan and South Korea may provide useful information for the development of medical/health informatics education in mainland China and other developing countries.

Abstract

The aim of this study was to understand status and trends in health/medical informatics research. We used the Scopus database to extract all papers published in Studies in Health Technology and Informatics from 2008 to 2017. This study presented the key bibliometric indicators such as annual publications, top 10 authors, institutions, countries, and co-occurrence of keywords. These findings can be used to enhance our understanding of health/medical informatics research.

Keywords:
Health informatics, Medical informatics, Research, Bibliometrics

Introduction

The Studies in Health Technology and Informatics is a book series published by IOS Press. "This book series was started in 1990 to promote research conducted under the auspices of the EC programmes' Advanced Informatics in Medicine (AIM) and Biomedical and Health Research (BHR) bioengineering branch" [1]. It presents the proceedings of many international health/medical informatics conferences (e.g. MedInfo). The book series "has developed into a highly visible global platform for the dissemination of original research in this field, containing more than 250 volumes of high-quality works from all over the world" [2]. Our study aimed to provide a macroscopic overview of the main characteristics of the book series based on a bibliometric analysis and visualization map. It will bring a panoramic view of health/medical informatics research to scholars and help them to identify suitable researching orientation as well.

Methods

A literature search was conducted in Scopus for publications from January 1, 2008 to December 31, 2017, and used the following publication name: "Studies in Health Technology and Informatics". All data were collected by two authors and downloaded in text format.

After that, the records including all essential information (such as paper title, abstract, keywords, authors' names, affiliations, and references) were compiled for further analysis. Data extraction and analysis were performed using Microsoft Excel 2016. VOSviewer (Leiden University, Netherlands), a software tool for constructing and visualizing bibliometric networks, was used to construct a knowledge map of all keywords relations.

Results

Of the 8129 articles retrieved, the majority were conference papers (n = 7227, 88.90%), articles (n = 682, 8.39%), editorials (n=123, 1.51%), reviews (n = 59, 0.73%) and conference reviews (n=38, 0.47%). They were all published in English. Subject areas included medicine (33.4%), engineering (33.3%) and health professions (33.3%). Figure 1 shows the annual distribution of publications from 2008-2017.

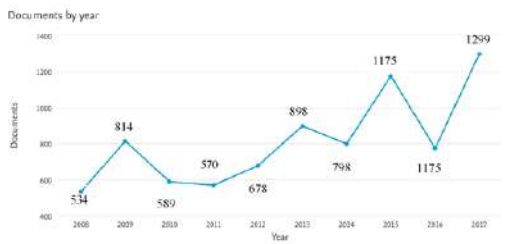

Figure 1 Annual distribution of publications

Institutions and Countries

The publications of Studies in Health Technology and Informatics originate from 111 different countries/regions and 14374 institutions/organizations. The top 10 productive institutions and countries are shown in Table 1. The greatest amount of research activity contribution in countries was from the United States (n=1592, 19.6%), followed by Germany (n = 818, 10.1%) and Canada (n = 660, 8.1%). The University of Victoria was the most productive institution (n = 284, 3.5%), followed by Inserm (n = 215, 2.6%), and Aalborg University (n= 155, 1.9%).

Contributing Authors

17476 authors contributed the 8129 papers. The top 10 most prolific authors in the book series, with their number of publications, are shown in Table 2. Borycki EM clearly obtains the first position with 95 (1.17%) articles.

Co-occurrence of author keywords analysis

The period ranging from 2008 to 2017 included 13438 keywords from 8129 articles, 1047 keywords appeared 5 or more times. The term maps show 500 keywords having the greatest total link strength (Fig 2a, 2b). It grouped 12 clusters. The most common keywords are "electronic health record/records", "virtual reality", "telemedicine", "ehealth" and "patient safety".

Table 1 Top 10 most productive institution and countries

No.	Institution	Record	Country	Record
1	Univ of Victoria (Canada)	284 3.5%	USA	1592 19.6%
2	Inserm (France)	215 2.6%	Germany	818 10.1%
3	Aalborg Univ (Denmark)	155 1.9%	Canada	660 8.1%
4	Univ of Athens (Greece)	110 1.4%	UK	560 6.9%

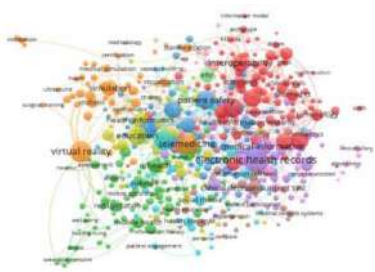

Figure 2a Network visual keywords analysis

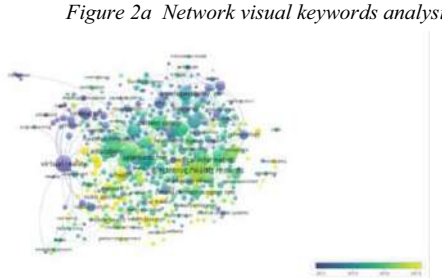

Figure 2b Overlay visualization keyword analysis

Discussion

The number of articles produced annually has obviously increased over this period (2008-2017). The number of publications has been considered a measure of scientific productivity and interest in health informatics research.

A co-occurrence analysis of authors keywords of the publications can provide insight into the main topics and research trends in health/medical informatics. In co-occurrence, the relatedness of terms is determined based on the number of publications in which two terms occur together. The result of the terms analysis is presented in Figure 2a-2b. The size of the circles represents the occurrence of a term (the bigger the circle, the higher the occurrence of a term in the author keywords). The overall distance between terms offers information on their relatedness. The shorter the distance between two terms, the stronger their relation. The relatedness of terms is determined by counting the number of times that terms occur together in the keywords [3]. The colors are used to distinguish between different clusters. The term map of overlay visualization is the timeline view of the network (Figure 2b). The color of a term indicates the term's average publication year (the terms with yellow show the times with more recent publication year). It shows chronologically the most applied keywords which are "big data", "universal design'', "mhealth", "social media", "health literacy", and "vocabulary". This transformation shows researchers are increasingly interested in these research themes.

Conclusions

These outcomes help us perceive the evolution of research in the field of health/medical informatics over a 10 year period. The study also shows Studies in Health Technology and Informatics is an important global conference proceeding in digital health and health/medical informatics.

Educational Game as an Aid to Good Practices in Dentistry

Maria Lúcia Bezerra Feitosa[a], Márcia Maria Pereira Rendeiro[a], Ana Emília Figueiredo de Oliveira[b]

[a] *State University of Rio de Janeiro (UERJ), Rio de Janeiro RJ, Brazil,*
[b] *Federal University of Maranhão (UFMA), São Luís, Maranhão, Brazil*

Abstract

The use of games may constitute an innovative strategy for training.

Objective: Develop an educational quiz type game, construct 60 assessment items and validate this content.

Methodology: Elaboration of the didactic-pedagogical project,

development of the game, creation of the assessment items and validation of the content.

Results: the technical evaluation obtained a Content Validity Index (CVI) over 80%.

Conclusions: The game can be used as a tool for making information available, thus contributing to the democratization of knowledge.

Keywords:
Experimental games, dentistry, infection control.

Introduction

Provision of health care is always associated with occupational hazards related to work practice. In several studies, there is a lack of compliance with current legislation concerning biosafety norms, which draws attention to the need for professional training [1,2]. Several researches are proposing the use of Serious game as an interactive, playful object, as well as a learning facilitator and supporter [3,4].This study aims to develop an educational game and validate, pedagogically and technically, the 60 assessment items to be used within the game, as an aid to educational practices on biosafety in Dentistry.

Methods

Elaboration of the Didactic-Pedagogical Project

The game, called "Biosafety in Dentistry", consists of 60 assessment items created from the main theme and arranged in a database. This number of items allows the random use of 20 questions in each game. The defined target player involves dental surgeons, undergraduate and graduate students in Dentistry. The developed assessment items underwent pedagogical and technical validation.

Development of the Serious Game / Motivation strategies

The educational game uses a 2D interface. The technologies used to develop this tool are three (03): Unity3D®, the game engine, Adobe Illustrator CS6®, arts authoring tool and Ableton Live®, for background sound editing.

To develop the game, participation and interaction of several professionals was necessary, all from several areas such as: Pedagogy, Technology, Health, Graphic and Instructional Design.

This computational system was developed and registered at the National Institute of Industrial Property (Portuguese acronym INPI), through process nº 51 2017 000649 0, by the Federal University of Maranhão Foundation - UFMA.

Five (05) developmental scenes were created, which are listed below.

Figure 1- Game opening

Figure 2- Character selection

Figure 3- Tutorial

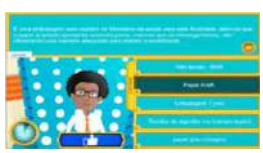

Figure 4- Gameplay

Figure 5- Final ranking

The game presents different tools and strategies: tutorials, scores, response time, opportunities to get tips and ranking, as well as the game topics, images and sounds, with characters in motion.

Creation of Assessment Items

The content is related to biosafety standards and hazard prevention.

Pedagogical Validation

It was carried out with the support of (02) evaluators of the Pedagogical Department of the Universidade Aberta do Sistema único de Saúde (UNA-SUS) and of the UFMA.

Technical Validation

The questions on the biosafety in Dentistry game were evaluated by (05) professionals of reference in biosafety, with expertise in the area.

Results

The 60 questions were submitted to the statistical analysis of data. For this analysis, the Content Validity Index (CVI) was used.

The concordance index between them was > 80%, referring to the criteria of textual clarity, practical relevance, suitability to the target player and response time.

Conclusions

At the end of this study, we conclude that the objectives of developing an educational quiz type game on biosafety and validating the 60 questions were pedagogically and technically achieved, with values over 80% for all the analysed criteria.

[f]*Department of Medicine, University of Montenegro, Podgorica, Montenegro,*
[g]*University Mediterranean, Podgorica, Montenegro,*
[h]*Institute of Modern Technology Montenegro, Podgorica, Montenegro*

Abstract

Montenegro plans to enhance and modernize the curricula and programs in public health fields in line with EU standards and hence the Erasmus-Phelim project developed a framework to develop, implement, and evaluate the education process. A stepwise approach consisting of three dimensions per step was implemented for workshop development.. For the evaluation, a train-the-trainer approach was developed and a self-regulation concept consisting of three phases was applied.. Semi-structured interviews with the workshop participants were conducted and results suggested that self-regulation is an understandable concept and can be applied as a training and knowledge transfer method.

Keywords:
Education, Public Health Professional, Self Concept

Introduction

Montenegro plans to enhance and modernize the curricula and programs in public health fields in line with EU standards. For this purpose the Erasmus-Phelim project developed a framework to plan, implement, and evaluate the educational process in an attempt to improve public health professionals' skills in creating sustainable and flexible health system that delivers good quality health care services and protects health of the citizens [1]. It is an important opportunity to explore to make educational activities, services, and programs an integral part of the community and to ensure their longevity [2]. Additionally, the sustainable educational approach will be developed at all levels from undergraduate to doctoral level that, includes evidence-based approach through innovative National Platform for Education and Research in Public Health.

During our project implementation, the educational activities required a train-the-trainer approach to workshops in which the Self-regulation concept was applied as shown in Figure 1. It consists of three phases: Forethought, Performance Control and Self-reflection [3].

Figure 1 – The Three Phases of the Self-regulation Concept

Furthermore, selected awareness programs about health prevention and public health promotion campaigns were communicated with Montenegrin citizens to engage them with public health issues and to improve the public health.

Methods

A new master's degree program was designed based on an analysis of the current academic programs in other European countries. A stepwise approach consisting of five phases was implemented during the project, with each step consisting of three dimensions by simultaneous and coherent actions. For the planned workshops, a train-the-trainer approach was developed and the Self-regulation concept was applied. The Self-regulation encompasses three phases: Forethought, Performance Control, and Self-reflection. Qualitative semi-structured interview with the workshop participants were conducted.

Results

The Stepwise Approach

A cyclical stepwise approach was implemented as illustrated in Figure 2. The first step was to provide detailed analyses of public health education in Montenegro and cross-matched with best EU standards and practices. The second step required the creation of core elements of formal educational system in public health (including all levels, from undergraduate to post-graduate studies, including master's and doctoral studies). At the third stage sustainable strategies for training of professionals in multidisciplinary public health fields were established. In the final step, evaluation of training strategy was implemented.

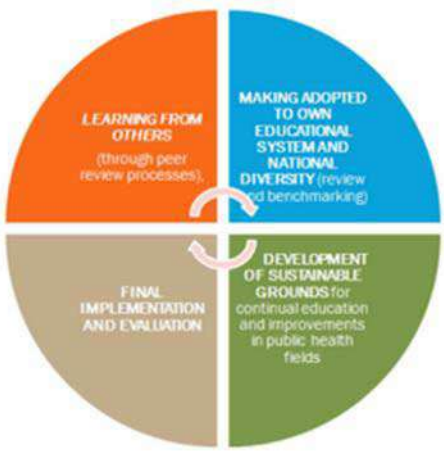

Figure 2 – The Stepwise Approach in Enhancing the StudyPprograms

The stepwise approach consists of three dimensions as shown in Figure 3 including the development of the curricula and training activities, the ongoing quality assurance of educational process. The public health promotion results are demonstrated in Figure 4.

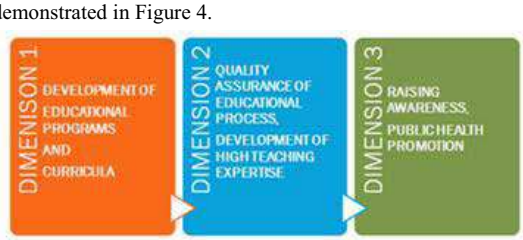

Figure 3 – The Three Dimensions of theStepwise Approach

Within this framework , the Self-regulation concept was applied in two training workshops. Qualitative Semi-structured interviews with the nineteen workshop participants were conducted and the results are shown in Figure 4.

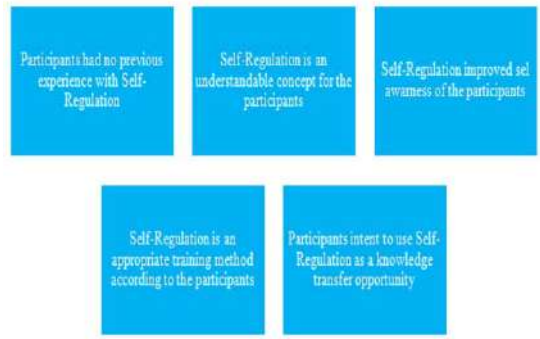

Figure 4– The Results of the Semi-structured Interviews

Conclusions

A stepwise approach for the development of the education process in Montenegro was applied, with each step consisting of three dimensions. A train-the-trainer approach was developed during the workshops and the Self-regulation concept was applied. The qualitative semi-structured interviews with the participants of the workshops suggested that Self-regulation was an understandable concept that can be used as an appropriate training method and a knowledge transfer opportunity to improve participants self-awarness.

Construction of a Home Digital Signage System to Promote Walking as a Physical Activity

Akira Ochiai[a], Tadamasa Takemura[a]

[a] *Graduate School of Applied Informatics, University of Hyogo, Kobe City, Hyogo Prefecture, Japan*

Abstract

Physical inactivity is a social problem related to health. Based on the concept of health communication, this study aims to construct a mechanism to provide continuous information to improve physical activity. We built a "home digital signage system" which consists of a function of collecting the localized information from the websites and distributing to the tablets. The results of the introduction of this system have been suggested to promote walking by increasing media exposure.

Keywords:

Health Communication, Exercise, Information Seeking Behavior

Introduction

Physical inactivity is thought to increase the risk of non-communicable diseases [1]. World Health Organization (WHO) guidelines for physical activity are recommended for walking that is easy to carry out with walking or shopping. The target values are also shown. However, in Japan, the number of steps from 2010 to 2015 tends to be flat [2]. With regard to such social problems related to health, there is health communication as a concept to effectively transform the behavior of the person. Health communication is defined that a process of promoting behavioral transformation and social change through message exchange and improving health results [3]. There are previous studies on health communication which carried out the campaign of improvement of physical activity and eating habits in the inter-mountain areas of Japan. Shimazaki et al. investigated the characteristics of the target group in advance and distributed the messages prepared according to gender and lifestyle through various information media. As a result, paper media such as leaflets and public relations magazines distributed to all households are reported to be effective [4]. The high awareness of information from media with many opportunities to see it is explained in the media exposure theory in a study that showed the impact of the provision of health information by mass media. The media exposure theory has been suggested how much exposure to health information affects information perception and behavior [5; 6]. However, providing continuous information in a wide area through paper media is difficult.

On the other hand, mass-media such as television, newspapers and magazines can provide to a wide area, but we have expected that the information becomes uniform and the cost becomes high. Meanwhile, the network environment has been improved, and it is becoming possible to provide dynamic information using a system that can always communicate. In advertisement media, digital signage for dynamically presenting information is spreading. Digital signage is possible to constantly display information in the living space, change to information of high interest according to the situation of the area and individual, and continuously provide information for a long time. This characteristic may increase media exposure.

Therefore, in this study, we built a digital signage system for home as a mechanism to promote walking as physical activity using information terminals such as tablet-type devices to continuously provide information according to the situation. We also examined whether information provision by these mechanisms affects the promotion of walking as physical activity.

Methods

Review of system requirements

We examined the mechanism of "home digital signage" from three perspectives: home digital signage terminal, information gathering, and distribution, user interface (UI).

Home digital signage terminal

We considered that digital signage terminals installed indoors need different requirements from the conventional terminals installed outdoors. Our preliminary interview about the size and installation place suggested to use tablets as terminals because most opinions were that "it is better not to be too big" and "I want to put it in a living room with a TV". In this study, we used iPad Air and installed in easy to see places.

Information collecting and distribution

There were many possible targets for information reminding of physical activity, but this time we focused on walking and used local information; nearby events, shopping facilities, tourist guides, and restaurant guides. These were based on our hypothesis “local information leads to leaving the house.”

In order to keep updating the information, we have needed a mechanism to automatically collect by using web scraping. However, due to the websites of the data sources often uploading data in the form of non-machine-readable content, we also needed human intervention. Regarding to distribution, the information should be automatically sent to the terminals.

User interface

Previous studies on methods of presenting health information have shown that using images and simple letters contribute to understanding of contents [7; 8], so the system should use images when available. With reference to the criteria for sighted people, including the elderly [9], the height of letters in this system should be set the body to 9 mm and the title to 12 mm. The animation sliding from the right to the left is easy to notice that the screen has switched [10], so we adopted a left slide show. The display time could be considered for 30 seconds with reference to the display time of one slide in a large digital signage tends to be 11 seconds or more and 30 seconds or less.

System construction

This system consists of a function to collect contents and a function to distribute contents to digital signage terminals. MySQL for database as technology, Python program for web scraping, content delivery, and screen display using HTML, PHP, and JavaScript.

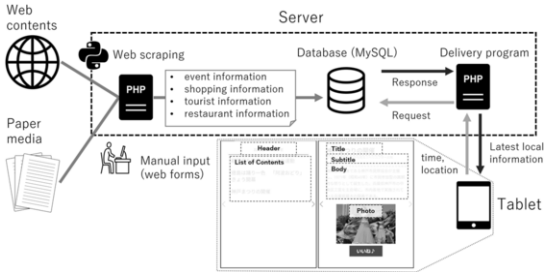

Figure 1– System outline and screenshot

As a specific operation, web scraping is periodically executed on the server, and information such as the date and time, location and contents of event information and shopping information is collected. In cases where web scraping would be difficult, we used input forms to obtain information directly. The collected information is accumulated in the database on the server as the distribution content of the digital signage. The tablets terminals periodically accesses the server to extract the latest local information, download the content to be delivered in webpage format, and display it.

Evaluation

In order to evaluate the influence on the promotion of media exposure and physical activity by this system, we conducted a hearing survey and measured the number of steps for subjects. We interviewed about the awareness of information and the willingness to practice walking, which are considered as factors related to the implementation of physical activity in the media exposure theory. The subjects recruited middle-aged and elderly non-workers in order to eliminate the influence of commuting. For ethical considerations, we explained that the purpose of this survey, protection of personal information, and right to cancel in the case such as negative condition occurred. There were three subjects: a man in his 90's, a woman in her 80's, and woman in her 50's. We investigated the frequency of access to the home digital signage terminals and the intention to go outside to walk. We also measured the number of steps through the wearable activity monitor "Fitbit Charge 2" for five days before the introduction of the system and for five days afterward. Fearing that the introduction of an activity monitor could influence the subjects' activity, we had them wear the activity monitors for a month to get used to them.

Results

With our constructed system, we were able to continuously display information to the digital signage terminal installed at home. The daily average number of steps increased after the introduction of the system (Table 1).

Table 1– Comparison of the daily average number of steps

Subject	Old	Sex	Before	After	Diff.
A	50s	Female	4,707	5,332	+625
B	80s	Female	2,482	2,603	+121
C	90s	Male	2,286	2,814	+528

The subjects answered that they would access the terminal once every one to three hours, for reasons such as "I wanted to know whether there was any new information" and "I checked it because it changes every once in a while." Regarding their will to walk after the introduction of the system, they made comments including the following: "I would see information on events and, when going out for other business, stop at the events" "In a month's time, I feel like I would go out and shop more" "I feel more stimulated to walk" "If the weather and my physical condition allow, I want to go out".

Conclusions

With this system, it became possible to continuously present the collected information. Subjects are browsing about once every 1 to 3 hours in anticipation of displaying the latest information, and the home digital signage system is thought to be effective in increasing media exposure. From the results of the step count data and the hearing survey, it has been suggested to promote walking by increasing media exposure. However, further examinations are required to assess the system's long-term effects on physical activity.

Abstract

With the increase of foreign residents in Japan, most of them are suffering from inadequate health information. In reference to an ethnography, we conducted fieldwork using a participant observation and an interview with 36 foreign Muslim women. Our study clarified they especially needed health information on childcare because of a lack of such information in their native languages, and needed the support of Japanese Muslims because of problems in communication with healthcare personnel.

Keywords:

Information Seeking Behavior, Cross-Cultural Comparison, Islam

Introduction

The number of foreign residents living in Japan has recently exceeded 2.3 million. Because they are living in a different cultural society, foreign residents tend to face language problems, difficulties accessing the healthcare service system, and preconceptions by Japanese people [1]. Moreover, it has been suggested that emotional and informational support is the most important for foreign mothers [2]. Studies of immigrant health that work with immigrant institutions are an important part of health promotion [3]. According to earlier research, faith communities can be effective partners in reducing health disparities among residents and promoting community health. An American study underscores the potential utility of sermons for health education programs and health behavior interventions in American mosques [4]. However, few studies on medical care focus on the community of foreign residents, especially regarding female Muslims.

Our study, therefore, targets Muslim women who experience many religious limitations and cultural differences in a Japanese context. In addition, we also wanted to present the actual situation of healthcare information shared among them using a social networking service. Our results may provide suggestions for health centers and medical institutions regarding potential support for those foreign residents.

The purpose of this study is to clarify the needs for health information by Muslim women and the role that mosques play to protect the health of foreign resident women and ensure they receive the proper healthcare.

Methods

In reference to an ethnography, we perfromed fieldwork to describe the basic behavior patterns of individuals and groups in this specific culture. In addition, we used the following models proposed by Leininger to understand participant groups because of differences between the researcher and participants in terms of country of origin, culture, and religion.

1. Stranger-Friend Model
2. Observation-Participation- Reflection Model (OPR)

Participants

Participants in this study were women, aged 20 and older who visited an Islamic religious institution (mosque) in "A" Prefecture.

Data collection

Participant observation

When the study began, we were not acquainted with any of the participants. Therefore, we first participated in worship services, dinners, study sessions, and meetings at the religious institution and started to observe the conversations and actions of the participants. We deepened our understanding of their circumstances and backgrounds by simply observing for a certain period of time before beginning to participate in a more direct way. We determined key informants who were regarded as reflecting the norms, values, beliefs, and general lifestyles of the culture, and who were usually interested in and willing to participate in the study. We consistently evaluated the relationship with the group, and when the relationship deepened, we strengthened our position as insiders and collected information. We recorded data in field notes instead of using a recording device.

Interview

After we examined the detailed information shared by participants during the observation process, if necessary, we individually questioned key informants about details with help from other Muslims who could speak Japanese.

Ethical considerations

All data collection began after IRB approval (17-1486). We obtained oral agreements during observations and informed consent from participants at interviews.

Data analysis

Before analyzing the data, we clarified our own personal faith, cultural backgrounds, and particular factors that would bias the data analysis. We scrutinized descriptions of the interviews based on a content analysis method. We analyzed and categorized the data from both "emic" (as an insider) and "etic" (as an outsider) viewpoints. In addition, we endeavored to analyze the data within its cultural context by confirming the content that we had obtained through interviews with key informants.

Results

Informant attributes

The 36 informants were in their 20's–50's. The participants came from countries in Asia and Africa: Afghanistan, Iraq, Indonesia, Uzbekistan, Egypt, Syria, Bangladesh, Malaysia, and Japan.

Results from participant observation

We summarized three themes from the 20 sessions of participant observation.

Emotional support

In the community room in the mosque, dinner was offered between worship times in the afternoon and evening every Saturday. The worship attendants could freely participate in the meal.

Strict times were observed for entering the room where the meal was held to keep men and women separate. A female researcher participated in the times for women. Therefore, we could observe the situation while only women and their children ate dinner. The participants formed groups of several people, talked, and sometimes shared information. Indonesian women, in particular, gathered together in groups of five or six each time and chatted pleasantly during dinner.

> *"Here [in the mosque, people are] the most reliable. Their [original] country is the same [as mine] and they are Muslim. There are some Indonesians who gave up coming to pray because [they live in] Japan. People visiting here are really reliable. [They are] friends."*

Discussions about childcare

Informants frequently conversed about childcare. These conversations included a varieth of content, such as school and after-school club activities. Sometimes, participants discussed topics related to Islam, such as

> *"Even if tomorrow is Eid[Islamic celebration], I will not let [my daughter] be absent from school [tomorrow]."*

In addition, the Malaysian participant described her experience of consulting with a Malaysian who had recently come to Japan.

> *"Vaccination. Japanese [vaccinations] are different from Malaysian [vaccinations]. Indeed, Japan has fewer [kinds]. She asked me what her children should have because [her children] may go back to Malaysia in the future".*

Requests for supports

In the Japanese mosque, Japanese Muslims are often asked by foreign Muslims to explain and translate school and hospital documents. We observed that Japanese Muslims explained referrals to a large hospital to foreign Muslims.

One Japanese Muslim who was very supportive of foreigners said,

> *"They ask me for various things such as reading [Japanese] documents. Sometimes I clearly express the Japanese in other words, then I feel [that it is] not my specialty..."* .

In addition, an Indonesian Muslim stated the following:

> *"Local anesthesia makes my heart beat fast. Though I told the dentist about that, he said just "relaaaax." He doesn't trust and understand me because I'm a foreigner"* .

Some foreigners feel that doctors do not carefully listen to what they say because they are foreigners.

Conclusions

Community within mosqus as emotional support

Even though they live in a cross-cultural society, the participants have developed emotional connections with people sharing a common attribute, such as religion or country of origin. Although they utilized a social networking service [SNS], they still needed face-to-face communication with each other. Further observation is required to determine how some groups, other than Indonesians, discuss and share information.

Concerns about childcare topics and requests for information about childcare

Conversations about childcare occurred frequently, indicating that these were topics that concerned participants a great deal. Because they were part of cultural and religious minorities, the participants faced troubles concerning their childcare and discussed those issues with each other. Future research should clarify these problems more concretely.

Support by Japanese Muslims

In addition to the support provided by participants from the same country, our results indicate that foreign Muslims often asked Japanese Muslims, whose nationalities are Japanese, for their support which could not be provided by SNS. Although Japanese Muslims did not have special knowledge about the topic of consultation, they easily understood the participants' problems because they usually talked with them. In addition, sometimes Japanese Muslims stood between foreign Muslims and other native Japanese, which made it easier to communicate even if the other Japanese person was prejudiced against foreigners. We should clarify the role of Japanese Muslims as advocates. These results could provide useful suggestions for improving the understanding of healthcare workers at health centers when they contact those foreigners.

mHealth Apps for Self-Management of Chronic Conditions in France: What Is out There?

Luiza Prado[a], Camille Carpentier[a,b], Marie Préau[b], Anne-Marie Schott[a], Alexandra Dima[a]

[a] EA 7425 Health Services and Performance Research, Université Claude Bernard Lyon 1, Lyon, France
[b] EA 4163 Groupe de Recherche en Psychologie Sociale, Université Lumière Lyon 2, Lyon, France

Abstract

mHealth apps use is rapidly increasing and has high potential value for people with chronic conditions, supporting behaviour change for self-management and improving patient-provider communication. To build a well-functioning app development environment, we need to examine the range of available apps according to their variability and content. A review of Google Play apps revealed limited availability for chronic self-management in France among substantial unrelated content. Most apps' content was difficult to understand and act upon.

Keywords:

Telemedicine, Chronic Disease, Self-Management

Introduction

mHealth apps are widely downloaded worldwide; over half of mobile phone users in the US have downloaded at least one health-related app in 2015 [1]. As people tend to carry their smartphones with them at all times, apps have the potential to help people improve their lives through learning to cope with different situations [2]. For chronic conditions, behaviour change is essential for reaching and maintaining quality of life and preventing premature death [3][4]. Best benefits can be achieved by targeting mHealth to the 4 groups of chronic conditions responsible for more than 70% of deaths worldwide: cardiovascular diseases, cancer, respiratory diseases, and diabetes [5]. Additionally, to evaluate if these tools are effective in supporting behaviour change, it is useful to consider them as health-related materials. As such, the information presented needs to be accurate; easily understood by persons with different communication competencies, styles, and health literacy levels; and must offer suggestions of actions the user can take concerning health events to optimize their reach and enhance health decision making [6].

We reviewed mHealth apps available in France on Google Play store in April 2018 to examine their content and relevance for self-management of chronic conditions. Here, we aimed to better understand the current offer to guide future improvements in the development and use of these tools, using the two main ways of finding self-management apps on marketplaces: the "TOP" list and keyword search. We also assessed the selected apps' understandability and actionability levels using the Patient Education Material Assessment Tool for audiovisual materials (PEMAT-A/V) [7]. This work is part of a larger project that evaluated mHealth apps in chronic conditions.

Methods

We extracted the first 500 free and 55 paid apps labeled as "TOP" on the "Médecine" category on Google Play store. We considered 500 apps to be a representative sample, and 55 was the display limit for paid apps. We also performed a keyword search using 12 popular words related to the 4 groups of conditions mentioned before (e.g., maladie cardiaque, accident vasculaire cérébral, maladie respiratoire, cancer, diabète). We included the first 20 apps for each keyword. Name, description, number of downloads, stars, ratings, version, last update, and developer information were extracted for all the apps. Apps in French were classified in 8 categories according to their store descriptions (Chronic conditions, Reproductive health, Students and professionals, Information for the general public, Nutrition, Pranks and fake tests, Other). This was an inductive categorization, following previous studies [8]. Each category was then subdivided following specific app purpose described on the marketplace. We compared the number of chronic condition self-management apps identified with "TOP" versus "keyword" search strategies.

When possible, apps were downloaded and assessed using PEMAT-A/V, a systematic method to evaluate and compare understandability and actionability of patient education materials. It includes 13 items in five topics (Content, Word Choice & Style, Organization, Layout & Design, and Use of Visual Aids) to evaluate understandability, and 4 items for actionability. Each item was rated with 0 (If Disagree) or 1 (If Agree), while not applicable items were labeled "N/A."

Results

Figure 1 shows the screening process for selecting the apps analyzed in this review.

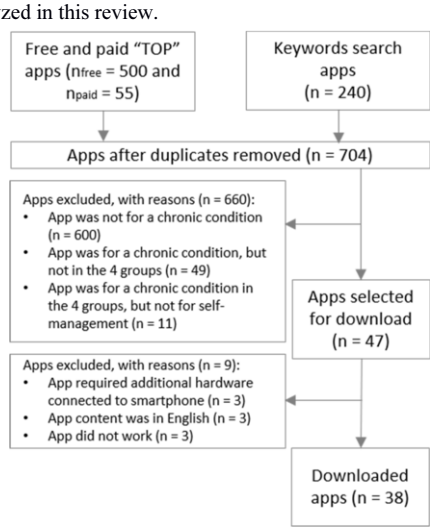

Figure 1 - Apps screening process

Of the 704 apps included after duplicate removal, 167 apps (23.72 %) were not in French (Table 1). From the 541 apps in French, 104 (14.77 %) targeted a chronic condition (such as migraine, back pain, speaking and hearing disorders, mental disorders, etc.). The "Other" category (17.47 %) comprised apps for finding the geographic location of pharmacies or defibrillators, for calling emergency services, for clinical analysis laboratories or hospitals, etc.

Table 1 - Apps categories and examples of subcategories

Categories	Examples	Freq	%
Chronic conditions	Cardiovascular diseases; Respiratory diseases; Diabetes and weight disorders; Chronic pain	104	14.77
Other	Health insurance, hospitals, laboratories; Games	123	17.47
Students and professionals	Interactive learning; Diagnostic, treatment or dosage aid	120	17.05
Information for the general public	Anatomy, biology, medical terms and tests; Diabetes and nutrition; Cancer	90	12.78
Reproductive health	Period tracking; Pregnancy, baby growth, delivery	48	6.82
Pranks and fake tests	Glucose, blood pressure, cholesterol, HIV fake tests	25	3.55
Consultations	Find professionals and book appointments; Home and online consultations	20	2.84
Nutrition	Food and weight diary	7	0.99
Other language	English; Spanish; Portuguese	167	23.72

In the "Chronic Conditions" category, 47 apps targeted self-management of conditions in the 4 groups with highest mortality risk. Of these, 22 were found only in the keyword search, 18 only in the "TOP" list, and 7 in both searches. Therefore, the keyword search resulted in finding 29 mHealth self-management apps out of 240 (12.1 %).

We were able to download and analyze 38 of these apps and understandability and actionability scores were computed (Table 2). Twenty-six apps (68.4%) presented understandability levels below 50% and 25 (65.8%) apps had null actionability scores.

Table 2 – Number of apps by PEMAT scores quartiles (range 0-100%)

	0-25%	*26-50%*	*51-75%*	*76-100%*
Understandability	*8*	*18*	*8*	*4*
Actionability	*25*	*5*	*4*	*4*

Conclusions

We conducted a descriptive analysis of mHealth apps available in France on Google Play store. We found a limited number of apps supporting self-management for people with chronic conditions in a considerably diverse market. Using keywords related to these conditions did not necessarily lead to finding more relevant self-management mHealth apps.

Apps presented low scores of understandability and actionability, which means users may not understand the information and may not be supported to take action. This is likely to limit the potential of these apps to help people with chronic illness to make positive changes on how they manage their condition in their daily lives.

It is important to mention that among the list of apps described here, there were several apps of questionable utility posing considerable risks of misinterpretation and dangerous health-related decisions, such as pranks and fake tests, especially for blood glucose and blood pressure measurement.

Potential users of mHealth apps, including both patients and healthcare providers, might require support to search and select relevant apps for themselves or their patients' needs. Research on mHealth apps selection and use patterns is required to inform the efficient adoption of such technology.

InfoSAGE: Usage Pattern of a Family-Centric Care Coordination Online Platform

Yuri Quintana[a,b], Juan Henao[a], Eli Kaldany[a], Max Gorenbeg[a], Yi-Pei Chen[a], May ADRA[a,b], Lewis Lipsitz[c], Charles Safran[a,b]

[a] Division of Clinical Informatics, Beth Israel Deaconess Medical Center, Boston, MA, USA
[b] Harvard Medical School, Boston, MA, USA
[c] Institute for Aging Research, Hebrew SeniorLife, Boston, MA

Abstract

Globally, there is an expanding elderly population, and families are finding it increasingly challenging to coordinate care for their older family members. This paper reports on the usage patterns of InfoSAGE, an online private social network that has tools for communication and care coordination for elders and their families. This descriptive analysis describes the types of family networks using the platform and types of functionality most used by elders and their family members.

Keywords:
frail elders, care coordination, smartphone, social networks

Introduction

The population of people over the age of 60 are the fastest growing demographic group worldwide, and are projected to triple from 901 million (12.2%) in 2015 to 3.2 billion in 2100 (28.5%) [1]. By 2050, it is expected that those aged 75 years or older will account for 11.0% of the population, up from 5.4% in 2010. This older population is projected to strain the healthcare system, with an average growth in health expenditure of 5.8% per year, and an estimated 20% of the total economy by 2025 [2]. Furthermore, when compared to previous generations at similar ages, baby-boomers experience higher rates of chronic disease). Families face increasing amounts of information and communication needs between family members involved in the care of frail elders. Those that cannot afford costly long-term care solutions will necessarily turn to family caregivers to fill the gap, with informal caregiving valued at $450 billion in 2009 alone [3]. Informal caregiving is associated with higher levels of stress, poorer quality of life, increased strain on family relationships, and substantial time commitments [4]. Often, informal caregiving falls disproportionately on a single individual, who may act as the coordinator of care in a family structure. Maintaining an accurate medication is a significant problem for elders and studies have shown that 30% - 80% of patients have a discrepancy between the medicines ordered in the hospital and those they were taking at home [5]. Caregivers and elders are increasing using the Internet for health care information and care coordination tools [6]. The use of communication applications on the Internet, for the care coordination of elders, has the potential to distribute tasks and alleviate stress among family members. Unfortunately, little has been reported on the use of the Internet or smartphones for those of 75 years and older for care coordination.

Methods

We developed InfoSAGE to understand how online and mobile technologies could families frail elders. The InfoSAGE website (https://www.infosagehealth.org) is a free-to-use Internet platform that is built around an elder that we call the Keystone. This Keystone is connected to care participants, such as family members, care providers, and neighbors and friends. When users sign up for InfoSAGE, they can choose to be an elder or a caregiver. Each family network has a minimum, a family dyad: an elder over 75 years of age (the Keystone) and an identified study partner ('Proxy' or 'Caregiver'), a family member who provides support or care. The platform allows the elder to control who is in their network. The system has a search tool that can be used to search curated resources for elder care; a message board for elder and family communcation; a shared calendar and task list; and a medication manager. Medications can be access-restricted to Keystones and proxies. InfoSAGE allows an elder or proxy to control and restrict access to certain features by type of user. Keystones and proxies can adjust the tiers at any given time. We partnered with local senior organizations, including two large retirement and continuing care communities in metro Boston. These organizations both helped to recruit potential participants and provided early feedback and helped shape the overall project design. We advertised the presence of the site through newsletters and town hall meetings. A member of the study team met with prospective users and families to help with enrollment and the online signing up process. Details of the system features have been described in detail through other works [7].

Results

From January 1, 2014, to April 6, 2018, there were 285 registered users and 18,499 page views. One-hundred-and-sixty-two users provided their year of birth, and 113 did not. Based on those who did report their year of birth, the average age of the Keystone users was 75.5 years, and the average age of the caregiver users was 56.6 years (Keystone median age 82, IQR: 23.5; caregiver median age 56.5, IQR: 11.0). There were 26 dyads (elder and caregiver pairs) that signed up for the detailed survey study. Of these users, 54% self-reported as Caucasian, 4% as African American, and the rest were unknown. Of those who did describe their relationship with a Keystone, 47% were daughters, 25% were sons, 9% were spouses, and 19% were other, including formal caregivers. We looked at what devices were used to log onto the website and, for all users, desktop/laptop devices accounted for 87.6%, while mobile/tablet accounted for 12.4%. Users in the

longitudinal survey were asked 6 months after sign-up "Do you feel comfortable using this system?" and they responded Strongly Agree=6%, Agree=19%, Neutral=56%, Disagree=19%, and Strongly Disagree 0 %. In analyzing our care networks, we observed that family members were distributed across 122 communities, so providing more geo-specific resources could be useful additions. Figure 1 shows a family network.

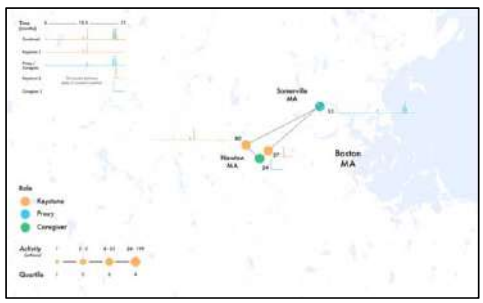

Figure 1 - Example Family Network

Figure 2 compares Keystone usage versus non-Keystone usage. The majority of InfoSAGE networks exist as dyad pairs, which may have resulted from the study design, although 24 family networks consist of three or more users. Network sizes range from one, in networks with a single keystone, to seven users, with several Keystones. The largest networks on InfoSAGE are multi-keystone clusters, encompassing multiple family networks joined by single or multiple users common to each individual network. These extended networks comprise 5% of all networks.

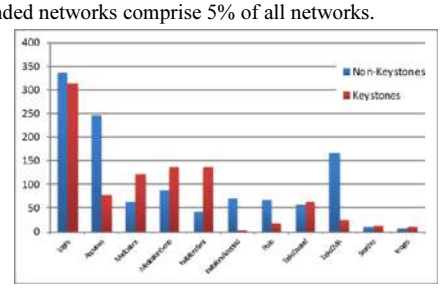

Figure 2 - Keystone usage versus non-Keystone usage

Roles within each network are managed by that network's Keystone or proxy. Of the 285 InfoSAGE users, 157 are keystones, 115 are proxies, 19 are caregivers, and 5 are participants, with 24 users having more than one role due to membership in more than one network. One example of a multirole user is in the case of married elders who are often keystones in their own network and proxy to their spouse.

Acute medical events often require enormous coordination of care, involving the distribution of information, at a sensitive and emotionally distressing time. Networks on InfoSAGE that have had sudden events occur to a family's keystone have seen a surge in task assignment and management, and communication associated therein. One such network had 18 tasks created and assigned over a span of two days, compared to two tasks in the preceding five months. During the following 30-day period, the creation and assignment of tasks returned to 'baseline' levels. This suggests that the ability to organize a list of assignable actions in one central, online source within a family network, that may be geographically dispersed, can bring a measure of order to a chaotic and overwhelming time.

The InfoSAGE platform is more useful if the user (elder or family) is already registered and familiar with the system before needing it, meaning that InfoSAGE, or other technologies like it, designed to support elders in their homes, have many functions and potential uses, such as medication lists, calendars, to-do lists, microblogs, personal stories, etc., that may play a role at different points in care. From a family's perspective, these tools are most useful during the transitions of care. For example, the system may be more valuable during a visit to the emergency room, or a discharge from hospital to home. However, the family needs to be familiar with and using the tools before these transitions occur in order to make information available at the time they are needed.

Reduction in isolation requires greater family support and communication. One barrier to the adoption of InfoSAGE in this context is the family's perception, structure, and support for using the tools. The perception of 'no-need', alternate forms of contact, or if there are no family caregivers, are reasons for non-use. One possible gap here is the difficulty of incorporating formal caregivers (home health aids, visiting nurses, social workers) and informal caregivers within one network. There needs to be more financial models for compensating formal care givers involved in remote care of older adults.

Conclusions

Our study shows that it is feasible to establish an online platform for elders over the age of 75 and their families and caregivers for information exchange and care coordination. Future research will explore barriers of adoption and sustainability in more depth. The barriers may be related to an added time burden for physicians, the lack of an informal or family caregivers, difficulty in accessibility to technology or Internet.

Safe Surgery: Application for Logistic Support for Safe Surgery

Marizete Campioni[a], Grace T M Dal Sasso[b]

[a] *Bridge Laboratory, Federal University of Santa Catarina, Florianópolis,, Santa Catarina, Brazil*
[b] *Health Sciences Center, Federal University of Santa Catarina, Florianópolis, Santa Catarina, Brazil*

Abstract

We developed and evaluated the usability of Check-up Surgery, a surgery application from the mApp® Platform. The Usability Engineering Cycle was used as method of development. The results showed that the Check-up Surgery application had excellent usability criteria with an average of 4.63 to 4.70 by 81% of the evaluators. For all the interviewees there was statistical significance in relation to the usability criteria of the application, with pValue ≤ .05.

mHealth, Medical Informatics, User-Computer Interface

Introduction

Every two years, the Global Patient Safety Alliance organizes a Global Challenge to motivate practitioners' perceptions of health safety and to establish public policies for good health practices [1]. From 2007 to 2008, the Global Challenge of Surgical Safety Practices centered on the implementation from the motto: *Safe surgeries save lives.* Therefore, whatever the reported problem, it must be corrected before the surgery begins [2]. Throughout the world, increased safety in surgical procedures provides dialogue oportunites to deepen the knowledge regarding the surgical act, both for the patient and for the healthcare team [3]. Safe surgeries require communication, teamwork and recognition of the importance of patient safety by the surgical team [4].

Studies also point out that there are still difficulties in fulfilling the WHO objectives checklist and the aspects for this are still unclear. [5].

Communication and information technologies (ICT), in addition to facilitating the dissemination of knowledge in the health area, can also support the critical decision-making of professionals, contributing to the achievement of reliable diagnoses and therapeutic guidelines as well as behaviors qualified intended for patients and users of the service. [6,7]. It is also emphasized that accessing information in real time and/or remotely contributes to resolving health problems/needs in different geographical regions, promoting broad coverage in terms of specialized healthcare, undertaken in the major urban centers. In this scenario, emphasis is placed on the phenomenon of the mobile technologies in particular, the use of applications. Apps are conceptualized as a set of tools designed to undertake specific tasks and jobs [6]. As a result, this study aimed: To develop and analyze the usability of an application for Surgical Safety, from the LAPETEC/GIATE App® Platform.

Methods

The Usability Engineering Cycle was used as method of development of the application. Three people participated in the development: a content designer, an evaluator and a systems programmer. After the application development, the usability assessment was performed by the Usability Instrument based on NBR ISO 9241-11, from June to July 2018. The sample was intentional non-probabilistic and consisted of 32 health professionals from a General Hospital of Florianópolis, Santa Catarina, composed of seven nurses, four anesthesiologists, eight physicians, two administrators, one pharmacist, six information technology professionals and four administrative technicians. For data analysis, statistical and descriptive and inferential statistics were used, with the ANOVA test presented for a 95% confidence interval and a pValue≤.005 significance index. The usability tool is organized into 19 items that correspond to the usability criteria of the application on a likert scale from 1 to 5. Being 5 = Very Good (MB), 3 = Good (B), 2 = Regular (REG) and 1 = Bad (R). It was considered in the evaluation that the values of the average between 1 to 1,5 received the classification (Bad); from 1.51 to 2.5 (Regular); from 2.51 to 3.5 (Good); from 3.51 to 4.5 (Very Good) and from 4.51 to 5 (Excellent). It was also defined as the minimum target average for the application to have usability criteria ≥ 3.

Results

The developed system can be accessed at the following link: http://site.erue.giate.ufsc.br:8080/marizete/.
An example of a developed screen is shown in figure 1.

The application was built to be instructive and allow user autonomy. In the next figure 2, the interrelationship of the components is presented in a graph of dependencies between the application flows. Fuzzy logic was applied. That is, according to the characteristics of the procedure and the patient, the application indicates the necessary materials and advises all the surgical team of the necessary logistics.

It was organized so that the screens are sequential in stages, to signal the information. If you need to replace some information that has already been flagged, you can return to that screen and make the desired change. Once the corrections/changes to the screen have been completed, simply go to the next screen and the flow continues in the direction to complete the planning.

Figure 1 *– Laryngeal procedure screen*

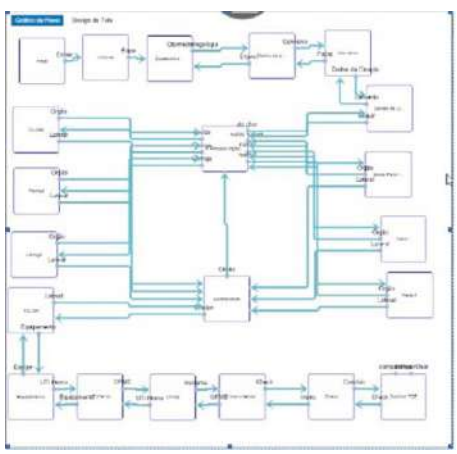

Figure 2: *Dependency Graph among Application Flows*

After application development was complete, the usability instrument was applied, yeilding the following results. The 'excellent' satisfaction rate is 69%, and the 'very good' rating was 21%. Followed by 7% who selected 'good', 3% as 'regular', and 1% 'bad'. The general average among the Administrators was 4.7 (Excellent) and pValue <.0007. The overall average among physicians was 4.75 (Excellent) and pValue<.0000. Among nurses and pharmacist, the overall mean was 4.65 (Excellent) and pValue <.00001. The overall average among IT professionals was 4.01 (very good) with pValue <.001122.

Discussion

The Usability Engineering Cycle, a method used in the development of the Check-up Surgery application, proved efficient and contributed to user-centered construction and followed the steps of analysis, design and testing. The application has usability criteria among the professional categories studied: doctors, nurses, pharmacists, anesthetists and IT professionals with pValue ≤.005. The interactive design based on fuzzy logic allows support for health professionals' decision making for the development of surgery.

Higher means of evaluation were observed by health care professionals directly involved with the patient and were not observed in the institution's managers. The content of the application was developed after extensive observations of the work performed in the institution and after the usability evaluation by the participants, these differences between averages presented by the institution's team can be related to the fact that the main usability problems are the distribution of information in multiple views, identification problems of the selected patient and the confidence of the basic daily tasks in the memory of the users. Thus, the results show that the relationship between usability, errors of use and patient safety should be understood and considered in the design of the health information system [8].

Conclusions

The use of computerized information systems cannot be considered as the solution to all problems of professional practice with regard to safety. This is due in part to concrete cultural changes in the behavior and the work process of the professionals involved, and a action in all decision-making instances. Despite the small sample that represents it, it is understood that this application Check-up Surgery, can contribute to the safe surgery especially for integrating the surgical team in the same information related to the equipment needed for the surgery. This is expected to reduce delays or lack of equipment during surgery and avoid exposing the patient to unnecessary risks.

Abstract

Eye-tracking has long been used to assess usability for the public web. Recently, it is used to assess user behavior with electronic health records (EHRs). We conducted a scoping review of studies involving eye-tracking for usability of EHRs to determine the current state. Three main themes emerged: studies of usual use of systems, development of new methods, and studies of new features. Detailed user behaviors revealed by eye-tracking can contribute valuable information to redesign efforts.

Keywords:

Eye Movements, Electronic Health Records, User-Computer Interface

Introduction

In recent years, the use of eye-tracking has spread from mainstream psychology and usability communities to its use by informaticians to study the use of health information technologies (HIT), particularly, electronic health records (EHRs). As usability of EHRs is a critical problem, we undertook a literature review to determine the current state and what kinds of studies involving eye-tracking are being done in the area of healthcare.

The tool permits detection of where on the screen a user is looking during task performance, giving us a much more precise measure than just clicks, screen transitions, think-aloud, and similar tools. It is routinely used in commercial usability studies and commercial design. The recent development of lower cost eye trackers and built-in eye trackers for certain gaming laptops adds to their availability and usefulness. Here, we review the current EHR usability studies and discuss future possible studies useful for the improvement of EHR design.

Methods

Searches were done in the literature with Pubmed, Google Scholar, CINAHL, web of science, and IEEE. Figure 1 shows the number of articles retrieved, inclusion/exclusion criteria, and final set of 15 articles reviewed here. Search terms were: Eye track* (or eye-track* or eye track*) AND "ElectRONIC MEDICAL Record (or EMR), Eye track* (or eye-track* or eye track*) AND electronic health record (or EHR), Eye track* (or eye-track* or eye track*) AND electronic patient record. English and French articles, qualitative, quantitative, and mixed methods studies including feasibility studies were included. Only completed studies were included.

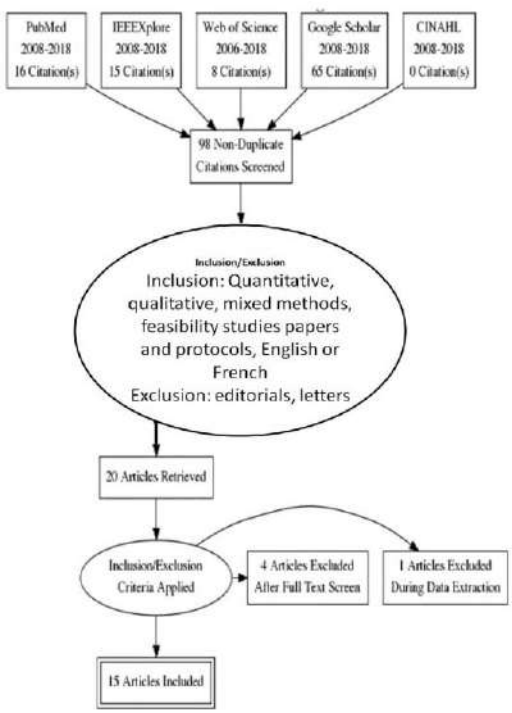

Figure 1 - Literature search and exclusion/inclusion criteria and results

The initial searches retrieved 98 non-duplicate papers after 2005; three researchers (EMB, YS, and JW) excluded 78 articles based on titles and abstracts, leaving 20; five were then excluded after full reading, for a total of 15 covered in this review. These were read and summarized by all the authors, using a summary table including bibliographic information, main research question, study design, sample, setting, outcome measures, results, discussion, limitations, and relevance to our research question. As the focus is how eye-tracking is being used to evaluate EHR usability we did not assess study quality.

Results

Overview

Within the selected studies there were three main areas of focus: use of eye-tracking to understand physician use of their usual

EHRs (five papers), development of new methods (four papers), and use of eye-tracking to evaluate new innovations in EHR design (six papers). Fourteen studies used simulations in academic health center settings. One tested only pharmacists while all others had physician subjects; one also included graduate students. All studies had generally low numbers of subjects (four to 34). Most were conducted in laboratory settings; there were also studies in an empty ICU bay, simulation centre, emergency department, and pharmacy. Both in situ studies had practical difficulties and thus incomplete information.

Findings

New methodological innovations.

King et al. compared performance of high- and low-cost eye trackers and tested the feasibility of automated detection of eye gaze [1] and found it both feasible and 88% accurate, which was adequate for most usability studies. This might become a method for mass collection of user behavior data, paving the way for predictive modelling and delivery suitable to specialty and task.

Studies of routine use of usual systems.

Gold et al. used a simulated rounding task with patient safety issues, finding that performance correlated (p=.0004) with patterns of rapid data scanning, increased numbers of screens viewed, mouse clicks, and saccades [2]. Mosaly et al. compared subjective and objective measures: eyetracking and performance measures, real and predicted [3]. They found heuristic measures are highly accurate in identifying usability issues. Additional measures were useful to identify differences in task complexity, and the unsurprising finding that note structure affects information reviewed. Amster BD et al. found in a simulated handoff task that more than 60% of the time was spent on impression and plan, with a pattern of skimming other sections. This pattern was affected by their level of trust in the author of the note [4]. Calvitti et al. conducted observations in two outpatient clinics to develop a picture of the physician, patient, EHR activity, and workload. They found different EHR functions or interfaces did not result in large differences in use patterns or objective measures [5].

Testing new interaction designs

Belden et al. found collapsible note sections and placement of impression/plan at the top of the note were associated with faster performance on their CET (author-developed Composite Eye-Tracking score) [6]. Moacdieh and Sarter found significant effects of cluttered displays in information extraction time, interaction with stress, noticing tasks, and screen time, but clutter was not significant in search accuracy or duration of specific tasks [7]. Wright et al. tested existing use with in-depth interviews. They discovered needs for dynamic display of new information, configurable displays which aid filtering and trending of the most recent data, and fast proven pathways to reduce navigation complexity [8]. Yoon et al. studied nurses' interpretation of a 3D infectious disease transmission visualization, finding a high degree of engagement and attention, and specific user preferences among the visualizations [9].

Conclusions

Eye-tracking is a useful technique for studying EHR use in three main areas to reveal new details about user cognitive behavior. Further evaluation and validation studies are needed to fully elucidate where it may be used productively in usability assessments and system redesign.

Study of the Usability of an Automated Coding Software for Causes of Death in an African Context

Seydou Golo Barro[a,c], Grégoire Rey[b], Pascal Staccin[a]

[a] Université Nazi Boni, Bobo-Dioulasso,Burkina Faso, [b] CepiDC-Paris,French,
[c] LabSTIC-Santé, Côte d'Azur Université, Nice, French

Abstract

IRIS is an automated coding software for the causes of death. It is used in many European countries for the production of death statistics. The purpose of our work was to study the usability of this software in Africa where the quality of statistics is insufficient. For this, we have developed a device consisting of two software: "collector" and "encoder" cooperating via the same database.

Keywords:

Cause of Death, Automated Data Processing, User-Computer Interface

Introduction

WHO considers that mortality statistics in OECD countries are sufficiently reliable to plan actions to improve health and prevent disease [1]. The reliability of these statistics depends on the quality of the death certificate established by the physician and the quality of the coding of the causes of death [2]. To ensure the quality of mortality data, WHO has developed standard procedures [3]. Despite the existence of these rules, manual coding contains errors and divergent interpretations [3]. That is why developed countries have adopted an automated coding system [4], named "IRIS" [5], consistent with the International Classification of Diseases (ICD) and the American MMDS system [5], [6]. In Burkina Faso, death data is unreliable because there is not yet an effective system of coding the causes of death [7] Mortality statistics are obtained by estimation or by population survey. The objective of this work is to study the possibility of using the IRIS software in an African context.

Methods

In countries where coding software is used, vital statistics data are imported from another source (INSEE for France) and matched with medical data for the production of mortality statistics [8].

In order to personalize IRIS and appreciate its use in the context of Burkina Faso, we have developed an application called "Mimir" that works with a MySQL database interconnected with the IRIS database. Mimir integrates three modules: 1) INSD module which provides the codes of localities of Burkina Faso; 2) ID module for each deceased person; 3) the MDD module in which Medical (textual) information and Demographics Data are filled.

The device was tested on the deaths of the intensive care unit of Souro-Sanou University Hospital Bobo-Dioulasso. The intensive care unit was chosen because it is the department that

has the most varied and complex clinical records. 14 voluntary investigators completed the paper version of death certificates in accordance with WHO rules. Two anesthetists in intensive care were responsible for validating the causes of death. An investigator-coder was responsible for coding the causes of death using the IRIS software.

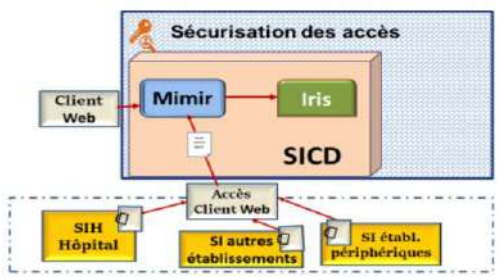

Figure 1: Model of information system on causes of death Usability

An investigator-coder was responsible for proceeding with the coding of causes of death using Mimir linked to IRIS. It was expected that the IRIS encoder could: 1) correctly recover data from Mimir; 2) anonymize death certificates; 3) assign an ICD-10 code to each textual cause of death; 4) automatically select the initial cause of death.

Results

As shown in Figure 2, the IRIS software retrieved all the registered certificates and anonymized them by assigning a unique key. For example, for patient A130027, IRIS automatically assigned a CIM code for each cause of death and selected the underlying cause of death for hematological malignancies (code C9.69) which is the origin of the death. In our study, IRIS was able to automatically encode 90% of the causes of death.

The conclusions of the study favored the deployment of the device at CHUSS. An organizational model has been set up allowing doctors to directly record the death certificate in electronic form or fill out the paper form in case of technical difficulty. All the actors have been trained [9] and the device has been functioning since 2014.

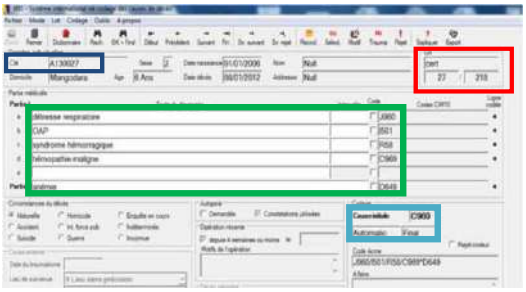

Figure2: Data Recovery and coding of causes of death by IRIS Relevant changes

After twelve months of exploitation, the statistics produced show that diseases of the circulatory system are the most common, followed by infectious diseases and parasites, but attention must also be paid to perinatal conditions.

Table 1: Distribution of causes of death by disease groups

ICD Code	Diseases	Number	%
A00-B99	Certain infectious and parasitic diseases	412	18%
C00-D48	Neoplasms	133	6%
E00-E90	Endocrine, nutritional and metabolic diseases	229	10%
I00-I99	Diseases of the circulatory system	431	19%
J00-J99	Diseases of the respiratory system	67	3%
K00-K93	Diseases of the digestive system	318	14%
L00-L99	Diseases of the skin and subcutaneous tissue	15	1%
N00-N99	Diseases of the genitourinary system	121	5%
O00-O99	Pregnancy, childbirth and the puerperium	96	4%
P00-P96	Certain conditions originating in the perinatal period	293	13%
V01-Y89	External causes of mortality	153	7%
	Total	2268	100%

Conclusions

The results of our study show that IRIS could be used to improve the quality and comparability of mortality statistics in Burkina Faso. Indeed, the coding with Iris can be regarded as reliable and complete because 100% of the certificates are recovered by the software and 90% of the causes are coded automatically [10]. Eventually, the device could be extended to the entire population of the country for the registration of community deaths through a verbal autopsy system [11,12].

Acknowledgements

This work was done as part of the process of modernizing the information system of the Bobo-Dioulasso hospital without special funding. However, the IT infrastructure and stakeholder training were paid from hospital funds.

Data Quality Governance at the Emergency Department: A Qualitative Study Influenced by Grounded Theory in Nine Swedish Emergency Departments

Niclas Skyttberg[a,b] , Joana Vicente [c], Rong Chen[ad] and Sabine Koch[a]

[a]*Health Informatics Centre, LIME, Karolinska Institutet, Sweden*
[b]*InterSystems, Sweden,* [c]*Linnaeus University, Sweden,* [d]*Cambio Healthcare Systems, Sweden*

Abstract

Vital Sign Data Quality is essential for successful implementation of clinical decision support systems in emergency care. Studies have shown that data quality is inadequate and needs improvement. This study shows that data quality is dependent on both technical and human factors and provides a conceptual model of data quality governance and improvement in the emergency department.

Keywords:

Electronic Health Records, Vital Signs, Quality Improvement

Introduction

Vital signs are central to decision making in the emergency department (ED). Vital signs data is used in calculations of risk and warning scores, where clinical decision support systems have shown promise in improving healthcare quality and productivity [1]. However, in order to reuse vital signs data in emergency care for clinical decision support systems, it needs to be correct, complete and current. Previous studies show that data quality in the ED is inadequate [2]. This study aims to explore how the quality of vital signs data may be governed and improved in EDs.

Methods

Qualitative data collection using semi-structured interviews, observations, and collection of documents in the EDs and field notes were performed. Data collection occurred in nine EDs, which were purposefully selected to represent a variety of size, regional spread and academic level. Data was analysed alongside the data collection using thematic analysis with constant comparison of new incoming data and the data already analysed [3]. Parts of the results presented here have been previously published [2].

Inclusion Criteria

This study included registered nurses and medical doctors that had worked a minimum of five years in the emergency care context. The participants were identified through the quality managers at the hospital level or through the head of staff at the included hospitals. Authors identified and invited a total of 16 participants through their e-mail address at work. All invitees accepted to participate in the study.

Data Collection

A total of nineteen interviews were conducted as evenly as possible between the nine sites. The interviews were about 45 minutes long using a semi-structured interview guide. The guide was developed and adjusted after peer-review and a pilot interview at one of the included sites. These aimed to cover participants' experience of data quality management with focus on completeness, currency and correctness [4]. The interviews were performed, either on-site or by telephone, and transcribed from a voice recording. During the data analysis three main workflows in vital sign documentation emerged and three sites were picked to represent these workflows in the observations. Observations were about 60 minutes per site and data were collected using a semi-structured observational protocol. During the observations, field notes were taken and additional documentation with relevance to vital sign data quality were collected.

Data Analysis

The transcribed recordings were analysed, coded and abstracted into categories and themes. This was done continuously using constant comparison during data collection. Coding and abstraction were performed separately by two of the researchers. However, discussions were held continuously on the emerging results within the research team, leading to an evolving model of data quality governance in EDs. Observational data and collected material from the EDs were included in the analysis. Over time fewer new codes emerged and the major concepts and themes stabilized. Upon researcher consensus that saturation had been reached, three additional interviews were performed with the participants to confirm the findings.

Ethics and Personal Integrity

The study was approved by the Stockholm Ethical Committee (Dnr 2014/1207-31/4). The researchers contacted the managers at the included sites, and they were able to grant permission to contact selected staff through work email. Each participant was given written information in advance and informed consent forms were collected for the study. All participation was voluntary, and participants had to opt-in for the data collection and they were given the right to opt-out at any stage during the analysis. Data were anonymized after collection and all participants were assured that no published information would be traceable.

Results

Three main outputs emerged from the analysis: identification of main workflows of vital sign documentation in EDs, categorization of factors influencing data quality, and creation of a conceptual model as to how these factors affect data quality governance and improvement in the ED.

Vital Sign Documentation Workflow

Only four out of nine hospitals documented vital signs data directly in the electronic health record. Five of the sites still used documentation based on paper-based templates. The main reasons behind the persisting paper-based workflows related to the interoperability and management categories described below.

Factors Influencing Data Quality

Human and technical factors were found to be the main themes affecting data quality at EDs as presented in Table 1 and Figure 1. All sub-categories had an impact on all aspects of data quality as described by Weiskopf and Weng [4], but the contribution to each one of the aspects varied between the sub-categories detailed in Table 1.

Table 1- Themes and categories affecting data quality and the order of impact on data quality aspects

Influencing Factors			Data Quality Aspects ○ Completeness √ Correctness ⏱ Currency		
Technical Factors	Interoperability and Functionality	Interoperability between systems and/or devices	○		√

	User needs	Workflow support	○	√	
		Documentation support		○	√

The results show that in order to improve data completeness and currency, interoperability and user needs are the most important factors. To improve correctness, standardization, education and competence were revealed to be the main contributing factors.

Data Quality Governance Model

The way main categories and themes influence data quality development and governance are described in a circular model (Figure 1). The governance and improvement cycle was found to start with a step that aimed to standardize the workflow and structure the documentation. In this step participants mentioned that documentation should have been connected to standardized terminology and specific keywords. Using such standards was perceived to link the documentation to the emergency care context. In the next step, results showed that both education and training were necessary to make the new workflow known and implemented. Management factors were perceived as important to ensure there was compliance in the organization to the agreed workflows, as well for follow-up and feedback on outcomes in the EDs. Such feedback was perceived to improve compliance and stimulate quality improvement initiatives. If there was lack of data in the follow-ups, the workflow effectiveness had to be evaluated and here the user needs would need to be balanced with the support provided by the functionality in the information systems. When required functionality would ideally improve and increase. An example mentioned was new functionality for the automatic calculation of national early warning scores. When such functionality was added it opened opportunities for new and more structured workflows to be developed, implemented and evaluated. This governance and improvement cycle were perceived to impact all three data quality categories: correctness, completeness and currency.

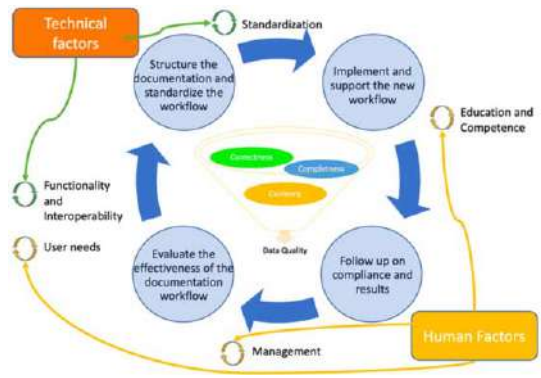

Figure 1 – The impact of human and technical factors on data quality governance in the emergency department

Conclusion

This study shows that the documentation workflow in Swedish EDs is still surprisingly manual and paper-based. Further, results show how technical and human factors impact data quality governance and improvement process in Swedish EDs. The study findings are relevant to anyone who wishes to improve data quality or reuse data from the EDs.

The Use of Theory in Mobile Health Interventions for Patient Self-Management of Chronic Diseases

Ting Song[a,b], Siyu Qian[a,b], Tingru Cui[a], Ping Yu[a,b]

[b] *Illawarra Health and Medical Research Institute, University of Wollongong, Wollongong, New South Wales, Australia*

Abstract

This study aims to investigate the use of theory in mobile health interventions for patient self-management of chronic conditions, with a focus on hypertension. We identified six theories in ten studies that were reviewed. These included Health Belief Model, Social Cognitive Theory, Self-Determination Theory, Theory of Planned Behavior, Transtheoretic Model, and Technology Acceptance Model. The findings are useful for further advancement of mobile health interventions to support chronic disease management.

Keywords:

mHealth; Social Theory; Self-Management

Introduction

Mobile Health (mHealth) interventions have provided patients with a unique opportunity to engage in self-management of hypertensive conditions. For example, patients with hypertension can use a mobile phone-based application to ensure their medication intake on time, to maintain a healthy lifestyle, and to monitor their blood pressure anytime, anywhere. In comparison of non-theory based interventions, theory-based mHealth interventions have been found more effective in changing health behavior [1-3]. Therefore, this study aims to investigate the use of theory in mHealth interventions that support patient self-management of hypertension. It focuses on addressing the following two questions:

- Q1: What are the theories commonly used to guide mHealth interventions that support patient self-management of hypertension? How are these theories used?
- Q2: To what extent are these theories reported?

Methods

A literature review was conducted following the guideline of Preferred Reporting Items for Systematic Reviews and Meta-Analyses [4]. We searched seven electronic databases in June 2018: Scopus, PubMed, PMC, CINAHL Plus with full text, MEDLINE with full text, PsycARTICLE, and PsycINFO. Terms and MeSH headings, such as "mHealth", "self-management", and "hypertension", were used in combination to identify English publications from 2009 to 2018 by the first author. Also, we conducted a manual search to ensure adequate coverage. The first two authors carried out the literature screening separately as per the following criteria, with further judgement by the fourth author if any disagreement occurred. Inclusion criteria were empirical studies that reported (1) mHealth hypertension intervention, (2) at least one theory, and (3) hypertension-related outcomes. Exclusion criteria (1) were studies in which the theory has nothing to do with the intervention, and (2) were reviews, protocols, or guidelines in the topic area. The Mixed Methods Appraisal Tool assessed quality [5].

Data were extracted using Endnote and an Excel spreadsheet, and data were synthesized and analyzed using an inductive method. Theory Coding Scheme developed by Michie and Prestwich was applied to evaluate the extent to which the theories were applied in each study [3]. As reported, use of theory was an inclusion criterion for our selection of studies; all studies selected satisfied the measurement item "theory/model of behavior mentioned", and thus, did not require any further assessment. Another two items, "quality of measures" and "randomization of participants to condition", were seen as irrelevant to the purpose of this review and were thus excluded. Therefore, the extent of theory application to each study was measured in two steps. First, we used the 21-item scheme to evaluate each study. If a study conformed to the statement of a measurement item, "yes" was recorded, and the study was scored 1, otherwise "no" was recorded, and the study was scored 0. Second, these items were further grouped into six categories of the Theory Coding Scheme (see Table 1), the number of items in each of these categories were 2, 7, 2, 2, 9, 2, respectively. In each category, every item was worth one score. Therefore, the total scores for each category were 2, 7, 2, 2, 9, 2, respectively. Afterwards, we calculated the mean score and the proportion of the record "yes" to evaluate the extent to which these theories were reported.

Results

Ten papers were eligible for inclusion into the review (see Figure 1). They all met at least three criteria of the Mixed Methods Appraisal Tool, indicating high methodological quality of these studies.

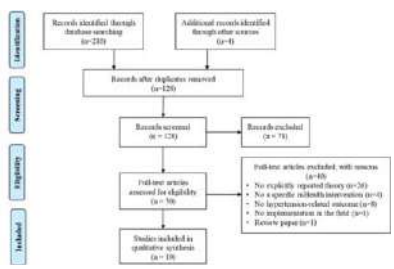

Figure 1– Literature Search and Screening Process

Q1: What are the theories commonly used to guide mHealth interventions that support patient self-management of hypertension? How are these theories used?

Six commonly used theories to guide mHealth interventions for patient self-management of hypertension are: Health Belief Model (HBM), Social Cognitive Theory (SCT), Self-Determination Theory (SDT), Theory of Planned Behavior (TPB), Transtheoretical Model (TM), and Technology Acceptance Model (TAM). Related constructs or processes to which these theories applied are mapping to the design, implementation, and evaluation of the mHealth interventions (see Figure 2).

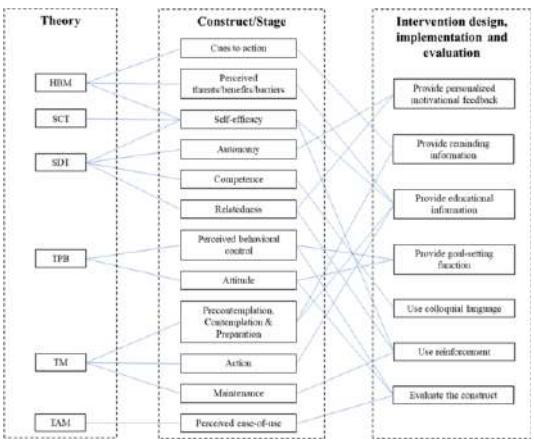

Figure 2– The Relations Among the Six Theories, Their Constructs, and the Corresponding mHealth Interventions

Q2: To what extent are these theories reported?

The mean scores for the six categories were shown in Table 1. Studies reported "Reference to underpinning theory" to a large extent. "Targeting of relevant theoretical constructs" was reported to a medium extent. "Using theory to select recipients or tailor interventions", "Measurement of constructs", and "Testing of mediation effects" were reported to a less extent. None of the included studies reported refinement of a theory.

Table 1– Frequency of Studies that Cover a Particular Category in the Theory Coding Scheme

Theory coding scheme category [3]	Item [3]	Total score	Mean score (%)
Reference to underpinning theory	1, 2	2	1.7 (85)
Targeting of relevant theoretical constructs	1, 4, 6-10	7	4.2 (60)
Using theory to select recipients or tailor interventions	4, 6	2	0.6 (30)
Measurement of constructs	11, 12	2	0.7 (35)
Testing of mediation effects	11-19	9	2.3 (26)
Refining theory	20-21	2	0 (0)

Conclusions

This review identified six commonly used theories to guide mHealth interventions for patient self-management of hypertension: HBM, SCT, TPB, TDM, TTM, and TAM. Most studies only mentioned the use of theory. Several studies described the relevant theoretical constructs. Only a few studies used theory to select recipients, tailor interventions, measure constructs, or test mediation effects. No study reported refinement of the theories. The results are useful for improving the design of future interventions for hypertension management as well as other chronic diseases.

Three Methods for Engaging Patients and Care Partners in Patient Portal Research

Gillian Strudwick[a], Craig Kuziemsky[b], Richard Booth[c], Sarah Rossetti[d], Anna Chyjek[a], Moshe Sakal[a], Alexandra Harris[e], John Strauss[a]

[a]*Information Management Group, Centre for Addiction and Mental Health, Toronto, Ontario, Canada*

[d]*Department of Biomedical Informatics and School of Nursing, Columbia University, New York, USA*
[e]*Trillium Health Partners, Mississauga, Ontario, Canada*

Abstract

There has been a significant increase in the volume of research conducted on patient portals in recent years. Similarly, there has been a number of benefits described in the literature when patients are engaged in research at all stages. This poster will provide an overview of three ways that patients can be engaged in patient portal research. The methods are based on those used in mental health patient portal research in Canada.

Keywords:

Mental health, Patient engagement, Patient portal

Introduction

Patient portals are increasingly being used in health settings globally as a way of providing patients with easier access to their health information, typically in the form of their health professional documentation [1]. Some of these portals also provide patients with features that allow them to book appointments, message a health professional, and obtain educational resources among other uses [2]. As portals become more commonplace, it is expected that there will be an increasing amount of research into the benefits and drawbacks of the technology, impact of the technology on health service utilization, perceptions of professionals and beyond. Given the literature that describes great benefits when patients are engaged in research, it is important that future patient portal research do so moving forward. Thus, this poster will review methods in which patients and care partners can be engaged in research on this topic.

Methods

The three methods described in this poster were used in research aimed at understanding how best to implement a patient portal in a mental health setting, and how to evaluate it [3,4]. The methods were selected based on those deemed feasible and potentially high impact from the literature on patient and care partner engagement in research [5]. They were not meant to be an exhaustive list. This research is on-going at Canada's largest mental health and addiction teaching hospital. Patients and care partners were engaged in all stages of the research. Benefits and drawbacks of the methods will be discussed in the poster.

Results

The three methods of engagement are:

Patient and Care Partner Representatives as a part of the research team: Patients and care partners are often open to contribute to research by being a member of the investigator team. By engaging these important stakeholders, the most important research questions can be identified and feasible data collection methods that involve patients can be uncovered. Other benefits and considerations will be described in the poster.

Engaging with a Patient and Care Partner Advisory Committee: Once research on the topic has been funded, it may be valuable to establish a committee to ensure the research stays on course, to support the many decisions that the researchers have to make, to support the creation of many patient-facing documents (e.g. recruitment materials), and to hold researchers accountable.

User-centered design and usability testing the patient portal with those who will use it: Before launching a portal for use by patients, it will be important to engage patients in the iterative design and development cycle as well as 'testing' it with patients to identify usability challenges. There are numerous simple, fast and cheap ways of doing this.

Conclusions

From the perspective of the researchers, the methods for engaging patients and their care partners in this research has been effective thus far. Findings have specific relevance to mental health patient portal researchers, and could have relevance to numerous studies conducted in the field of health informatics. Next steps may include the development of a toolkit to support others in effectively engaging patients and care partners.

Effectiveness of Cisual Messages to Promote Help-Seeking for Depression

Machi Suka, Takashi Yamauchi, Hiroyuki Yanagisawa

Department of Public Health and Environmental Medicine, the Jikei University School of Medicine, Tokyo, Japan

Abstract

In order to develop more persuasive messaging to promote help-seeking for depression, we created six, differently designed visual messages and tested their effectiveness with possible audience members. Different visual designs brought differences in emotional responses to the message and willingness to use the message. Help-seeking intentions for depression increased significantly after exposure to either the plain text message or the visual messages.

Keywords:
Depression, Emotional Responses, Persuasive

Introduction

Failure and delay in initial treatment contact for mental disorders has been recognized as an important public health problem. Communicating persuasive messages may be useful in solving this problem. However, further evidence is needed to identify strategies for successful, public health messaging with the aim of promoting access to mental health care.

We have undertaken a research project to develop persuasive messages encouraging help-seeking for depression. At the first step, we developed rating scales for measuring the audience's perceptions of effectiveness of health messages [1]. At the second step, we created and pretested depression help-seeking messages, and then found out that the message of 'depression needs treatment' may be most effective in increasing people's help-seeking intentions for depression [2,3]. As the final step, this study attempted to enhance the effectiveness of the message by applying visually appealing design in accordance with the CDC Clear Communication Index (https://www.cdc.gov/ccindex/).

Methods

Development of visual messages

Our depression, help-seeking message consisted of three parts [2,3]. The first part was the main message statement: depression needs treatment - about 80% of untreated patients will not recover. The second part provided information on early signs of depression: depression can be recognized early by mental symptoms such as depressed mood, loss of interest, etc. and physical symptoms such as disturbed sleep, increased fatigue, etc. The last part was the call to action: if you think you might be depressed, speak with your familiar primary care doctor.

Six kinds of visual messages were created by professional designers based on different design concepts (Figure 1). We confirmed that all messages were ideally designed in accordance with the CDC Clear Communication Index.

Assessment of visual messages

Study 1: A web-based survey was conducted in August 2018 among Japanese adults aged 20-34 years (young group) and 60-74 years (old group). Eligible participants (young group n=2,944, old group n=3,237) excluding those who had received treatment for their mental disorders were randomly assigned to one of the six visual messages. After they read the message for at least 15 seconds, they were asked to rate it in terms of persuasiveness, future use, design quality, and emotional response. All items were scored on a 1-to-5 point scale [1-3].

Study 2: A web-based survey was conducted in August 2018 among Japanese adults aged 35-45 years. Those who had not received treatment for their mental disorders and did not report a positive help-seeking intention for depression were selected through a prescreening process. Eligible participants (n=7,017) were randomly divided into four groups: assigned no message, plain text message, and selected visual messages ('Percent' and 'Heart'), respectively. Intension, subjective norm, and attitude toward help-seeking for depression were measured using the vignette methodology after exposure to the message [2,3].

The mean scores were compared using two-way analysis of variance. The prevalence of intention, subjective norm, and attitude toward help-seeking for depression were compared using chi-square test. Significant levels were set at $p<0.05$.

Results

Study 1: The ratings of messages did not differ significantly between the two age groups. Significant differences between the messages were found in the future use, four of the five design quality items, and four of the seven emotional response items. Overall, 'Percent' and 'Heart' were rated relatively high, while 'Greens' and 'Photo' were rated relatively low (Table 1).

Study 2: Compared with the no message group, the other three groups showed significantly greater increases in the prevalence of intention, subjective norm, and attitude toward help-seeking for depression after exposure to the messages. However, no significant differences were observed between the plain text message group and the visual message groups (Table 2).

Conclusions

The application of visually appealing design brought about increasing emotional responses to the messages and willingness to use the messages. Help-seeking intentions for depression increased significantly after exposure to the messages, however the magnitude of this effect was not significanly different between the plain text message and the visual messages.

A Review on Health Information Behavior Study Between 1998 and 2018 in China

Xinglong Tang[a] Shijuan Li[a]

[a] Department of Information Management, Peking University, Beijing, China

Abstract

As a part of our research project (Beijing Social Science Foundation Project, No. 18XCB007), this study aims to provide an overview of the state of art of health information behavior study in China for the past decades. There were 43 studies that met our selection criteria, and they were reviewed regarding to their research objects, methods, and frequent research topics respectively, which provides guidance for future research in this area.

Keywords:
Consumer Health Information; Information Seeking Behavior; Publications

Introduction

Study in health information behavior has been developed rapidly for the past decades, not only in introducing studies abroad to China, but also in bibliometrics analysis [1], model building study [2] and reivews of abroad study such as in elderly health information searching [3], etc.. However, a holistic view of the current state of art of this topic in China is lack.

Methods

Literatures were extracted from three Chinese primary academic resources, including China Academic Journal Network Publishing Database, China Science Periodical Database, China Science and Technology Journal Database. A complex search strategy was utilized, and the search string included "user health informatics", "consumer health informatics", "health information technology", "user health information behavior", "consumer health information behavior" and "health information bahavior". The literature selection process is shown in Figure 1. 309 full text journal papers published between 1998 and 2018 in the Library Information Science (LIS) field were found.

The papers were included if they are: (1) journals papers; (2) written in Chinese; (3) Full-text; (4) in the LIS field. After removing duplication automatically by Endnote and selecting manually, there were 43 papers included finally according to the above selection criteria.

Results

The literatures were reviewed regarding to research objects, research methods and frequently occurred themes.

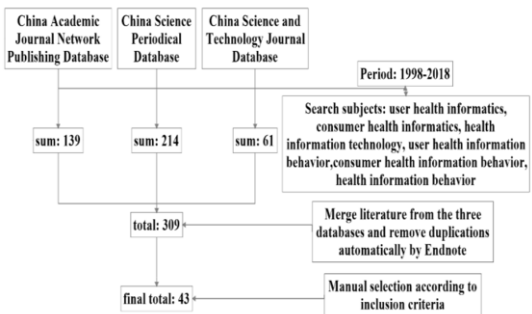

Figure 1– literature search and selection process diagram

Research Objects

The study objects cover both the general consumer [4-9] and specific groups. Especially, the elderly [10-12] and the youths [13; 14] such as undergraduates [15-25] have been paid more attention. Wang's research explored the elderly's health information avoidance behavior, trying to investigate related factors [26]. Other work stated that college students were capable of screening health information in social media [25]. Moreover, specific groups [27], such as public library users [28], sports online community users [29], even Chinese living in the U.S. [30], were paid attention.

Research Methods

Both qualitative and quantitative [31-33] methods were used in the research. Semi-structured interview was utilized to explore the urban and rural young people's health information seeking behavior [14]. Wang etc. used questionnairs to investigate the relationship between two behaviors: browsing sports online community, and purchasing and using smart wrist strap [29]. Moreover, mixed methods were utilized to address the research purpose. Zheng etc. used questionnaires to investigate the participants' related personal characteristics and then interviewed them to have a greater understanding of their attitudes [13].

Frequently Occurred Research Themes

Most frequently occurred research themes in the health information behavior domain fall into three categories: health inforamtion needs, health information seeking and health information adoption.

Health Information Needs

According to Wilson's information behavior model in 1996 [34], health information needs is the precondition of seeking behavior. Cao etc. surveyed public library users' health

information needs with focus on promoting library service [28]. mHealth users' needs were studied, too, by Xu and Zhao. They found mobile health APP users pay more attention to health care, health improvement, medicine and health tracking service information [35]. Limited work has been found that emphasized the information needs of consumers' family members, or carers, or guadians, which is regarded as a research gap found.

Health Information Seeking

This is one of the most prosperous area reviewed. The elderly's health information seeking behavior [10-12], the youths' searching behavior [15; 20; 23; 24] and the public consumers' seeking behavior [7; 9; 19; 20; 36] were all explored. Wu and Yi's experiment for the old adults found out that they have limited capabibliy in searching, and they strongly depend on the quality and credibility of the website [10]. Li etc. compared information seeking behavior between urban and rural youths and led to the concept of "digital gap", however, it's expected to be illustrated in more details [14].

Health Information Adoption

Health information technology acceptance and adoption is another rich publication area in recent years. Li etc. found the factors (credit level of hospital, friends' recommendation, etc.) contribute to the consumers' trust formation, therefore, they have influence on people's acceptance and adoption for health information [18]. As is shown in Hou's work, most users in China are lack of the capability of screening information, and even trust the harmful information [8]. However, the university students were doing better in this [25]. The research objects were restricted to undergraduates, which couldn't lead to a generalization for wider population.

Conclusions

There were 43 studies reviewed, which tried to describe the current research status in China with respect to research objects, research methods and frequently occurred research themes in the field of user health information behavior. Progress has been achieved during the past decades, especially in the Health Information Seeking, and Health Information Adoption area. However, still there are research gaps found, such as the information needs of consumers' family members, or carers, or guadians, etc. Moreover, it has been desired to propose solutions to help disadvantaged groups, such as the elderly, to acquire health information, and suggest proper mechanism especially with the development of innovative information technology.

Should the Picture Archiving and Communication System (PACS) Settings Be Standardized? Questionnaire Survey for Safe Medical Image Management

Takumi Tanikawa [a], Ayako Yagahara[a], Akihisa Fukuda[b], Daisuke Ando[c], Tatsuya Suzuki[d], Kouhei Harada[e], Shuichi Karata[f], Masahito Uesugi[g]

Abstract

The purpose of this research was to record the differences in picture archiving and communication system (PACS) settings in hospitals. A questionnaire survey was conducted among 261 hospitals that used the PACS system in Japan. As a result, the image deletion method in the PACS server, and other rules were different among hospitals. Furthermore, these variations were dependent on settings of each medical institution. It seemed necessary to define standardized rules for safe image management.

Keywords:
Picture Archiving and Communication System, Data Curation, Surveys and Questionnaires

Introduction

The Digital Imaging and Communications in Medicine (DICOM) standard contributes seamless information exchange such as image diagnostic equipment and picture archiving and communication systems (PACS) in medical institutions. Based on DICOM standard, commercial products such as image diagnostic equipment and PACS have already been supplied to many countries around the world, and are mainly operated in medical institutions. Over the decades, based on requirements from customer hospitals or competition among companies, many common functions between these products have developed besides the DICOM standard functions.

The image management function of PACS plays a very important role in maintaining confidentiality, integrity, and availability while electronically preserving medical records. Furthermore, patient history is recorded for trace management, and a mechanism, in accordance with the regulation for electronic preservation of medical records in Japan, is also implemented. However, details of these mechanisms vary from manufacturer to manufacturer, which could be a problem if system specifications or image management functions are not confirmed by user during system installation or operation.

In this study, we conducted a questionnaire survey on the PACS image management targeting the radiological department of hospitals and evaluating variations in management manners and system settings.

Methods

A questionnaire survey was conducted between February and March 2018 in all 261 hospitals having the PACS system in Hokkaido prefecture, Japan [1]. Questionnaires were sent to the system personnel and administrators in the radiology departments of all these hospitals.

The contents consisted of a face sheet and the following two items: 1) rules regarding the PACS receiving image of data that was already registered (whether the PACS server rejected the resent image data or overwrote it?), 2) PACS image deletion method (whether the PACS storage server deleted the image logically or physically). Additionally, if the answer was to reject the image data, indicators that decided the rejection, such as “study instance UID”, “series instance UID”, “SOP instance UID”, “accession no.”, and “AE title”, were subsequently asked. These questions were decided upon as image management functions were different among the different vendors and/or products in PACS. Candidates for each answer are provided by several options, which can be freely described if necessary.

In the face sheet, following items were asked regarding hospital information: number of hospital beds, number of staffs in the radiological department, whether medical information staff were internally assigned in the radiological department, vendor and product names of the current PACS, year in which the current PACS was introduced, and storage size of the PACS.

The survey sheets were sent by mail and collected by web base response sheets (Google Form). This study was conducted with the approval from the Hokkaido University of Science Ethics Committee.

Results

Responses were received from 93 hospitals (response rate: 36%). In computed tomography (CT) examination, 54.8% hospitals always overwrote data if existent image data was resent to PACS, while 40.9% refused to receive data based on certain rules such as “study instance UID” and/or “SOP instance UID”. This trend was similar in computed radiography (CR) and magnetic resonance imaging (MRI) examination. In

67.7% of hospitals, the authority of deleting images from PACS was limited to specific staff, whereas 32.3% had no such limitation. In 50.5% of hospitals, logical deletion was adopted for image deletion from PACS, but 33.3% adopted physical deletion. This trend did not depend on the particular vendor or manufacturer, but on the individual settings of each hospital.

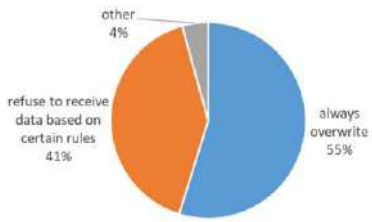

Figure 1. Response in cases of image resent to picture archiving and communication system (PACS) and computed tomography (CT) (n=38)

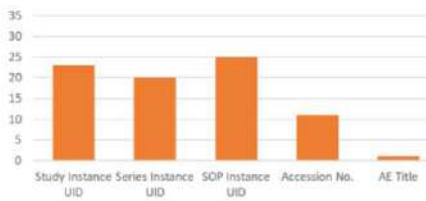

Figure 2. Indicators for refusing to receive data computed tomography (CT) (n=38)

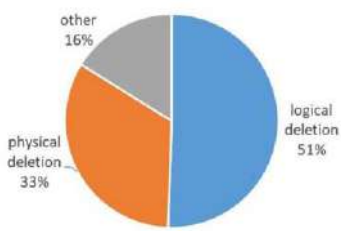

Figure 3. Deletion policy in PACS (n=93)

Discussion

The two methods of image deletion are physical deletion and logical deletion. Physical deletion is a method of deleting images from the storage completely; therefore, once deleted, restoration is extremely difficult. Logical deletion is a method of adding an identifier for hiding an image, and the image is held on the storage in practice. Physical deletion poses the problem of difficulty in restoring the data from the past if the operator mistakenly deletes the image. Although logical deletion is inferior in terms of storage cost, retaining deleted images as history has a larger merit in maintaining important medical records. From the viewpoint of information security and medical safety, it is necessary to standardize the image deletion method.

Images are resent to PACS in case of post-processing the images or modifying the DICOM tag information. Although resending images caused by post-processing has a different frequency among each modality, distribution of overwriting and rejection were almost the same in every modality. SOP instance UID is uniquely numbered to identify the image; however, whether the new number should be registered to the post-processed image has not yet been defined in the DICOM standards. The meaning of "unique" and its reference point are left to the judgement of the operation side, and this fact could be a reason for this variation. With respect to preserving evidence, it is also necessary to standardize the definition of uniqueness of an image, and the handling rule of the image in PACS.

The DICOM standard is a standard for the interface between equipment, so internal functions of the equipment are not covered by the standards. The results of this study indicated that PACS image management method was different among hospitals, and the difference did not depend on vendors or manufacturers but on the setting of each equipment. For the safety management of medical information systems, it is necessary to observe each nation's laws and regulations. Indeed, if this regulation is applied to management of medical images, every vendor and manufacturer would also conform to them. This study focused on the legal gray area. Simple operation of image management using PACS is necessary for the hospital staff. The results of this study indicated the need for standards and regulations in the PACS image deletion method and rules for image data received by PACS of already registered data.

Conclusion

The aim of this study was to record the problems related to the PACS image management function from the view point of medical institutions. Results of the questionnaire survey showed that the image deletion method in the PACS server, and the overwriting rule in case of existent images being re-transmitted to the server were different between different hospitals. Furthermore, these variations were not dependent on the vendors or manufacturers, but on the settings of each hospital. Since the image management method of PACS is not standardized, it was proposed that appropriate regulation was needed for safe management of electric medical record as per the law.

Navigating the Search for Patient Generated Health Data

Victoria L. Tiase[a,b]; Katherine A. Sward[b,c]; Mollie R. Cummins[b,c]

[a] Department of Information Services, NewYork-Presbyterian Hospital, New York, NY, USA; [b] College of Nursing, University of Utah, Salt Lake City, UT, USA; [c]Department of Biomedical Informatics, University of Utah, Salt Lake City, UT, USA

Abstract

With massive amounts of mobile health data generated by patients, there is a growing amount of research conducted to understand their impact on patient care. The MeSH heading for patient generated health data was established in early 2018, complicating searches for PGHD research prior to 2018. In conducting a search of scientific databases, keywords are presented along with their degree of representation in the literature to help inform future searches.

Keywords:

Patient generated health data, patient portals, patient reported outcome measures

Introduction

With the proliferation of mobile health tools and technologies, such as smartphone apps, activity trackers and sensors, patients are generating more data than ever before. As defined by the U.S. Office of the National Coordinator for Health Information Technology, patient generated health data (PGHD) is 'health-related data created, recorded, or gathered by or from patients (or family members or other caregivers) to help address a health concern [1].

To facilitate optimal use of PGHD, methodological research is needed for feasibility, evaluation, metric selection and data modeling [2]. However, the MeSH term for patient generated data was initiated in January 2018, making the search for scientific works prior to that time difficult for researchers. We seek to support research in this area with proactive identification of optimal keywords to utilize in searches.

Methods

An iterative process of multiple searches was conducted using the PubMed database using various keywords related to patient generated health data. A search filter was applied to restrict publication dates to the last 10 years. Documentation of the inclusion and exclusion search terms along with the number of results generated from each keyword search term was recorded in Microsoft Excel. Histograms were created to depict the distribution of search terms relating to patient generated health data.

Results

Approximately twenty-seven search terms were identified. One key finding was the importance of using hyphens with keywords. Some examples of this are patient generated and patient-generated; patient reported and patient-reported; and self tracking and self-tracking. This is an example of one of the graphs that will be reported in the results section of the poster.

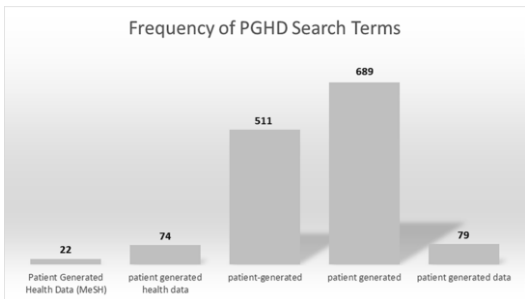

Figure 1 - patient generated health data search terms

Conclusions

Exploring research related to patient-generated health data is important for an understanding of the state of the science in this area. Due to a lack of MeSh terms and the hyphenation of words associated with PGHD, understanding the frequency of keywords can be helpful to researchers in creating search strategies and expediting searches in this area.

A Framework for Applied AI in Healthcare

Tran Truong[a,b], Paige Gilbank[b], Kaleigh Johnson-Cover[b], Adriana Ieraci[b]

[a] Techna Institute, University Health Network, Toronto, Ontario, Canada,
[b] Translational Research Program, University of Toronto, Toronto, Ontario, Canada

Abstract

Significant efforts are being made to develop artificial intelligence technologies for health settings. In a health system that has been notoriously slow to adopt innovative technologies, it is important to consider the implementation of a new technology early in the development stage, especially one that will have added challenges of trust and transparency. To facilitate this process, an implementation framework for artificial intelligence technologies in clinical settings has been created.

Keywords:

Artificial Intelligence, Health Information Systems, Data Science

Introduction

As technology advances and the use of Aritifical Intelligence (AI) technology is adopted in various fields, there are increasing efforts to develop AI technology for healthcare applications. Within the class of AI technology, Machine Learning (ML) systems are being developed that draw from statistics, mathematics, rule-based systems and biological systems to create solutions that can adapt and learn, thus reducing manual burden. Private companies are building ML into medical decision-making, pursuing tools that support physicians [1]. Physician-researchers are predicting that familiarity with ML tools that analyze big data will be a fundamental competency for the next generation of physicians, leading to improved care in areas such as radiology and anatomical pathology [2]. Millions of dollars are being invested in AI, most implementations are still proofs of concept and there remain few examples of successful widespread implementation in health settings [3].

Due to the "black box" nature of AI and the high dependency on accurate patient data for model training, there are unique challenges to successful implementation of AI in healthcare that are not encompassed in common implementation frameworks, such as the Ottawa Model of Research Use [4]. Creating an implementation framework to help healthcare orgainzations understand the key considerations and guide implementation efforts for AI will accelerate adoption and ensure that these technologies are optimally integrated to improve both patient care and patient outcomes.

Methods

An environmental scan was conducted utlizing informal meetings with eight Subject Matter Experts (SMEs) from four hospitals, one national homecare organization, and one academic institution. The SMEs provided examples of health AI technologies and talked about the considerations and challenges of implementation. The learnings from these meetings were then brought to a brainstorming session where the Affinity Diagram grouping method, common in human-centered design [5, 6], was used to help identify key themes that were recurrent in the experiences of implementing AI technologies in the health setting. A literature review was then conducted to further explore the identified themes. A visualization of the framework was created utilizing a nested hierarchy to demonstrate thematic importance. To further understand the critical factors to clinician buy-in, a qualitative research study is underway. This study aims to uncover clinician perceptions, acceptance levels, and professional standards around AI for clinical settings.

Results

The key themes that were identified from the experiences of implementing AI technologies in health settings include data, trust, ethics, readiness for change, expertise, buy-in, regulatory strategy, and scalability.

- Data: AI technology can only be as good as the data used to create it. Thus, factors including data quality, quantity, and collection need to be controlled for.
- Trust: Trust is generated by understanding, transparency and overall explainability of AI technologies, and is needed by both patients and physicians for effective adoption.
- Ethics: Ethical challenges arise with the collection and use of patient data, with implementation and dissemination of the technology developed.
- Readiness: The readiness for change of a given clinic or healthcare institution greatly influences the successful implementation of any new practice. Key factors include appropriate infrastucture, sufficient understanding of AI, and effective change management procedures at the institution.
- Expertise: The input of leaders in the field, including technologists, front-line hospital staff, and clinicians, is required to ensure effective development and implementation of user-friendly technology.
- Buy-in: Successful implementation is facilitated by generating buy-in from all levels of staff from the very beginning of any given project. All members/stakeholders must understand the value and need of the chosen technology.
- Regulatory Strategy: AI technologies that impact patient care will be subject to regulatory oversight in the jurisdiction of commercial use. It is important to have a regulatory strategy during the product development, to ensure a streamlined process.

- Scalability: Challenges for dissemination and adoption by other clinics or hospitals. ML models trained with local data may have biases that prevent them to be generalizable.
- Evaluation: It is essential to have a plan to evaluate the success of the implementation by predefined metrics, including impact on care, medical outcomes or patient experience, integration into workflow, sustainability, and economic considerations.

Utilizing a nested hierarchy of thematic significance, a visualization of the implementation framework was compiled (Figure 1). At the core of the framework is the crux of all ML projects: data. Data in healthcare includes large volumes of heterogeneous data from various systems, with different levels of veracity. These qualities of health data create a challenge for AI technologies [7] that require large amounts of high quality data to achieve high levels of accuracy. Availability, quantity and quality of health data are key considerations in the framework. Without these assurances, a ML initiative cannot gain enough traction to be considered at the next level of implementation. The second level includes the ethics around privacy and secondary use of data [8] and the trust of AI "black box" technology [9] by healthcare providers and patient users. These themes are fundamental to be able to achieve the next level in the framework, including buy-in, readiness and expertise [10]. These involve many levels of stakeholder engagement and organizational strategy alignment, making them vital to successful implementation. Healthcare organizations will need to recognize the value in AI technology and support the required development of infrastruture and expertise. Finally, in the outermost level of the implementation framework are the themes: regulatory, scalability and evaluation. These themes focus on ensuring the value and the long term sustainability of the AI technologies. It is worth noting that all themes should be considered throughout the design and implementation process.

Figure 1– Preliminary Framework for Applied AI in Healthcare

Conclusions

With the rapid emergence of AI technologies for health, organizations need to better understand the key considerations for successful implementation of such technologies. The implementation framework presented identifies these considerations in a nested hierarchy to demonstrate the core dependencies, with data at the center. This framework can be used by healthcare organizations to inform strategic initiatives to ensure readiness for AI technologies or inform individual technology implementation. Companies developing AI technologies can use this framework to understand the implementation requirements when they work with healthcare organizations.

Discussion

The implementation framework presented is a preliminary framework and requires further development. A qualitative study is underway to explore the core themes of data, ethics and trust from the perspective of the health care providers. Results from the study will be used to iterate on the framework.

Personal Health Information Management Practices of Older Adults: One Size Does Not Fit All

Anne M. Turner[a, b], Katie Osterhage[a], Andrea Hartzler[b], Jean O. Taylor[a], George Demiris[c]

[a] *Department of Health Services, University of Washington, Seattle, WA, USA,*
[b] *Department of Biomedical Informatics and Medical Education, University of Washington, Seattle, WA, USA,*
[c] *Department of Biostatistics, Epidemiology and Informatics, University of Pennsylvania, Philadelphia, PA, USA*

Abstract

Older adults are the largest consumers of health care, have the greatest number of chronic conditions, and generate the greatest amount of health data. Yet, information systems designed to aid health information management do not align with their needs and practices. We describe a process of identifying the personal health information management (PHIM) activities and objectives of older adults (60 years and older) from different residential settings.

Keywords:

Aging; Information Technology; Consumer Health Information

Introduction

Aging often brings increased utlilzation of health care services, resulting in personal health information (PHI) which must be recalled, recorded, organized, and utilized through various personal health information management (PHIM) strategies. PHIM practices, which enable a person to retreive and utilize PHI for maintenance of their health, have been observed in select populations [1; 2]. Research examining PHIM practices of older adults calls attention to barriers to PHIM technologies [3] and facilitating roles of healthcare providers [4] and caregivers [5; 6]. Less is known about PHIM practices of older adults themselves [7].

We sought to better understand the PHIM practices of older adults. This study is part of the larger SOARING project (Studying Older Adults and Researching their Information Needs and Goals) at the University of Washington, a longitudinal study investigating PHIM needs and practices among older adults aged 60 and above in a variety of residential settings (i.e., independent living, retirement communities, assisted living). The goal of the SOARING project (soaringstudy.org) is to inform the design of health information technologies that better meet the PHIM needs of older adults.

Methods

We conducted home visits with 88 older adults. We used purposive sampling to recruit participants from a variety of living situations from a metropolitan area in the US Pacific Northwest. Ethnographic tools were used including interviews, observation via photographs of information artifacts and living arrangements, along with surveys about burden of disease, health literacy, and decision-making. Interviews were audio-recorded, transcribed, and uploaded into an online qualitative analysis software (Dedoose) for coding and analysis. Two researchers applied codes to the interview transcripts. To check for inter-coder reliability 10% of the transcripts were double coded by the two researchers. Inter-coder agreement was 90%. Through thematic analysis of interview transcripts, survey results, and photos, we identified distinct PHIM activities of older adults.

Results

Participants: The 88 older adult participants had an average age of 76 years (sd 10), were predominantly female (69%), white (72%), and had at least a bachelor's degree (61%). Participants resided in diverse living situations: independent residences (25%), independent-shared dwellings (27%), retirement communities (27%), assisted living facilities (19%), and homeless (2%). Seventy percent of participants lived alone. Most participants reported having access to a computer (89%) and Internet (83%) where they lived.

PHIM activities: We identified five key PHIM activities of older adults through thematic analysis of interview transcripts. For each activity, we identified the "objective", or goal, and the "approach" used to meet that objective (see Table 1). Older adults varied in how they sought, tracked and organized information as well as the degree to which they involved others in PHIM activities.

Discussion

Given that older adults' approaches to PHIM activities vary, a uniform health information management technology will not meet the needs of all older adults. Our findings demonstrate the need for informatics tools that can be tailored and adjusted to the needs and preferences of individual older adults. Tools should be designed to consider the experiences of individual users (e.g., cognitive and functional ability, experience with technology) and their distinct approaches to carrying out PHIM activities.

Table 1– PHIM Activities

PHIM Objective	PHIM Approach	Distribution (n=88)
Organizing: Strategy used for handling health-related print materials	• Filing • Piling • Tossing	48.9% 38.6% 12.5%
Tracking: Generating and/or logging of health-related measures	• Never • Sometimes • Consistently	44.3% 28.4% 27.3%
Seeking: Type of engagement with obtaining health-related information	• Active • Combined • Passive	51.1% 29.5% 19.3%
Sharing: Including others (family/friends) in communication and management of health-related information	• Independent but shares • Collaborative-team/partnership • No sharing • Proxy	44.3% 36.4% 11.4% 8.0%
Emergency Planning: Preparing / maintaining information for health-related emergency	• Yes-by self • Yes-by others • No planning	40.5% 29.8% 29.8%

Conclusions

Older adults displayed a variety of approaches to meeting the objectives of specific PHIM activities. Technology designed to support older adults should take into consideration this variety as well as personal preferences with respect to PHIM, remembering that one size does not fit all.

Abstract

Serious games have been used to increase the accuracy and usege of clinical guidelines during routine clinical practice. This document presents the development of a serious game called SIM-GIC, a video game designed to simulate virtual patients and evaluate the decision making of players based on computer-interpretable clinical guidelines. The system is currently being developed with a content focus on antenatal care guidelines, where a number of obstetric guidelines were coded in XML files.

Keywords:

Game Development, Medical Education, Serious Gaming, Virtual Simulation, Role Play

Introduction

Clinical practice guidelines are used by students and professionals as aids during medical encounters [1], to standardize care protocols based on clinical features of the patients [2]. Clinical guidelines containsets of recommendations to make the best decision possible based on available evidence [3; 4]. For health-care institutions, a high adoption level of clinical guidelines would in an increase the frequency of the application of the best clinical practices, avoiding the use of ineffective treatments and optimizing the use of scarce resources [2; 5].

Regardless of these efforts, adherence to guidelines often remains low, causing omission of therapies recommended in the guidelines and contributing to preventable harm [6]. The low adoption levelsare mainly due to the difficulty in translating the evidence into practice, particularly where guidelineadoption would require changes in routine clinical practice[7; 8]. Several initiatives to target this issue of increasing adherence to guidelines have proposed educational resources implementated in video-games [6], where virtual patients can be used to promote guideline uses in a effective and fun way [9]. The following poster presents SIM-CIG, a video game designed to simulate virtual patients and evaluatethe decision making of players based on computer-interpretable clinical guidelines.

Clinical guidelines are often written as large documents in textual and diagrammatic format, making it difficult to integrate and apply in a standardize patient care process as it is [10]. Computer- Interpretables-Guidelines (CIGs) appeared as translations of guidelines from their published formats into computer interpretable algorithms translating written guidelines into computing tasks that unfold over time [11] using an inference engine to interprets the computer statements corresponding to guideline text [12].

SIM-CIG attempts to adopt CIGs in the design of game objectives, where the information in the CIGs would control the actions required to be performed by the studentto "win the game". With the implementation of CIGs as a game objective , we aim to develop a video-game with editable game objectives similar to how clinical decision support systems works, avoiding source code edition as much as possible and allowing for institutions or individuals modify the CIGs according to their needs.

Methods

Games Objectives: SIM-CIG is limited to simulated an antenatal health-care environment, evaluating decision making of professionals relative to obstetric guidelines based on the pregnancy conditions of virtual patients. Clinical functionalities were extracted through a systematic review of guidelines related to antenatal care. The selected guides can be found in references [13]. Each functionality was classified and grouped into: physical actions and interaction with the patient, equipment required, record of information about in the Electronic Health Record (EHR), prescription, management and cessation of medication, clinical orders carried out for screening, diagnostic or with therapeutic purposes, instructions and information provided to the patient.

CIG Syntax Implementation: There are many ways in which the terminology can be defined, it was decided to use terms related to the planning theory in artificial intelligence [14]. Where the knowledge is structured in terms of actions and their consequences, and the syntax is structured around a condition called goal, with a sequence of actions need it to achieve it. This terminology was used to designed the game planning syntax structure where the medical knowledge will be codified. It is decided that our CIG will be in XML file format. In simple terms, information in clinical guidelines is generally found in terms of actions suggested based on specific clinical features presented in the patient, and this will be the core idea of how the game will evaluated player's actions, where every rules will at least have a goal, a precondition and an action. For each condition, a boolean expression is declared with logical operators, inside each boolean expression a semantic path reference is described to relate the information with a specific ID in a database.

Pregnancy Model: The pregnancy simulation is based on Synthetic Patient Population Simulator pregnancy model [15], which can model some pregnancy data and conditions that contribute to the medical history of the synthetic patients.

Synthea provides a JSON file format for each disease and medical conditions. To implement the pregnancy model for the game environment the JSON files were transformed into XML files and limited to simulating a 9 months' normal pregnancy and one with preeclampsia complications.

Database data model and Electronic Health Record: Records and logs of activities are stored in a Microsoft SQL Server database with a data model similar to the openMRS [16], selected due to how drugs, orders and information is handle, making it possible to employ ICD-10, SNOMED-CT or RXNORM coding. Our CIG references a specific ID of the db Concept table and evaluates the game objectives achievements based on the values registered in the OBS database.

Results

Clinical knowledge was coded in the XML file that used the games to stablished the rules. For example, one of the goals is to treats a patient whose Rh type is negative, and according to clinical guidelines after 28 weeks of pregnancy a patient with Rh type negative should be treat with Prophylactic Anti-D.

In Figure 1. is presented how SIM-CIG looks alongside the EHR designed to register and evaluate the information acquired in the encounter.

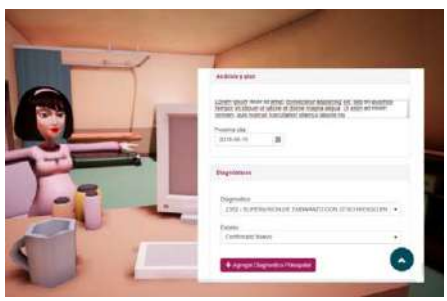

Fig. 1: Medical Encounter SIM-CIG .

Discussion

In this first approach the knowledge code from the clinical guidelines is mainly for obtetric care, after finishig the test stage next step involves covering additional guidelines and evaluated more knowledge. Synthea is the main core of the patient data generation, but still don't cover majors aspect of a real pregnancy. Future versions will attend this issue to bring more reality.

Conclusions

CIGs demonstrated to be integratable into the source code of a serious game, creating a customizable objective game for evaluating medical knowledge. The Synthea Patient Generator can be used to generate data with sufficient clinical information to simulate a pregnant virtual patient in order to provide experience with antenatal care guidelines in a serious game environment.

Change Management in Healthcare Organizations: *Soft Skills* Training Strategies Through Blended Learning Environments

Giussi Bordoni MV[a], Baum A[a], García G[a], Moriñigo P[a], Luna D[a], Otero P[a], Otero C[a], González Bernaldo de Quirós F[a]

[a] Department of HealthInformatics, Hospital Italiano de Buenos Aires, Argentina.

Abstract

Teaching soft skills for change management in healthcare organizations is becoming increasingly necessary, even more, when implementing health information systems (HIS). There is little evidence that these skills can be learned through online teaching environments. This paper describes the experience of having taught soft skills to health informatics master's degree students, through blended learning environments.

Keywords:

Environment, Health information systems, Students

Introduction

Implementing change management in health information systems (HIS) requires leaders with highly developed soft skills. [1; 2] According to the literature, competencies such as empathy, flexibility, active listening skills, clear communication and negotiation strategies can be developed or strengthened through training programs. The development of pedagogical strategies to strengthen these competences through e-learning has been, so far, hardly explored. [3]

The International Medical Informatics Association (IMIA) cites several competencies that health informatics professionals (HIP) should have. Among them, HIP should be able to handle the resolution of socio-organizational issues, so as to achieve a successful change management. [4] Including information and communication technologies (ICT) in the education field can result in a new teaching-learning process, overcoming the barriers of space and time presented by face-to-face training modality. Distance learning has become an alternative at postgraduate levels. Advantages of e-learning have been widely reported, but there is scarce literature describing pedagogical strategies to teach soft skills through it. [5]

The aim of this paper is to describe the design and development of a course to teach soft skills for managing change in HIS projects, to professionals of different disciplines, through a master's degree in health informatics within a blended learning environment.

Methods

Setting

Hospital Italiano de Buenos Aires (HIBA) is a third-level university hospital created in 1853. In 2016, the professional master's degree in Health Informatics was created as a blended learning program. The graduate profile that this master's degree proposes is a professional capable of leading digital transformation projects within the healthcare field.

"Organizational Issues and Change Management" Class Design

The "Organizational issues and Change Management" class takes place within the second year of the master's degree. It delves into content related to soft skills and lasts a total of 12 weeks in virtual mode and 4 hours of face to face activities.

The teaching team is responsible for selecting the subject's contents, designing pedagogical strategies, and guiding students along the course.

The contents were divided into three different sections along the 12 weeks course. In section 1, the students reviewed concepts related to organizational behavior and theories, paradigms' changes (from the industrial to the digital era) and people's behavior. Concepts related to healthcare organization's particularities, organizational culture, diversity of actors, hidden organizational charts, power relationships and types of change, were addressed in section 2. Finally, in section 3, students were provided with tools to better handle resistance to change and the topics reviewed were Information System Implementation Change Management-barriers and facilitators-, sociotechnical approach, communication strategies, support and training, conflict negotiation tools, and evaluation and management monitoring. Contents were approached through individual activities in the first 2 sections and through group activities in the 3rd section.

Results

The first cohort participated between March and June 2018. 53 students from different professions participated (Medicine, Nursing, Engineering, others). 64% of the students were male.

To reach the goal of consider resistance to change as a natural attitude of human beings, the students were called to reflect on their own resistance to the changes and build a collaborative board (Padlet) with representative images. Other goal of section 1 was to identify organizational properties, people's behavior and tensions generated when introducing changes. To reach these, students watched a film and completed a chart. The aim of section 2 was to understand the complexity of healthcare organizations, recognize the type of changes (Lorenzi), list restraining and driving forces (Lewin´s Force Field Analysis Model), and identify types of technology adopters (Rogers). To reach this, students watched Grey's Anatomy's "Bad blood" chapter and completed the evaluation chart. Finally, in section 3, students were asked to analyze a HIS implementation case in order to position themselves as leading agents of change and develop skills to handle difficult conversations. Training in active listening and acquiring negotiation skills were goals of section 3 too. All sections

were accompanied by forum discussions to enrich the knowledge of all the participants.

Discussion

One of the challenges of teaching through virtual environments is to design pedagogical strategies to simulate usual scenarios of health information systems (HIS) implementation, allowing students to learn key skills for their graduate profile. Along their virtual training, students were asked to experience first-hand how it felt to identify themselves as protagonists when managing change. We identified that it was easier for students to solve activities based on the analysis of cases reported in third person. For example, it was easier to answer questions such as "Why do people resist change?" than the question "Why do I resist change?" Students were gradually able to embrace the role of leaders and respond to assignments with a greater degree of personal involvement.

Face-to-Face training was key to empathize with conflict scenarios and integrate what was learned through virtual training. Since virtual and face-to-face training generate completely different feelings and experiences, teachers have been challenged to come up with strategies to transform the way virtual learning is perceived.

Limitations

Although this paper describes a local experience, the reported teaching strategies could be considered for similar projects.

Conclusion

There is a clear need to include soft skills training in health informatics' education programs. Teaching these skills through virtual environments can be challenging.

Adoption Factors Related to Electronic Vaccine Record in the Public Primary Care Network of Buenos Aires City

Vazquez MV[a], Palermo C[a], Islas M B[a], Zapata M[a], Giussi Bordoni MV[a], Esteban S[a], Baum A[a]

[a] *Health Information Systems Office, Ministry of Health, Buenos Aires City, Argentina*

Abstract

The Electronic Health Record used in the public primary care network of Buenos Aires City has a specific module for the vaccines registration. The present study explores the factors of EHR adoption by nurses. We found 5 barriers and one facilitator for adoption. Barriers are related with organize the flow of patients especially during vaccine campaigns, adapt the work stations and integrate the records with the vaccine central program.

Keywords:

Nursing Records, Vaccines, Electronic Health Records

Introduction

In accordance with CDC recommendations, several public health agencies have implemented Immunization Information Systems (IIS) for the collection of data about the immunization status of the population and the individual [1].

Many Electronic Health Record (EHR) can help track planned vaccinations [2]. There are three main immunization record issues an EHR can help solve: the human error in the administration of a vaccine not according to the age of the person, the visualization of the calendar and vaccination status of a person in a flexible way, and the tracking of the stock of vaccines, this last is important since they are the most expensive input in primary care.[3] Another important factor is that the vaccination electronic recording may people reduce revaccination due to the loss of paper-based record [4].

In Buenos Aires public healthcare network the vaccination is carried out by nurses who are responsible for the record in order to comply with the Ministry of Health vaccination program. In the last 2 years an EHR was implemented but still electronic vaccination record coexists with the paper record. This paper analyzes the facilitators and barriers for the vaccination record adoption in the Primary Care Centers where vaccination is available.

The Buenos Aires city healthcare network is conformed by a Ministry of Health, 35 Hospitals, 74 Primary Care Centers (44 where vaccination is available), 1 Ambulatory Reference Medical Facility and its structured into 12 geographical areas in order to organize health care delivery. Since June 2016 an Electronic Health Record (EHR) is being gradually implemented in outpatient [5].

In Argentina, the National Vaccination Calendar includes 19 vaccines whose administration is mandatory and free. It is accessed in public health centers [6]. Each healthcare facility registers the application of vaccines in a paper form. These are compiled by the Vaccination Program of the Ministry of Health of the Buenos Aires City. This information is value for vaccine replacement and control of the immunization status of the population of the city.

Methods

We developed an exploratory design with mixed methodology that combines quantitative and qualitative tools.

To determine the level of electronic vaccine record adoption in each primary care center (n = 44), the number of vaccine records in EHR was compared with the amount reported to the vaccine program in paper format for the same period of time. Three ranges were defined, being considered 'high' the cases in which the registry in the HCE exceeded 70%, 'medium' between 40 and less than 70% and 'low' less than 40%.

To determine the factors of adoption, between May and July of 2018, 16 semi-structured, 13 group and 3 individual interviews were carried out with nurses from primary care centers, accomplishing 44 interviewees. In the same period of time, participant observations were carried out.

The analysis of the results was made based on the principles and procedures of the grounded theory [7] and the common themes found are listed in the Result section.

Results

The level of electronic vaccine record adoption in each primary care center (n = 44) is shown in Table 1.

Table 1 – Electronic vaccine record adoption by primary care facility.

High Adoption Level	14
Middle Adoption Level	16
Low Adoption Level	14

The sample consisted of 16 primary care facilities with different levels of use -high level=6, middle level=5 and Low level=5- in order to understand the factors that could influence in

adoption level. The factors found in the interviews were grouped into 5 dimensions:

Transition from paper to electronic record: the vaccine module is not yet integrated with the centralized vaccine report. This results in double registration by the nurses, longer time in the registry and possible delays in care. Given this situation, nurses prefer to comply with the paper record for the centralized report.

Patient flow: the procedure through which EHR is opened requires an administrative process [8]. It was observed that most of the time, patient's access to the immunization sector without going through the administrative post. This fact determines an obstacle to electronic registration. Other factors perceived as barriers to adoption are: the large influx of people during vaccination campaigns, compulsory health checks on children at school entrance and the overload of tasks of administrative staff if all patients went through their post.

Work overload: another obstacle is the large number of tasks performed by the nursing staff, in addition to vaccination. The nurses state that they prioritize care and paper registration over the electronic, a fact that leads to the accumulation of paper records that are sometimes transcribed to the EHR at the end of the day overloading their work.

History of autonomy from the rest of health professionals: the nurses pointed out that the EHR is a tool aimed at other healthcare professionals: *"the EHR is oriented to the medical practice".* Before EHR implementation in Primary Care, the staff of nurses had a fragmented record of their own practices, disintegrated form the whole clinical notes. Some professionals asked for a specific module within the EHR for the record of nurses practices: "*There should be an exclusive module for nursing*".

Nurses Workflow*:* two issues related to the nursing workflow were noticed in the participant observations. The first one is that usually while a nurse vaccinates the patient, the other registers in the EHR. The second issue is that there is not one computer per nurse, but per office. This result in many records made on paper and then transcribed to the system.

Perceptions of advantages and disadvantages of the electronic vaccine record: the main perceived advantage is that the electronic vaccine record avoids people revaccinations in case of paper-based record loss, improving continuity of care. Among the disadvantages are the time that the registration takes and the impossibility of completely replacing the paper.

Conclusion

The use of the EHR by the nurses of Buenos Aires city primary care network is related with multiple factors descripted in literature and not exclusively related to software issues [9]. Among the most important are the need to organize the flow of patients, adapt the work stations and integrate the records with the vaccine central program. Thus, it is important to emphasize that workflow considerations are decisive factor regarding the adoption of an IS. The perception of lack of representation of nursing workflow in the EHR was a recurring concern in the interviews conducted. Different papers report the lack of articulation of nursing records with physicians ones [10]. The most important limitation of this work is related to the impossibility of the methodological tools used, to be able to account for the non-explicit factors that are related to the adoption of the EHR. It is hoped more data-driven studies can be developed to strengthen the validity of the factors listed, and may suggest accurate interventions to improve workflow and system integration.

A complete and appropriate electronic immunization record guarantees a higher quality in patient care. It also allows the generation of statistical information related to the vaccination status of the population, improving decision-making and healthcare management. Exploring the barriers and facilitators of the EHR adoption is a key to improve immunization records.

A Comparison of In-Person and Online Training in a Statewide Clinical Education Program for Dissemination of HIV, HCV and STD Clinical Evidence

Dongwen Wang

Department of Biomedical Informatics, Arizona State University, Scottsdale, AZ, USA

Abstract

We compared in-person and online training in a statewide education program to disseminate HIV, HCV, and STD clinical evidence. In a study period of three months, 250 clinicians completed four training courses delivered in dual formats. Course evaluation was positive regarding useful information, easy comprehension, knowledgeable trainer, appropriate format, knowledge increase, intention to use knowledge, and plan to change practice. Online training became a preferred format by clinicians when compared to in-person training (p=0.01).

Keywords:

Internet training, teacher training, knowledge

Introduction

The pandemic of HIV infection has been a major public health challenge for decades. Hepatitis C virus (HCV) infection has also increased rapidly in recent years. Co-infection of HIV, HCV, and other sexually transmitted diseases (STDs) such as syphilis and gonorrhea is frequently reported. With the frequent updates of clinical evidence on HIV, HCV, and STD, timely and effective dissemination of the latest research to community healthcare providers is crucial for translating medical knowledge into routine patient care [1-2].

Since the early 1990s', the New York State Department of Health AIDS Institute has been sponsoring the Clinical Education Initiative (CEI) program for community healthcare providers serving HIV, HCV, and STD patients [3]. In the early years, the CEI program utilized a traditional, in-person approach for training by sending domain experts across the state to give lectures or workshops. This in-person education program successfully trained thousands of clinicians. With the development of information and communication technologies, CEI initiated its online training program in 2008, aiming to complement and to integrate with in-person education. Since then, CEI developed hundreds of multimedia learning modules, online continuing medical education (CME) and continuing nursing education (CNE) courses, interactive case simulation tools, and other digital resources [4-5]. These resources were disseminated through the web, mobile apps, email newsletters, and online social networks to thousands of clinicians from 170+ countries over the world [6]. The participating clinicians had very positive evaluations of the CEI online training program [7-9].

Compared to traditional in-person continuing professional education, online training is advocated for wide geographical availability, rapid outreach to the target audience, flexibility in resource access and use, as well as cost-efficiency [10-11]. Yet studies to compare online and in-person training directly are scarce and inconclusive.

Here we report a study to compare online and in-person training within the New York State CEI program. The results from this study can help to compare online and in-person cross-disciplinary continuing professional education for HIV, HCV, and STD clinicians, and to guide the future design of education programs for more effective dissemination of clinical evidence to community healthcare providers.

Methods

We conducted the study in a period from April 1, 2015, to June 30, 2015. Among the hundreds of courses and training sessions offered by the CEI program, we selected for analysis only those delivered during the study period in both online and in-person formats to clinicians. For a traditional in-person training session, a clinician in the community first participated in a lecture or workshop delivered by a domain expert, and then logged on to the CEI Student Portal online system to complete a course evaluation. For an online course, a clinician logged on to the CEI Student Portal system, selected a specific course, reviewed the multimedia course materials, and then completed the same course evaluation as for in-person training [9].

For study measures, we focused on the training content, format, participants' improvement in knowledge, and impact on their clinical practice. Specifically, we collected the following self-reported data through course evaluation: (1) usefulness and relevance of the information in a training course; (2) easiness of comprehension; (3) expertise/knowledge of trainer/speaker; (4) appropriateness of training format; (5) participant's knowledge of the clinical topic before and after the training; (6) intention to use the knowledge learned; and (7) plan to change clinical practice after training. We used a five-point Likert-scale measure (*strongly agree*, *agree*, *neutral*, *disagree*, and *strongly disagree*), which were further grouped into positive (*strongly agree* and *agree*) and non-positive (*neutral*, *disagree*, and *strongly disagree*) responses for data analyses on items (1), (2), (3), and (6). For item (5), we used five discrete levels to indicate a clinician's knowledge on a specific training topic (*novice*, *not very knowledgeable*, *knowledgeable*, *very knowledgeable*, and *expert*) before and after the training, and then calculated the difference (*at least one level increase* vs. *no increase*) for data analysis. Additional details of CEI program evaluation can be found in our previous publications [7-9].

We used the SPSS package for statistical analysis [12]. We compared the proportions of positive responses between in-person and online training. We used the chi-square test to examine the statistical significance of differences.

Results

During the study period, four training courses were delivered in dual formats to 250 clinicians (online 131, in-person 119). These four courses were: (1) *STD-HIV Inter-Relationship* (81 completions); (2) *Treatment for Hepatitis C: New Tests, New Drugs & New Recommendations* (91 completions); (3) *Vaginitis* (32 completions); and (4) *The Clinical Diagnosis and Treatment of Syphilis* (46 completions).

Clinicians' course evaluation was positive for both in-person and online training regarding useful information (in-person 96%, online 92%), easiness of comprehension (in-person 91%, online 93%), knowledgeable trainer (in-person 97%, online 90%), and appropriate format (in-person 74%, online 87%). In terms of the impact, we found: (1) 56% clinicians participated in in-person training and 43% in online training reported at least one level increase in knowledge; (2) 87% clinicians in in-person training and 86% in online training intended to use the learned knowledge; and (3) 39% in in-person training and 22% in online training planned to change practice. In-person training recorded better evaluation in terms of knowledgeable trainer ($p=0.04$), improvement of knowledge ($p=0.03$), and change of practice ($p<0.01$). Online training recorded better evaluation in terms of appropriate format ($p=0.01$). No significant difference was found in terms of useful information ($p=0.25$), easy comprehension ($p=0.49$), and intention to use knowledge ($p=0.79$). The detailed evaluation data are shown in Table 1.

Table 1 – Evaluation of In-Person and Online Training

Measures	In-Person (n=119)	Online (n=131)	Total (n=250)
Information Useful and Relevant			
Positive	114 (96%)	121 (92%)	235 (94%)
Non-Positive	5 (4%)	10 (8%)	15 (6%)
Easy to Comprehend			
Positive	108 (91%)	122 (93%)	230 (92%)
Non-Positive	11 (9%)	9 (7%)	20 (8%)
Knowledgeable Trainer*			
Positive	115 (97%)	118 (90%)	233 (93%)
Non-Positive	4 (3%)	13 (10%)	17 (7%)
Format Appropriate*			
Positive	88 (74%)	114 (87%)	202 (81%)
Non-Positive	31 (26%)	17 (13%)	48 (19%)
Improvement of Knowledge*			
Positive	67 (56%)	56 (43%)	123 (49%)
Non-Positive	52 (44%)	75 (57%)	127 (51%)
Intend to Use Knowledge			
Positive	104 (87%)	113 (86%)	217 (87%)
Non-Positive	15 (13%)	18 (14%)	33 (13%)
Will Change Practice*			
Positive	46 (39%)	29 (22%)	75 (30%)
Non-Positive	73 (61%)	102 (78%)	175 (70%)

* Significant difference ($p<0.05$) between in-person and online training detected

Conclusions

Both online and in-person training can effectively disseminate HIV, HCV, and STD clinical evidence to community healthcare providers. Although online training is still not equal to in-person training in certain aspects, it has become a preferred format by clinicians to update their knowledge. Future research is required: (1) to verify the generalizability of the findings from this study; and (2) to combine the features of online and in-person training to better address clinicians' needs and preferences for more effective knowledge dissemination.

Abstract

Family health history (FHx) is vital in early detection of genetic diseases. This research studied two different FHx collection interface and compared them based on the IBM CSUQ usability metrics. We found the conversational interface to be significantly better in terms of overall satisfaction, system usefulness, interface quality and information quality than the traditional interface.

Keywords:
Family health history collection, usability, user experience.

Introduction

Family Health History (FHx) play an important role in understanding the risk of individual illnesses, especially those with genetic causes [1–2]. Diagnosis of these diseases at an earlier stage is vital for initiating preventive measures [3]. For efficient and accurate diagnosis, having accurate FHx information is critical. Various methods like emails, phone conversations have been employed by the medical service providers to collect these FHX information. However, Qureshi et al., (2009) portrayed that self-collection FHx tools have certain advantages like improved accuracy and quicker data collection than the traditional methods [4].

Although there are different types of self collection tools, electronic FHx tools have been at the forefront in the recent years. Electronic FHx tools have the advantage of easy editability and the ability to share the information among their family members. This helps in getting accurate information and is a quicker way to collect the information.

Despite all the advantages of the electronic FHx, its usability is crucial since a very diverse user population from different age and education groups will interact with the system [5]. Previous studies have focused on the usefulness and potential difficulties of the FHx tool [6,7]. Wang et al. (2015) developed a virtual assistant tool and compared if this new tool could identify more health conditions compared to the Surgeon General's My Family Health Portrait [8]. However, none of the studies focused on including the diverse age group and/or studied the usability of such interfaces.

In order to bridge this knowledge gap, we tried to understand the effect of the different age group on the usability and interface design for collection of FHx data.

Methods

A total of 54 participants (27 males and 27 females) with a mean age of 44.91 years (SD=22 years) were recruited for this study via email and word-of-mouth. On completion of the study, the participants were compensated with a $20 Walmart gift card.

Apparatus

The study was conducted in a quiet and contolled room on a desktop with a 17.5 inch monitor. Two FHx interfaces analyzed in the study were:

Conversational interface

This interface consisted of a conversational dialog box in the bottom right as the data entry method as shown in the figure 1. In addition, the family pedigree provides a real time update as the family history is entered using the dialog box.

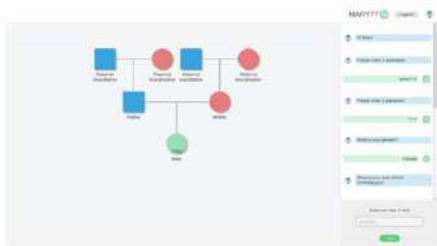

Figure 1.– Conversational interface

Traditional interface

This interface consisted of the traditional method of data entry, i.e. by clicking on the pencil icon (update history column) to enter the family health information as shown in figure 2.

Figure 2.– Traditional interface

Procedure

A mixed experimental design was used with the type of interface being the within subject variable and age group (young adults: 18-30 years, older adults: above 60 years) being the between subject variable. Participants were randomly

assigned to the FHx interfaces and were counterbalanced to avoid order effects. Participants were provided with a fictional family health history information that included the family member's information and past cancer history in the family. Overall, the participants had to complete 5 tasks for each interface: i) create a user profile, ii) add the family health history, iii) re-access the platform, iv) edit the information and v) share the information with a family member. On completion of the tasks using either of the interfaces, the IBM Computer System Usability Questionnaire (CSUQ) was given to the participants to evaluate the usability of the interfaces [9].

Hypotheses

- **H1**: Age group moderates the relationship between the interface design and the overall satisfaction, with an increase in the satisfaction as the interface design changes from traditional to conversational and age group changes from younger to older adults.
- **H2**: Age group moderates the relationship between the interface design and the interface quality, with an increase in the perceived interface quality as the interface design changes from traditional to conversational and age group changes from younger to older adults.

Results

Usability Evaluation

The participants had a higher overall satisfaction on using the conversational interface (M= 5.65, SE=0.12) than the traditional interface (M= 4.77, SE=0.18) and system usefulness score on using the conversational interface (M= 5.79, SE=0.12) than the traditional interface (M=4.82, SE=0.21).

There was a statistically significant interaction between the age group and the interface type on information quality and on interface quality. For the information quality, in the younger age group, the participants reported a higher information quailty score on the conversational interface (M = 5.65, SD = 0.85) than the traditional interface (M = 4.51, SD = 1.30). For the interface quality, in the younger age group, the participants reported a higher interface quality score on the conversational interface (M = 5.79, SD = 0.96) than the traditional interface (M = 4.38, SD = 1.41).

Conclusions

This study looked at the effect of aging on the usability and interface design of the FHx data collection process. Although we did not find an interaction with the overall satisfaction as hypothesized, we did find a significant main effect of the interface design. We found the conversational interface was rated higher on all the usability metrics on the IBM CSUQ scale. Participants were highly satisfied using the interface as they only had to answer the questions asked by the conversational virtual agent to complete the task. Unlike in the traditional interface, where they had to manually search for all the data entry boxes to enter the family health information.

Abstract

Recently, visualizing location of people and things in a hospital has become an issue particularly for improving work efficiency and incident prevention. Although radio frequency waves such as Wi-Fi and Bluetooth are commonly used in indoor positioning, they have several limitations owing to their physical characteristics. We proposed in-hospital hybrid positioning technique, involving a combination of radio waves and geomagnetic fingerprinting techniques. We compared accuracy of proposed technique with that of Wi-Fi- and BLE-based techniques.

Keywords:

Geomagnetic fingerprinting localization, hybrid in-hospital positioning, Wi-Fi and Bluetooth low energy beacon

Introduction

Recently, IoT technologies have influenced various fields to improve operation efficiency and prevent accidents by using smart devices; particularly, in logistics and factory automation fields by visualizing people and objects for 24 hours on a massive scale, they have succeeded in reducing costs, workers' burden, and workplace hazards drastically [1]. Moreover, in the medical field, issues regarding increase in medical care expense and shortage of medical staff, accompanied by rapid progression of the aging problem increased urgency to reduce labor costs and burden on medical staff without increasing medical incidents. Visualization of location is a key technology in this cross-sectoral innovation. For example, in factories, reducing movement of workers by a single step can improve efficiency due to reduced time wastage and mistakes. Furthermore, by introducing smart devices such as smartwatches, some companies have succeeded in reducing workers' heatstroke accidents. Generally, localization methods are divided into two ways: outdoor and indoor. Most outdoor positioning systems are represented using a global positioning system (GPS). However, indoor positioning systems do not have a *de facto* standard method. Generally, radio frequency (RF) waves such as Wi-Fi, bluetooth low energy (BLE), indoor messaging system (IMES), and indoor GPS are used as reference points for position estimation. However, these RF based techniques have accuracy limitation due to signal attenuation, radio interference, and hardware variability (standard compliance) problem.

In Nagoya university hospital, we have been considering ways to localize smartphones that are used in nursing service. Use of Wi-Fi access points and BLE beacons were rejected due to saturation of 2GHz band radio waves in the ward. Hence, IMES was incompatible with the smartphones. Thus, we decided to introduce geomagnetic field pattern matching developed by GiPStech for device localization. Their indoor positioning technology won GeoIoT World for Indoor Localization & Proximity Services, 2016 award [2]. The position estimation strategy based on geomagnetism uses pattern matching of a 3D magnetic vector field map. Current position can be calculated by comparing continuous magnetic vector measurements using particle filter algorithm. The advantage of this method is that although it requires certain number of cornerstones such as BLE beacons to stabilize accuracy, it can be used in places without a good number of beacons. It can cover a wide area seamlessly and at less maintenance cost. However, there were no preceding reports on use of geomagnetic localization in the hospital. Thus, in this study, we compared accuracy of in-hospital geomagnetic field fingerprinting with Wi-Fi and BLE beacon techniques.

Methods

Comparison of position measurement accuracy experiment using geomagnetic field (GM) only, a hybrid of GM/Wi-Fi, and GM/BLE was performed in general inpatient ward (8th floor, 52 beds). As shown in Fig.1, we set up seven test-paths that cover the ward. Node was used when setting up test path on a system for creation of correct answer data of position information set pillars, which helped to easily determine accurate position.

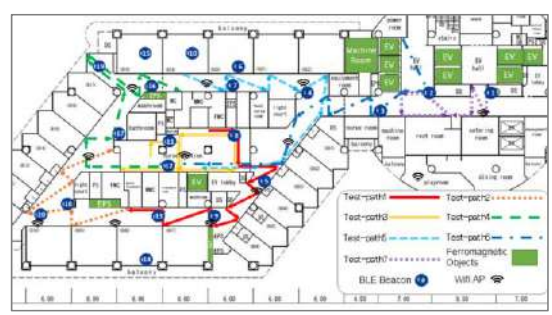

Figure 1-Seven test-paths settled in the 8th floor ward.

Before examination, magnetic field information was pre-logged and stored as geomagnetic field map in a database server in advance. For Wi-Fi positioning, we used 12 existing wireless access points in the ward as a cornerstone. With transmitter power control turned off, we obtained maximum Wi-Fi radio field intensity (RSSI) and MAC address of each access points. RSSI and multilateration techniques were used for location measurement [3]. For BLE positioning, we installed 20 beacons

in the ward and registered their absolute positions. Beacons were installed in the corridor and nurses' station on a wall at 2.00m high. Based on bluetooth radio wave intensity received from multiple beacons, its position was measured using three-point positioning method.

Next, we verified measurement using the most accurate positioning method in the experiment. We set three routes, assuming medical staffs' movement, and made positioning. To prepare correct answer data of position information, we attached the barcode to the wall of the hospital rooms' doorway. We obtained barcode image using smartphone camera and matched that information with actual position and timing. We chose the hospital room selected during verification as a general hospital room in a quadruple room.

Results

The overall average positioning errors in GM only, GM/Wi-Fi, and GM/BLE were 7.62m, 3.19m, and 2.60m respectively. The most accurate method was GM/BLE used in three routes assuming medical staffs' actual movement.

Table 1-GM only, GM/Wi-Fi, and GM/BLE positioning errors (Meter, Average ± Standard Deviation) of 7 Routes

Route	GM only	GM/Wi-Fi	GM/BLE
#1	5.74 ± 7.03	2.20 ± 1.82	2.72 ± 2.55
#2	5.58 ± 6.43	1.93 ± 1.03	1.76 ± 1.18
#3	6.28 ± 9.90	2.25 ± 2.83	2.21 ± 2.93
#4	0.98 ± 0.53	2.75 ± 2.28	1.27 ± 0.98
#5	3.88 ± 7.20	6.99 ± 2.81	1.59 ± 1.41
#6	18.10 ± 15.48	1.18 ± 0.78	2.61 ± 2.64
#7	12.41 ± 10.45	4.84 ± 3.13	6.24 ± 4.39

Hospital rooms without barcode during verification were excluded from accuracy calculation of the experiment. The hospital room selected by this route used common room of bay for verification. The average positioning error was 1.20m.

Table 2-Result of GM and BLE beacon hybrid method, of path 1-3

	Absolute Error (m)		
#Node	Route1	Route2	Route3
#1	1.76	0.51	0.94
#2	1.31	1.00	0.68
#3	0.28	0.73	1.52
#4	0.74	1.39	0.52
#5	2.10	1.57	0.80
#6	0.72	0.70	1.24
#7	1.04	0.68	2.53
#8	2.25	0.87	0.91
#9	0.68	0.80	0.66
#10	0	1.69	1.41
#11	1.46	0.30	1.40
#12	0	1.68	1.55
#13	-	1.46	0.57
#14	-	0	0.90
#15	-	2.21	1.40
#16	-	0	0
#17	-	-	2.20
#18	-	-	0
Average	1.24	1.11	1.20
SD	0.73	0.62	0.65

Discussion

Regarding positioning accuracy in Nagoya university hospital, we believe that positioning accuracy of about 3.00m is sufficient to grasp identity of person being treated because the area per patient of a four-person room is 3.00m^2. For radio frequency beacons placement, most of the positioning method places beacons in polygons at short intervals every few meters. For example, it requires to place 5 beacons in 5.00 m^2 area to obtain an average of 1.20m positioning accuracy inside a hospital [4]. Notably, the positioning of beacons is very important when measuring positioning accuracy. Thus, it is often common practice to examine placement position several times. However, in the verification performed, we only examined beacons placement once. The beacons were arranged at average intervals of 10.00m. We did not verify accuracy of Wi-Fi only nor BLE only methods, these would be assumed to be very low. According to the relationship of distance of mean error and number of beacons by Li, estimated mean error of BLE only method would be much worse than 2.33m with beacon density of this experiment [4]. Concerning the result, any magnetic substances such as pipes and communication cables in wall of the hospital building helped form a characteristic magnetic field space, which is easy to extract. Conversely, the magnetic field can be influenced by ferromagnetic objects such as an elevator (EV in Fig.1) and electric power space (EPS in Fig.1) resulting in loss of precision as seen in route #5/6/7. We recommend using several beacons when using GM method in-hospital and believe that adequate beacon settings in high magnetic field fluctuated area needs to be further verified when using GM/Beacon hybrid method.

Conclusions

Hybrid localization using geomagnetic (GM) fingerprinting and Bluetooth low energy (BLE) beacon were found to be accurate in conducting in-hospital tracking in this study. The experimental results show that although a small number of BLE beacons were placed and arranged in position without careful planning, a good position accuracy value was obtained. Therefore, it can be said that the position measurement method using geomagnetism is an effective method for indoor position measurement in a hospital.

Making Sense of Clinical Laboratory Results: An Analysis of Questions and Replies in a Social Q&A Community

Zhan Zhang[a], Yu Lu[a], Caleb Wilson[b], Zhe He[b]

[a] *Department of Information Technology, Pace University, New York, New York, USA,*
[b] *School of Information, Florida State University, Tallahassee, Florida, USA,*

Abstract

Previous literature has revealed that patients have difficulty making sense of their clinical data. To address this barrier, we first need to understand what kinds of support that patients may seek. In this study, we analyzed question posts and their replies in a social Q&A community to understand what types of support people are providing to and receiving from the community and what contextual information they provide in order to elicit relevant answers.

Keywords:
Consumer Health Information; Information Seeking Behavior

Introduction

Growing evidence suggests that patients are increasingly interested in timely and easy access to their clinical data, such as laboratory test results [1]. With the wide adoption of personal health record technology, such as online patient portals, healthcare organizations are enabling patients' easy access to their clinical data. However, patients' current use of clinical data is significantly limited due to the techical nature of the clinical report, preventing patients from making informed health decisions based upon it [2]. Our ultimate research goal is to address this barrier by designing and developing novel informatics tools to help patients better understand their clinical data and make personalized decisions. To achieve this goal, we first need to understand what kinds of support that patients may seek.

There is an ongoing trend for patients turning to online resources, such as social Q&A sites and health forums, to fill their knowledge gaps [3]. These online communities provide us an opportunity to examine consumer information searching and types of information that people need concerning a particular disease and their querying behavior in online health communities [4]. In our recent study, we analyzed the questions that people posted on a major social Q&A site, Yahoo! Answers, to understand lay people's information needs in making sense of their laboratory test results, one type of clinical data. In this paper, we take our analyses a step further to answer two research questions: 1) what kinds of *contextual information* people provide in the question in order to elicit relevant answers, and 2) what types of support people receive from the online healthcare community. We believe that this could provide a foundation for our future work to design and develop informatics tools to provide more personalized information that better meets patients' needs. Towards this end, we further analyzed the question posts identified through our previous work and report the methodologies and results below.

Methods

In our previous work, we collected a total of 58,422 questions and their threaded replies in the diabetes category of Yahoo! Answers between 2009 and 2014. We retrieved potentially relevant posts in this dataset using keywords suggested by the literature [5], such as "blood sugar", "glucose", and "HbA1c". Then, we took a random sample of 1619 posts containing keywords. Two researchers independently reviewed posts for relevance. Duplicate and irrelevant posts were discarded. This screening resulted in 967 posts eligible for further analysis.

Two researchers independently performed content analysis on the relevant 967 posts. We first iteratively developed a codebook for the kinds of contexual information provided in the posts, using the open coding technique. Two coders, C1 and C2, independently analyzed 100 randomly sampled posts and created the initial list of codes. Researchers then discussed the codes in a group session to determine which codes to keep, merge, or remove. After the list of codes was set, we created a data dictionary, defining each code to standardize the coding process. Next, C1 and C2 independently coded another set of 100 posts to test inter-rater agreement (90%). Once resolving all disagreements, C1 and C2 coded the rest of the posts to conclude the analysis. When reviewing the replies to relevant question posts, we focused on the "best answer", which was selected by the person posting the original question. C1 and C2 followed the same procedure to review the replies.

Results

Types of Information Provided by Askers

Askers provided a variety of information in the question to effectively communicate their current conditions and informational needs to the community members. Table 1 shows the types of information that askers provided in their questions and the frequency of being provided in the posts (if a particular type of information was provided more than once in a post, it was considered as appearing one time in that post). As shown in the table, askers provided mainly two types of information, demographic and medical information, to contextualize their questions.

Major demographic information provided in the questions include age, gender, height, and weight. Less frequently, askers provided pregnancy information to help others better

interpret their problems: "*What does it mean if I am pregnant and my homocysteine level is low, particularly 4.9.*"

Furthermore, askers provided many different types of medical information in their questions, including lab tests, symptoms, medication, medical and family history, doctor's diagnosis, and lifestyle. More specifically, to help others interpret their lab test results, askers provided readings from lab tests. Askers also provided information about their symptoms to help others interpret their problems. Some askers went further to provide information about their personal medical hisotry or family medical history to ask the community for opinions.

Some askers also mentioned medications that they are currently using: "*My dosage now is 112mcg […] My doctor suggested that I need to lower my dosage. Need help understanding, I am very confused*." Lastly, a great number of askers also listed information about their lifestyle, including diet, exercise routines, drink, and smoke.

Table 1– Types of Information Provided in the Questions

	Provided Information	Frequency
Demographic	Age	148
	Gender	105
	Height	28
	Weight	67
	Pregnancy	16
Medical	Lab tests	678
	Symptoms	167
	Medication	84
	Medical history	68
	Family history	47
	Doctor's diagnosis	70
	Lifestyle	175

Supports Received from the Online Community

The contextual information provided by askers in their questions helped community members to provide relevant answers. The answers addressed the original question by providing suggestions, opinions, information, personal experience, and emotional support. They also requested more information from the question poster.

Suggestion: The community mainly provided suggestions about the next step, medication, and lifestyle. Many replies suggested that askers should see a doctor, get a second opinion, and discuss their questions/concerns with their physician. Some answers also recommended additional tests that the asker may need to take. Furthermore, based on the provided information, answers also suggested treatment and medication (e.g., "*Metformin to start. Never ever take Actos or Avandia. They may kill you*"). Finally, the community emphasized the importance of having a healthier lifestyle.

Information: The community provided information on a number of topics, including tests, symptoms, treatments, and resources. For example, answers explained genernal information about about a particular lab test, such as normal value range, test options for evaluating a disease, and lab procedure. Answers also provided information on common symptoms associated with a particular disease, and potential risks and common causes of these symptoms. Furthermore, community members provided information on treatment and medication, including general treatment approach for a given condition, treatment risk, medication side-effects, and general knowledge about a particular treatment/medication. Finally, it is interesting to see that answers would point the asker to external websites for further information.

Opinion: Furthermore, community memebers provided their personal opinions and interpretations regarding test results (e.g., "*…indicate that you are at the pre-diabetes stage of developing type 2 diabetes*"), prognosis (e.g., "*The high glucose is likely due to the pneumonia*"), and treatment (e.g., "*That is a terrible drug*").

Personal Experience: Sometimes, answers shared personal experiences to offer emotional support or to provide "assured" information to support their opinions or suggestions.

Request More Information: Finally, answers often asked follow-up questions and requested more information so that they would be able to help more.

Conclusions

This study is part of a large research effort supportting patients to better understand and act on their clinical data. This preliminary work provides a foundation for our future work. For example, we will use these results to design surveys and interview protocols to further understand the challenges that lay individuals have in comprehending clinical data and to guide the design of consumer-facing informatics tools to better present data of varying technical complexity to lay individuals. Furthermore, our findings revealed that members provide both objective and subjective information to the community. This observation highlights the importance of developing mechanisms to address quality of online health information. Lastly, our future work will expand to other health conditions (e.g., cancer) and health forums and include other types of health information (e.g., radiology report) to assess the generalizability of these findings.

Abstract

Lung cancer is the leading cause of cancer-related death in the United States. Low-dose computed tomography (LDCT) for lung cancer screening (LCS) can reduce lung cancer deaths by 20% compared to chest x-rays. Nevertheless, the uptake of LDCT is low for high-risk smokers. In this study we used Twitter data to understand laypeople's emotions towards LCS, find topics on LCS-related tweets, and assess the impact of promotional information on laypeople's discussions.

Keywords:

Social media, early detection of cancer, lung neoplasms

Introduction

Lung cancer is the leading cause of cancer-related death in the United States. In 2018 it was estimated that 234,030 new cases of carcinoma of the lung were diagnosed and that 154,050 patients died from this disease [1]. Research has shown that screening for lung cancer with low-dose computed tomography (LDCT) reduces deaths from lung cancer by 20% compared to chest x-rays [2]. However, our recent study showed the uptake of LDCT for lung cancer screening (LCS) remains low and there was inappropriate use of LCS among individuals who were ineligible in 2015 [3].

Social media is more than a network to connect or build virtual relations with friends. It reignited research into studying public health-related topics using user generated health data. In our previous study, we used Twitter data to understand the impact of promotional information on laypeople's discussions in the case of Lynch syndrome [4]. In this study, we used a similar approach to answer 3 research questions (RQs): 1) what are laypeople's emotions towards LCS; 2) what are common topics associated with LCS-related tweets; and 3) what is the impact of promotional information on laypeople's discussions.

Methods

Our approach, as shown in Figure 1, started with collecting tweets from two different data sources by using a list of LCS-related keywords. We then classified tweets into promotional information vs. laypeople's discussions, assessed laypeople's emotions and attitudes towards LCS when they discuss LCS on Twitter, and compared the topics addressed in promotional information and laypeople's discussions.

Figure 1– The study workflow.

Step 1: Data Collection

Our data were queried from two different sources. First, we collected tweets related to LCS from December 9, 2017 to October 26, 2018 using a Twitter crawler based on a set of keywords related to LCS (e.g., "low-dose ct"). The list of LCS-related keywords was developed through a snowball sampling process, where we iteratively queried our collection of Twitter data and randomly selected sample tweets to discover new LCS-related keywords until no new keywords were found. We also used the same list of keywords to extract tweets from our random sample database, which was collected using the Twitter streaming application programming interface (API) from January 1, 2013 to December 30, 2017.

Step 2: Data Preprocessing

We preprocessed the collected data to eliminate tweets that were duplicates or not in English. We also geocoded the tweets using a tool we developed in our previous study [5].

Step 3: Tweet Classification

We annotated 1,121 tweets to create training data, and then experimented with two deep learning methods, convolutional neural networks (CNN) and long-short term memory (LSTM) networks, to automatically classify the tweets into promotional information and laypeople's discussions groups. This method classified 621 of the training tweets as promotional information and 400 as laypeople's discussions.

Step 4: Sentiment Analysis

The Linguistic Inquiry and Word Count (LIWC) [6] is a validated text analysis tool which can assess indivdiuals' emotions through counting the percentage of emotional words used in a given text. We applied the LIWC tool on all of the tweets in the laypeople's discussion cateogry to assess their emotion scores (i.e., positive emotion, negative emotion, anxiety, anger, and sadness).

Step 5: Topic Modeling

Topic modeling is a statistical, unsupervised model that can discover abstract topics in a collection of documents. We used the Biterm algorithm [7], which has shown superior performance compared with the commonly used Latent Dirichlet allocation (LDA) model on short texts, to find the abstract latent topics presented in the overall Twitter data. We then used the trained model to infer topics for each tweet.

Results

Data Collection

Overall we collected 29,775 tweets and retained 25,576 for analysis after excluding duplicates and non-English tweets.

Tweet Classification

The CNN model outperformed the LSTM classifer on the training data. Using the trained CNN model, 25,576 tweets were classified as promotional information and 16,360 tweets as laypeople's discussions (from 9,216 unique individuals).

Sentiment Analysis

For RQ1, we applied LIWC analysis on tweets of laypeople's discussions. As shown in Figure 2, laypeople's emotion towards LCS fluctuated across the years.

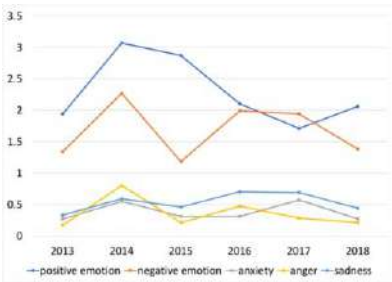

Figure 2– Laypeople's emotion changes towards LCS by year.

Topic modeling

The Biterm topic model was trained on all LCS-related tweets to extract 100 topics. The topic with the highest probability produced by the Biterm model was selected for each tweet. The top 6 topics are shown in Figure 3.

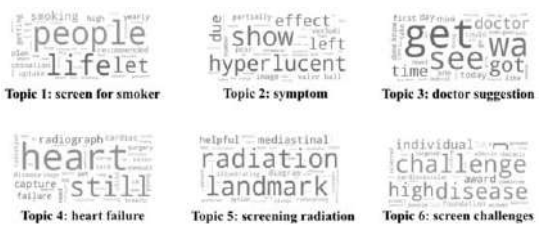

Figure 3– Top topics among lung cancer screening-related tweets in both promotional information and laypeople's discussions.

For RQ2, we calculated the top 5 topic distributions on promotional information compared to laypeople's discussions. As shown in Figure 4, topics in laypeopole's discussions are similar to the topics in promotional information, confirming the impact of promtional information on laypeople's discussions in Twitter.

To answer RQ3, we calculated the Pearson correlations of different topics between promotional information and laypeople's discussions based on the monthly tweet volume as shown in Table 1. There was a high correlation on the topic of "screen challenges" and moderate correlations on the topics of "heart failure" and "screen radiation". In other words, promotional information has an impact on laypeople's discussions related to "screen challenges", "heart failure", and "screen radiation".

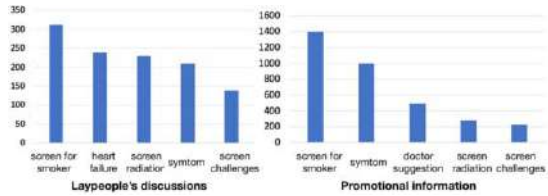

Figure 4– Top 5 topics between promotional information and laypeople's discussions related to lung cancer screening.

Table 1– Pearson correlation coefficients of different topics between promotional information and laypeople's discussions based on their monthly tweet volumes.

Topic	Correlation coefficient	p-value
heart failure	0.67	0.03
screen challenges	0.70	0.02
screen radiation	0.66	0.03

Conclusions

Our results demonstrated that using natural language processing tools and machine learning models can be useful to assess people's emotions towards a health-related topic, discover themes in their discussions, and understand the correlation between promotional information and laypeople's discussions.
